SCULPTURESQUE PHOTOGRAPHY—A NEW STYLE OF STATUARY PORTRAITURE.

For many years an imitation of statuary has been made by photography. This has generally consisted in double printing, that is to say, the head of a living sitter is printed upon the bust of a figure cast in plaster, the head of which is stopped out in the negative. Some exceedingly incongruous photographs have been made in this way, although justice compels us to say that in the hands of a real artist some good ones have also been turned out.

An American artist, Mr. C. W. Motes, of Atlanta, Georgia, has produced the finest "statuary" group we have seen. But he has entirely disregarded the meretricious aid of plaster or marble, and has produced his effects solely by lighting. A reduced copy of a large picture 21 by 17, entitled *The Sisters of Bethany*, is given in *Wilson's Photographic Magazine* of last month, and this, as hinted, comes nearer to our beau ideal of a statuary group than any similar work yet presented for public inspection.

The Sisters are clothed in white attire, and suitably posed on a plinth composed of square slabs of granite. We shall say nothing concerning their bare arms, their attire, or their banged hair, because, after all, the Bethany mentioned may not necessarily be that of Palestine, but the name of a town, village, or even a villa residence in Georgia, for in the United States of America Palestine, no less than Great Britain and the Continent, are laid under contribution in supplying names for their rapidly increasing towns and villages; hence a possible explanation of the costumes and personal accessories of these Sisters of Bethany. But, apart from this hypercriticism, the idea is so good and so well carried out, that in the interests of our professional brethren who are longing for something new to give a fillip to business we shall, with the aid of the description of Motes's methods, say a few words more on the subject.

The figure is attired in white and posed against a black background. A black velvet or a green baize background, we learn from Mr. Wilson, is used, a ground of this nature conducing greatly to the effect in general—to the roundness, fulness, and detail of the figure. It is essential that the drapery as well as the figure be artistically posed and hang gracefully. This it is quite possible to do even with our nineteenth century female costumes. But alas for those of the male sex! Unless something of the old time cloak or the Inverness cape be adopted, and these constructed of some white material, the photographer has to face an insuperable, if not unsurmountable, difficulty.

The lighting has to be very soft and diffused so as to avoid deep-cast shadows, and yet there must be a dominant light to prevent flatness. The carrying out of these conditions must be left to the skill and taste of each individual artist. As the maximum of softness and avoidance of heavy shadows are paramount considerations, a generous exposure is necessary.

We have spoken of the background as being black. Where this is not the case in any special picture not expressly produced for "sculpturesque photography," it is not a difficult matter to effect it by a subsequent operation. We have lying beside us a negative as yet undried, by which we have satisfactorily demonstrated this, by obliterating every portion of the background that surrounds the figure. The means adopted were the making up of a strong solution of potassium cyanide in which was dissolved iodine in such proportion that the solution would have remained of a permanent purple colour but for the further addition of a small lump of cyanide, by which it became colourless. This forms an exceedingly powerful solvent of a negative image. To prevent its spreading, a little gum arabic should be dissolved in it so as to impart a body. When, by means of a camel's-hair pencil or fine quill pen, this is passed round the outline of the image, the parts thus acted upon immediately become transparent, all that is then necessary being to wash it off very quickly before the detergent has had time to spread and attack the outlines of the figure. Slightly tepid water dashed on in a spray serves the purpose very well.

While on this topic, we may say that striking effects may often be produced in lantern photographs of portraits by denuding the backgrounds of the negatives of all detail, thus causing in the slide the picture to be seen with a black background.

In conclusion, we are quite at one with the editor of our transatlantic contemporary when he speaks of the inharmonious results obtainable by hoisting the bust of a person "upon a pedestal, which is photographed from a rough pen drawing, and calling it a photo-sculpture. But when we see living figures draped in white, so gracefully and so artistically posed as to represent a work in marble so exactly and faithfully as does this group, we think we have something that is worthy of following." This exactly expresses our sentiments, and we shall be pleased to show the excellent illustration in *Wilson's Magazine* to any who call at our office for that purpose.

DIFFUSED LIGHT.*

The various media employed by photographers for avoiding the effect of direct light have to be considered not only from their aspect as regards diffusive properties, but as to their reflecting and absorptive powers A medium may diffuse light very effectively, but it may also absorb a large amount and reflect more than is convenient if transmitted diffusion is made use of. Thus, one of the speakers at the meeting where Dr. Sumpner's paper was read, Mr. A. P. Trotter, had been interested in the subject for many years with a view of obviating the glare in arc lamps. Another, Mr. Addenbrooke, had been impressed with the importance of the subject when he passed through America three years ago, and noticed the crude manner in which electric lighting was there carried out.

The earliest mode of diffusing the light from the electric arc was by means of globes of ground glass, and, afterwards, of opal glass.. Though Dr. Sumpner's table gives an absorptive power in ground glass three times greater than that of light opal, the effective light is greater from the former, owing to the fact of the more refrangible rays being absorbed to a greater extent by opal.

Suitable diffusion is the key-note of the successful application of artificial light to photographic portraiture. An early exhibited mode, avoiding the difficulty of the glare of the arc lamp for purposes of every-day life, was to hide the light itself and permit its direct and reflected rays to illuminate what was in effect a white ceiling, the light diffused from which was the sole source of illumination in the apartment electrically lighted. For some reason, probably the great loss by absorption, it was not a commercial success. But for photographic portraiture it is the plan best known. The particular plan first utilised in this direction forms the basis then adopted by a multitude of followers. It is, in brief, an arc light (hidden from the spectator) fixed in the focus of a large whitewashed concave reflector—something like a huge movable umbrella whitened in its inner surface—and the lamp fixed about or near the supporting stretchers meet upon the stick. The light from the umbrella, and not the lamp direct, illuminates the sitter. Now, it is quite obvious that, if a suitable diffuser could be placed between the light and the sitter, a far larger proportion would be utilised; but, actually, no such plan has hitherto been successfully devised. The difficulty lies in the utilisation of the rays that fall obliquely on the diffusing surface, few of them are diffused in the direction of the sitter. We consider it would be by no means impossible to devise a system of combined reflectors and diffusers which should waste a minimum amount of the light produced. If there were sufficient demand, there is no reason why a manufacturer should not be able to produce sheets of glass moulded into sets of prismatic indentations, the prisms acting as reflectors set at increasing angles of incidence, as their situation was removed from a normal from the sheet to the light. If such prisms were small enough, they would act as diffusers; if too large, there could be interposed suitable diaphanous media to act as such.

Some such method as this, applicable as it would be to gas, magnesium light, electric arc, or other source of light, would be an immense boon, and would cause artificial illumination to become a "boom," to use an expressive transatlantic phrase. We now bring our remarks and suggestions to a close by appending below the list of media experimented upon by Dr. Sumpner, with their respective reflecting, absorptive, and transmitting power:—

Material.	Percentage Reflecting Power.	Percentage Absorption.	Percentage Transmission.
Blotting paper	82	13·8	9·2
Cartridge paper ...	80	12·2	11·2
Tracing block	35	15·0	54·4
Tracing paper	22	7·0	76·0
Ordinary mirror ...	82		
Ordinary foolscap...	50 to 70		
Tissue paper (one thickness).....	40		
Tissue paper (two thicknesses)...	35		
Yellow wall paper	40		
Blue paper	25		
Dark-brown paper	13		
Yellow painted wall	20		
Black cloth	12		
Black velvet.....	0·4		
Arc Lamp Globes.	Apparent.		
Light opal	15		
Dense opal	39		
Ground glass	42		

It will, of course, be understood that the optical, and not the actinic, effect is referred to in these experimental records.

* Concluded from vol. xxxix., page 819.

Patents in 1892.—The number of new patents applied for during the year just ended was 24,166. This is the largest number that has hitherto been applied for in a year, and exceeds by 1288 the applications for 1891, and by 2863 the year before. Photography, as our weekly lists have shown, has contributed its full quota to swell the numbers.

The New Methylated Spirit in Gelatine Emulsions.—Last week a correspondent sent us two negatives made with boiled emulsions, to one of which rectified spirit was added, and to the other the mineralised spirit. Both negatives were excellent in quality, and fully bore out our correspondent's remark, that the latter spirit appears to be harmless in boiled emulsions. It remains to be ascertained, however, whether its presence in an emulsion prepared with ammonia would be equally innocuous.

Exhibition Rules.—Among the rules for competitors in the forthcoming exhibition of the Fillebrook Athenæum Photographic Society, we note that the competition is open to professionals and amateurs alike, and that there will be no division into classes, with the exception that photographs, which have gained awards in any open competition previous to February 24, 1893, or reproductions of the same, will be placed in a separate class. Fourteen medals "will be placed at the disposal" of the Judges.

The Electric Light in the Studio.—The London Stereoscopic Company have recently adopted the electric light in their Cheapside studio. The power of the light is, we are informed, about fifteen hundred candles, and it is collected and dispersed by a reflector, or, rather, radiator, of the usual pattern. The direct light is cut off from the sitter by means of a small opaque disc placed very close to it; but no transparent screen of large dimensions is employed. The mechanical means for swinging the reflector to any desired position were devised, we were informed, by the Company. Very soft and admirably lighted effects are produced by the light—a fact which should be instrumental in inducing many photographers to adopt the electric light where a supply of power is available from a company' main.

Free Portraits.—The free-portrait scheme, which hasso frequently been exposed in these columns, appears likely to receive another check. The Treasury have now taken up the matter. On Friday last, three men, one of whom is not yet in custody, trading as the Imperial Portrait Company, were charged at the Folkestone Police-court with conspiring to defraud and defrauding. The Inspector of Police stated that the people had also traded under the titles of "The Judge Publishing Company," and "The Star Portrait Company." After certain affidavits had been read, the Bench granted a remand, and liberated the accused on bail. It has long been a surprise to most photographers that the Treasury have not interfered in the matter before.

Photography and the Oscillation of Projectiles.—Before the Physical Society of Berlin, on November 18, Professor Neesen gave an account of experiments made with a view to the photographic recording of the oscillation of projectiles. He employed hollow projectiles, in whose interiora was placed a sensitive plate, illuminated by sunlight through a small opening. During its rotatory flight the ray of light described curves on the plate, from whose position, taken in conjunction with that of the sun, the oscillation of the axis and point of the projectile would be calculated. The results obtained showed that both the axis and point perform oscillatory movements during the flight which are very different from those usually believed to take place. In order to study these more accurately, Professor Neesen is busy with the construction of some arrangement which may admit of the introduction into the projectiles of sensitive plates which shall not participate in the rotatory motion.

Enamelled Carbon Prints.—*Apropos* of the article last week on a simple method of producing enamelled prints we may mention that, if any uncertainty is experienced in judging of the development when plain glass is employed, it may be obviated by very simple means. A plate of transparent glass can, for that purpose, be rendered equivalent to one of opal very easily in the following manner:—Clean one side of the glass perfectly; then soften a piece of double transfer paper in warm water in the usual way, and squeegee on to the glass, and allow it to dry; when dry, immerse in a dilute solution of alum for a few minutes, rinse, and again allow it to dry. Now, if the print be developed on the other side of the glass, there will be no more difficulty in judging of the development than if opal glass were used. The paper backing, being unaffected by the warm water, by reason of its coating being rendered insoluble, will last for scores of developments. Indeed, the only deterioration it is likely to undergo is mechanical injury.

Yellowing of Platinotypes.—During the past year several examples of what have been termed "fading" platinotypes have been brought under our notice. In every case there has been no trace whatever of fading in the true sense of the term, though there has been a decided yellowness in the whites of the picture. Unfortunately, when a photograph undergoes any change whatever, even if it is only in the paper itself, it is put down to fading. This is not the case with engravings. When the papers of these acquire a yellow tint, as most papers do with age, the print is said to have improved, and become more valuable, on account of its "mellowness." Now, the image of a platinotype is practically as permanent as that of an engraving, though the yellowing or the toning of the paper is not looked upon in the same light, yet the effect is very similar and with some is considered an improvement, rather than otherwise. Be that as it may, there should be no change; and, if there is, it is a proof of carelessness in the removal of the iron salts after the image is developed. We are aware that many so-called platinotypes that have been issued during the last two or three years are nothing more than bromide prints, and, it so happens, the yellowness, so frequently seen with the latter, is much more objectionable than it is with the former. With an albumen print it is even worse.

Copyright in America.—A case of considerable interest to English publishers, with regard to American copyright, has recently been decided in the United States Circuit Court for the district of New Jersey. It is the first case that has been decided under the new Copyright Act, by which English publishers are enabled to obtain copyright in the States. Briefly stated, the case was this. The Woodburytype Company published an engraving from Sant's painting, *Little Lord Fauntleroy*. The engraving was duly copyrighted in the United States. Shortly after the first artist's proofs were placed in the American market, the engraving was pirated in the form of a chromo-lithograph. Upon this the Woodbury Company (Eyre & Spottiswoode) commenced an action and obtained a preliminary injunction, and since decrees have been entered. The final decrees now entered recognise the rights of the complainants, and provide for perpetual injunctions restraining the sale of the chromo-lithographs. From this it will seem that English publishers have a remedy against the wholesale piracy of their works from which they have so long suffered, and that the new Act is not altogether so one-sided as at one time it was thought it would prove.

"We Live and Learn!"—The *Pacific Coast Photographer* says: "It is a pleasure to note how often useful machines of service to the fraternity hail from America. We make here finer optical apparatus than can be produced anywhere in the world. Our cameras are acknowledged to be far superior to those of any other country in all respects—compactness, lightness, finish, handiness, and rigidity. Since the McKinley tariff bill placed a higher tax on albumen paper, a surprising increase in the number of factories manufacturing photographic papers is seen on every side, and the consequence is that the photographer, who growled at first from morn till night at what he was wont to term an unjust enactment, is really benefited tenfold. No less than twenty-five different collodion and gelatino-chloride papers have been placed on the American market in the last two years, and it is but a short time ago that we noticed a writer in an English contemporary in which the author bemoaned the fact that the gelatino-chloride papers of England were nowhere near the standard of those of America. It is estimated that over 300,000,000 eggs will be used this year in the manufacture of American albumen paper, while ten years ago the number was hardly worthy of notice!!!"

The Daguerreotype.—While it is an undoubted fact that the Daguerreotype is, and has proved itself to be, the most permanent of all silver pictures, the image is really more delicately constituted and more liable to suffer injury from disturbing causes than any other kind of photograph. This tender condition of the image is often not fully realised by those who have only had to deal with collodion and gelatine negatives, and the prints therefrom, until, perhaps, a valuable portrait has been irretrievably ruined. We have known of scores of such instances. Here is a case in point that has just come under our notice. A Daguerreotype, that was as perfect as it was when taken between forty and fifty years ago, was placed in the hands of a professional photographer to copy. The copy was made, but, instead of the original being returned to its frame, and that made airtight, it was allowed to stand on a shelf for a day or two, where it was exposed to dust and the sulphurous fumes from a coke stove. The result might well be anticipated by those having but a superficial knowledge of the process. The image was almost obliterated with tarnish and, in removing the dust, it was badly scratched. Here was a picture that had endured unchanged for nearly half a century, ruined in a few hours, entirely through ignorance of the conditions. The tarnish it is true, could be removed, but the scratches never. It may be assumed that a Daguerreotype is never required to be copied now unless great value is attached to it by its owner; therefore the greatest care should be taken with it by the photographer. When it is taken from its frame, if there is any dust upon it that cannot be removed by blowing, it may be lightly dusted with a soft and perfectly dry camel's-hair brush, and, as soon as the copy of the picture is made it should be restored to its frame and at once hermetically sealed up as it was originally. The "fading" of a Daguerreotype is simply a tarnishing of the plate, just as silver or plated goods tarnish by exposure to the atmosphere, and is very rapid when sulphurous vapours are present. Although the cleaning or "restoring" of a Daguerreotype is a simple matter, it should not, if the picture is a valuable one, be attempted by a novice.

A NOTE ON HALATION AND DOUBLE FILMS.

It is not my intention to discuss the theory propounded by Mr. Gregor Grant in his communication to the West Kent Amateur Photographic Society published in last week's JOURNAL, beyond remarking that, if it be correct, then it seems impossible to produce a negative with clear shadows on the plates he mentions. With regard, however, to the use of an under-film containing chromate of silver, alluded to by him as having been proposed by Mr. W. K. Burton, I think it is easy to prove that such would be utterly impracticable.

En passant, I think the writer of the article is scarcely correct in his facts when he states that Captain Abney was "the first person to lay down any law" on the subject of halation—to, in fact, point out that it is due, in some cases, to reflection from the back surface of the glass. Captain Abney would, I am sure, be the last to make any such claim, as this, one of several causes of halation, was first pointed out by Mr. Marlowe as far back as 1860 or 1861, and the remedy—backing the plate—was indicated by the late Major Russell in 1864. I myself used annatto in that year, and subsequently burnt sienna and gum, or dextrine, and few dry-plate workers of that period and later, until gelatine came in, ever dreamt of using unbacked plates. As a matter of fact, we have had what is simply a resurrection of "backing" in connexion with gelatine plates of late years, and some people seem to regard it as a new idea.

Turning to chromate of silver, I have not the means at hand of referring to Professor Burton's communication on the subject, and do not remember his suggestion as quoted, though it is very likely it was made *as* a suggestion. I recollect his publishing some experiments on the sensitiveness to light of chromate of silver, which I was unable to repeat. Chromate of silver is extremely soluble in ammonia, and forms double salts with other alkalies. The effect of applying alkaline development to that salt would therefore be to form a soluble silver salt, which would necessarily be reduced by the pyro or other reducing agent unless the liberated chromic acid instantly recombined. At any rate I could never obtain any definite reduction that could be fairly ascribed to the action of light with pure chromate of silver.

But chromate of silver in the presence of a silver haloid is a different matter altogether. Captain Abney was the first person to point out some fifteen years ago the action of the bichromates, in destroying the effect of light, and this action has an important bearing on the suggested application of the under film of silver chromate. Upon the application of a developer the first effect following, or rather accompanying, any reduction, however slight, would be the liberation of bromine or other halogen, which would next combine with the free alkali of the developer, or, more probably, go direct to the chromate of silver to convert it into bromide and liberate chromic acid, which in turn would combine with the alkali of the developer. At the very outset, before reduction had become visible, in all probability a free soluble chromate would be present to arrest all further developing action—to, in fact, destroy the effect of the action of light. How minute a trace of chromic salt suffices to do this will be familiar to those who have employed bichromate for the purpose of curing foggy emulsions. Even after a very considerable amount of washing, such emulsions are often extremely insensitive, although the proportion of chromic salt remaining is so small as to escape any but the most careful tests.

I have never actually tested the chromate under film, nor, indeed, have I tried the effect of a developer upon one containing chromate as well as bromide of silver, but I can describe the effect of an analogous mixture, namely, bromide of silver and chromate of cadmium, that is to say, bromide of silver in the presence of an insoluble chromate.

At the period of Captain Abney's publication of the effect of bichromate in destroying the latent image, in the course of experiments having for their object the clearing of foggy emulsions, it struck me that we should find bichromate a useful "indicator" in accurately adjusting the combining proportions of silver nitrate and soluble bromide. Accordingly, an emulsion was made with excess of silver, allowed to ripen for the usual period, and then a single drop of saturated solution of bichromate added, which, of course, changed it to a red colour. Alcoholic solution of bromide was then added gradually until the red tint was just discharged, after which the emulsion was washed in the usual manner.

In my previous experiments in washing the emulsion in solution of bichromate in order to eliminate fog, I had attributed the absence of sensitiveness to the employment of too strong a solution; but when I found that the emulsion which had had so small a quantity as one drop of aqueous solution in five or six ounces, was absolutely without sensitiveness even in strong daylight, I was puzzled. The result, however, was precisely the same after two or three repetitions.

The cause at length dawned upon me, and actual trial proved the truth of my auspicion. The collodion was bromised with cadmium or rather with the double bromide of cadmium and ammonium, and the same salt had been used to correct the excess of silver thus forming by the decomposition of the small quantity of silver chromate, chromate of cadmium, which remained in combination with the silver bromide. The chromic acid was converted to the soluble state by the developer, or rather a soluble chromate was formed, and this prevented any reduction. After a prolonged washing in very dilute ammonia, the sensitiveness was partially restored, owing to the removal of the insoluble chromate, but never completely.

As the result of that experience, I am very doubtful of the possibility of any useful application of chromate of silver as a photographic agent.

W. B. BOLTON.

ON THINGS IN GENERAL.

A HAPPY NEW Year to all my readers; plenty of business for the "Pros.," few failures for the amateurs! I wonder if the last wish is really a good one? My experience of the photographers who "never have any failures" is, that their work is worthless and their opinions useless. I cannot, however, say the same of some work of letter-writing, which THE BRITISH JOURNAL OF PHOTOGRAPHY has recently had good share of, referring to exhibition matters. Mr. Hector Maclean has hit the exact blot when he writes: "In most assemblies, and particularly restricted ones, there is to be found one man palpably taller than the rest—one whose *obiter dictum* has almost the force of law, and is in itself powerful enough to prevent the formation of any independent judgment." Exactly so! Three or four good men and true in matters photographic, when left by themselves, suffer themselves to be pooh-poohed by one of their number, famous, perhaps, for his work, his medals, or his general ability, or, possibly, his loud voice, and scarcely venture to assert their individuality, or have the courage of their opinions, if traversed by this mental tall one. The practical result is, that the judging is his, with a reserve power of throwing the onus of imperfect judging on his fellow-jurors. It is, virtually, one-man judging, and, as such, has merits of its own. I entirely agree with Mr. Maclean's suggestion, that the judging be done by the "mark system." Only, if so, let it be carried out in its integrity in the manner he indicates. I well remember one occasion, when I formed part of a "jury," all the members starting out with this laudable system in view, but, when notes came to be compared, the result was, practically, that A, B, and C stated which pictures they considered entitled to awards, talked it over if there was no unanimity, and amicably settled matters. A good English system of compromise, no doubt, but not the *mark system*. If well carried out, there would be no room for such injurious insinuations as recently appeared over the signature of "Young Member," who, so far, does not appear to have redeemed his promise to the Editor, that he would reveal his identity by signing a reply letter with his own name.

I have been much interested in the question of magnifiers for retouching, treated by the Editor and Mr. G. R. Baker, the latter, as one commercially conversant with the optical requirements of the public, and possessing further a knowledge of optics, giving advice of the soundest character. Nothing could be more timely or nearer the truth than his remark that "there is no doubt that in many simple or every-day matters of optics a great deal of carelessness is at times shown, and consequently that precious organ of sight, the eye, seriously affected." In his comments about astigmatism, where he states that a great many persons are affected by it, I believe he might have gone further, and said a large majority possess eyes with that peculiarity more or less developed. But few are aware of the defect, or when very marked simply put it down to weak or near sight, and are always experimenting with spectacles of various strength, none of which of the ordinary double convex kind, of

course amend the optical definition to any serious extent. But, turning now to the origin of the matter, the inability of a retoucher to use a pair of spectacles of eight-inch focus, though a four-inch diameter magnifier of the same focus was easy and satisfactory to use, it is singular to find that two such excellent authorities as our esteemed Editor and Mr. Baker have entirely missed the point. The difference between the use of the above magnifier and a pair of spectacles is that in the latter the eyes are placed almost close to the lens. In the magnifier the eyes are always used at a distance of several inches. The action of the lenses and the extent of the apparent amplification is entirely different. Indeed, a perfectly satisfactory result is obtained when (looking at the lens from a prismatic standpoint) an object is viewed through a large magnifier in such a way that both eyes are on one side of the prism. This is readily seen by covering one-half of such lens by a piece of cardboard. Good results will be obtained whether the cardboard be held vertically or horizontally across the lens.

But, speaking of optical matters, one of the richest things I have seen for a long time is an article in the *New York Photographic Times* over the signature of P. C. Duchochois. He is correcting an article, a reprint from the *Scientific American*, which had previously appeared in the *Photographic Times*. The following sentence from the second paragraph in his correction is quoted verbatim:* "Objects at various distant planes appear in relief when seen at a certain angle, theoretical for our vision, one having for its base the distance which separates the centre of the two eyes, about 2¾ inches." The spelling of the word "centre" suggests that the sentence itself may be a quotation: but, however it may be taken, it appears to be meaningless. Then, to explain matters, he takes two woodcuts of stereoscopically different places, one the right way up and the other upside down, and calls them pictures seen by the right and left eyes. He then repeats the two engravings upside down, and calls them the pictures seen by left and right lens. He ends by stating that a stereoscope "consists of the two halves of a bi-convex lens, which consequently give to the rays of light exactly the same direction: they are convergent." This is too delightful—rays the same direction, and convergent. Finally, he ought to know that the idea that the lenses should be prismatic in their section for stereoscopic effect to be produced is long ago exploded. The best form of stereoscope is one in which whole lenses are employed and the view looked at through their axes.

FREE LANCE.

BREADTH.

AMONGST all the terms imported into the vocabulary of the photographer from the artist none is being more frequently used at the present time than the term "breadth."

That photographers should gradually appropriate the expressions of artists is not to be deplored. These terms have most of them been long in use, long before photography was dreamt of: and the fact that they still survive may be taken as proof that they fulfil their functions satisfactorily. These terms, somewhat meaningless in themselves, have come to have a very definite meaning attached to them: and, as the term "breadth" is frequently quoted in an erroneous way, it might be profitable to inquire into the precise meaning of the word. While it might be difficult to frame a hard-and-fast definition of the quality denominated breadth, it is not difficult to explain what it is. It is that quality which makes for simplicity; it may apply to outline or form, to light and shade, or to colour.

In an outline drawing whatever deviations break in upon the general direction of the line render the design more complex, and therefore destroy breadth. Again, in light and shade, whatever deviations break in upon the general tone of a mass destroy its breadth. The power or effect of a mass of colour depends entirely upon its being as far as possible unbroken. I do not enter into the question of how far this quality of breadth or simplicity is to be carried out; manifestly it might be carried too far. I am only concerned with its identity. Now, to what extent can it be said that photographs have breadth?

If we narrow the meaning down to that quality which an artist puts into his work as deliberate design or intention, *apart from Nature*, I am ready to argue that they have none of this quality, notwithstanding the out-of-focus dodge. On the other hand, if you admit breadth of effect in Nature, then, of course, a photograph will have breadth or no, according to what effect was there when the plate was exposed.

But, since the latter statement has never been denied, let the attention be entirely confined to the former conditions, that is, where Nature herself is rather too complex for either artist or photographer to treat with success pictorially—where, indeed, Art can improve on Nature, bringing order out of disorder.

Now, let us clearly understand what has to be done. First, in order that the *outlines* may be more evident and easily followed, deviations from the general direction of the lines must be curtailed. By this means the eye follows with ease the simpler lines; in other words, breadth is introduced.

But photographs from Nature are not merely outline drawings—they have light and shade, and breadth must be introduced here also. There is only one way of doing this, and that is by a process analogous to the former. All deviations from the general tone value of the mass must be curtailed. Just as unity is power in social matters, so unity is power in pictorial matters, and by bringing a host of independent entities into subjection the design is simplified, and power correspondingly increased. Now, since the artist makes his picture *ab initio*, he can, of course, introduce breadth to any extent; but how about the photographer?

It has become a part of the advanced photographer's creed to put down want of breadth in a photograph to an over-abundance of *detail*. Accepting the objectionable and slipshod expression, it is not difficult to show that there is no such thing as detail *per se* in any picture, that is, since everything in a picture is represented by outline, light, and shade. When an individual says there is too much detail, he must only mean that both outline, and light, and shade are too complex for effect. It is now proposed to mend matters, by putting the picture, to some extent, out of focus; and, first, what effect will this have in simplifying outline?

It must be admitted that this will, to an *infinitesimal* degree, curtail deviations from the general direction of the lines; but note that it is at the expense of a hazy outline, which, in place of being more easily followed by the eye, is still more difficult. Contrast this with what one sees in Nature. As objects recede from the eye the outline gets less and less intricate, but the *general* outline remains quite sharp, till at last the distant hills at the horizon, in place of having a "fuzzy" outline, stand out with razor-edged sharpness against the sky, and this, too, so long as there is a trace of them visible.

When the artist would introduce breadth into his picture, he simplifies the outline by sinking deviations from the general direction of the lines, not by making a fuzzy outline. In this he copies Nature, acts on her plan.

I repeat that, in Nature, as the complexity of the outlines gets less and less by distance, so the general contour gets more and more definite; but, bad as an out-of-focus picture is in outline, it is still worse as to its light and shade, for, since by no reasonable amount of racking out or in can the light and shade in any photograph be materially altered, by robbing the shadows of their detail their identity is lost, and they become meaningless patches of black. The same holds true of the lights, of course.

In point of fact, detail, to use the word in its somewhat indefinite but ordinary sense, may be present in a high degree without interfering with the breadth of a picture at all, the only condition being that it be invisible from the distance necessary to command the composition as a whole, in which case I admit its uselessness, of course.

The distance to which one must retire in order to command the composition as a whole ought to determine the amount of so-called detail, for, while more of it may not, if judiciously handled, injure the breadth of the picture, it is at least so much labour lost if it is not visible from the standpoint proper to view the picture. In my opinion there is only one way of introducing breadth into a photograph—choose a subject having the desirable quality in itself.

HOW TO MAKE PEN-AND-INK DRAWINGS FOR PROCESS WORK.

IT will be remembered that in a recent number I explained as far as could be done on paper, the process by which phototype illustrations are produced for the Press, and the manner in which copies may be taken from photographs for this purpose. I will now endeavour to make clear in as precise a manner as possible the way in which the illustrations, technically known as "line" drawings, are produced.

In the first place, it has often been said, even by men occupying high positions in the artistic world, that artists are born and not

made. To a certain extent this is correct, as no doubt in this profession as in all others, the genius of the first water, the man who stands head and shoulders above all his contemporaries possesses an inborn talent for his work; but it is possible for any one gifted with an ordinary amount of intelligence and capability for hard work to make a more or less skilful draughtsman. The path to success, however, is by no means an easy one, continual study and labour being essential at every stage. In fact, it is impossible to become absolutely perfect. For the artist of feeling the whole world, animate and inanimate, affords interesting matter for thought and study; and, as one of the chief means of obtaining a hearing in a profession already overcrowded with men struggling to get a foothold is to strike out an original line, it is necessary that the student should possess a keen eye for fresh subjects, and a vivid and retentive memory. Granted these conditions, the ambitious pupil may commence his studies.

As the general reader is probably ignorant of even the first principles of an artist's method of work, it may not be uninteresting to state briefly some of the leading rules by which it is necessary that he should be guided. It is useless to commence drawing anything unless you have a clear and definite perception and grasp of your subject, and thoroughly understand its proportions and have defined its limits. As in photography, so in a greater degree in draughtsmanship, a clear knowledge of the value of lights and shades, and a thorough acquaintance with "perspective" is of first importance, and it is here that a great deal of hard work can be put in. Perhaps the best books for a beginner are Vere Foster's, where the information is prepared and arranged in a most careful and commendable style.

For landscape work, after the preliminary courses have been gone carefully through, the student should endeavour to advance by very easy stages—that is to say, to choose at first a subject which he can clearly grasp, where only one line of perspective is required, and where the background is not confused by a variety of objects.

For instance, we will imagine that the scene chosen is a country lane, with a wall on one side and an open field on the other, with a farmhouse in the far distance, and a few trees within the line of sight, behind the wall. It will be easier to attempt this in winter time, when the branches of the trees are quite bare, as the leaves very often prove extremely difficult to render naturally. The student should be careful to avoid standing in a too central position, and should endeavour to reproduce the shadows only, taking no notice whatever of the lights, as a much finer artistic effect is obtained by adopting that course. It is a mistake to suppose that the outline itself of the subject should be drawn; it is the shadows that should be filled in, and the real outline, as far as possible, merely reflected, or suggested by broken lines. By broken, I mean that the pen should be held very loosely, and should be guided so as to produce a wavy rather than an absolutely straight line, and it should be lifted altogether from the paper at intervals of from a quarter of an inch upwards, according to the size of the sketch. Straight and unbroken lines make a very crude and unnatural impression when the drawing is finished, and, in fact, a true picture could not be drawn if continuous lines were used. Tints are got by varying the thickness of the lines. Thin and open lines must be drawn to depict the lighter shades, and as the shade deepens in intensity the lines should gradually increase in thickness and at the same time be placed closer together. Care should be taken to keep the lines from running into each other, and to make no attempt at crossing until the strokes are dry. If this is not carefully watched, the risk is incurred of losing part of the effect by the confusion and running of the lines, whereas, in crossing, it is necessary that each stroke should be quite separate and distinct.

In order to train the eye to appreciate beauty and flow of line, the beginner would do well to study the lines used by some of the best artists whose drawings are reproduced on wood, especially as regards the angle at which lines running transversely should be drawn, as nothing is so detrimental to a pen-and-ink sketch as to see the lines crossing at wide angles. In the case of rural scenes, and, in fact, in any kind of work, with the exception of architectural subjects, it is desirable to avoid using photographs except as an after-guide for the sake of comparison; but with buildings it would save time and trouble if the student procured a photograph of the subject chosen. He would in this case be enabled to obtain a more strictly correct drawing than if he merely sketched it upon the spot, for in such work the lines are necessarily longer, straighter, and firmer than in figures or landscapes. After carefully copying with pencil every detail as an architect would do, he should proceed with pen and ink to suggest the shadows, as stated previously, rubbing out all lines in the high lights. This gives a very sketchy appearance to the drawing which the novice is apt to believe is easily produced, but it is, in reality, only obtained by taking the greatest care in the first drawing out. The pupil, by studying the works of Joseph Pennell, who is considered the best artist in pen and ink of the present day, will get a better idea of what I intend to convey in the foregoing.

Without the aid of explanatory illustrations, it is exceedingly difficult to describe exactly the means which are used to obtain artistic effect and workmanlike appearance in a sketch; but perhaps these few hints will help to a better understanding of artists' methods when their bearing is taken in conjunction with specimens of work such as I have described.

Of course, much difference of opinion exists as to the degree of merit of different artists, but, in the main, it will be seen that they all work from the same basis and use the same means to obtain what, by virtue of their various methods of execution, gives to the eye an altogether different effect when completed.

Now, with regard to figure drawing, it is worse than useless to attempt to copy photographs unless, perhaps, those taken by the stereoscopic process, which, when focussed in the special lens made for this purpose appear as they would viewed from the figures themselves. In order to be able to sketch true to the life, in addition to his lessons in pen and ink, an artist should carefully study the principles of physiology and anatomy, and endeavour to make a true delineation of every bone and muscle in the human body. The proper course to follow to gain this knowledge is to join what are known as the "Life" classes. Here the construction of the frame is first explained by means of casts of different portions of the limbs and body, and the student is gradually led to the higher studies from the nude. In this connexion also, it may be said that perfection is never reached. The frame is made up of so many delicate and intricate muscles and sinews that to trace, and faithfully copy, every one is the work of a lifetime.

After finishing the English classes, many of the promising men are sent to Paris, where, as every one knows, art is supposed to have reached its topmost pinnacle. Germany and Italy also afford vast fields of knowledge for the artist who desires to become a true cosmopolitan in his profession. Of course in Italy the schools are mostly devoted to the teaching of painting, as in that country one is able to obtain probably the finest scenery in the world. A. J. Gough.

PHOTOGRAPHY AT THE MUNICIPAL TECHNICAL SCHOOLS, MANCHESTER.

At the Municipal Technical Schools, Manchester, the optical lantern is extensively used by the various teachers, and the slide supply is an important branch of the "preparation." Many, if not most, of the slides are necessarily made from drawings, diagrams, &c., in the various text-books, and it is to the reproduction of such illustrations that a special department has been created, which has been found an immense boon in many ways. There are two rooms occupied, one containing the apparatus for making negatives and for finishing the slides, the other as a dark room.

The apparatus used is that invented by Professors Strode and Barr, and it is a marvel of compactness and efficiency, the illumination used being that obtained from two Argand gas burners. The plates used are "the Castle brand," the exposure varying from one minute to two. The whole arrangements are brought down to almost a mechanical operation, as scales are fitted at all points. For instance, we will suppose a diagram nine inches long is to be reduced to lantern-slide size, the book containing it is placed on the top of the box, the diagram being hung opposite the camera, or, if a loose diagram, it is pinned upon a board, which can be hung *in situ* without trouble. The camera stand is next pulled away until a pointer on bottom is at figure 9 on the tramway. The back of camera is also pulled out until a similar pointer is at 9 on the base of camera, a glance at a scale running up the side of it perhaps shows that the bottom line of diagram is eight inches from top, and that the top line of diagram is two inches from the top. These two added together total ten, so a small screw at the side is loosed, and the camera raised or lowered until a pointer on side is at ten. Then, on glancing at the ground-glass screen of camera, we shall find that the image is the right size, is in centre of plate, and is in good focus. Remove the focussing screen, insert the dark slide, and with 105 seconds exposure we shall obtain a correctly-timed negative.

In entering the dark room strangers always step in very gingerly, and ask if the floor is safe, because the room has been the shaft of a lift; this room is lighted from the top, being covered in with two thicknesses of orange fabric for lighting in the evening, or, in dull weather, a small incandescent lamp in an orange bag hangs conveniently over the bench, and the current can be switched on without any trouble. A special hydroquinone developer is used, and is

generally allowed to act whilst two more exposures are being made by which time, as a rule, the negatives are fully developed, ready for washing and fixing. After fixing, they are thoroughly washed in an automatic apparatus, then put on rack till dry; when dry, the negatives are examined, and those needing the operation are intensified, bleaching with mercury, followed by ammonia, or by hypo, if only a little extra density is required. The slides are made upon Mawson's lantern plates, the exposure being made to the light of a gas-jet at a distance of nine inches, the developer being hydroquinone. When ordinary photographs are to be copied, about three times the exposure is necessary, the developer used being pyro soda for the negatives, and hydroquinone for the slides. Slight over-exposure in the slides is corrected by immersion of the slide in a mixture of hypo and ferricyanide of potassium.

The department is worked entirely by Miss Williams, and, although only of very recent establishment, the slides produced are of a high class, and the quantity sufficient for this unique school. The present schools (three separate buildings) are shortly to be superseded by a magnificent pile of buildings, in which photography will be allotted a good position.

The classes on photography and photo-mechanical processes are quite new, but up to the present are well attended, and the pupils show some excellent work. The lectures are practical as well as technical, and treat of modern methods instead of, as is usually the case, obsolete or nearly useless ones. W. T. Wilkinson.

A SUGGESTION FOR REGULATING AWARDS AT COMPETITIVE PHOTOGRAPHIC EXHIBITIONS.

Most will agree that the task of awarding medals and adjudicating upon the respective values of pictures sent to photographic exhibitions has hitherto been of a somewhat thankless and unsatisfactory nature. Why this is so is hard to define with any certainty, for those to whom the task is entrusted are invariably selected for their known discrimination and knowledge in matters of the kind. No matter who the Judges may be, there is always more or less grumbling at the results, and not always from the non-recipients of the awards.

I will now suggest what, perhaps, may be when more elaborated an improvement in the system of judging usually adopted. My idea is that there should be a kind of *standardised opinion*, to be settled by committee as to details, but constructed on the following lines. To make myself clear, I will sketch how the judging is frequently managed. The gentlemen appointed for this office examine the photographs one by one, or ought to, and put down on a strip of paper a certain number of marks, as representing the value of the picture under their examination. The higher the number, the more favourable the opinion; from one to ten is usually adopted. At the end of the examination the numbers given by each Judge are added together, and the photograph receiving the greatest number of marks is considered the prize picture. It will be seen that this system is defective, because each of the four or five censors may estimate the value of the picture from quite a different standpoint that can have little or no connexion with the other. One may appraise a picture for its artistic qualities, and another for its manipulative excellencies, and others from standpoints in their own minds utterly distinct from the rest, with the result that good qualities of different kinds actually *neutralise* each other; and the whole ends in an unsatisfactory muddle, the Judges themselves being more or less surprised at the result, although it would seem no better plan could be adopted than the absolutely unbiassed opinion of capable men so obtained.

My proposition is that, in the first place, *definite* qualities shall be adjudicated upon, and these classed under four heads:—

1. Artistic excellence—grouping, lighting, posing, and form.
2. Manipulative excellence—brilliancy, delicacy, and freedom from defects of all kinds.
3. Colour and texture.
4. Mounting and framing.

Printed lists should be provided as indicated in diagram. The first column containing the number of the pictures, and the following ones headed as above, with a division for remarks.

	1	2	3	4	Remarks.
1					
2					
3					

Suppose each Judge is supplied with one of these printed lists. He will examine No. 1 picture, and place so many marks, according to his judgment, under the different headings from I to 5; the higher the number, the higher his estimate. While, for example, let us say of No. 1 that 5 will express his estimate of the first division, 2 of the second, 2 of the third, and 5 of the fourth. Now, proceeding to No. 2, his figures might be 1 for the first division, 5 for the second, 5 for the third, and 5 for the fourth. The aggregate total of marks would be 14 for No. 1, and 16 for No. 2, giving preponderance to the less important qualities; but, as in the first division No. 1 is of more importance than in No. 2, the excellence of the picture is estimated to be better in No. 1 than in No. 2, on account of division I being the most important in picture-making. But it will be said that this is judging the picture from a solely artistic standpoint, and making the other divisions of no account. So it would if this was the end of it; but to remedy this *the standard must be formed* to fix how much more *proportional value* shall be given to No. 1 division over No. 2, and No. 2 over Nos. 3 and 4. I would propose the proportion to be 9 for the 1st, 3 for the 2nd, and 1 for the others. It would then be very easily estimated which picture was best *according to this standard*, and by adopting the same at all photographic exhibitions I think a fairer estimate would be given to the work than by the present system. The aggregated lists might be prepared and exhibited in the show-room, and would indicate to all the points and qualities that influence the Judges in making their awards. The column for remarks might contain the collective opinion of the censors on the work in its entirety, or refer to any particular or unusual quality in it.

There are some who think in giving a decision *no reason* should be publicly announced; but I think in this case the indication of the grounds of the nward would be both an advantage and satisfaction to all concerned. This is, however, but a crude notion of a plan I fancy would work satisfactorily if carefully elaborated, the dominant idea being the *foundation of a standard* that would be the means of *fairly* estimating the *different* qualities of a photograph, each of which may be equally good in its way when estimated from different points of view, but not one that would permit a fair estimate of the work when taken *en gros*. Edward Dunmore.

COMMERCIAL MOUNTANTS.

[American Journal of Photography.]

The word mountant has long been adopted as a convenient expression to denote the mixture made use of to confine paper prints in their proper position on the cardboard. It is thus one of our technical terms in photography, but persons sometimes go wrong in the use of even these simple expressions, and we remember once seeing this term mountant translated into a German photographic contemporary by language meaning a man who goes up mountains!

The chemical relation between mountants and the fading of mounted prints is a matter which still commands the attention of practical photographers, and it is to be regretted that no specific directions how to make silver prints permanent can be given. It is impossible for us to say, Make your prints on this or that paper, silvered thus, toned thus, and fixed and mounted thus, and then they will never fade. All that we can do is to take the ripened experience of many years and say, Avoid certain things in making your prints, for it is known that they cause fading in a comparatively short time.

Commercial mountants may be divided into three classes, the gelatinous, the starchy, and the mixture of the two together. Now, nothing is more convenient than to have a bottle of mountant always in readiness, so that prints may be mounted at short notice; but is this proceeding a safe one as regards the permanency of the print? While we believe that an affirmative answer might be given in the case of platinum and, perhaps, bromide prints, we certainly condemn the using of any other mountant than a fresh-made one for prints made on silvered paper; moreover, we assert this most strongly against gelatine mountants of all kinds, but particularly those to which glycerine has been added.

Some of the less conscientious persons in the photographic calling do not scruple to mount silver prints with the commonest kind of glue. We merely allude to this matter in order to express our strongest disapprobation. Almost everybody knows that the difference between refined gelatine and common glue is one of degree rather than of kind; but even the finest commercial gelatine is not now deemed safe. Gelatine is a substance possessing a strong affinity for water, and this is greatly increased by the addition of glycerine. The glycerine is very desirable, almost indispensable indeed, in a pure gelatine mountant, because it renders the mixture less horny, and more workable. Now, it is open to doubt whether prints mounted with such a compound ever really dry. We have known prints so mounted, and kept in a perfectly dry place, to leave their mounts at the slightest touch, while others framed and hung on a wall began to fade almost immediately.

These remarks will be understood as applying to the ordinary silver print on either albumenised or plain paper. As we said a moment ago, platinum or bromide prints could fairly be expected to last better, because neither of them contain that delicate albumeno-silver compound upon which the beauty and the instability of the silver print both depend. It is also well known in photography that all developed images are more permanent and lasting than those which are "printed out." On this ground alone, better results in permanency are to be expected from bromide and platinum.

There is a class of commercial mountants partly or wholly starchy in character. All the forms of parlour pastes rank in this category. It seems strange that, while plain boiled starch fresh made is the best and safest mountant, flour paste should have always been in bad odour amongst photographers. Yet practice and experience—the safest guides to follow—prove this to have plenty of foundation. Pastes made of ordinary wheat flour are very prone to mould; and, while this tendency can be counteracted in great measure by certain additions, they themselves have an injurious effect upon either the silver compounds in the print or upon the whiteness of the paper. Dextrine also belongs to this class, being a derivative of starch. Gum arabic is out of the question, being at once too much inclined to turn sour, and very expensive if good qualities are selected. Indiarubber was at one time quite in vogue, and if it played the same trick as gelatine with glycerine, in letting the print scale off after a time, it was at least harmless as regarded any injurious effect upon the stability of the print.

Silver prints of large dimensions are sometimes sized with a gelatine sizing and varnished. The practice cannot be called a safe one, however. Recent experiences point strongly to the danger of using gelatine in any form with a silver print. This applies also, we regret to say, to the cementing of prints to glass. It is probable that Canada balsam could be made to serve for this purpose. If gelatine must be used, however, we advise the best quality only, carefully tested for acidity, and used if possible without glycerine. If the prints peel off the glass, the glycerine will have to be added. Cemented prints ought always to be hermetically sealed in their frames, or at least as nearly so as possible, and hung in a place perfectly free from dampness.

On talking these matters over with one of our oldest and best photographers, he went so far as to condemn commercial mountants altogether, calling them "a lazy man's resort." While this may be an extreme view to take of the matter, so far as amateurs are concerned, we are, nevertheless, sure that it is the correct and safe one for the professional photographer. Starch paste, the best and safest mountant, is made in a few moments with little or no trouble and expense. It should be made fresh every day, and never kept over; and the brushes and vessels well washed the last thing at night, to be dry and ready by morning.

ELLERSLIE WALLACE.

PHOTOGRAPHING LOFTY INTERIOR WORK.

HAVING read an article in a recent issue of this JOURNAL on "Photographing Stained-glass Windows," it occurred to me that a plan I have found useful for, not only windows, but for any other lofty-situated subject (as capitals of pillars, carvings, and such like), might be useful if more generally known. All that is required in addition to the usual apparatus is a supply of string and a pair of tall steps. The steps are almost always to be found in churches and cathedrals, or the verger will supply them. The idea is to raise the camera, roughly focussed, centrally as convenient with the object to be photographed, and expose by means of a cord attached to the lens cap and focussing cloth by the operator standing on the ground. In the first place, set up the camera, and ascertain the distance required to get the proper-sized image. This can be done on the floor of the building with very little trouble. This being ascertained, set up the steps in the right position, and secure the camera on the top of them by cords, or by boring a hole through the top step, which is better, and using the camera screw as though it was being attached to the tripod—an extra-long screw may be kept for this special purpose.

This done, the *exact* position and focus can be settled by standing on the steps, and focussing in the usual manner. The focussing cloth is then adjusted over the camera, with a *lot of loose folds* in front, to the edge of which a long cord has been fastened, so that a slight pull from below will draw it over the lens. The same cord is also attached to the top of the cap of the lens. The dark slide being inserted, the shutter is opened, and the cap of the lens eased almost off, just leaving it sufficiently on for safety. Descend the steps, and when all vibration has ceased, a slight pull will remove the cap, and make the exposure; another pull will draw the focussing cloth over the lens when the exposure is completed. Mount the steps, cap the lens, close the shutter, remove the dark slide, and the operation is completed, without any shake and without any danger; and you have the advantage of a lofty scaffold platform without any trouble.

EDWARD DUNMORE.

WINTER PHOTOGRAPHY.

IN cold weather photography does not work with the smoothness and certainty it does in warm. The light is deficient in actinism, and unless the solutions are warm the negative is wanting in detail and in density. In fact, the absence of warmth is more often responsible for poor results than is the feeble light.

Pyrogallic acid in solution will, in cold weather, discolour far quicker than when warmer, and this in spite of an increase of a preservative, such as nitric acid, sulphite of soda, &c. Therefore, when good work is required, care must be taken that the temperature of the solutions is not allowed to fall below 60° F. The dishes used for development must also be warmed prior to use, as it will obviously be useless to pour warm developer into a cold dish, and then expect that the solution will warm the dish and retain sufficient heat to perform its functions properly.

When a negative is developed in a warm solution, not only is it better, but it is also cleaner and freer from stain than it would be if developed in a cold solution. Present-day dry plates will bear a solution as warm as 80° without danger, but 65° will be as high as is necessary for the developer to be before pouring over the plate. A cold developer, as well as giving poor negatives and causing stains, also causes frilling and blisters. The blisters sometimes dry out without leaving marks, but frilling caused by cold solutions is far more difficult to deal with than is frilling caused by hot weather or by the use of a developer containing an abnormal quantity of fixed alkali.

Cold weather also has a deleterious effect upon printing methods. The light, being weak, does not penetrate the denser portions of the negative, consequently the lighter half-tones are deficient in detail. To some extent this may be remedied by extra depth of printing, but not altogether, because it is generally necessary to print somewhat deeper in dull weather in order to get a bright print.

For winter printing weaker negatives will always give better results than very dense ones, but in this connexion it is necessary to observe that the full gradation is present. A negative, whether strong or thin, must be so, from the highest light to deepest shadow. An under-exposed negative is bad for either summer or winter. In washing paper previous to toning, water, with a temperature of at least 60° Fahr., should be used. After toning, the temperature is of little importance, but the toning solution should never be below 70°—that is, where good, brilliant tones are required. These remarks apply as much to gelatino-chloride papers (printing-out paper) as to albumenised paper; but, if the temperature of the solutions be too high, the gelatine papers are apt to frill and the image float off the paper. They will withstand a temperature of 70° without danger, but not higher.

A point of great importance in connexion with gelatine-coated papers is this, they must be washed in warm water (60° to 65°) before toning; it is quite useless to wash in cold water (below 40°), then tone in a solution about 70°; the tones are poor, and the half-tones suffer.

Gelatino-chloride prints, intended for enamelling, will be found to strip off the glass better if soaked in a solution of aluminium chloride for ten minutes, and washed afterwards; in fact, all gelatino-chloride prints are better for this treatment, as the chloride has such a hardening effect upon the gelatine as to make it more brilliant, and make it practically insoluble.

W. T. WILKINSON.

COLOURLESS ALKALINE PYROGALLOL.

As illustrating a lecture on oxygen or air, says Mr. Alexander Johnstone in the *Chemical News*, a strong solution of pyrogallic acid in KHO or NaHO is often exposed to the gas or the atmosphere to show its great power of absorbing free oxygen, and its instant change of colour when exposed to it. This experiment "tells better" if a clear, *colourless* solution of alkaline pyrogallol be shown to the class before exposure to oxygen. This can be done very easily and quickly. Into a rather deep test-glass, such as is ordinarily used in lecture experiments, place some solid pyrogallic acid, and then a little water, just enough to barely dissolve it. Next put a small handful of sodium carbonate into a flask, and cover with HCl to drive the CO_2 off. Pour the CO_2 gas into the glass above the pyrogallol, and then add the KHO to the latter. The class will see that the alkaline solution below the CO_2 remains colourless. To show the change caused by the presence of O, pass the latter from a tube into the lower stratum of the CO_2 covering, or incline the glass so as to throw out the CO_2 and admit the air. The change will be instantaneous.

MEASUREMENTS OF CLOUD HEIGHTS AND VELOCITIES.

THE *Annals of Harvard College Observatory* contain a discussion by H. H. Clayton of the cloud observations made at Mr. A. L. Rotch's observatory at Blue Hill, Massachusetts. The details given may be of interest to those who make cloud photography a study. One of the most noticeable facts brought out by the measurements of cloud heights and velocities, which have been conducted with great care, is the difference in height between the same clouds in summer and winter, the clouds, with few exceptions, being lowest in winter. The bases of the cumulo-nimbus clouds, however, are generally lower in summer, while, at the same time, their tops are higher than in winter. The heights of the different clouds were found to maintain an almost constant ratio to each other. The mean velocities recorded showed that the entire atmosphere moves twice as fast in winter as in summer. The mean velocity of the highest clouds in winter was about 100 miles an hour; the extreme velocity amounted to 230 miles an hour, from which it appears that the upper currents are much more rapid over America than over Europe, which possibly explains the greater velocity of the storms in America. As regards the direction of cloud movement, the tables show that from the highest clouds to the earth's surface the prevailing wind is west; about 4000 metres more than ninety per cent. of the observations show the clouds from some point between south-west and north-west inclusive. In the cirrus and the cumulus regions, and near the earth's surface, the prevailing direction is from a little north of west, but in the intermediate levels, from a little south of west, the excess of the southerly component in these regions being possibly due to the influence of cyclones.

AMONG THE BEES WITH THE CAMERA.

[Greenwich Photographic Society.]

EARLY this summer I first made my acquaintance with the bees with the camera, though I had done a lot of photo-micrography of the anatomy of the bee, and the pictures I shall show are the results of my various excursions to Orpington and Bromley, in company with Mr. Broughton Carr, editor of the *British Bee Journal*, to whom I am much indebted for the arrangements of the hives and various appliances that I have photographed.

A prosperous colony of bees at the beginning of the swarming season consist of a fertile queen, a few hundred drones, and from 30,000 to 50,000 workers; the mother bee, or queen, as she is usually called, is a perfectly developed female, and deposits all the eggs from which the other bees are produced. These eggs are of two kinds; the one develops into drones, and the other, under ordinary treatment, produces worker-bees, which are undeveloped females; but the same eggs, under different treatment and care, produce perfect females, or queens.

The queen usually lives from three to four years, and is distinguished from the other bees by her form, size, and colour, being longer, darker, and of more slender structure, with comparatively shorter wings than either the drone or worker, as but one queen (except in rare circumstances) is allowed in a hive at one time, young queens are only reared when a colony is deprived of a queen, is about to swarm, or if she becomes aged, or her fertility ceases. In from three to five days after birth she leaves the hive for fertilisation by the drone or male bee, which, when once accomplished, suffices for life, as ordinarily she never afterwards leaves the hive, except when accompanying a first swarm. If her death occurs, or she from any cause becomes unproductive when there are drones in the apiary, and young brood or eggs in the hive, the workers construct larger cells, called queen-cells, supplying the larva with abundance of rich food, and the eggs which would otherwise produce worker-bees are developed into queens. If the queen does not deposit eggs in any of them, the bees will supply them with eggs, which they remove from worker-cells. If they are not able from any reason to become fertilised, she will only lay drone eggs. The queen has a curved sting, which she uses when contending with a rival; she is capable of laying as many as from 2000 to 3000 eggs a day, and is in her prime the second season, after which her laying powers decrease.

The drones are more bulky than the queens, and are larger than the workers. They have no stings, lead an idle life, and, with the exception of assisting to keep up the temperature of the hive, do no work for the support of the hive, but feed upon the produce of the workers. At the end of summer, when their services are no longer required, food is withheld from them, and they are turned out to perish.

The workers, which are the most diminutive in size, are too well known to need description. The slide shows the queen, drone, and worker; it is a photograph of the insects set out so that the relative distinctions of form may be compared. Upon this bee devolves all the work of collecting and defending the stores, building comb, feeding drones, and feeding and protecting the queen and brood. They rule and regulate the whole economy of the hive, and perform all its offices, except those which have direct reference to the reproduction of the species. During the summer months the workers do not live more than six to eight weeks, owing to the hard work they have to perform, but worker-bees hatched in the autumn usually live through the winter, and commence the work of the hive in the spring. An egg deposited by a queen in a cell prepared by the workers hatches into a small grub in three days; it is cherished and fed until the ninth day, when it becomes a nymph, and is sealed in its cell to emerge a perfect bee.

Having taken up too much time in describing the three bees, I will pass on more quickly with the photo-micrographs of some of the parts of the bee. It will not be necessary to go into the detail of class, order, or family to which they belong, except to say they are of the order *Hymenoptera*, genus *Apis*, species *Mellifica*, this being indigenous to Great Britain.

There are no less than eight distinct hairs on the bee. I am sorry that I have not a slide to show you. The most important part of the bee is its head, which differs very much in form in the three bees.

The tongue consists of no less than five parts. The centre is the tongue proper; the two parts on either side form the cover, or sheath; the two above form another cover, into which the whole is drawn when not in use. At the end of the tongue is what is called the spoon, circular and concave, with a row of pale clavate hairs along the edge, and short, hooked hairs on the inside. At the narrowest part of the tongue, just above the spoon, there is a fringe of guard-hairs.

The eyes consist of a pair of large compound eyes and three simple eyes. In the slide of the compound eye we shall find the outer layer divided into a number of hexagonal facets, which are convex, and form the cornea. Between most of these facets are seen long, straight hairs, which act as protection to the eye similar to eye-lashes, and they are also sensory.

The second and third segment of the thorax support the wings. The lower wing, along the upper edge, has a row of hooklets, twenty-three in number, which, when the wings are extended, catch in the fold of the upper wing, and this gives to the consolidated combination of the two a greater surface and force in beating the air to accelerate its progress and carry its body.

The third legs of workers serve as gatherers and carriers of pollen. The upper joints are covered with long feathery hairs, the tibia or second parts, constructed for the conveyance of pollen and propolis, being framed externally like a little basket. It is smooth and hollowed, and the lateral edges are fringed with recurved hairs, which retain anything that may be placed in it. Along the lower extremity it has a row of stiff bristles, called the comb. The first leg, as shown, you will notice near the upper end, and on the inner side there is a deep curved incision, called the sinus, terminating in currycomb. Its function is to keep the antennæ clean and free from pollen. When the insect wishes to clean one of its anteunæ it lays it within the comb, and the velum of the spine upon it; the combined action of the comb and the velum removes anything that is upon it. The operation may be frequently observed, and it would be noticed that the antennæ on the right side are cleaned by the device on the left leg, and the antennæ on the left by that of the right leg.

A few words here on the breathing apparatus will not be out of place. If you look at the diagram, you will see that the air enters through the spiracles at the side of the abdomen into the tracheal tubes or air sacs; by means of these tracheæ air is carried to every part of the body.

Each spiracle consists of two, opening one behind the other, the inner one being closed by a valve, and the outer one is provided with short hairs along the edge of the opening to prevent dust and other impurities from entering.

This slide (of the sting of the bee) shows the whole of this complex apparatus with the poison bag, consisting of the barbed lancets and the divided sheath and the palpi, which are covered with sensitive hairs, so that the bee can find a soft place to insert the sting.

This slide shows the barb more highly magnified. The lancets have a fine cutting edge, and are provided along their outer edges with ten deep retorse barbs, down which the poison flows. If the bee is not disturbed, after it has inserted its sting, it can by giving it a twisting motion withdraw it, but it generally leaves its sting behind, tearing away the whole apparatus and part of its abdomen.

This shows the skin of the abdomen with its hairs and wax plates. The salivary gland would take too long to describe now. I will show the most interesting of my pictures—the outdoor work with the camera among the bees. This is a photograph of an old cottage apiary, and shows you how not to keep bees if you want to keep them clean and healthy. We had a great deal of difficulty in getting this photograph, as there is so very much superstition among bee-keepers. They were afraid

something terrible would happen; either the bees would all take flight, or the queen die, and they would get no honey; but I believe, beyond a good row, nothing has happened.

This shows a modern apiary, all of the newest, up-to-date hives, and is the property of Mr. Broughton Carr, through whose kindness and help all the slides to be shown have been done. It stands with a southern aspect, with a high bank to shelter it from the north wind, and under some small trees of apple and plum.

Here we have the bee-keeper tiering a hive. When the honey begins to flow, and the brood is well in hand, the bee-keeper puts on a tier of comb or sections for the bees to fill with honey. In these frames are put twenty-one sections, and when they are nearly completed, twenty-one more are put on, and the ones nearly full are lifted up and put on the top of the others, and it is possible to get as many as seventy sections filled with honey from one hive.

To examine a hive it is necessary to quiet the bees, and the best means of doing so is to use a smoker. The hive cover is taken off, and the quilt just turned back at the corner when a little smoke is puffed in.

This is bee dress with veil, which at times is very useful, as in hiving a swarm, changing the hives, and many other occasions. Having quieted the bees the cover can be removed, and a frame taken out to see how the brood is getting on, and that there is no foul brood or parasites about. Now, to look at the other side of this frame, one has to be very careful, or else the comb will drop out. It must not be turned over, but must be kept in a perpendicular position.

Catching the queen. This frame of comb had been taken out of the hive to see how the work was going on, and on looking over it we found the queen. There was a great uproar in the hive during the absence of her majesty, and, when the frame was replaced, it was curious to note the change of tone and hum of satisfaction that took place. Had she been absent a little longer, most likely all the bees would have been off.

Taking a swarm under great difficulties. This swarm was very unsettled, half the bees were on one tree and the other half on another tree some ten yards apart. The day was intensely hot, a clear sky and burning sun, so that the bees would not make up their minds where to settle, and kept flying backwards and forwards from tree to tree; at last they began to cluster on the top of an apple-tree; so you will see the difficulty one had to get this photograph. When they were ready, my friend got up into the tree and shook them off into the skep, lowered it half-way down into the tree, and soon all the bees had gone in.

Now comes the process of hiving this swarm. A hive has been go ready, filled with foundation frames; a large white cloth spread on a platform made up in front of the hive, on which the bees are to be shaken out. This skep was nearly full, and probably contained about 30,000 bees. With one jerk the bee-keeper shook all out. I never saw such a mass of moving insects. The photograph was taken the moment they were down, for in less than five minutes all had entered the hive, so anxious are they to get comfortably housed; and we were anxious to see the queen enter, but in the mass we were not successful.

The bees may be driven out of the skep, and the combs transferred into a movable-comb hive, or a skep may be made to swarm artificially. To drive bees, this should be done on a fine, warm day, when many of the bees are away. The skep has been removed to a quiet spot, and placed on an old tub. Before you remove the hive you blow a little smoke into it; the bees at once gorge themselves with honey, and after a few minutes you puff in a little more smoke, and remove the hive, invert an empty skep over the top, bringing the edges together at the point towards which the combs run, then prop up the front with two iron rods bent at right angles at either end; you then commence patting the hive with your hands, hard enough to shake the combs; after a few raps, the bees will begin to swarm out and go up into the empty skep. In about ten minutes all the bees may be driven out; then they may be transferred to other hives, or whatever you may wish to do with them.

It was curious to see how the bee can be subdued and handled without being stung. After the bees had been driven into the skep, a table was brought out, covered with a white cloth, and the bees shaken out on it, when Mr. Carr took them up and threw them over his hands without one of them stinging him. It will be seen that to make bees harmless it is simply necessary to frighten them into gorging themselves with honey, when they may be handled with impunity. The hive having been brought back and placed on the table, with the bottom just propped up, how quickly they made their way across to the hive, when a few crawled up the rods, and soon formed two beautiful columns of bees, which soon again became a mass. Closing up all the front in this way, the whole of the bees soon got back into the hive.

A large quantity of surplus honey is collected in sections. These are made of one long strip of wood, so cut that it will fold over into a square frame, about 4×4. In the middle is fixed what is known as a wax foundation, so that the bees, instead of making wax, find it here already for them. They have only to work it, that is, to pull out the wax from either side, and build up its cells; and, as it takes from thirteen to twenty pounds of honey to produce one pound of wax, it will be seen that the bee-keeper that uses comb foundation must have a great advantage over one who does not. These sections are sold at about 1s. each, and as many as twenty-one sections are placed in the hive, one sees how very profitable bee-keeping may be made; and in a good season three lots of these sections may be made. The large frames are filled in the same way. Only pure wax should be used.

It would take too long to go into the detail of all the work of the bee-keeper; but, any one wishing either to study the natural history of the bee or the practical work of the bee-keeper, I would refer them to Mr. T. W. Cowan's two books, *The Honey Bee: its Natural History*, and *The British Bee-keepers' Guide-book*.

This paper is, perhaps, rather disjointed, but it was roughly put together, and illustrated by some forty-five lantern slides, many of which are not described here.

T. E. Freshwater, F.R.M.S.

THE USE OF PHOTOGRAPHY IN PHYSICAL RESEARCH.

This is the title of a very interesting and instructive lecture delivered before the Physical Department of the Brooklyn Institute of Arts and Sciences, December 13, by Professor Edward L. Nichols, of Cornell University.

The lecturer began by stating that photography is now used in almost every branch of physical research; that it is often used advantageously as a substitute for drawing when making observations. Professor Nichols projected upon the screen a number of views, illustrating the exploration of the magnetic field, showing the lines of force, and of various phenomena which have heretofore been illustrated by drawings made by the hand of the observer. In some cases the hand-made drawings compare favourably with the photographs, while in others they appeared to be incorrect. The lecturer spoke of the value of photography in making long-continued observations; also in making observations of phenomena developed instantaneously, as in the case of lightning flashes, electrical discharges, sound vibrations, &c. He also showed upon the screen a plate illustrating diffraction fringes formed by a small triangular aperture in a piece of tinfoil, the figure being very intricate, and altogether different from what might have been expected.

An interesting illustration was that of photographs of the manometric flame, the flame for this purpose being produced by a concentric burner, the illuminating gas being supplied to the central orifice while the oxygen flowed through the annular orifice. The photographic flames produced in this way were very bright, clear, and sharply defined, and, although drawings heretofore made compared favourably with the photographic record, they were not, of course, as accurate as the photographs.

Interesting views of the electric arc were shown, with which the hand-made drawings heretofore used compared very favourably. The photographs, however, revealed some phenomena which had not been observed by the eye. Among these were the brilliant particles thrown off from the arc, also the superior actinic quality of the light given by the incandescent copper covering of the carbons. A photograph of an arc on an alternating circuit showed a succession of light flashes, proving the intermittent character of the arc when produced by an alternating current. Other peculiar features were shown, among them an illustration of the arc oscillating from one side of the carbon to the other. This the lecturer supposes to be due to the attraction and repulsion of the earth's magnetism. He stated that the singing of the arc was clearly due to rapid intermissions, and that the pitch of the sound proceeding from the arc was what would be expected from the rate of the reversals of the current.

An attempt has been made to produce a photographic record of the alternating current by means of a telephone having attached to its diaphragm a mirror, the incident beam being projected on the mirror, the reflected beam being received on a moving sensitive plate. The result showed that the fundamental vibration of the telephone diaphragm interfered with the production of a correct record. For this method was substituted one in which a stream of mercury carried the alternating current, the apparatus being so arranged as to allow the stream to pass between the poles of a magnet. The mercury was oscillated by the attraction and repulsion of the magnet, the movement corresponding exactly with the reversals of the current. The mercury stream was photographed through a slit located at the point of greatest amplitude of vibration, and the curve produced was the sinuous curve expected from an alternating current produced by a machine working normally.

One of the most interesting illustrations of the evening was that of sun spots taken by means of the spectroscope. This method of investigation appears to have shown conclusively that the fecula around the dark portion of the sun spot correspond with the flames projected from the sun.

THE PARA-AMIDOPHENOL AND AMIDOL DEVELOPERS.

[Section of Photography of the Academy of Sciences, Chicago.]

These developers, although of recent date, are now articles of commerce. The former was, I believe, first introduced by Dr. Andresen, which, for brevity, we will refer to as "phenol;" the "amidel," by J. Hauff. Each of these developers is considered by many whose opinions are entitled to great weight to excel all other developers.

I have used the "phenol" for bromide-paper transparencies, and even half-tone negatives for photo-engraving, with good results. I used generally substantially the following formula:—

Sulphite of soda crystals, C.P.	2 ounces	4 drachms.
Distilled water.....	12 ,,	4 ,,
Phenol		2 ,,

One grain of bromide of potassium may be used to each ounce of developer.

Dissolve the sulphite in the water while boiling, and, when dissolved, put the phenol in before it cools. I have used this developer thus compounded five months after it has been made without any apparent depreciation of strength or utility.

For use, take one ounce of this stock solution, and add from four to six ounces of water with about one grain of bromide to each ounce of developer.

I found upon using this identical formula, except that the developer was mixed with cold water, that it was an utter failure, hence the importance of using boiling water. In cold weather, unless this developer is kept at a high temperature, a copious amount of crystals will be formed on the bottom of the bottle. These crystals will consist mainly of the para-amidophenol.

This I consider an excellent all-round developer. It may be used for any dry plates that have come under my notice, isochromatic, orthochromatic, or otherwise, for making positives or negatives by contact, and for making negatives in the camera, for general portrait work, or behind a line screen for half-tone photo-engraving. It makes a negative almost, *if not quite*, equal to the old wet plate. It allows great latitude in development, and should be very fully developed to allow for the density which it will lose in the fixing bath. It makes a fine-grained negative, but not as fine as the amidol. It does not require the same skill and care to work it as the amidol, and may be used for many purposes for which that developer is useless. From eight to ten plates may be developed with a solution of this developer.

I first used the formula sent out with the amidol as follows:—

Amidol	80 grains.
Sulphite of soda crystals, C. P.....	800 ,,
Distilled water.....	8 ounces.

Then took one ounce of this stock solution, and added from four to five ounces of water, with a plentiful supply of bromide of potassium. With proper exposure the image does not appear with undue haste, but after making its appearance it proceeds to complete development with great rapidity, but will not be injured by remaining in the developing solution for a short time. I found by adding seven ounces or more of water to the ounce of stock solution that the negative or positive developed in it would be covered with a surface fog or veil so as to make it entirely useless.

The above formula I will designate as No. 1. It was made four weeks ago, and the developer is but slightly discoloured, and works as well as it did the day it was mixed. On yesterday morning I made a developer which I will call No. 2, precisely like No. 1, except that it contained forty grains of amidol instead of eighty. By examining the bottle, which I have here, it will be seen that the solution is clear, which is undoubtedly owing to the great amount of sulphite of soda it contains. At the same time I made developer No. 3, precisely like No. 1, except that it contains 400 grains of sulphite of soda instead of 800, and, after mixing the developer, it was boiled all together, the sulphite having been first dissolved in boiling water. The wine colour of the developer may be in part attributed to the small amount of sulphite of soda, and in part to the boiling of the solution after the amidol had been added. I would not recommend the boiling of the solution after the amidol has been added. It tends to discolour the negative or positive as well as the solution, which will be seen upon an examination of the bottle which I have here.

I then made developer No. 4, precisely the same as No. 1, except that it contains 400 grains of sulphite of soda instead of 800, and the amidol was added after the solution containing the sulphite had become cold. It will be observed that the solution is slightly discoloured, which is probably owing to the small amount of sulphite it contains.

In all of these four developing solutions, the sulphite of soda was dissolved in boiling water, as it should be in all cases, and the amidol should be put in when cold.

The solution No. 1, according to the formula which accompanies the amidol, as will be seen by six positives which I have here, works well when used with plenty of bromide of potassium.

The formula No. 2, reducing the amidol from eighty to forty grains, is, for some purposes, an improvement upon the original formula No. 1.

The formula No. 3, reducing the sulphite of soda from 800 to 400 grains, and boiling the developer when mixed, cannot be recommended. The same may be said of formula No. 4.

In two cases, after exposure, I gave the plates a bath for three minutes in a ten per cent. solution of bromide of potassium, and then developed them while wet. It will be seen, by an examination of these two positives, that the bromide bath improved their density. It did not materially prolong the development.

Amidol is the cleanest working of all the developers, and gives the finest-grained positives of any, and, in my opinion, cannot be excelled for making positives; but I have serious doubts whether it will ever come into general use for negatives in the studio of the practical photographer. The plate developed with amidol loses no density in fixing. The colour is black and white like a wet plate; but, while the black is fine in colour, it is not always opaque enough to make a good printer. Under certain circumstances, this is the worst of all developers to fog a plate.

Amidol loses its active working strength when it has developed three or four plates, and should then be thrown away.

I used in making these experiments, Carbutt's "A" Sen. No. 10, and Cramer's transparency plates, Sen. No. 12. My experiments with Carbutt's orthochromatic and Cramer's isochromatic plates with amidol were not successful.

I regard a very free use of bromide as indispensable to the successful working of the amidol developer. It not only keeps it within due bounds, but prevents surface fog, and adds to the clearness, brilliancy, and beauty of the negatives or positives.

J. B. Bradwell.

PHOTOGRAPHY OF THE LIGHT WAVES OF THE SMALLEST WAVE-LENGTHS.

At the meeting of the Mathematical and Natural Science Section of the Imperial Academy of Sciences of Vienna on November 10, Professor V. von Lange presented the following communication from Herr Victor Schumann, of Leipzic:—

"The photographic energy of the ultra-violet rays on collodion and gelatine plates decreases strikingly at the wave-length 200 $\mu\mu$, and falls off to a similar extent towards the more refrangible side. The cause of this decline in energy lies in the fact which I have established spectrographically; (1) in the impermeability to light of the collodion and gelatine, in which the sensitive ingredient of the coating of the plate, *i.e.*, the silver haloid, is embedded, and (2) in the impermeability of the air which the rays have to traverse on their way to the plate. If we remove these two absorbents, the silver haloid shows itself many times more sensitive for the rays beyond 200 $\mu\mu$ than it was in presence of the collodion and gelatine, and the photographic efficacy extends far beyond the previous limit of the ultra-violet light (wave-length 185·2 $\mu\mu$). The production of a film of pure silver haloid on the plate offers great difficulties. A method for this purpose was hitherto not known. After numerous experiments I found a process by which I have now for two years prepared all the plates which I have required for observing the rays beyond the wave-length 185·2 $\mu\mu$. The air could only be removed from the rays by exhausting the spectrograph. In this manner I have hitherto been able to follow about twenty different spectra far beyond 185·2 $\mu\mu$. All of them develop here an unexpected wealth of rays, but none to so high a degree as the hydrogen light of the Geissler tube. I estimate the number of the hydrogen lines, which I have isolated at 600, and the shortest of their wave-lengths at 100 $\mu\mu$. I have not as yet effected the measurements, for which, however, I have already made preparations." For illustration the speaker exhibited a tableau composed of Herr V. Schumann's original plates, showing the portion of the ultra-violet hydrogen spectrum first photographed by the latter.

A KODAK GATHERING AND PRESENTATION.

Bloomsbury Hall was, on Thursday last week, filled to overflowing by the *employés* of the Eastman Company both in London and Harrow, from which latter place a special train had been chartered to convey to London the numerous people there employed in the Company's factories. Their Paris and Nice branches were also represented, the former by the Manager and Manageress, and the latter by choice bouquets of flowers sent in profusion for the adornment of the room and the ladies who were present, for, in addition to the Chairman and some of the Directors of the Company, there were a few invited guests and friends.

The occasion was ostensibly a musical and dramatic entertainment, but it was in reality an occasion for the *employés* to signify their appreciation of Mr. W. H. Walker's management and kindly feeling towards them by presenting him and Mrs. Walker with a tangible recognition of their esteem.

It has for some time been known that this gentleman's health was giving way under the strain which he has undergone since 1885 in the establishing of the large business which now crowns his labours, and it was found that a long furlough from the active duties of the general

managership was absolutely necessary to recruit his health. His retirement from this post at the close of the year was seized upon as a fitting time to present him with a testimonial.

It is creditable to the Company that the musical and dramatic programme was ably supplied by its own officials, in which the Harrow Kodak Glee Club came well to the front.

At the termination of the first selection of music, Mr. Archibald Rider, the Secretary of the Company, said he had been asked by his colleagues to act as their mouthpiece to-night in connexion with that part of their proceedings to which they had now arrived, and to which they had all been looking forward with the greatest possible interest for some considerable time; and it afforded him the more pleasure to do so in that it gave him the opportunity of publicly testifying his own personal and warmest thanks for the many kindnesses he had experienced at the hands of Mr. and Mrs. Walker.

They were met here to-night to do the greatest honour they could to Mr. and Mrs. Walker, and to present to them a token of their love, respect, and admiration for their many endearing qualities. As soon as he learned that Mr. Walker had definitely decided to retire from the active management of this Company, it occurred to him that the occasion was the one opportunity they had for some time been looking out for of expressing in a tangible form that regard and esteem held by all for their chief and Mrs. Walker. The idea, when broached to his fellow-workers, was received with the greatest acclamation and enthusiasm. Everybody wished to go one better than his neighbour; but it would be invidious for him to mention individuals where all have worked with such a will to make a success of this movement.

Paris, represented by Mr. De Bedts and Mlle. Leonardon, Nice, Harrow, represented by about 120, and Oxford-street turned out to a man, were unanimous in their regret at the loss of such a chief, and in their love for and admiration of his great abilities and attractiveness of character.

They all knew that the result of Mr. Walker's experiments and investigations in the art, in conjunction with Mr. Eastman, had been the greatest revolution in photography that has occurred for many years; and he felt sure that, when the future history of photography came to be written, Mr. Walker would of necessity occupy a very high position in the ranks of those to whom photographers are mostly indebted for their fascinating and lovely art. His and Mr. Eastman's invention of films and methods of using them alone has made photography a recreation, a pleasure, a delight, and last, and most important of all, for without it we could not enjoy the others, a health-giver to thousands.

They were all well aware that our leading physicians now prescribe a Kodak to their patients, especially to those suffering from idleness, and the cure has been pronounced most efficacious. Therefore they would agree with him that, without any lack of modesty, Mr. Walker might, with far more justice than many who lay claim to it, pose as a philanthropist. But there are other reasons, which for the present more directly concern us, why he should claim our greatest possible love and esteem. He did not think it would be here out of place to briefly detail Mr. Walker's connexion with the business in this country. As most of us are aware, Mr. Walker came here early in the year 1885—like all good Americans, for a few months only, which from force of circumstances invariably turn into years—with the intention of making known to the photographic public of Europe the result of his and Mr. Eastman's discoveries. This he did through the medium of the Inventions Exhibition, then being held in London. The Photographic Committee of this Exhibition were so struck by the bold departure and possibilities of these inventions that, although they had already made up their minds in regard to the award for the greatest invention of the year in connexion with photography, they unanimously accorded the medal to the Company represented by Mr. Walker.

Now, that was a very striking and encouraging success—so encouraging that Mr. W. immediately opened an office at 13, Soho-square. It was then the speaker's great good fortune to join him before even the fittings were complete, and he could picture him now as he then first saw him. He was sitting in a chair very much tilted back, with a cigar in his mouth, his feet on the table, superintending the fitting up of the office and endeavouring to instil into the workmen some of his own great energy.

He soon made a host of friends, and of necessity—being so successful—a few enemies; but they have, with hardly an exception, come to value his great abilities and fine character, and are now numbered among his warmest friends.

The business grew rapidly and continuously, and with it the staff and offices. From one office and a dark room we blossomed to two rooms and a dark room. Then were annexed two attics for storing purposes, but at that point the capabilities as an office of 13, Soho-square were exhausted. Although the business had developed so rapidly, and was so highly successful—so successful that most men would have rested on their laurels—Mr. Walker, with characteristic foresight, saw that, if the business was to be that great success he always intended it to be, a larger and retail establishment must be opened. So, with great energy and determination, and in the face of almost insuperable obstacles, he finally obtained the premises at 115, Oxford-street we now occupy. This was at the end of the year 1887.

"The wisdom of this policy was immediately, and in a startling manner, shown by the tremendous increase in the business. In 1889 we developed from a branch to a tree, and took firm root in our own soil as the Eastman Photographic Materials Company, Limited. From this point we are all familiar with the steady growth of the Company and its interests.

Again and again have we outgrown our clothes and required new ones. 1. The factory at Harrow was built and started, entailing such an enormous amount of work on Mr. Walker as would have appalled most men. 2. Then he inaugurated a branch at Paris. 3. From that one at Nice. And lastly, we at 115 have overflowed into 117, Oxford-street. All this has been the work of one man.

"Ladies and gentlemen" (continued Mr. Rider). "there are now employed by this Company over two hundred persons, all of whom are indebted to Mr. Walker's intellect, energy, and business capacity for their present positions, in most cases for their very livelihood.

"But, as if that were not sufficient to command our grateful love, he binds us to him with the strongest chains by the kindness and consideration he has always shown to us all. Nobody, however humble his position, has received anything but the greatest possible courtesy and consideration. It matters not our position, we are all listened to with unfailing courtesy and patience, and he has always been most just in his treatment of us.

"These are but very few of the many reasons we have for thanking him. Time will not permit me to mention everything he has done for us, but I am certain that, whatever I have left unsaid, Mr. Walker will understand that he has our warmest affection, and that, wherever he goes when he leaves us, he will carry with him our best and heartfelt wishes for a long and pleasant life. I am sure that I am but echoing the sentiments of all when I say that I feel the greatest pain at Mr. Walker's retirement; but, in view of the incalculable benefits he has conferred on all of us, it would be most ungracious to begrudge him the rest he needs and has so well earned. There is, you will be rejoiced to hear, a bright speck in our present somewhat clouded horizon, inasmuch as Mr. Walker still remains on their Board of Directors; and, knowing what I do of him, I feel sure that he will not cease from all active connexion with the Company, and, doubtless, we shall still often see him among us. I wish—and I know you are all with me—that I could say more, but perhaps Mr. Walker himself may think this a fitting occasion to raise our hopes.

"I fear that Mr. Walker's qualities have caused me to neglect somewhat the claims Mrs. Walker has on us. Those who have enjoyed, as I have had the great pleasure, Mrs. Walker's friendship know how much she has at heart the welfare of everybody in the Company's service. She has done for a number of us considerably more than we know of, and I know personally of several instances where her influence on—and, failing that, scolding of—Mr. Walker has given more than one of us another chance. Why, if it were not for her sending Mr. Walker to us in extra good humour some mornings, where would some of us be now? The quality of mercy has been strained very considerably with some of us, and might have been broken quite but for Mrs. Walker's kindly intercession." Turning to Mr. and Mrs. Walker, he said, "It is my pleasing duty, on behalf of the *employés* of the Eastman Company, to present to you this small token of our great respect, regard, and admiration. In your retirement you carry with you our deep regret at the parting, and our heartfelt desire that you and Mrs. Walker will be spared many years in which to enjoy your well-deserved rest and new life."

Amid great applause the curtain was raised, and displayed to view a large and massive silver salver with a suitable inscription engraved on it, together with a silver-mounted album, containing groups embracing every individual in the Company's employment both in this country and on the Continent.

Mr. Walker, in acknowledging, on behalf of himself and Mrs. Walker, the handsome testimonial, expressed his extreme gratification at the spirit by which it had been prompted. He had always had the greatest faith in the idea which he, assisted by Mr. George Eastman, had endeavoured to carry into practical effect, and he could not but feel proud at the result of their labours as evidenced by the large numbers of those employed by the Company then before him. In future, although they would not see so much of him as they had done, he would always be among them in spirit, and would cherish the remembrance of the geniality of his intercourse with them and especially of that happy meeting. He concluded by formally introducing Mr. Dickman, his successor in the managerial chair. The meeting broke up at eleven o'clock.

Our Editorial Table.

SINCE describing the Hemery's Medallion Group System of portraiture in our number of last week, we have been placed in a position to illustrate what we then said with two blocks, which show the nature of the invention better than could be given by a verbal description. In one the number of figures is four, in another, eight, but there is really

no limit to either the number capable of being printed on a card or their arrangement on it. As we have previously said, Messrs.

Marion & Co. are the agents for this useful novelty, which affords the means of presenting the whole of the members of a family on one card.

"Name-it."

This useful invention of Mr. A. Gray, 44, Snow-hill, E.C., affords a means for printing the names and subjects on the negatives in a really neat style. Previous to its introduction, the lettering of negatives was a laborious proceeding, and few of those who attempted it achieved anything like success, but since "Name-it" came on the

stage, the operation has become one of extreme simplicity. It consists of a small box, having compartments for types of letters alphabetically arranged, there being enough of each to serve in the composition of a longer title than is ever likely to be required in the naming of a negative. There are also figures, spaces, an inking roller, and the other things which go to the making up of a complete printing outfit, as shown in the cut. "Name-it" has been subjected to considerable improvement since it was first introduced, resulting in the ability to print a clear, sharp title on the negative. For the purpose for which "Name-it" has been introduced we can strongly recommend it.

The *Year-book of Photography*, edited by T. C. Hepworth, F.C.S. (London: Alexander & Shepheard), comes to us this year printed in large type—in this respect like the American annuals. In the "Guides to Practice," Captain Abney leads off with a seasonable article on "Winter Photography." Mr. Bothamley follows with "Lantern Teachings," and he, in turn, is followed by others of good reputation. The Editor's article on "Gas Cylinders in Transit" will prove useful to those who have to carry large cylinders with them for lecturing purposes. There are two full-page collotype illustrations, by Waterlow & Sons, and a pen-and-ink reproduction of a photograph, together with much that is useful reading matter in the shape of hints by the Editor.

The British Journal Photographic Almanac, 1893.

Edited by J. Traill Taylor. London: Henry Greenwood & Co., 2, York-street, Covent Garden.

The editorial article this year treats of "Some Modern Methods of Book Illustration." Captain Abney writes on "Shutter Diagrams;" Mr. R. H. Bow on "Achromatism and the Secondary Spectrum;" Mr. Pringle on "Shutters;" Mr. George Davison on "Mounting;" Mr. Bothamley on the "Focal Length of Lenses;" Mr. G. W. Webster on "Single Lenses;" and there are nearly 160 other articles by the ablest writers in the world of photography. Naturally we are precluded from indulging in any critical review of the literary contents of the volume; but it is at least due to the various gentlemen who are responsible for the illustrations that we should here refer to those admirable embellishments. By consent Messrs. Morgan & Kidd's machine collotype picture of Miss Vanbrugh as *Anne Boleyn* is remarkably good and effective. The charming and artistic pictures of Mr. Wellington, Mr. Hastings, and Mr. Woodward lose nothing in the highly effective manner in which the Meisenbach Company has reproduced them, while Messrs. Waterlow, with their half-tone process picture, exhibit a capital specimen of thia now popular class of work. The half-tone picture by Mr. Sutton's process exhibits the latter in a degree of excellence which augura well for its commercial success. It may, in conclusion, be noted that the Almanac is the largest so far issued, both in regard to its literary contents and commercial announcements.

Photogravures.

By Herr Paulussen, Vienna.

The common belief that photogravure on the Continent is practised to a higher degree of perfection than in this country receives considerable support from an inspection of Mr. Paulussen's small reproductions of some of Mr. Tagliafèrro's pictures, with which the latter gentleman has favoured us. Most attendants at the principal exhibitions are acquainted with the quiet humour and truly artistic feeling which Mr. Tagliafèrro has so long displayed in the prosecution of photography. In the photogravure reproductions before us, it may be fairly said that the excellence of the originals has been admirably conserved. For technical delicacy and beauty of detail, Herr Paulussen's work, as those who saw the small exhibition of photogravures at the Great Britain Society a few months ago will allow, is difficult to excel.

Printing-out Opals and Lantern Slides.

We have received from the Paget Prize Plate Company samples of their printing-out opals and lantern slides. In the brief intervals of sunshine with which the Clerk of the Weather has recently favoured us we have ascertained that they print out with about the same rapidity as ordinary sensitised paper. They are toned and finished in the same manner, and yield most pleasant warm tones. The Company are also supplying a special frame for the purpose of printing-out, of which we hope to report on a future occasion.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 9	Camera Club	Charing Cross-road, W.C.
,, 9	Darlington	Trevelyan Hotel, Darlington.
,, 9	Dundee Amateur	Asso. Stodio, Nethergate, Dundee.
,, 9	Lantern Society	20, Hanover-square.
,, 9	Norfolk and Norwich	Bell Hotel, Norwich.
,, 9	North Middlesex	Jubilee Hall, Hornsey-road, N.
,, 9	Putney	Boys' Gymnasium, Charlwood-road.
,, 9	Richmond	Greyhound Hotel.
,, 10	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 10	Derby (Annual)	Smith's Restaurant, Victoria-st.
,, 10	Great Britain	59, Great Russell-st, Bloomsbury.
,, 10	Hackney	206, Mare-street, Hackney.
,, 10	Manchester Amateur	Lecture Hall, Athenæum.
,, 10	Newcastle-on-Tyne & N. Counties	Central Exchange Art Gallery.
,, 10	Paisley	9, Gauze-street, Paisley.
,, 10	Stockton	Mason's Court, High-street.
,, 11	Ipswich	Art Gallery, Ipswich.
,, 11	Leicester and Leicestershire	Mayor's Parlour, Old Town Hall.
,, 11	Munster	School of Art, Nelson-place, Cork.
,, 11	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 11	Southport	The Studio, 15, Cambridge-arcade.
,, 11	Stockport	Mechanics' Institute, Stockport.
,, 12	Birkenhead Photo. Asso.	Y.M.C.A., Grange-rd., Birkenhead.

,, 12	Hull	71, Prospect-street, Hull.
,, 12	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 12	North Kent (Annual)	Gravesend.
,, 12	Oldham	The Lyceum, Union-street, Oldham.
,, 13	Bristol and West of England	Roome, 28, Berkeley-sq., Bristol.
,, 13	Cardiff	
,, 13	Croydon Microscopical	Public Hall, George-street, Croydon.
,, 13	Halifax Camera Club	
,, 13	Holborn	
,, 13	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 13	Maidstone	"The Palace," Maidstone.
,, 13	West London	Chiswick School of Art, Chiswick.
,, 14	Hull	71, Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 29, 1892,—Mr. P. Everitt in the chair.

THE AFFILIATION SCHEME.

A letter from the Assistant-Secretary of the Photographic Society of Great Britain was read, intimating that it was contemplated to have two lectures on photogravure in February, to be given in London, by Mr. H. Dennison, of Leeds.

PRINTING-OUT OPALS.

Mr. T. E. FRESHWATER asked how to ascertain how a printing-out opal or lantern slide was sufficiently printed?

Mr. W. E. DEBENHAM suggested looking through the picture, and judging the relation which the intensity of the deposit bore to the intensity of the negative.

The CHAIRMAN remarked that Mr. Cowan, Mr. Ashman, and Mr. Prestwich had invented special frames for the purpose. An actinometer could also be used.

Mr. J. S. TEAPE remarked that there was always some uncertainty as to the amount of the deposit that would fix out.

PORTRAITURE BY ELECTRIC LIGHT.

Mr. A. HADDON exhibited a negative (being the portrait of a lady) which he had that afternoon taken with the electric light. The light was not more than 1000 candle power. In order to use as much as possible of the arc, it was placed in about the focus of a concave reflector of about two feet in diameter. In front of the light was placed a screen, covered with thin tissue paper, a large sheet of tissue paper being placed on the shadow side. He used a rapid rectilinear lens, working at *f*-11, and gave an exposure of ten seconds. The screen was placed at about a foot from the light, and six from the sitter.

The lighting of the negative was thought excellent.

CURVILINEAR DISTORTION WITH SINGLE LENSES.

The following question from the box was read: "What determines the curvilinear distortion of a single lens, and how may it be modified?"

Mr. DEBENHAM stated that it was determined by the position of the diaphragm, and might be modified by altering it, while it might be entirely got rid of by making the lens itself the diaphragm. The diaphragm causes certain parts of the lens to select certain parts of the picture. Mr. Debenham illustrated his remarks by diagrams on the blackboard.

IMPURE OXYGEN.

Mr. HADDON alluded to a recently published letter of Mr. T. C. Hepworth, in which it was stated that commercial oxygen was sometimes contaminated to the extent of forty-five per cent. of nitrogen, and said that, as there were many lanternists among the members of the Association, it might be useful to them to know how to be able to test a sample of oxygen for purity. He promised to demonstrate the test at a future meeting. Mr. Grundy (of the Royal Naval College) had recently found that a sample of oxygen contained forty-five per cent. of nitrogen, while another of a special make only contained about eight per cent. In no case had the percentage been so low as five per cent. Other samples had contained up to fifteen per cent. of inert gas.

REMOVING THE DEVELOPED IMAGE.

A question having been asked as to the best method of removing the developed image of an unfixed plate, Mr. THOMAS BEDDINO suggested either chlorising the image and dissolving it off with ammonia, or immersing the plate in a solution of tannin, to harden the film, and then dissolving out the image with nitric acid, 1 : 5.

The meeting then adjourned.

Croydon Camera Club.—A discussion on *The Best Printing Process* to take up was opened by the PRESIDENT at the meeting on January 2 in favour of bromide paper. In the course of his remarks, he emphasised that the lack of recognition which the said process has hitherto received is mainly due to the small proportion of men in the front rank who work it, and also that a very small proportion of those who take it up acquire the requisite experience and skill in order to turn out prints of the highest attainable quality. In the resulting discussion various processes were advocated by Messrs. Oakley, Packham, Letts, Sampson. Carden, White, Hirst, and Neeves, most of whom showed large collections of prints in illustration of their contentions. Mr. A. R. Dresser also sent a number of bromides developed with amidol, to show that the process in question can be made to yield very satisfactory results. At the termination of an animated debate a vote was taken, with the result that platinotype and gelatino-chloride tied for first place, and bromide was second.

West Kent Amateur Photographic Society.—December 29, 1892.—The PRESIDENT (Mr. Andrew Pringle) gave a demonstration of the *Theory and Practice of Making Gelatino-bromide Emulsion.* Having described the process in general terms, and explained the lines on which the operations are performed, he proceeded to make an emulsion, first with soluble bromide and silver nitrate, and then with ammonio-nitrate, explaining the advantages and disadvantages, in his opinion, of each process. A description was next given of various methods. Finally, a plate was coated, the speaker stating that, in his opinion, very few commercial plates were coated thickly enough, but that, in these days of keen competition among manufacturers, economy must be observed somewhere.

Dorset Amateur Photographic Association.—The annual meeting was held at Dorchester, on Monday, January 2. The outgoing officers were re-elected, viz., *President:* Rev. W. Miles Barnes.—*Committee:* Rev. E. J. Pope, Messrs. D'Aeth and Skene.—*Hon. Secretary and Treasurer:* Rev. T. Perkins. The Treasurer reported a good balance in his hands. The quarterly prizes given for the best prints contributed to the albums circulated during the past year were awarded to Rev. T. Perkins, Mr. Skene, Miss Skirrow, and Mrs. Perkins. A special prize for a single print, given by Mr. Skene, fell to Mr. D'Aeth, and the prize for the best set of six lantern slides shown at the meeting was awarded to Mrs. Perkins.

RECENTLY ELECTED OFFICERS OF SOCIETIES

(*Received too late for the* ALMANAC).

ACCRINGTON AND DISTRICT CAMERA CLUB.—Established 1892. Meetings, first Monday in each month. *President:* Dr. Clayton.—*Vice-Presidents:* Joseph Barnes, — Cheney, Dr. Geddig, Rev. J. R. Rendell, — Stanley.—*Hon. Treasurer:* John Hanson. *Hon. Secretary:* Isaac Hanson, Rothwell Heights, near Accrington.

AUCKLAND PHOTOGRAPHIC CLUB.—Established 1889. Meetings, second and fourth Thursday in each month. Annual Meeting, second Thursday in October. Rooms, Australian Mutual Provident Society's buildings. *President:* Dr. J. Logan Campbell.—*Vice-Presidents:* Josiah Martin, J. R. Hanna.—*Committee:* A. J. Hunter, W. C. Fraser, W. G. Churchward, G. M. Maingay.—*Treasurer:* R. Mason, Gas Company's Office.—*Secretary:* G. R. Boulton, Bank, New South Wales.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.—*President:* W. H. Hunt, D. Mus., London.—*Vice-President:* C. B. Reader.—*Council:* G. Latimer, G. E. Thompson, H. B. Millar, W. T. Briggs, G. A. Carruthers, W. A. Brown, C. Male, Thomas Mansell, J. H. Walch.—*Librarian:* J. A. Forrest.—*Lanternist:* F. N. Eaton.—*Auditors:* A. Bradbury, H. S. Nicklin.—*Treasurer:* A. F. Edwards.—*Hon. Secretary:* F. Hope-Jones, Prenton, Birkenhead.

BRIGHTON NATURAL HISTORY SOCIETY (PHOTOGRAPHIC SECTION).—Established 1892. *Chairman:* D. E. Caush, L.D.S.—*Committee:* A. H. C. Corder, J. Hunter Graham, G. Foxall, W. Mitchell, J. P. S. Slingsby-Roberts.—*Hon. Secretary:* Walter Harrison.

BRISTOL CAMERA SOCIETY.—Meetings, second and fourth Thursday in each month at 10, St. Augustine's-parade. *President:* C. Bryant.—*Council:* J. H. Brock, W. T. Crank, H. J. B. Davies, M. E. Dunscombe, G. A. Evans, E. Jakeways.—*Hon. Treasurer:* G. L. Wood.—*Hon. Secretaries:* M. W. Dunscombe, H. G. Tasker.

CALIFORNIA CAMERA CLUB. — Regular Monthly Meetings, first Tuesday after first day of month. Club Talks every Wednesday night. Illustrated Lectures at Metropolitan Temple monthly. Address of Club Rooms, 819, Market-street, San Francisco, California. *President:* H. B. Hosmer.—*First Vice-President:* H. C. Tibbitts.—*Second Vice-President:* F. E. Smith.—*Librarian:* H. C. Owens.—*Treasurer:* George W. Reed.—*Secretary:* James W. Duffy.—*Corresponding Secretary:* Charles Albert Adams.

DEVON AND CORNWALL CAMERA CLUB.—Established 1889. Meetings, on alternate Mondays at eight p.m. Place of meeting, The Athenæum, Plymouth. Annual Meeting in September. *President:* Lieut.-Colonel R. Barrington Baker.—*Vice-Presidents:* R. Burnard, W. Gage Tweedy.—*Council:* D. Aldridge, A. A. Carnell, J. S. Hawker, Miss E. Keen, E. H. Micklewood, D. Roy, Colonel Stewart, R.E., Captain Waye, R.N.—*Treasurer:* C. Russel Rendle.—*Secretary:* R. Hansford Worth, C.E., 42, George-street, Plymouth.

LLANDUDNO CAMERA CLUB AND LANTERN SOCIETY.—*President:* The Right Hon. Lord Mostyn.—*Vice-Presidents:* Rev. John Morgan, B.A. (Rector of Llandudno) and Mr. W. A. Whiston.—*Committee:* W. D. Henderson, Hughes-Jones, W. Owen, Waterson.—*Hon. Secretaries and Hon. Treasurers:* A. Campbell Paradwys, A. H. Hughes, Rochester House, Llandudno.

PHOTOGRAPHIC SOCIETY OF INDIA.—Resuscitated in 1885 from the Photographic Society of Bengal. *President:* The Hon. Sir Comer Petheram, Q.C.—*Vice-Presidents:* J. G. Apcar and J. S. Gladstone.—*Committee:* Colonel Rogers, R.E., P. Donaldson, N. Giannacopulo, B. A. Samuells, B.A., C.S., J. H. Lane, W. H. Jobbins, A. Tocher. T. H. Wilson, E. M. Showers.—*Treasurer:* George Ewing.—*Secretary:* T. A. Pope, Photographic Society of India, Asiatic Society's Buildings, Park-street, Calcutta.

QUEENSLAND AMATEUR PHOTOGRAPHIC SOCIETY.—Founded 1888. Meetings held on first Friday in each month at the Builders' and Contractors' Exchange, Courier-buildings, Queen-street, Brisbane. *President:* Dr. J. Thomson.—*Vice-Presidents:* J. W. Sutton, D. T. Lyons, F. R. Hall.—*Committee:* Dr. J. Wheeler, T. W. Bertinshaw, G. R. Robson.—*Librarian:* E. H. Alder.—*Treasurer:* J. J. Campbell.—*Secretary:* A. R. L. Wright, Telegraph-chambers, Queen-street, Brisbane.

RICHMOND (VA.) CAMERA CLUB.—Established 1890. *President:* E. F. C. Davis.—*Vice-President:* R. A. Lancaster, jnn.—*Executive:* E. F. C. Davis, R. A. Lancaster, jun., Dr. Phil Tayler, R. B. Blankenship, C. D. Hobliston.—*Secretary and Treasurer:* C. D. Hobliston, 628 and 630, E Main-street, Richmond, Virginia.

TASMANIAN PHOTOGRAPHIC, SCIENCE AND ART ASSOCIATION, HOBART.—Established 1887. Meetings second Friday in each month, at Royal Society's Museum. *Patron:* His Excellency Sir Robert G. C. Hamilton. — *Vice-Patrons:* His Honour Sir Lambert Dobson, Hon. Dr. Agnew.—*President:* William Lovett.—*Committee:* Curzon Allport, Russell Young, A. Morton, A. L. Butler, H. Downing, R. Shepperd, E. Robinson, E. Scott, D. Allport, W. K. Morris, R. McGuffie, E. R. Ash, and H. J. Buckland.—*Treasurer:* F. J. Paterson.—*Secretary:* Nat. Oldham, Claremont, Hobart.

TORONTO CAMERA CLUB.—Club Rooms and Studio, Second Floor, corner of Yonge and Gerrard-streets. *President:* E. Havelock Walsh.—*First Vice-President:* A. W. Croil.—*Second Vice-President:* W. H. Moss.—*Committee:* Hugh Neilson, N. A. Powell, M.D., Professor W. H. Ellis, M.D., J. G. Ramsey, George H. Gooderham, G. Townsend.—*Treasurer:* R. G. Muntz.—*Secretary:* Ernest M. Lake.

VICTORIA CAMERA CLUB.—Established 1887. Meetings first Monday in each month. *President:* Hon. F. S. Dobson, LL.D.—*Vice-President:* A. M. Henderson.—*Committee:* James Pettigrew, A. Harper, H. B. Clutten, and J. J. Rouse.—*Secretary and Treasurer:* Alfred H. Farmer, 54, Elizabeth-street, Melbourne.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

INDIA-TINTING PHOTOGRAPHS.

To the EDITOR.

SIR,—All photographic *artists* should be grateful to you for the prominence you have given this subject, and also to the source from whence it emanated, for undoubtedly it is by similar means true artistic effect will be secured, effects which are otherwise beyond the reach of ordinary photographic resources.

To this judicious over-tinting the painter-artist is greatly indebted for many of his startling results in harmony and atmospheric effect; it is by similar means he tones down his work in a marvellous manner, rendering that which had been previously harsh and without character agreeably beautiful, and thereby enhancing the effect in creating an individuality all his own.

The painter names this process *glazing*, and, if it is admissible for painters' work, it surely is equally and legitimately available to the *sun artist*, if produced solely by photographic or chemical means, unaided by brush work, for, unless colour retouching upon the print be admittedly correct, it would be equally unfair to allow what is technically known in the dyeing trade as *cutting out* or *discharging*, as it would be only retouching reversed—*i.e.*, removing instead of adding to the shadows in order to increase the value of the gradations by unorthodox means, and not by the ordinary photographic procedure.

But are not similar effects to this proposed *India tinting* produced by the ordinary processes of photographing, where the positive delineation of the picture predominates over the negative ground colour of the paper; and was this not pronouncedly evident in several of the more successful pictures of the year, especially in the landscapes where extensive cloud effects existed? And may we not presume that the eye of the observer frequently supplies sympathetically the actual *India tint* demanded, where no discordant wide areas of inharmonious ground colour exists to produce a discord? This effect is perhaps more evident in pictures of a warm tone, as, for instance, in warm bromides, sepia, and in semi-sepia platinotypes.

These *India tintings* must of necessity be of the most delicate character to be effective, and unfortunately this great delicacy warns us that if permanency be our aim, great precautions are necessary, for, if the presumed increased effects are arrived at by this tinting, it would be very distressing that their enhanced beauty prove to be only a temporary excellence.

Knowing how readily all delicate tints are degraded or bleached out—in other words, how readily they fade away—additional precautions should be adopted in preparing the prints for such tinting, and in selecting the tinting agent.

The aniline colours are notably of a most unstable character, by no means suitable for the purpose, and coffee staining, although it may be of a somewhat more reliable nature, it must be remembered varies in every sample, the colouring matter as a dying agent being largely, and in many instances almost entirely, composed of semi-charred saccharine or similar matter. The tea staining may be more reliable, but why not employ some colouring matter of a thoroughly permanent and constant character, tannic acid, catechu, indigo, &c.? There are several of the old-fashioned, and now much disused, dyers' drugs which, in combination with suitable mordants, are not only beautifully delicate, employed as tints, but are of acknowledged stability.

One other precaution will in every instance have to be kept continuously in mind. Hypo and all the sulphur salts must be thoroughly eliminated to secure permanency, for they are powerful bleaching agents.—I am, yours, &c.,

J. P.

January 4, 1893.

ALUMINIUM MOUNTS.

To the EDITOR.

SIR,—On the appearance of this year's PHOTOGRAPHIC ALMANAC, I referred to its pages in hope of finding some mitigation in the charges made by our best opticians for aluminium lens mounts, but in vain. Can any of your readers solve this problem? If X has a high reputation for optical work, should he charge for metal mounts in the same proportion?

As an illustration of the diversity of charges made for aluminium mounts, I send you the following table. The makers names are substituted by letters:—

Rapid Symmetrical Series.	A.	B.	C.	D.	E.	F.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Focus 6 inches	1 6 0	0 15 0	0 17 6	—	0 10 0	0 14 0
,, 7¼ ,, ...	1 7 0	1 0 0	1 5 0	0 11 3	—	—
,, 9 ,, ...	1 9 0	1 5 0	1 5 0	—	0 10 0	0 18 0
,, 10½ ,, ...	1 14 0	1 10 0	2 0 0	0 14 5	—	1 0 0
,, 12 ,, ...	1 14 0	—	—	0 16 10	0 12 0	1 4 0
,, 14 ,, ...	2 0 0	1 15 0	1 15 0	1 4 0	0 15 0	1 4 0
,, 16 ,, ...	3 10 0	2 5 0	2 5 0	—	—	—
,, 18 ,, ...	5 0 0	—	—	1 12 0	1 0 0	1 4 0
,, 20 ,, ...	6 0 0	3 10 0	3 10 0	—	—	1 7 0
,, 24 ,, ...	8 0 0	5 0 0	6 10 0	—	1 5 0	2 0 0
,, 30 ,, ...	10 0 0	10 0 0	8 0 0	—	—	—

Granted that our best opticians are entitled to the full value of their reputation, as represented by the higher prices they can command for lenses mounted in brass, it none the less seems exacting, that they should charge for aluminium by the standard of their optical work. Why should a monopoly price be placed upon a 24-inch lens mount, represented by the difference between 8*l.* and 1*l.* 5*s.* or 2*l.*? But if we examine further, the charge of 8*l.* for the aluminium mount of a 24-inch lens appears still more extraordinary. This lens is three inches in diameter, but if we take a Zeiss lens of Series III., diameter three-and-three-quarter inches, focus twenty-three inches, the charge for aluminium mount, Iris diaphragm included, is 4*l.* Deduct 2*l.* 15*s.* for Iris diaphragm, as charged by the same optician for a lens of three-and-three-quarter inches diameter, we then arrive at 1*l.* 5*s.* for the aluminium mount, the same as charged by the cheapest optician.

If the cheaper opticians have the truth of their advertisements at heart, concerning the quality of their lenses, I would advise them to attach full Kew certificates at an extra charge. No doubt they would then find a large demand for aluminium mounted instruments, especially in the large sizes.—I am, yours, &c.,

PHILIP EVERITT.

January 2, 1893.

"TWO MR. BROWNS."

To the EDITOR.

SIR,— May I ask your kind insertion of the following disclaimer?

In the index published with last week's issue you couple an article on "Photographer's English" with one on "Platinum Toning as applied to Gelatino-chloride Papers," and credit the two to one author. The latter article is from my pen, but I should not like any of my friends to believe me responsible for the former; hence this note.

Photographer's English concerns me not; I am only solicitous as to the purity of my own.—I am, yours, &c.,

JAMES BROWN.

31, *Market-street, Newcastle-on-Tyne, January* 2, 1893.

[We extend our apologies to our friend for having, in the index, confused him with the "other Mr. Brown." Dare we plead, in extenuation of the slip, that there is a seducing similarity in the names?—ED.]

MOUNTING GELATINO CHLORIDE PRINTS.

To the EDITOR.

SIR,—Having several times noticed inquiries respecting the difficulties many workers find in mounting gelatino-chloride paper so as to retain the perfect enamel surface produced by squeegeeing on to glass, I am glad to be able to give a few hints which will enable any one to mount this paper with ease and certainty. The difficulty I found was to obtain a mountant that had strong adhesive qualities with but little moisture, and quick drying. Having found such a one, to use it I hold the print (just as stripped off the glass and *unbacked*) face down in the hand, then brush a thin layer of the mountant along each edge. Next brush over the centre of the mount with a solution of three quarters mountant and one quarter water (use as little of the mixture as possible), place the print in position on the mount, and rub all over with a silk handkerchief. Do not use any other pressure. I have mounted some hundreds this way both large and small, and never have one spoilt. The gloss remains quite uninjured.—I am, yours, &c.,

ARTHUR C. COCKBURN.

22, *Sheatley-road, Brondesbury, N.W., January* 3, 1893.

THE LATE MR. W. R. HARRISON.—The announcement of the death of a quondam French correspondent of this journal is received with regret. For some time anterior to 1866 Mr. Harrison was our regular French correspondent. He was a gentleman of ripe experience and a colleague of Bingham and other men of note in those early days. He died on December 28, aged seventy years.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange Slingshy's flash stand, with six Marion's lamps, equal to new, for head-rest or studio furniture.—Address, ARTHUR WHETTON, Market-place, Deddington.

Will exchange my whole-plate, 8½×6½, Stereoscopic Company's portrait lens, quite new, for a whole-plate rectilinear lens, by any good maker.—Address, P. TARRANT, Westcott-hill, Dorking.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

JAS. CREIGHTON.—Received.

LENS.—We think that the lens you suggest will serve the purpose very well.

THOS. BLOE.—A fifteen-grain solution of protosulphate of iron, to which is added one drachm.

B. D. HIGGINS.—Remove the bad varnish with methylated spirits of wine, and revarnish with a better varnish.

H. FLATHER.—Received; thanks. We had already had a similar communication from another correspondent.

"STAR" READER.—Mr. Charles Beresford and all his works have frequently been denounced in our columns. See sub-leaders.

WM. HARROP.—There is no advantage in the use of a yellow screen with non-orthochromatised plates. It simply prolongs the exposure.

SCEPTIC.—We agree with you that it is doubtful whether, in practice, the most rapid plates of to-day are more rapid than those of ten years ago.

C. DUNCAN.—No special medium is required for working up bromide enlargements in water colours; if the paper is rough, crayons may be used.

A. LEWIS.—The great depth of the shadows is a common failing with bromide prints when they are much under-exposed and the development is forced.

ELECTRIC.—With a light of from 1000 to 2000 candle-power, and under the circumstances you mention, an exposure of eight seconds, approximately, would be required.

PLATEN.—Details of a collotype process, which we are aware was worked with great success in America, are given in the editorial article of the current ALMANAC.

N. FARRELL.—1. We are not aware that collodio-chloride paper is manufactured in this country. 2. Dr. Van Monckhoven is said to have been the originator of the process.

STANLEY G. DICKER.—Squire's lenses had a high reputation in their day. They were considered as acting rapidly. If the lens is in good condition you are safe in purchasing at the price mentioned.

G. BENSON.—In putting your lenses together after cleaning them, the relative positions of the lenses forming the back combination have not been noted. Reverse the crown glass and all will go on well as before.

R. BEDWELL.—If on the addition of more liver of sulphur to the old hyposulphite of soda no further turbidity is produced, it may be safely concluded that all the silver has been precipitated, and any further addition will do harm rather than otherwise.

A. M. Z.—You will find the camera referred to described in an article on page 39 of the volume of this JOURNAL for 1891, which will probably answer your question more fully than we could devote space to here. The principle of the camera is as old as it is excellent.

L. MELDON says: "A correspondent last week sent a description of a dip-bath for development. His letter appeared in the paper, but not the description. I should be glad to get the description therein mentioned."—We shall probably be giving a full description of the bath in our next.

A. Z. J. says: "I have seen some pictures on opal of sea-pieces of a peculiar greenish-blue tone, very suitable indeed for such subjects. I am sure they are not bromides, unless some developer has been used, the formula for which has not been published. Can you give me any information on the point?"—We have no doubt whatever that the pictures in question were produced by the carbon process. Although we have not seen those referred to, we have seen others of similar subjects which answer to the description, and they were printed in carbon.

A. W. F. writes: "Last March I entered into an agreement as printer and mounter for one year's services. As I learnt that all the photographers in this place were going to close on the day following Bank Holiday, I asked my employer if he was going to do the same. He said No, and that I must be at work that day as usual, and, if I was not, I was to consider myself discharged. As all the other photographers in the town were closed, can he legally discharge me for not going to work, which I did not?"—Yes, certainly he can. The Tuesday was not a legal holiday, although many houses closed to enable their *employés* to have an extra day's relaxation.

L. C. M.—Luminous paint is an outcome of a discovery made over forty years ago by Becquerel that the sulphides of strontium and barium became phosphorescent after exposure to strong light. We are not able to inform you the method by which the paint is manufactured. Sulphide of calcium is the phosphorescent agent.

F. E. G. says: "To-day, when developing in the dark room, I unintentionally placed a number of negatives in a dish of water which had had a small quantity of strong sulphuric acid left in, and when I let in the daylight I found the water quite milky, and each negative coated with a bluish-white opalescence, part of which I was able to wash away (from the surface only). Several of the negatives, however, are utterly spoiled, unless they can be cleared, as they are irregularly clouded, owing to the negatives which had been resting on top of them. I shall be much obliged if you can assist me out of the difficulty."—The negatives, we presume, were placed in the sulphuric acid solution immediately after being taken from the hypo. In that case sulphur was doubtless precipitated, the "clouding" being silver sulphide, which we fear is irremovable from the negatives.

LEYTONSTONE CAMERA CLUB.—January 25, Members' Lantern Evening.

THE West London Photographic Society's annual *conversazione* and exhibition of members' work takes place on January 10 and 11 (next week).

CROYDON CAMERA CLUB.—January 16, *Spanish Slides* and lecturette by Mr. Cembrano. 30, *Slide-Making by Reduction*, by Mr. B. Gay Wilkinson.

PHOTOGRAPHIC CLUB.—January 11, Members' Open Night; demonstration with the amidol developer. 18, *Glass and Fabrics for Dark Room Illumination.*

PROFESSOR ARTHUR H. ELLIOTT has resigned the joint-editorship of *Anthony's Bulletin* on account of defective eyesight, being succeeded by Mr. F. P. Smith, who for the past year has been his assistant.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—Meeting, January 10, 1893. Lecture and demonstration on *Platinotype Printing*, by S. G. B. Wollaston, at Art Gallery, Newcastle, at half-past seven.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Instead of Wellington Hall, the meetings of this Society will in future be held in the Constitutional Club, Canonbury Tower. The joint Secretaries are Mr. W. T. Coventon and Mr. Alex. Mackie.

MESSRS. FUERST BROTHERS inform us that they have appointed Mr. L. E. Morgan (formerly with the Fry Manufacturing Company) for the purpose of giving practical demonstrations of the use of the amidol developer. They would be glad to receive applications from any photographic societies or clubs that may be desirous of arranging for Mr. Morgan's attendance at their meetings in order to demonstrate development with amidol.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 12, *Testing Oxygen Gas*, by Messrs. F. B. Grundy and A. Haddon; also *The "Kolm" Magnesium Lamp*, demonstrated by Mr. J. G. Hudson. 19, Monthly Lantern Night. 26, *Photographing Paintings by Artificial Light*, by Mr. W. E. Debenham. February 2, Special Lantern Evening, *Norway and its People*, by Mr. S. J. Beckett. 9, Opening Lecture of the Technical Series announced recently. 16, Monthly Lantern Night. 23, Annual Musical and Lantern Entertainment in St. George's Hall, the Champion Hotel, commencing at half-past seven.

FORTHCOMING EXHIBITIONS.

1893.	
February 1	*Cleveland Camera Club. Hon. Secretary, J. J. Hallam, 11, Amber-street, Saltburn-by-the-Sea.
,, 7, 8	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.
,, 14	Durham City Camera Club. Hon. Secretary, R. Haux-well, The Avenue, Durham.
,, 16–18	*Woolwich Polytechnic Photographic Society. Hon. Secretary, W. Dawes, 145, Chesnut-road, Plumstead, S.E.
,, 18	Holborn Camera Club. Hon. Secretary, F. J. Cobb, 100 High Holborn, E.C.
March 1, 2	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
April 17–29	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

JOURNAL OF PHOTOGRAPHY.

No. 1706. Vol. XL.—JANUARY 13, 1893.

REVERSED NEGATIVES IN PRACTICE.

The subject of reversed negatives has frequently been treated of in times past, but it appears, from queries we have to reply to, that additional interest is now being taken by photographic experimentalists in the various mechanical processes—particularly since the issue of the Almanac—in some of which reversed negatives, that is as regards right and left, are imperative. We shall not here go into the details of all the numerous methods by which reversed negatives can be made, but shall confine ourselves to explaining, for the guidance of novices in the work, the strong and weak points of those most generally practised. In the first place, it must be borne in mind that one of the most important points with negatives for photo-mechanical work is extreme sharpness in all parts of the plate. Therefore it will be manifest that this quality is secured in the highest degree by utilising an original negative instead of having to reproduce it, whatever be the means by which this is accomplished.

There are several ways of producing reversed negatives direct. The one most generally followed by professional workers is that of taking the negative with the aid of a prism, or mirror of plane glass silvered on its surface, placed at an angle, either in front of or behind the lens, for it matters not which position it occupies. In some respects the prism is the more convenient in use, but for large sizes it becomes a costly piece of apparatus. Hence the mirror is usually adopted for all sizes, at least in England. The prism is, however, often used on the Continent. Whichever instrument be employed, this system of working direct is at once the simplest and the best method of obtaining reversed negatives, as it involves no more trouble than making them in the ordinary manner, while their quality is in no way inferior.

Reversed negatives may also be taken direct by placing the plate the reverse way in the slide, and exposing through the glass, allowing, of course, for its thickness in the focussing. But it will be obvious to every one that any dirt or scratches on the glass, or imperfections in it in the form of air bubbles, &c., will be reproduced in the negatives, and these defects are not always discoverable with dry plates. Nevertheless, this system is universally followed by some houses who work the "zinco," and what may be termed other rough processes. There, however, the process used is generally the wet-collodion, and this gives the opportunity of careful examination of the glass before it is coated. Where this system is adopted, the ground glass of the focussing screen is usually fitted with its smooth side towards the lens. The carriers of the dark slide are also supplied with small springs at the corners to press the plate, from the back, against the wire corners which are fixed in register with the ground surface of the focussing screen.

Celluloid films, it has often been stated, can be printed from either side without loss of sharpness. This is practically the case with those of the thinnest kind, when used for some purposes. But practical workers tell us that, even with the thinnest, there is a perceptible loss of sharpness in the grain, when they are used in some mechanical processes, even when the greatest care is used with the light in printing.

Here is another method of producing reversed negatives that is, perhaps, more extensively followed abroad than it is here, particularly by collotype workers, namely, removing the negative from the glass upon which it is taken in film form, and printing from it with the side that was next the glass in contact with the prepared plate. If the negative is made by the wet-collodion process, the glass is French-chalked prior to collodionising. Then, when the negative is finished, a thin sheet of softened gelatine is squeegeed upon it, or the negative is placed on a levelling stand, and a solution of gelatine poured on. When dry, in either case the negative can readily be stripped off for use. Dry plates, specially prepared for stripping, are now articles of commerce, and the negative, after it is taken, may be treated in the same way as collodion negatives, as regards stripping. If ordinary dry plates—that is, those not prepared for stripping—be used, the film can also be removed by treating it with very dilute hydrofluoric acid, after the manner of Plener. Obtaining a reversed negative by stripping it from the glass of course involves more trouble than taking it reversed in the first instance. But the stripped film often possesses advantages over the one on its rigid support, inasmuch as perfect contact can always be ensured in printing, a condition not possible if the glass negative be uneven. If, however, the stripped film be backed with a piece of plate glass, absolute contact in all parts is at once secured.

We have hitherto been dealing with negatives taken reversed or with a view to their reversal afterwards. But in general practice a large number have to be utilised that were not, and, more often than otherwise, they must not be tampered with as in stripping, hence there is nothing to do but to reproduce them. It follows, as a matter of course, that, if the reproduction be made direct from the negative, the greatest possible degree of sharpness should be secured. There are several methods by which this can be done. There is, for example, the method of Colonel Waterhouse, with the thio-carbamides, the reversed action of light method, and the method of Mr. Bolas, by treating a dry plate with bichromate of potash before exposure, and some others. As a matter of fact, however

although they are all capable of yielding excellent results, they are but little used, if at all, by commercial workers.

The plan usually pursued by professionals is to work by way of a transparency, either by contact printing, or more generally, with the camera. The latter way becomes imperative when, as is often the case, a size different from the original is required. The transparency is sometimes made on a dry plate, and sometimes in carbon. The latter possesses some advantages over the former, inasmuch as, if the negative be on uneven glass, perfect contact will still be secured through the flexible nature of the tissue, hence a sharper result. For the new negative, either wet collodion or dry plates can, of course, be employed.

Here is another method by which a reversed negative from a transparency can be obtained by contact printing alone. A carbon transparency is made in the ordinary way, and from this a negative is printed on a dry plate. It might be surmised in this case that, as the carbon image is more or less in relief a sharp negative would not be secured. But this, in practice, is not really the case if the usual transparency tissue be employed, as with it the relief is so trifling, that it may be disregarded if tolerably parallel light be used in printing the negative.

The extra trouble involved in having to reproduce negatives is often compensated for, inasmuch as then one has the opportunity of securing in the reproduction a negative having the characteristics required for the work in hand, and which the original frequently does not possess. We have not alluded to nearly all the different ways by which reversed negatives are obtainable, but we have indicated those most in every-day practice.

CHANGING BOXES *VERSUS* DARK SLIDES.

II.

The first idea of the "grooveless" changing box, alluded to in our last issue but one, was due, we believe, to Mr. P. Mawdsley —at present on a visit to this country from America—at least, it was, we believe, in his hands that we several years ago saw the earliest attempt to utilise this principle. The details of Mr. Mawdsley's method, so far as we remember, were as follow :—

The box itself in general construction was upon the same lines as Hare's automatic changing box and slide, but without grooves, and was made of such dimensions as to carry the required number of plates in contact with one another, thus saving a considerable amount of space. We have said the plates were in contact with one another, but this is hardly correct, as they only came in contact at the edges. Obviously, it would be scarcely desirable that even the toughest and hardest of gelatine films should slide in contact with the back of another plate in changing, and, in order to avoid this, Mr. Mawdsley attached to the opposite edges of the *back* of each plate, by means of glue, a narrow strip of thin cardboard to form a bearing surface, upon which the next plate could slide without injury to its surface. So mounted, half or two-thirds as many more plates would pack into the same space as when the ordinary grooved box was used.

In working the changing box the dark slide is attached in the ordinary way, and the box held in such a position that the first plate is at the top of the pile, and, sufficient "play" being allowed for the purpose, it then easily passes into the dark slide. After exposure the dark slide is again attached to the box, and the sliding lid moved to the side occupied by the *last* plate, which is now brought into the uppermost position, when the exposed plate can be returned to the box behind the unexposed ones, and so on until the whole have been exposed.

On actual trial, we find that twenty plates of ordinary thickness, packed hap-hazard from a pile, will go comfortably into the space of a grooved changing box intended to hold a dozen, allowing space also for the necessary number of cardboard strips, so that possessors of existing changing boxes who may wish to increase their carrying space for glass may easily do so to that extent by clearing out the grooves; but, if films are to be employed instead of glass, in the same space from fifty to a hundred may be included, according to the thickness and character of the holder or carrier. Thus in the simple form of carrier we shall describe later, if used as a double one, a hundred films will easily go into the ordinary one-dozen grooved box; that is to say, fifty carriers may be used, each holding either one or two films, as may be decided.

In order to utilise the double carriers, however, some extra provision must be made, either in the form of a double dark slide—the ordinary one being single—or, perhaps, better still, by providing the means of reversing the position of the slide in attaching it to the box. Such an arrangement was described, at page 568 of our volume for 1889, by Mr. W. B. Bolton. It consists of an attachment in the form of a pair of false jaws fitting on to the box in place of the slide, and into which the slide itself can be inserted in the reverse position, so that, after the whole of one side of the film-carriers have been exposed in the ordinary way, the extra jaws can be placed in position and the opposite sides exposed in the same manner.

In 1881, provisional protection was granted to Mr. C. Sands for a changing box and slide in which the principle of the grooveless box was utilised, though the details of construction varied from those detailed above. The lid of the box was fixed, and was provided with two separate openings for the exit and ingress of the plates. The opening and closing of these slots was automatic, being performed in the act of attaching the dark slide by two pins fitting into corresponding holes; the slide itself, if we remember rightly, was opened and closed by means of a sliding strip of metal. The plates were placed in "carriers"—which, of course, rendered the changing box bulkier in every way than an ordinary one—and it was adaptable to either single or double carriers.

As to the respective merits of double slides, and the method of reversing the single slide, it may be pointed out that the former has the advantage of only one changing operation for each pair of plates, though, at the same time, some little trouble is involved in construction, in order to secure correct register of both plates in the camera, and at the same time to permit the carrier to slide freely in and out of the holder. Another point in favour of the double slides is that the exposures run consecutively from one end of the box to the other, while, by the reversal method, they run from one end to the other and back again, so that the first and last exposures in the box will be in the same carrier. This is apt to cause some little difficulty in identifying any particular exposure, if it be desired to develop before the rest; but, after all, the same, or a greater, difficulty exists in the case of the continuous films of a roll-holder, and it may be minimised by a careful numbering of the carriers in their proper order.

Results of Solar Photography.—Mr. George E. Hale writes in *Astronomy and Astro-Physics*: "In view of the fact that the study of prominences, facula, and sunspot spectra by photographic means has now been taken up by several investigators, it seems desirable to bring together the results of the work in this direction which has been in progress at the Kenwood Observatory since April last, 1891." In furtherance of this view he has entered into an interesting series of descriptions in each department, which, though concerned with matters photographic, are not capable of useful abbreviation, and we therefore refer our readers to the original paper in No. 109 of the journal quoted, or as abstracted into the *Chemical News*, p. 4, No. 1728.

A Word of Warning as to Corrosive Sublimate.—Though a photographer, perhaps, does not expose his hands so much as a surgeon does to the effects of solutions of corrosive sublimate, the fact that this chemical is much employed by some operators renders it advisable to put photographers on their guard by stating the experience of Professor Albert. At a meeting of the Vienna Medical Society he gave an account of the ill effects he had experienced, he having used the solution daily in his work as a surgeon. He found that he suffered from dyspeptic troubles, and lately that some of his teeth were falling out, effects which he traced to the absorption of mercury through the skin. It is evident, therefore, that photographers have another chemical to add to the list of those which are injurious to the system, if the hands are immersed without protection in solutions of such substances.

Photographing the Motion of Vessels.—In *La Nature* last week will be found two singular-looking engravings, which, though of photo-astronomical interest, it would be impossible to understand without the accompanying letterpress. The illustrations are, in point of fact, views of an eclipse of the moon taken on board a vessel with exposures of two minutes' duration. The rolling and pitching of the ship has caused the image to describe a series of gyrations and convolutions on the plate, which are faithfully brought out on the negative. M. Gaston Tissandier suggests of them that, as a method of registering the movements of a vessel when sailing has often been sought, these pictures furnish a solution of the problem, a negative of the moon or sun being employed instead of, as hitherto' one of the horizon.

The North London Photographic Society.—This well-known Society, which represents in its history and connexions the earlier days of photography, and which has numbered among its members many of the men whose names are household words among photographers, is about to move its quarters from Wellington Hall, Islington (where it has had temporary accommodation since the pulling down of its old rooms at Myddelton Hall) to Canonbury Tower, Canonbury-square, arrangements having been made with the Canonbury Constitutional Club, who occupy the premises, for the use of the necessary rooms. The first meeting in the new home will be on Tuesday the 17th inst., when it is expected that there will be a goodly gathering of members to "warm the house," and greet the new Hon. Secretary, Mr. W. T. Coventon, of 50 Highbury-park, N., the late Hon. Sec., Mr. W. Bishop, having regretfully resigned his post under pressure of other engagements, though still retaining his interest in the Society.

Differences in Value between Eye and Photographic Star Maps.—At the last meeting of the Royal Astronomical Society considerable interest was aroused in a discussion on the new star in Auriga, which now appeared to be becoming brighter to the eye, though, in the photographs, it was less bright. The explanation offered by Mr. Taylor is as follows, and, as it embraces points of great importance, deserves to be well studied:—As the brightness of the new star diminished, and, presumably, its temperature fell, its spectrum would change very considerably. The line at wave length 5005 had become by far the brightest in the spectrum—indeed, was the only line recorded by several observers. A similar change of spectrum had been noticed in all temporary stars which had been spectroscopically examined. This line, which appeared to be the characteristic nebular line, was in a region of the spectrum to which ordinary photographic plates were only slightly sensitive, while it was near the region of maximum visual brilliancy of the spectrum for ordinary eyes. The line was therefore taken into account in visual estimations of magnitude, and practically ignored in photographic estimations, and it was a remarkable fact that the presence or absence of this line should have made a difference of three magnitudes in estimations of the Nova.

New Mode of Enlarging the Telescopic Image for Photographing.—Mr. Davidson, reported at the above meeting that he had taken some enlargments of Jupiter, which showed that a newly proposed method would be very useful. It consisted in applying, after the fashion of the tele-photographic lens, a suitably corrected concave lens, placed at a distance behind the object-glass. Mr. Maunder had experimented with such an apparatus, in view of the coming eclipse in Brazil and the West Coast of Africa, and had obtained direct images of the moon one and a half inches in diameter.

Covering Metal with Glass.—A successful mode of covering metallic surfaces with a durable coating of glass is a problem which, if successfully solved, would be of vast usefulness in photographic work generally. In case of any of our readers wishing to experiment in this direction, we give details of a method which has been suggested for this purpose:—Take 125 parts, by weight, of ordinary flint-glass fragments, twenty-nine of carbonate of soda, and twelve of boric acid, and melt. Pour the fused mass out upon some cold surface, as of stone or metal, and pulverise. When cool, make a mixture of this powder with silicate of soda—water-glass—solution of 60° Baumé. With this coat the metal to be glazed, and heat in a muffle, or other furnace, until it has fused. This coating is said to adhere very firmly to steel or iron. We see no reason why if, on a comparatively small scale even, a method of surfacing iron with glass, either by the above or other means is possible, it should not be adopted, and thus be of the greatest value for such purposes as the ordinary steel plate of rolling presses is now put to. We are aware that plate-glass beds are supplied to some machines, but it is evident that they are not applicable where heat is applied. A rolling press, supplied with a plate with a glass surface, which would not scratch or become rusted like steel, nor break with a certain amount of heat, would be invaluable.

A SEASONABLE PRINTING PROCESS FOR AMATEURS.

It is probably owing to the reluctance on the part of the grea majority of amateurs to venture on to new ground that one of the best and oldest of our printing methods is almost entirely neglected by them, in spite of its various advantages, including indubitable permanence. I allude to the carbon or autotype process, which after silver printing on plain and albumenised paper, takes rank amongst the oldest of our modern printing processes.

The principle of the process is so utterly different from most other methods, and the manipulations so far removed in their character from those with which the amateur is familiar, that he may perhaps be excused for imagining difficulties which a simple trial would soon dispel; for, after the first mastery of the details of the exposure and development, the carbon process is one of the, if not the, easiest and most certain in its results of the large number that are now at the disposal of photographers. In fairly practised hands the beauty and uniformity of the results produced by this form of printing, combined with the ease in working and the small percentage of spoilt prints, is really remarkable, and cannot, we venture to think, be surpassed by any other.

But at the present season of the year carbon printing offers special advantages over most other methods that cannot fail to recommend it if it be once tried. Its superior rapidity in printing will be especially appreciated during the short dark days of winter, while the less liability of the tissue to injury from damp while in the printing frame gives it the preference over many of the newer processes. From the nature of the sensitive material there is, of course, an end to all difficulty in securing satisfactory and uniform tones, but perhaps the

greatest advantage of all is its wonderful adaptibility to negatives of greatly varying density and quality. It is scarcely too much to say that by suitable modification in the treatment of the tissue, both in sensitising and development, prints of excellent quality may be obtained from negatives which it would be hopeless to attempt to print by any other method. It is, in fact, the process *par excellence* which does *not* require a special type of negative, being as well adapted to dense slow printers as to thin, delicate, and even flat ones.

In connexion with this quality, it may be further remarked that for getting the best possible result from many of the only half-exposed hand-camera negatives that form so large a proportion of modern work, there is no process that can in any way approach carbon, for, by suitably reducing the strength of the sensitising bath, vigorous and well-modelled prints may be obtained from the most ghost-like negatives. Again, in the case of small negatives taken chiefly with a view to enlargement, it is well known that the best results are obtained from these delicate negatives full of detail; but if direct prints be attempted from such negatives in silver or platinotype, the chances are much against satisfactory results, as these processes require a more robust type of image. But such negatives are just the ones that will give the very finest quality of result in "carbon," and therefore the process can with still greater confidence be recommended to the notice of the large army of users of hand cameras of one sort or another.

A possible objection to the process may be found by some in the necessity for sensitising the tissue when required for use, as, although it may be obtained commercially in the sensitised condition, it requires to be used up within a comparatively short period. This objection, however, may be put on one side, for the worker who will not incur the slight amount of trouble involved in sensitising is not one that is likely to venture far enough out of the beaten track to try the process at all. But it is, after all, a very easy matter, when a day's printing is to be undertaken, to sensitise, over night, as much tissue as is likely to be used, and it will be ready for use in the morning. Moreover—and especially at this season of the year—the sensitised tissue may be comfortably kept for ten days or a fortnight, if protected from damp, in one of the ordinary tin cases. The full extent of its deterioration—if such it can be called—when properly kept, will be that it will take longer to develop, and will probably require hotter water; though, as a partial set-off to this, many operators claim that a better quality of results, as regards fineness and gradation, is obtained with tissue that has been sensitised for some days.

I do not suppose many of your readers will venture to the extent of making their own tissue, nor is there any necessity to do so, unless it be for the sake of producing special colours not found amongst the commercial samples. These are offered in such a variety of tones of the usual photographic kinds that for ordinary work there is no necessity to go to the trouble of preparing for oneself. But if by chance it should become necessary, there is not the slightest difficulty in the process, far less, indeed, than in the preparation of an emulsion, while the quality of the product need be in no way inferior to the commercial article. It is true that in the manufacture of the latter elaborate machinery is employed, as well as a large staff of more or less skilled assistants; but these are only required by reason of the magnitude of the operations and the necessity for having everything done in the most expeditious and economical manner possible.

(*To be concluded.*) W. B. Bolton.

CONTINENTAL NOTES AND NEWS.

Silver Lactate Plates.—Before the Antwerp Section of the Association Belge de Photographie, the President, Mons. Joseph Maes, recently gave a demonstration of the development of some transparencies on plates prepared with lactate of silver. The whites of the images were said to have been very pure, and the blacks very intense. The plates are rapid enough for reduction in the camera.

"The Question Box."—Before another Section of the same Society one of the members, Mons. Ed. Sacré, brought forward (as he had already done several times) a proposition for the institution of a "question box," so that members might have the opportunity of submitting questions without disclosing their identity. The report does not state whether M. Sacré's proposition was carried, so that we may suppose that that gentleman will bring the subject before the Section again. Among the few English Societies who have a "question box" we are not sure that, as a means of enabling an inexperienced member to obtain information upon a matter which he is reluctant, for fear of ridicule or criticism, to introduce in the usual way, it is of any practical use, it being as a rule more honoured by neglect than by use.

Sodium Sulphate in the Developer.—Herr Pippel, in a German contemporary, recommends the use of sodium sulphate (Glauber's salt) instead of the sulphite in the developer, it yielding clean negatives of a rich black colour. For a properly exposed plate he recommends immersion for a few seconds in a bath of—

Pyro	1 gramme.
Saturated solution of soda sulphate	20 to 40 c.c.
Water	100 c.c.

to which, being returned to the developing measure, is added 2 to 10 c.c. of a saturated solution of sodium carbonate, development then being resumed with the mixed solution. For over-exposure, bromide; more detail, an increase of carbonate; and for under-exposure, more of the latter, plus 20 to 30 c.c. of the sulphate solution, are recommended.

A Black Stain for Wood.—The photographer who makes his own apparatus may desire to know a good and cheap black stain. According to *Science en Famille*, the following fulfils those requirements:—

Extract of logwood	15 grammes.
Chromate of potash	2 „
Water	1 litre.

The extract of logwood is dissolved in boiling water, and the chromate then added. The colour of the liquid is a deep violet, which changes to a pure black in contact with the wood.

Vibration of Photographic Apparatus, &c.—To judge of the steadiness of photographic (or photo-micrographic) apparatus, &c., a contemporary recommends that a glass vessel, charged with mercury, be placed on the top of the camera or other convenient position. The least possible movement of the apparatus is shown by the numerous and varied little waves which appear on the surface of the mercury bath. These minute undulations are immediately perceptible to the eye, which sees, as it were, the images obtained by reflection on the brilliant surface of the mercury.

Writing on Glass.—For "matt" inscriptions on glass it is suggested to dissolve in 500 grammes of water 36 grammes of fluoride of sodium and 7 grammes of potassium sulphate, and in another 500 grammes of water 14 grammes of zinc chloride, 65 grammes of hydrochloric acid being added. For use, equal parts of the solution are mixed, and the inscription made on the glass with a pen or brush. In about half an hour the lettering so traced will present the customary "matt" appearance.

Varnishing Zinc Trays.—When zinc trays, &c., are used for washing plates or prints, says "Ki-Non" in *L'Amateur Photographe*, the deposited hypo reacts on the metal, which, if coming into contact with prints, stains them. This, he says, may be avoided by varnishing the vessel with bitumen of Judea (5 parts dissolved in 100 parts of benzol). The varnished vessel is placed in sunlight in order that the bitumen may be rendered insoluble. He advises two applications of the varnish, and to repeat the operation as occasion may require.

Impurities in Reducing Agents.—As the result of an examination of the developing properties of gaïacol, as alleged by Colonel Waterhouse, Messrs. A. & L. Lumière state that that sub-

stance in the purified form does not develop exposures on the silver haloids, the developing action being due to the impurities with which it is contaminated. Treating of the developing powers of certain substances at a very high degree of dilution, they mention the interesting fact that an alkaline solution of para-amidophenol at the strength of 1 : 10,000 is sufficient for the purpose.

WINTER TROUBLES.

It may seem something like "locking the stable door after the horse is stolen," to raise a note of warning after an accident has happened, but as we can scarcely hope that the present thaw closes our winter, the same trouble may occur to others that has fallen within my own experience. This, though perfectly explicable, is to me, after many winters' acquaintance with chemical and photographic apparatus, entirely novel in its form, and, as a very simple precaution will prevent its recurrence in other cases, I make no excuse for narrating the circumstances.

Just previous to, or in the early part of the late severe frost, a large and valuable porcelain dish, after being used for washing a batch of prints, was roughly wiped out and reared on edge against the wall in one of my work rooms. The dish, I may say, was, up to this time—so far as I was aware—perfect, the enamel not even being cracked, as is so often the case with such dishes, even after comparatively little use. Judge my astonishment, therefore, when, on going into the room one day, I noticed a crack extending from one of the lower corners, as it stood against the wall, to nearly the centre. A rough examination led to the conclusion that the crack was a new one, probably the result of a recent knock, though I could not remember having administered one, and nobody else had had access to the dish.

The crack at this stage did not appear to be a very serious one, not sufficiently so to cause the dish to leak or to unfit it for the purposes of washing to which it was usually applied; but in order to guard against further damage, it was placed more carefully in its proper rack, one of a series of shelves on which it rested in the horizontal position. Here it remained for probably a week until I required it for use again, when, on taking it out, I was disgusted to find that not only had the crack extended nearly right across the dish, but it had become at its starting-point at the edge nearly an eighth of an inch wide.

An examination showed that the crack was filled up along its entire length with ice, and this gave a clue to the cause; and a subsequent closer and more careful scrutiny proved my original supposition to have been correct. A very slight crack, possibly not visible at the time, in the lower corner as the dish stood against the wall had absorbed a certain amount of moisture, which in freezing forced the edges of the crack wider apart, and probably opened it up a little in length, and into the newly opened portion fresh moisture found its way by capillary attraction, to be frozen in turn and still further extend the damage, until the wedge of ice, as I have said, had opened the crack at its widest to nearly an eighth of an inch.

In this condition the dish was perfectly firm, the two portions being held together by the intervening strip of ice; but, on pouring a little warm water into it, the expansion of the material caused the fracture to extend, with a faint report, to the opposite side of the dish, and, the cohesion of the intervening ice being simultaneously destroyed, the two portions fell apart. It required but a brief scrutiny to show that a crack scarcely two inches long had existed in the upright *side* of the dish, and through only a portion of its thickness; this much was evident from the slight discolouration of that portion. The rest of the fracture caused by the ice was perfectly white and fresh.

Curiously enough, though this was the first occurrence of the kind that ever came under my notice, within a day or two a precisely similar accident happened in the domestic department; a large jug, having been hung up damp, was fractured in the same manner, and fell in pieces when warm water was poured into it.

The lesson taught is a very simple one, namely, never, but especially in frosty weather, put porcelain, or similar vessels, away damp. The danger is greater in the case of dishes, jugs, or other utensils used for pure, or, at any rate, ordinary water, than those containing solutions of chemicals, as the latter will, to a certain extent, prevent, or arrest, the freezing of the liquid. Still, the careful man, who always washes his dishes or measures before putting them away, would be wise in carrying his care a step further, and making it a point to systematically dry them before considering his task performed. Neglect of this simple precaution has cost me a useful and valuable dish.

It will surprise many amateurs who have not tried it, how small an amount of heat will keep the frost out of a dark room. A plan I have adopted with satisfaction for several years past, consists in keeping burning, in my sink, when not in use, an ordinary benzoline lamp, over which is placed, on a retort tripod, a tin can, containing about three pints of water, which absorbs and radiates the heat that would otherwise be diffused and wasted. The shelves on which my bottles are stored are in close proximity to the sink, and these get the benefit of the genial warmth, though the far-off corners of the room may be below freezing point. With this simple arrangement, not even "saturated" solutions of oxalate of potash, or sulphate of iron, need give any trouble in the coldest weather. The cost is less than a penny *per diem*.

OLD COLLODION.

SOME CONTRIBUTORIES TO ARTISTIC RESULTS.

[Hackney Photographic Society.]

My intention in engaging your attention to-night, with some of the minor matters which may or may not contribute to the artistic result of our work, was not to deliver a discourse of a learned kind, but rather to select one or two matters, and, having expressed some views thereon, to have left the thing to general subsequent discussion. Those who are sufficiently serious in their endeavours for improvement probably have as much solid food as they can digest provided by the weekly journals, so that I sometimes think our lectures and essay readings at society meetings are not always the best possible appointments for the good of individual members. Thus, for instance, as a contributary to general good effect, I might have selected frames and mounts. I should have raked together specimens of mouldings and cardboards from the four quarters of the earth, and come ladened like a picture framer's agent. I should then have suggested the respective merits of black and gold, white and gold, English gold, and the gold which, though it glitters, is made in Germany, dark woods and light woods, black or brown. Then there would, of course, be plushes and silks, and wondrous fabrics to be considered; there is the clear white glass and the greenish glass, with all sorts of specks and bubbles in it, and a hundred other aspects from which one may usefully consider and discuss the framing and mounting of our pictures. It is an important matter; a good picture is worth well mounting, and, in order to decide on the mount most suitable, no ordinary care, judgment, and taste are needed.

Exhibition Frames.

As it is, however, I have none of these specimens here, nor perhaps is it necessary to have such. Most of us have seen a few exhibitions, and in that case have had opportunity of seeing every kind of frame which human ingenuity could invent, and we must in many cases have been convinced that with some competitors the frame was the thing exhibited, with some apology for a picture thrust in the opening just to fill it up. I have thought sometimes that in the frames you may find an index to the exhibitor's character and condition. There's the man of magnificent ideas, but lacking the means of carrying them out, glorious in florid gilt, crimson flock inches wide, and he who has money and loves to spend it, who frames his things regardless not only of expense, but of the fitness of things. The man of original ideas is soon recognised, and often his originality gets the better of his judgment, and the unconventionality becomes affectation, and he who copies or imitates is apt to imitate blindly, and misapply the models which he has set up.

And now, if one should say, What amongst the many ways of framing and mounting is the best which will secure for me the commendation of those who judge? I should say that your good taste in framing will be best displayed when your frame itself is not noticed. No paradox is this, but solid truth, and hence one advantage of having every picture in the room framed with uniformity no *one* attracts more than another, and so we shall escape that most irritating remark, as open-mouthed wonderment says, "What a beautiful frame?" I well remember visiting Mr. F. Hollyer's exhibition of photographs at the Dudley Gallery privately, with some half-dozen *confrères*, and immediately on entering the room each one of our number exclaimed, or his looks expressed it, "What capital framing!" Then we laughed that we too should have done what so many have been ridiculed for doing—admiring the frames before thinking of the pictures. But do not mistake me, the case was very different; it was not actually the frames that awakened remark, but the excellent judgment shown by the artist in using such material, and of such colour that, although we could if we thought about it tell what manner of frames were there, yet throughout a walk round the gallery one was never conscious of frames at all. The pictures might as well have been let into the walls of the building, and been part and parcel thereof. To my mind that is ideal picture-framing.

The Right Frame and Mount to Use.

Can you remember, for instance, some picture, some photograph, which pleased you a good deal, but, if asked, you cannot remember anything of the mounting or frame? Well, then, be sure that was just the right frame and mount for that particular picture. How are you to imitate it if you can't remember what it was like? My good sir, no one suggests—or, at least, I do not—that you should imitate that or anything; what suited that picture may not suit yours; your only way is to select such a surrounding for your picture that it shall be wholly forgotten and kept in subjection when looking at the picture. Someone challenges me by referring to the ponderous mass of gilt which usually surrounds the best of paintings. Well, the way to avoid attracting attention is sometimes to do the time-honoured ordinary and usual thing, and so it has become customary to put oil paintings in heavy gold frames. Perhaps the safest thing is to follow so widely adopted a custom. Still, we may notice already in some of the newer picture galleries the conventional gold frame does not rule supreme, quite a number of blackwood mouldings being introduced; moreover, the artist's fine contempt for the frame-makers' craft is seen inasmuch as somewhat shabby and far from new frames are employed, but with just that amount of good taste which, without effort or intention, saves the artist from error in the opposite extreme. I have hinted that the conventional and ordinary may, when we are in doubt, be the safest course to adopt. I give this as a point for discussion; and further that, all things considered—and I must emphasise this qualification very strongly—all things considered, and allowing for some exceptions, the safest and best mounting for our photographs, as taste and feeling goes at present, is the plain wood, oak or dark colour, and the cream-toned mount on a white board, as has become very widely used.

But I fancy already some one is beginning to resent my expending so much time in talking about so dry a subject as frames and framing.

Cutting Down Prints—The Knife and Scissors.

Well, then, if I had had proper time to prepare my subject for you this evening, I should have brought here to-night a printed photograph cut down to all manner of sizes, and I would have discoursed on the scissors and knife as a powerful contributary to final artistic result. As it is, I have brought no examples; I content myself with submitting to the suggestion that, as a rule, we are all too much afraid of using the knife. We are too inclined to be influenced by the standard commercial sizes; if 12+10 is the size of our plate, we must fill every inch of it; this at least seems to be the prevailing idea. Even those who are thoroughly acquainted with the often-used argumenta in favour of liberty of size and shape, still, as it were, reluctantly fall into the groove, and strive more than for anything else to make the subject fill the entire plate.

There is nothing new in all this; our teachers have been pointing out the advantages of cutting down our prints so as to improve the composition for years past, still we may notice the same old faults committed on all hands, for want of a little strength of mind in putting in the knife and cutting away some pretty little bit, some favourite corner, because, although good enough itself, it does not help the picture as a whole—and it does require no small strength of mind, as I myself know full well. Am I not conscious of being a grievous sinner myself in this direction? It is hard to deliberately cut away and destroy some, it may be, particularly interesting object, something especially well rendered, because it does not help the picture as a whole; but its good qualities, technically considered, must be no reason for saving it. By this I do not, of course, mean that the chief and central object in a composition is to be cut away, though it sometimes may happen that the object we had intended as an important item in the scene does not quite come up to our expectations, and we can secure a satisfactory picture by reducing the size of the print very considerably. To give you an example, I not very long ago spent a day with the camera on the marshes below Old Winchelsea. Some of you may know the spot, and will remember how delightfully the abrupt hill on which Winchelsea is built rises from a vast green level. Here black-faced Kentish sheep browse by thousands, and I conceived the idea of getting a group of sheep on the left of the foreground and including the hills in middle distance. And so I did, yet, when printed and finished, the thing was far below my expectations, and I could not for a long time decide what was amiss. I was so intent upon my picture of sheep that it never occurred to me that the sheep and the hills had no connexion until, with a boldness of which I am not often capable, I cut the thing in halves! Now, I found I had, by two strokes of my knife, constructed a picture in the half which still contained the hills, but; alas! the group of sheep, which I had waited hours for, which I had wearied my attendant in driving and coaxing into position, were abandoned—the object of all my care and patience is cast into the waste-paper basket.

When producing the first print from a negative, I usually lay it out flat, and take four strips of brown paper and lay them so as to temporarily frame my print; then I shift them in a variety of ways, each time including within their boundaries a different part of the print. By this means I ascertain what part of that landscape is best retained and what best discarded, often with the most heart-breaking results. How often has a 15×12 view, made with great care, been reduced to as small as 6×4? And when I have recalled the real hard work and fatigue which attended the carrying of large camera and heavy apparatus, it seems a good deal to have gone through for the sake of a little print.

Size and Artistic Effect.

Closely akin to this is the notion that size has a good deal to do with artistic effect—an erroneous idea that a large picture is artistically superior to a small. Possibly some scenes are more suitably produced on a moderately large scale; but, as a general rule, I do not hesitate to say that a quarter-plate *may* be as completely (nay, often is) a work of art as your 24×18. Now, Mr. Chairman and gentlemen, if I had prepared for this evening, as I ought to have done, a should have submitted to you occular proof of this by exhibiting I print 3×4 by the side of one 30×40; as it is, I must put it to you that *size*, that is measurement by inches, contributes nothing of artistic effect.

The completely successful picture is the one which, whilst giving a pleasant impression, does not make its size *felt*. A little picture may be of such a character that the spectator is not made conscious of its restricted size; the selection of subject, and the treatment of it, may convey a sense of breadth and largeness, which, to my mind, is a most important characteristic.

Why Adopt a Rectangular Form of Picture?

Why do we usually adopt for nearly all subjects a rectangular form for our pictures? The eye does not form a rectangular figure when looking at nature, but a vignetted ellipse. It was probably convenience in the first place which decided the matter, and then custom grew upon this, so that now we use a rectangular form because, being conventional, it attracts least attention, and the spectator is *unconscious of* the boundaries. The arrangement or composition of every picture should be such that its boundaries should not be felt to be restricting, and there should be such interest within the confining lines that the eye feels no desire to wander, and the mind no wish to inquire of what else the world was composed, or what came next in the landscape panorama. I might suggest such arrangements of lines, such combinations or such dispositions of central objects, and so forth, which I have myself found to assist in this direction, but beyond this neither I nor any one else can tell you how to make your small picture overcome its impression of littleness. It is a thing to be found of experience and observation, and to be attained as others have attained it—on the steep ladder of many failures.

A Definition of Artistic Effect.

I should not have to look very far back to find the time when it would have been necessary for me to preface such remarks as I had intended making, and have already been stumbling over, with a definition of what I meant by artistic effects; but I am seriously glad to believe that in some sense we have got beyond that necessity, and that, in a general manner at least, most of my patient audience have some idea as to what an artistic picture should be, namely, not an imitation of nature, or a copy of nature, but rather an interpretation, that is, *a general and broad representation of the impression made upon the artist's mind by the scene, and containing an expression of the sentiment or idea which it awakened.*

Before exhausting the list of factors which might be considered in the light of contributories to artistic effect, we should have to discuss: Figures supplementary to a landscape scene, also cattle and the like; and we might note how and when they contributed or detracted from the well-being of the picture; also clouds and the employment of a second negative; colour, whether of the image produced or of the paper used, which may make or mar our work; position of light and the amount of it, also the relative tone of various parts; and we should hardly escape discussing the question of focus and amount of detail permissible, and you know if we started that topic to-morrow's sunrise would find us still at it, and this room bearing close resemblance to a battlefield or the sequel of an Irish wake.

"An Evil Reputation."

Has any gentleman here, I wonder, ever had an evil reputation foisted upon him which he does not deserve? Has any one who, being a man of very temperate habits, found suddenly that his neigh-

bours have quietly agreed amongst themselves that he is much addicted to whisky drinking, and that when he goes out of an evening, professedly to a meeting of the Hackney Photographic Society, his best friends spread the report that the Hackney Photographic Society only means a wild bacchanalian revel, or a disguise for entering on a housebreaking expedition? If so, he will be able to sympathise with *me*, for somehow my photographic friends have decided amongst themselves that I believe in nothing but photographs put confusedly out of focus, printed on exceedingly rough papers and in a reddish-brown colour fallaciously called sepia.

A. Horsley Hinton.

AN APPARATUS FOR THE DEVELOPMENT OF PHOTOGRAPHIC PLATES WITHOUT THE USE OF A DARK ROOM.

[Journal of the Society of Chemical Industry.]

The apparatus which I bring before you to-night was in use for two months before I learned that a "portable developing box," similar to it in many respects, had been described by Dr. T. W. Harvey in the *International Annual of Anthony's Bulletin* for 1888. But as the apparatus about to be described differs from it in principle, and is based on the photo-chemical investigations of Messrs. Hurter & Driffield, I have thought that this communication might be of interest to the Society.

In the paper which we had the pleasure of listening to last session (this Journal, IX., 455–469), Messrs. Hurter & Driffield have shown that of all the conditions involved in the production of a "perfect negative," those relating to the exposure are by far the most important, and if the exposure factors are so adjusted as to give the "correct exposure," the development is of secondary importance, as the density gradations of the negative are entirely due to the action of the light.

It therefore occurred to me that, with a correctly exposed plate, development might be carried on quite mechanically, as the required density can be regulated by the length of time of development.

On trying the experiment of allowing plates which had been exposed by the aid of Hurter & Driffield's actinograph to remain in the ferrous oxalate developer for different lengths of time, it was found that, with the same quality of plate, satisfactory negatives could be obtained in ten minutes with a strong solution, and in fifteen minutes when the solution was diluted with an equal volume of water. When the time required to obtain a suitable printing density had been ascertained for a particular plate, it was found that there was nothing gained by watching the progress of the development, and consequently the dark room might be dispensed with if means could be found to keep the plate in the dark during development, and in its transference from the dark slide to the developing vessel.

In order to attain this object I have devised the apparatus which I have named a dark developing bath.

It consists of a metallic case, A (fig. 1), only slightly larger than the plate for which it is intended, which can be closed light-tight by means of the lid B. It is furnished with two tubes, one, C, entering at the bottom of the bath, which can be connected by a piece of india-rubber tubing, E, to the funnel D; the other is near the top, just above the level of the plate P. The former serves to introduce the developer into the bath, and the latter, F, allows the air to escape and also acts as an overflow.

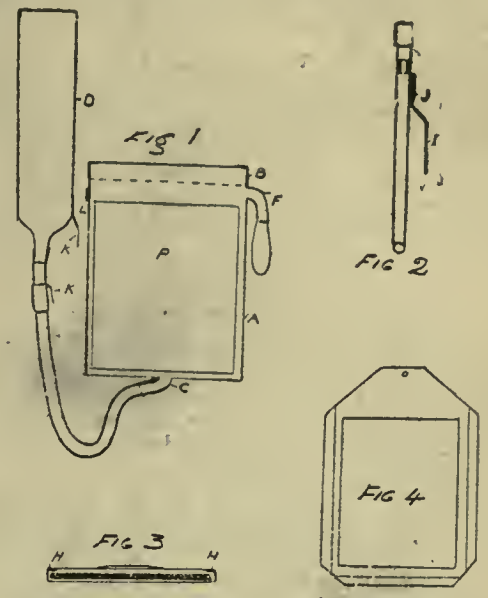
The funnel, D, and the indiarubber tube, E, are supported by means of the hooks K K, which fit into the eye L. The tubes are so bent that no light can enter the bath. An end view of the bath is shown in fig. 2, in which a movable hook, I, fitting into the socket, J, serves to fix the bath to any convenient support.

A section, Fig. 3, shows the plate P, the film side of which is kept from contact with the side of the bath by means of the metallic strips H.

When the bath is intended for the development of films or paper prints, it is furnished with a carrier (fig. 4) into which the film or paper is inserted before being put into the bath, and when required for the development of several plates at one time, it is constructed with grooves as in an ordinary plate box.

The bath is used as follows:—The dark slide containing the exposed plate and the bath are placed in a changing bag, into which it is only necessary to insert the hands. The plate is then transferred from the slide to the bath, care being taken to keep the film side towards the back of the bath.

After being closed, the bath is withdrawn from the bag into daylight, and fixed vertically to any convenient support by means of the hook. A vessel is placed under the overflow tube, and the inlet tube is attached to the funnel, which after being filled with the developing solution, is raised and lowered several times, to alternately fill and empty the bath, and so ensure the removal of air-bells from the surface of the plate. After standing sufficient time to complete the development, the solution is run off from the bath. The plate is



washed by running water through the bath (either by means of the funnel or by attaching the india rubber tube direct to a water tap), after which it is taken out, in daylight, and "fixed" in a covered tray.

If it be desired to "fix" entirely in the dark, the operation may be conducted in the same bath or in a similar one to which the plate has been transferred in the changing bag.

The final washing of plate may be done either in the bath or in the usual way.

The best developer for use with the dark bath is ferrous oxalate, on account of its property of not producing "fog," even when a plate has been left in it for an hour (Hurter & Driffield, loc. cit. p. 459). It should be made just before use from the following solutions prepared according to Thomas's formulæ:—

No. 1.

Potassium oxalate	300 grammes.
Potassium bromide	2·2 „
Water to make	1000 cc.

No. 2.

Ferrous sulphate	400 grammes.
Sulphuric acid	3 cc.
Water to make	1000 „

To *four* parts of No. 1 *add one* part No. 2, and water to make *eight* parts.

When the developer is used at once with Thomas's "Extra Rapid" plates, from twelve to fifteen minutes in the bath at about 15° C. is sufficient to give a satisfactory negative, if the exposure has been correct.

The time required to obtain a suitable density is found by placing the exposed plate in the bath and adding the amount of developer required to fill the bath, in four equal portions at intervals of five minutes. Four densities are thus obtained by developing for five, ten, fifteen, and twenty minutes respectively, from which observations the time that gives the desired density is selected.

A very small bath to contain *four plates* (a quarter plate cut into four) is useful for the development of test plates exposed in the camera on a landscape in order to ascertain the speed of the plate, as recommended by Mr. V. C. Driffield (*Photographic Soc. Reporter*, April 1889).

A developing bath constructed as above, besides enabling plates to be developed *without a dark room*, has some other advantages over the ordinary developing tray. The bath being used vertically presents a very small surface of liquid to the air, thereby preventing the rapid oxidation of the developer. As the solution is introduced at the bottom, under pressure, it flows up evenly over the plate, carrying the air before it and so prevents air-bells. The plate is com-

pletely immersed in the solution during development. The bath being quite light-tight, there is no risk of "fog" from access of light to the plate, and it is therefore especially suitable for the development of isochromatic and other very sensitive plates. The tubes attached enable the solution to be readily run off and replaced by one of altered composition, and also allow of a continuous flow of developer through it.

As this apparatus has been designed for the development of correctly exposed plates, any plates developed in it which are either over or under-exposed will be more or less defective. If, however, the exposure has been nearly correct, a passable negative will be obtained, but if it has been *widely different* from the correct one, as no provision is made for remedying the defect, the negative will be a failure, but if such a result should lead to more attention being paid to the exposure it will not be altogether to be regretted.

ALEXANDER WATT.

"BREADTH."

MR. TULLOCH'S letter has started a subject which will bear much reflection, and I wonder if nineteen out of every twenty photographers ever think about this artistic quality in the production of their prints, or how many understand what it means, and yet it is the *one chief objection* which painter artists raise against photography, that photographs are so deficient in "breadth."

Thousands of amateurs have taken up, and will take up, photography as a pastime who have never had any training in drawing or painting in oil or water colours, and therefore have had no chance of becoming acquainted with terms used in art and their meanings, and it naturally follows that they cannot apply these principles to their work in the form of study of composition, light and shade, and breadth of treatment, and it is mainly here that others who have enjoyed such opportunities, and have been draughtsmen or painters *before they took up photography*, step into the front ranks, and show superiority in their photographic work, and the best thing those who desire to excel can do is to take a term of training in any of the numerous schools of art now existent in every town of any size, and so qualify themselves *to see* in nature *with educated eyes* things they now look at with a pleasing, but at the same time artistically uneducated, effect.

If I were asked to define in as few words as possible the meaning of "breadth" in a picture or photograph, I should be disposed to say that it is the *absence of spottiness*, or the reverse of the effect of spottiness, and that abundance or minuteness of detail in the picture or print has nothing whatever to do with it either one way or another, provided that detail (though microscopically sharp) *is kept in subordination to the general tone of the parts of the picture or print where it exists.*

"Breadth" is a quality of great convenience to the painter; it enables him *to ignore* the wealth of detail which would cost him infinite time and labour to produce with brush or pencil, and which, if produced, would distract the interest of the spectator and attract attention, to the detriment of the principal "motive" of the picture. Therefore he subordinates detail, or, if painted in, he "glazes" it over and tones it down with some transparent pigment which, whilst it prevents undue attraction to the eye, permits it still to be found by any one who *seeks for it*.

Breadth is so essentially an *artistically created* quality that it is not frequently seen in nature, except under special conditions of light and shade. This is sufficiently evidenced by photography itself, from the fact that so few photographs possess it. If any one desires to study the effect of "breadth" in natural landscape, they must be on the watch for it soon after sunrise on summer mornings, or in the late afternoon and evening, when the sun is at a comparatively low altitude, and how few photographers ever attempt to get their negatives taken at such times. Wait till the sun reaches an altitude of sixty-five or seventy degrees, and it becomes very difficult to find "broad" effects of lighting, because every object becomes so generally illuminated that "spottiness" in the lighting is universal, and it is only by selection of larger masses of shadowed subject that "breadth" can be obtained.

Again, after a shower of rain, when every atom of foliage sparkles in the light with wet reflecting surfaces, the quality of breadth is absolutely impossible to secure, and such a subject may be taken to express a quality the very opposite of "breadth." The moral is, Don't take any negatives under such disadvantageous circumstances, however beautiful the view may appear to your senses; the result in the photograph must be general spottiness, distraction to the sight, and vexation to the perception of artistic friends.

How, then, is "breadth" to be secured in our photographs? In two ways—partly photographic and partly artistic. First, by careful study of the time of day, early or late, when the subject is broadly lit, and taking negatives at such times. Second, by imitating the work of the artist and toning down in the finished print such obtrusive spotty lights as tend to destroy the breadth of the picture, and which have been found impossible to avoid in the natural view.

The followers of the fuzzy definition school had the attainment of this quality of breadth very strongly in view in adopting the "out-of-sharp-focus" principle, but it appears to me that it is a mistake to suppose that it can be attained by that means. The broken effect of spotty lights amongst broad shadows is just as apparent, though not so strongly accentuated, when they are thrown out of focus, and the distracting effect is the same, and, therefore, nothing is gained by diffusion of focus; but if these disturbing lights, which *will* come where they are not wanted, can be toned down so as not to be obtrusive, the effect of breadth can be secured *without the sacrifice of good definition*, which has such a charm in photographs when well managed, and which artists enjoy as much as any one else when kept down in proper subordination to the general tone and lighting of the picture.

Another method of securing breadth to a large extent is by giving *full exposures*. We all know that the consequence of under-exposure is great contrast of light and shade, and the more the negative is forced to bring up latent detail in shadows the more accentuated becomes the contrast and the spottiness. The reverse is the case with over-exposure, as the proper balance of contrasts is overdone, and general flatness is the result, which constitutes an exaggerated and spurious kind of breadth. Those who delight in so-called "brilliant" and "sparkling" negatives, and aim at sufficiently short exposures to secure them, often err by obtaining negatives deficient in the quality of breadth by reason of this very "sparkle" and "brilliance," and it is just the *critical point in correct exposure* to obtain the true effect of breadth without either spottiness on one side or flatness on the other, and it is only to be got by *sufficiently full* exposure and restraint in development. This will secure it photographically, but, allowing for accidents in timing the exposure, or *impossibilities in obtaining perfect natural lighting*, it is as legitimate to adopt the artist's method, and to tone down objectionable lights in the print, as it is for him to "glaze" or "scumble" his effects on his canvas, and, as a final resort, is often the only way to obtain the desired effect of breadth.

"LUX."

THE PINHOLE SOCIETY'S OUTING.

IT was resolved that the members of the Pinhole Society should have an outing. Fine weather brightened the heart of the amateur, and he in return spent many evenings in brightening his beautiful set. Then came the difficulty, what part of England should be favoured by the Pinholes on this particular day? Sixty members each selected, and hard indeed was the task to get the remaining fifty-nine to go in unison. All expressed their objections, and the chairman found it a very lively meeting. Some had taste for water pieces, others wanted landscapes, a few preferred figures, while one had a strong taste for trees, and a good house of refreshment near. Finally came a mutual settlement, every member promising to be at the appointed spot, and to bring a friend if possible. When the morning arrived, the full muster numbered four. The remainder of the society had, in the meanwhile, decided if the others *would not*, they *would* go to the spot of their own choice. So they went.

The four turning up together were bent upon the real thing—a jolly day first, and pictures second. Away steamed this little party, all loaded with oddities connected with, but never separated from, the art of their heart.

When a party of camera men meet on a rail car, all charged with hopes and strong tobacco, what talk! The usual lady and gentlemen passengers sit by and wonder, and again wonder, at the strange language they hear flow so fluently from the lips of these camera men. The gentle sex are said to talk, but are not in the running with a merry party of photographers. Processes and developers containing the whole letters of the alphabet are rattled off with the greatest speed. A good photographic gossip is far more gratifying than an outsider can imagine. It comes to all who ride this hobby horse. And so the four men of the camera sped on. Each knew the best developer and worst make of plate, and all four disagreed thoroughly and candidly over each. One's success proved another's failure, and so trouble came and trouble went. More talk, more smoking! Grand old meerchaum! strong old briar! all burning and roaring at full blast. The male and female passengers slowly but surely become saturated with long words and tobacco smoke. They wonder, as the train dashes on, where and what are the stations. To see is impossible, and with clatter of train and language of a country porter without and confusion of tongues within, they begin to feel uneasy. They shrink from asking a question of the camera men, as to do so would break their run of words, for they now think photography a sacred science,

and photographers strangely wonderful men, while much regretting they had allowed themselves to remain so long in the same compartment.

At last came a pause, the four men knock their pipes on the edges of their shoe-leather, put them away to the pocket nearest the heart, and, with camera-case on the tripod slung over the shoulder, each makes a long down step, and all four, with packs and bags, are safely landed at their destination. The two passengers also get out, and push by with a rapid farewell glance. After a short halt, on they go, until the leader gives the word, "Halt! present arms, and blaze away!" Then, in quick time, comes the sight of tools in their multiplicity. Here you have demonstrative proof how some carry the fullest detail in all the likely and unlikely requirements of his art. One has a range of lenses from decimal focal length nothing, to that eight times the boundary length of his plate, with which he says he can "bring down" an object as near as his eyelash, or as far off as the moon. Everything he carries opens one into another, with the ingenuity worthy a Chinaman. He even wears a wonderful suit—all secret drawers and pockets. Touch a button, when out comes a dark slide. Pull a string, when out hops a pretty little magnifying glass. From a fob comes the neatest finder possible; also quite a portable photographic store. If you are in doubt as to the light he, in a jiffy, hands you the very latest actinometer, supplemented with a thick volume of closely printed instructions. The standard tables of exposures, position, and light are also there to the least degree, with such information—"failures" cannot be thought of, least of all explained. Another of the four has a rough-looking lot indeed; he feels some reluctance to open up beside his elaborately equipped comrades, so, under the shadow of a big tree, he raises gently and quickly his cheap set to its stand, which is, in itself, a noble piece of English oak, heavy enough to resist the quarter or 15 × 12 camera, which retains a power, like Sandow, for more weight. The best-looking thing he carries is the black velvet focussing cloth, and soon it acts the part of pall to his seedy camera box. How, all day, he so cleverly and, in a way, seemingly unintentionally arranges this cloth to always remain without exposing his lot, is worthy one's admiration. His slides are stronger than highly polished mahogany; they require no brass bindings, being in themselves sheet iron. His exposures are made by his own judgment—without reference. He takes everything cool and easy, and seemed thoroughly confident of the results. And so both the men, with their chums, worked away the day, all getting home well pleased, and feeling better for the outing, and ready for a good, enjoyable night's rest, as payment for a day's toil. On the following fortnight, once more the "Pinholes" met; all mustered in fair numbers, anxious to see the results. The four chums sat together. The owner of the exquisite lot seems to have downcast features. They compared results—without doubt he owns the worst work. How to account for it he does not know. Possibly, in the excitement, he mistook *f*-8 for *f*-32, and fogged all by over-exposure. His ideas had become confused by too many items of detail in his bound book. He got a bit mixed, while the man with the cast-iron slides had little incumbrance, and turned out the most successful pictures. It was therefore further resolved, before the close of the meeting, that the said four should once again take another outing, and carry as few articles of apparatus as possible, and, *for certain*, leave behind the bound volume of tables. TOM COAN.

DERBY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THIS Exhibition was held on January 4. A local critic writes:—"The pictures hung numbered 367, and included some of the finest amateur works which have ever been brought together in this or any other town. The specimens included a set of grand platinotypes by Mr. A. H. Bennett, which won the silver medal presented by Mr. W. Bemrose, J.P., as well as the series by Mr. F. E. Bemrose, which gained the bronze medal given by Dr. Rooney. Mr. J. Riches' collection gained the certificate given by the Society and were also capital pictures well deserving the award. We might mention that the merits of the exhibits were decided some time ago, the judge being Capt. Abney, the President of the Society. Mr. Councillor W. W. Winter exhibited a number of large photographs, which were very much admired, especially *Galatia* and *Maggie*. Mr. R. Keene had on view some excellent architectural studies, whilst leaving the professional pictures and coming to the amateur views Mr. E. C. Green's large collection were very deserving of notice. They were principally land and sea-scapes and were highly finished works of an enchanting art. Mr. J. Scotton's locomotives (silver print process) were highly meritorious, as all this gentleman's works are, whilst Mr. T. Scotton's views of interiors of Midland Railway buildings, were admirable. Mr. J. Flint's *On the Trent*, as well as his photograph of the fountain in Derby Arboretum, were striking pictures, taken with care, and Mr. J. Eastwood's frame of eight included a magnificent portrayal of the interior of Lichfield Cathedral. Mr. F. G. Thurgood had some capital views hung, all well-known local scenes, and Mr. T. Scotton's picture, *A Heavy Load*, was another work which could not be passed without notice. The same gentleman had *A view near Barnt Green*, which demanded attention. Next came some really excellent fruit by Mr. S. C. Riley, with some high-class amateur work, by Mr. A. B. Hamilton, in the platinotype 'A' process. One of these, which had been enlarged by Mr. Keene, is a portrait of Lieut-General Sir John Stokes, K.C.B. The same exhibitor has an amusing series of small works entitled *Where are you going to, my pretty Maid?* Another fine picture is *Honfleur*. Views of Derbyshire are shown by Mr. C. H. Rourdin, and are very interesting indeed, both scenery, style, and effect being all that could be desired. The pictures which won the medals are specimens which speak for themselves, but Mr. Bennett's are undoubtedly the best. Mr. Riches' comes very near the winners, and his efforts well deserve the reward they obtained. All the other works are quite up to the average, and we must not omit to mention those of Mr. G. Walker and Mr. J. Fleet. On Wednesday evening the medals were awarded by his Worship the Mayor (Mr. Councillor W. H. Marsden), in the presence of a large number of ladies and gentlemen, including Messrs. R. Keene, T. Scotton (Hon. Sec. to the Society), J. Scotton, A. B. Hamilton, W. Wilkinson," &c.

WEST LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

IT is a pleasure to visit such an Exhibition as that of the West London Society, which was held at the School of Art, Bedford Park, Chiswick, on Tuesday and Wednesday last, as, from former experience, one may with tolerable certainty rely upon seeing a collection of high-class photographs ably hung, and with the other details of an exhibition gratifyingly well managed. No small share of the undoubted success of this year's Exhibition may easily be traced to the efforts of the President (Mr. John A. Hodges), who, besides being a cultivated photographer, is also a working President (and therefore commendable to other Photographic Society Presidents for imitation), taking an active part in the work of the Exhibition, and also contributing several of his own pictures thereto.

About 180 frames of photographs were hung, the high average of merit displayed making it a trifle difficult for the critic to select individual works for praise, while happily there was little if any room for adverse comments, unless, maybe, the now inevitable opportunity at photographic exhibitions for airing a preference for one of the two methods of focal treatment in vogue be taken advantage of.

A capital exhibit was that of Mr. James J. Adam, his winter effects being so realistic as almost to cast one into a chill. For one of them, *A Frozen Swamp*, he was awarded the President's silver medal. A bronze medal went to Mr. L. C. Bennett for *In the Pool*, a study of craft below bridge, and the same gentleman showed studies of *The Conch Digger*, and *The Cress Gatherer* (a man gathering cress in an ordinary piece of landscape, very cleverly treated to make quite an artistic picture). In *Rejoining their Ship* a boat laden with two or three figures is seen making for a distant vessel, but, to complete, or rather to tell, the intended story, Mr. Bennett might have made an attempt to show us the faces of the sailors, and could well have afforded to have been a trifle less fuzzy. Mr. W. A. Brown showed an excellent rendering of *The Brook*, a water-cum-tree bit which the late Lord Tennyson might conceivably have had in his mind when writing the poem. An untouched, out-of-door *Portrait of a Lady*, by Miss Brigg, showed soft lighting, and ease of pose, and in *On the Basingstoke Canal* Mr. W. L. Colls was represented by a tender and harmonious view. Mr. S. T. Chang merits our congratulations for his continued improvement, his Holland House interiors, *Cottage near Witley* and *Church near Godalming*, showing care in the treatment.

The President (Mr. Hodges) received a bronze medal for *Drear December*, a large study of a bit of desolate landscape with trees, which, to our thinking, would have been more effective had a cold instead of a slight sepia tone been employed. Anyhow, the same gentleman's Welsh series, *Shallow Waters*, *In Conway Vale*, and the other pictures of his which we have noticed before, are, to our thinking, as good as anything he has ever shown, and much superior in handling and effect to the picture here medalled.

Mr. George Lamley, a painstaking artist, showed several, including *A Sluggish River* (a charming study previously noticed), and received a bronze medal for a study of trees and loneliness—*Solitude*. Mr. W. S. Rogers' small picture of craft, *Coaling—Tyneside*, and his roadside view, *The King's Highway*, were full of delicate detail, and deserve high praise, as did Mr. H. R. Rainger's small study of *Richmond Bridge*. Mr. Rogers' delicacy of treatment pleased us very much. He received a bronze medal for *The Year is Dead*, a bleak view of leafless trees. By the way, a distinct vein of pensive melancholy ran through the Exhibition, in which there were any number of frost studies, twilights, deserted mills, departing days, winters, *et hoc*.

Mr. A. W. Scanlan, with *The Return of the Herring Fleet*, a large, breezy study of sea and craft, having a pleasant, warm tone, and an admirable view, *Haymaking*, Messrs. H. and L. Selby, and Mr. T. Tripplin (vigorously rendered, if rather heavy-shadowed, Norwegian views), all showed good work. Mr. C. R. Whiting's bustling, boldly-handled views of *Seddon Harbour*, *Plymouth*, were very fine in technique, but possibly would have looked better in a less bilious tone. Mr. Charles Winter deservedly gained a medal for a capital outdoor untouched por-

trait of *My Mother*, and showed several winter views of great merit. We liked a little view of *Spring* by Mr. George Way, a sharp, crisp study, as spring effects should be. Two interior views of Hampstead Parish Church, by Mr. A. A. Boucher, were, perhaps, the best interior work shown, and one of them gained a medal.

As we have already said, we have nothing but praise for the Exhibition as a whole, which may in some degree account for the fact that we have been able to find so few faults with individual pictures. A happy feature of the display was the inclusion among the exhibits of a collection of photographs medalled at previous exhibitions of the Society. The Judges were Messrs. A. Horsley Hinton and J. C. Dollman, R.I., from whose report we cannot help making the following extract, which may be of interest at the present juncture:—"The Judges wish it to be distinctly understood that they do not consider the entries in the Outing Class are any of them deserving the distinction of a medal, but, as they are asked to award a silver medal, they consider *Near Weybridge*, by Mr. L. Selby, the best of the class. They would like to add that they only award this medal feeling themselves bound by the printed conditions, which leave them no option but to award a medal to work which they consider deserving or otherwise."

Our Editorial Table.

Handbook of Regulations and General Information regarding the Chicago Exhibition.

This handbook contains an important mass of well-arranged information relating to the World's Fair, and certainly ought to be in the hands of every one who feels at all interested in it. Among the drawings are a bird's-eye view of the Exhibition, and a view of the principal buildings devoted to special departments. The tables showing the M'Kinley Tariff rates are significant, as showing the heavy duties to which articles imported into the United States are subject. This handbook is issued from the offices of the Royal Commission, Society of Arts, John-street, Adelphi, London, and all communications must be addressed to the Secretary.

PATENTS COMPLETED.

An Improvement in Carriers used for Holding Slides in Magic Lanterns.

No. 1635. Henry Grant Madan Conybeare, The Hut, Ingatestone, Essex *December* 3, 1892.

My invention relates to improvements in lantern-slide carriers, such as those used for holding slides in optical or magic lanterns, and has for its object the provision of means whereby the lantern slides may be ejected from the carrier, automatically by, and simultaneously with, the movement of slide within its frame, in its operation from side to side, thus greatly facilitating the manipulation of the said slides when changing, and obviating the necessity of handling the slides so that the fingers come in contact with the faces of the slide, and thus soil them.

My invention is essentially an improvement of the invention described in Letters Patent No. 20,972, and dated December 23, 1890, and consists in the application to such a sliding carrier of means for the automatic operation of the ejecting lever by the sliding movement of the carrier.

In carrying out my invention I provide a carrier, into which the lantern slides are inserted through openings at the top of the frames. This slide-carrier is adapted to slide in a suitable frame. I pivot a lifting lever on each side to serve the two slide spaces. The back end of each lever is operated by a pusher-rod.

The under side of the top part of the frame is recessed along its centre portion, such recess terminating at each end by an inclined plane, against which the end of the pusher-rods can engage. The recess is made deep enough to allow the pusher-rods to move high enough for the end of the lever to occupy the lowest position when the lantern slide is resting in proper position in the frame for projection.

When, now, the slide-carrier is moved toward one end of the frame, so that one of the openings in the carrier, with its slide, corresponds with the opening in the frame, the inclined plane at one end of the recess in the upper part of the frame engages the end of the pusher-rod, depresses the shorter end, raises the longer end of the lever, and lifts the slide into such a position as to allow of being taken hold of by the hand for removal from the carrier, upon which a new slide can be inserted. The carrier can then be slid along so as to register the new slide in position, and the slide previously being shown is ejected partially from its position at the other end of the slide-carrier.

A suitable recess may be formed in the lower portion of the frame to allow room for the movement of the levers if thought desirable.

What is claimed is:—1. In a lantern-slide carrier, a sliding frame having levers pivoted thereon in combination with means for the operation of the said levers during, and by the sliding movement of, the slide-carrier. 2 In such a lantern-slide carrier, a pivoted lifting lever in combination with an inclined plane, upon the frame in which the slide-carrier moves, and adapted to engage with the said lever to effect the lifting of the lantern slide, substantially as described.

Improvements in or relating to Photographic Cameras.

No. 2852. Griffith David Hughes, Cheadle Hulme, Chester. *December* 3, 1892.

This invention relates to apparatus I have designed for photographic cameras for holding a number of prepared plates to receive the negatives, one of which will be presented at a time to receive the picture.

It consists essentially in the combination with the apparatus of a rotating holder or carrier, comprising a number of sheaths, or receptacles, or slides, in which the photograph, prepared plate, or other object can be placed, a spring barrel or other motor by which these are rotated, and a catch or clip, which will release one of the sheaths or receptacles at a time whilst retaining or preventing a forward movement of the others.

In carrying out the invention in a suitable position, in the casing which surrounds or contains the apparatus I affix a spring barrel, or other rotating

mechanism, capable, when set, of a continuous movement for several revolutions. Affixed to, or carried by this barrel, radiating from its centre, are a number of sheaths, slides, or receptacles to receive cards, plates, or other flat objects, which can be rotated round the centre of the drum.

The sheaths, slides, or receptacles which carry the object are preferably loose on the spring barrel, and free to move about the barrel centre independently of any movement of the spring barrel. In addition to these, the barrel carries a projecting finger or catch, which comes in contact with, or engages with, the receptacles or objects, and carries them round.

A spring catch or other clip is affixed to the frame to retain the object or plate at the desired position to yield the image or receive the impression, and which, when moved, will release one at a time, which then drops forward of its own gravity. A catch, in the form of an escapement or other similar device, may be employed for the purpose.

The sheaths or receptacles for the plates may rotate in a cylindrical chamber, with a packing of velvet or other light-tight material between the tops and sides, and an opaque back of blackened wood or other material may be applied to each sheath or receptacle to prevent the passage of light through from one plate to another, or to prevent light reaching a plate after it has been exposed.

The patentee claims: 1. A rotating carrier or holder for a number of sensitised plates for a photographic camera, comprised of a number of sheaths loosely pivoted to the periphery of a rotating barrel, and held in position, when not exposed, by a catch, and from which, as the barrel is rotated, they are released or displaced singly, and move forward in succession at each movement, exposing a fresh plate, and withdrawing the previously exposed plate from the field of light substantially as described. 2. The combination with a photographic apparatus of a holder or carrier for a number of prepared plates or other sensitised objects comprised of a number of sheaths, in which the plates are placed pivoted loosely by a wire or rod attached to each on a rotating or movable support, so as to have an independent movement, and provided with a catch, by which they are held in position, and from which they are released by the movement of the holder, dropping forward in succession of their own gravity from a horizontal to a vertical plane (or *vice versâ*, as arranged), substantially as described and shown.

A Process for Developing Photographic Images.

No. 4498. Julius Hauff, Feuerbach, near Stuttgart, Germany. *December* 3, 1892.

In the course of my experiments on substances which may be utilised for the development of photographic images I have made the discovery that the o-p-diamido-phenol surpasses by far all other substances capable of developing photographs. Whereas, with the developing organic substances hitherto used, it was always necessary to add thereto caustic or carbonated alkalies in order to effect the thorough reductions of the halogen silver which had been exposed to the light, the diamidophenol develops without carbonated or caustic alkalies, with the aid of the sulphite of the alkalies, in a quite sufficient manner, so that the use of carbonated or caustic alkalies may be entirely dispensed with. If only a very small quantity of carbonate of soda is added to a solution of muriate of diamidophenol, the solution acts upon exposed plates with such an energy that the unexposed halogen silver is likewise reduced, and thus the appearance of an extraordinarily powerful veil or shroud is caused. Further, I have discovered that the development can be delayed by the addition of diluted acids, whereas hitherto bromide of potassium had to be used under the same circumstances. It is obvious that the use of the bromides or chlorides of the alkalies is not excluded in this case, for if the proper doses are used the desired results can be successfully obtained with those substances.

I am well aware that diamidophenol has been already often mentioned and introduced for the development of photographic images, but it has not yet been properly taken into consideration and appreciated, probably because the product used did not possess the purity with which I am able to prepare it, or because experiments with diamidophenol were not made in this direction.

The properties of diamidophenol are thoroughly misapprehended, especially there is no information as to its extraordinarily great solubility, which alone is sufficient to allow of its being used in the manner before stated.

The particular advantages of this substance are its extraordinary developing power, its practically unlimited durability and utility, its absolute immunity of action on the fingers, as well as on the gelatine films, and the fact that ordinary water can be used therewith.

The developing process is carried on as follows:—A salt of the o-p-diamidophenol, with a sulphite of the alkalies in the proportion of one of the former to ten of the latter, is dissolved in a sufficient quantity of water, and the exposed plate is developed therewith, further quantities of a sulphite solution being added when a powerful development is required, and diluted acids or bromide and chloride of potassium for a weak development.

For ordinary portraits the following recipe will be found to answer the purpose: 0·45 grammes of hydrochlorate of diamidophenol, 4·5 grammes of sulphite of soda, and 60 cubic centimetres of water. The action is slowed either with a few drops of a ten per cent. solution of bromide of potassium or a few cubic centimetres of a ten per cent. solution of sulphuric acid strengthened with a sulphite of one of the alkalies.

Concentrated solution may be obviously prepared beforehand, and diluted according to requirements, for instance, 5 grammes of hydrochlorate of diamidophenol and 50 grammes of sulphite of soda may be dissolved in 100 grammes of water, and diluted to the extent of thirty times its volume. A solution of 0·5 grammes of hydrochlorate of diamidophenol and 5 grammes of sulphite of soda in 100 cubic centimetres of water will properly develop plates which have been too long exposed.

Diamidophenol develops, according to the above given directions, without any veil or shroud being formed, and without colouring the gelatinous film; after weeks of exposure in the light and air, the solution with sulphites of the alkalies takes scarcely a somewhat reddish colour, while the solution, when mixed with small quantities of carbonated or caustic alkalies, takes a brown colour, after about half an hour.

Having now particularly described and ascertained the nature of this invention, and in what manner the same is to be performed, I declare that what I claim is:—A process for the development of photographic images in layers containing halogen silver, consisting in the use of aqueous solutions of a salt of the pure o-p-diamidophenol and a sulphite of the alkalies in the proportion of one of the former to ten of the latter, without the simultaneous presence of carbonated or caustic alkalies, the action being intensified by a further addition of sulphite and weakened by an addition of diluted acids or diluted solutions of bromide or chloride of alkalies.

Improvements in Lenses for Telescopes, Photographic Cameras, and Magic Lanterns.

No. 18,919. Maurice James Gunn, 1, Priory Villas, Brownhill-road, Catford, London, S.E.—*December* 3, 1892.

This invention relates to an improved construction of lenses for telescopes, photographic cameras, and magic lanterns, and has for its object to provide a lens which will be less expensive than the ordinary solid lens, the invention being more particularly applicable to lenses of large size.

In carrying out my invention, I construct a hollow case, as hereinafter described, in the form of a lens but hollow, and made mainly of glass or other transparent material, hereinafter referred to as glass.

Within this case or hollow lens is placed water or other clear liquid, the whole forming a complete lens. The lens is formed by two plates of the transparent substance, one or both of which is or are curved in the desired manner, and the two are connected together by a metal or other tubular case.

According to one arrangement there is an annular projecting part around the interior for each glass, against which the edge of the glass rests, being fixed by cement. This annular part may be formed by turning in a lathe, or by forming a channel in the case at the required parts.

Instead of fixing with cement a cap may be employed, screwed on to or into the tube, and fitting closely around the edge of the glass, and pressing it against the annular projection. With this arrangement the lens can be readily taken to pieces and fresh glasses put in.

Indiarubber or other soft material must be placed between the ledge and the glass in order to render it less liable to get broken. A simpler form, in which the parts are not detachable, consists in making the ends of the tube slightly thinner, forming a ledge against which the glass would rest, the ends being then turned over on the glass, fixing it in place. In order that the liquid may be admitted, a hole is formed in the case, or, in some cases, in the glass itself, closed by a cap or other suitable means, or, when the opening is in the glass, by sealing it after the liquid has been inserted. The tubular case into which the glasses are fitted may be made in two parts, one screwing over the other or sliding over it, the two fitting tightly together in order that the thickness of the lens may be regulated to any desired amount. The lens is preferably filled with liquid at a rather high temperature, higher than it is likely to reach when in use, so that on cooling a slight space is left with vacuum to allow for any expansion that may occur.

This will not interfere in any way with its use, as the sides of a lens are never used, and the tube or aperture used for filling may be made sufficiently large to serve for the empty space. A lens may also be formed with a cell wholly of glass, the two parts being formed with rims, or cylindrical sides, which are placed together, and joined by a band of glass or suitable material, liquid being inserted as before.

In order to form the glasses for the lens, I may blow a hollow sphere in a mould or box of the required form, manipulating the mould in the manner well known to glass-blowers, in order to get an even surface and thickness. I afterwards, with a cutting instrument, cut the sphere into parts of the required diameter, the size of the sphere regulating the curvature of the lens, so that a regular and known curvature is always obtained.

According to another arrangement the glasses are moulded or pressed into shape. When used in photographic cameras the usual stops are employed in front of or between the lenses to reduce the light and give the required clearness of image.

[Probably the patentee was not aware that Archer's fluid lenses, Sutton's panoramic and cylindrical lenses, and some others were constructed on this principle.—Ed.]

Improvements in Photographic Lenses.

No. 21,933. Thomas Rudolph Dallmeyer, 25, Newman-street, Middlesex.—*December* 10, 1892.

My invention relates to a lens for the production of large primary images by the employment of a negative element as a posterior lens, fractional in its focus as compared with the anterior positive lens. This negative element is a double combination, and is corrected for both actinic and spherical aberration. The annexed drawing at figure 1 shows a combination in accordance with my invention.

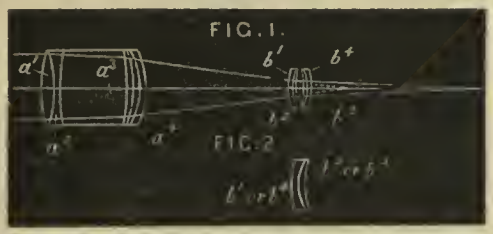
The anterior positive element represented in this figure is a well-known portrait lens; it is in four parts. a^1 a^2 a^3 and a^4, and of these the hindermost, marked a^4, can be screwed out a short distance. The focal length of the combination is 8½ inches, and its aperture 2¾ inches. The negative element is in four parts, b^1 b^2 b^3 b^4, which constitute a symmetrical double combination, b^1 and b^4 are similar, and so also b^2 and b^3. One of the pairs is shown separately and in full size in figure 2. The parts b^1 and b^4 are of hard crown glass (refractive index 1·5179), and b^2 and b^3 are of heavy flint (refractive index 1·6202). The anterior surface of b^1 is convex, and the radius of curvature is 4·396 inches. The posterior surface of b^1 is concave, and the radius of curvature is 0·9 inches. The anterior surface of b^2 has the same curvature, and is cemented to the posterior surface of b^1.

The posterior surface of b^2 has a curvature of 1·375 inches.

There is an air space between the surfaces of b^2 and b^3, and these surfaces may be separated by a considerable interval, but the study which I have made of the subject since the date of my application leads me now to prefer that b^2 and b^3 should be nearly in contact at their edges

The negative focal length of the element b^1 b^2 b^3 b^4 is 2 inches, and it is so mounted that by a rack and pinion the distance between it and the anterior element can be varied.

The correction of this negative element is auch that it is complete for an object 12 feet in front of the camera focussed at a distance of 12 inches. When any deviation is made from these positions there is a resulting aberration in



the combination, which can be corrected by screwing out the lens a^4 a short distance. The measurements which I have given above admit of variation.

For the positive element any (preferably large aperture and short focus) photographic objective may be employed, but it is expedient that it should admit of the spherical correction being varied.

The negative element is in all cases to be a double combination corrected for actinism and spherical aberration; it is to be convex on its anterior and posterior faces and its focal length is to be less than that of the positive element.

The negative element may be constructed as indicated in fig. 1 of the drawings accompanying my provisional specification, the heavy flint glass being external in place of internal, but the arrangement above described is that which I prefer.

In the use in the camera of the instrument represented by fig. 1, the focussing glass is first set at any distance from the posterior face of the negative element, according to the amount of the magnification it is desired to obtain. Then the focussing is effected by moving the positive anterior element to or from the negative posterior element by means of the rack work provided for the purpose. Finally, the sharpness desired is given to the focus by unscrewing the posterior lena a^4 of the anterior element to the necessary extent.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is :—A photographic lens for the production of large primary images, and consisting of an anterior positive element and a posterior negative element, the latter a double combination convex on its anterior and posterior faces, corrected for actinism as well as for spherical aberration, and of shorter focal length than the anterior positive element.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 16	Camera Club	Charing Cross-road, W.C.
,, 16	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 16	Fillebrook Athenæum	Fillebrook Lecture Hall.
,, 16	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

JANUARY 10,—Mr. T. Sebastian Davis (Vice-President) in the chair.

Mr. H Wilmer was elected a member.

The Chairman announced that the Lincoln Camera Club had been admitted to affiliation of the Society, and that the annual dinner of the Society would be held on February 13 next.

The Chairman also stated that Mr. William Bedford was critically ill.

Auditors and scrutineers were appointed for the forthcoming annual meeting on February 14.

EXPERIMENTS WITH TWO NEW DEVELOPERS.

In the absence through illness of Mr. J. Spiller, his paper on the above subject was read by his daughter, Miss Spiller, who brought a number of negatives developed with both amidol and metol, samples of which were shown.

With regard to amidol, Mr. SPILLER said that, from experiments made at various times during the past six months, he was inclined to think that it is best to weigh out a certain number of charges, and keep these separate lots of amidol in dry glass tubes, dissolving them up, one at a time, in a nearly saturated solution of sulphite of soda to prepare a concentrated developer, which then only requires dilution for use. For professional practice the mixed developer, especially if concentrated, will keep in good working order long enough to justify the preparation of a stock solution. For this take

Water	7 ounces.
Sodium sulphite cryst.	1½ ,,
Amidol	60 grains.

Mix, as required for use, with about three times its bulk of water and a trace of bromide, or none, according to circumstances. It is possible to make the same dose of amidol do duty for two or three plates in succession, and then to fortify it and go on again, but it is better to exhaust it entirely, either by adding weak alkali—dilute ammonia, carbonate of soda, or borax—and then throw it away. For over-exposure, a weak developer and free use of bromide is the best treatment, and for the opposite case, or even for building up extra intensity in normal exposures, use a stronger solution with an increased proportion of sulphite, if the alkaline method is not resorted to. As a rule the image should appear in eight or ten seconds, and be fully developed in about four minutes. The negatives are of a coaly black or pencil-lead colour, more like ferrous-oxalate than pyrogallic deposits, and print quickly. As a consequence it is necessary to carry forward the development to a stage beyond what is ordinarily required in brown negatives. Hence an impression is given that the silver image loses by immersion in the fixing bath, which he does not think is actually the case. "Metol" is the other new developer referred to in the heading, and with this also he had made a good many experiments. Dr. Eder speaks of it in the highest terms of approval, and predicts that it will speedily depose all other known developers. Dr. Stolze and Dr. Just report well of it, and for many reasons he (Mr. Spiller) feels inclined to agree with them, mainly because metol is so remarkably permanent even in solution, and certainly superior to amidol in this respect. On a recent occasion he developed a few plates with a stock of developer prepared last June. The deposit is of the neutral grey colour and free from stains, and can easily be worked up to any required degree of density. Dr. Eder's formula stands thus :—

Solution A.

Water	1000 parts.
Metol	10 ,,
Sodium sulphite cryst.	100 ,,

Solution A.

Water	1000 ,,
Sodium carbonate cryst.	100 ,,

Mix in equal proportions, or less of the soda and more water, according to requirements. For landscapes a more dilute solution is prescribed than for studio work, but the printed instructions are, perhaps intentionally, left rather wide and indefinite, so as to give ample scope for the exercise of judgment on the part of the operator. The leading principle is, however, to use A and B in equal parts for ordinary work, *diminishing* the alkali to get softer results, and *increasing* it to obtain hard negatives or those those presenting the greatest amount of contrast. Then, again, it is recommended to add solution B gradually, using no more alkali than is required to build up the picture, and so be ready to correct for errors of exposure during the progress of development. It is a good plan to begin with a solution which has done duty before, and then no bromide need be added.

Mr. FUERST (Fuerst Bros.), who was present, said that the amidol which was originally put on the market was a potash salt, and that which had recently been introduced (a whiter variety) was an acid salt which might be better to use, although perhaps its action was not so certain.

Mr. A. R. DRESSER had made a series of experiments with amidol, and had found it excessively good for negative work as far as instantaneous exposures went. He had recently given exposures of one two-hundred-and-fiftieth of a second on the ice, and had developed with pyro, eikonogen, and amidol, and found that with the latter there was a distinct advantage in density and detail. With over-exposure it was so excessively quick that many who used it came to grief, but they need not be frightened if the image came up fogged, as the fog, which only seemed to attack the surface, could be removed in the reducing bath. For bromide work he had found no developer to beat it; indeed he had got results with it which he would not have believed possible. He showed a number of 30×22 enlargements from quarter-plates, developed with it. He had come to the conclusion that the formula put on the market was radically wrong. With sulphite alone it did very well as a one-solution developer, but one great fault of it was that it turned brown in a short time. Hence he decided to try the substitution of metabisulphite. The inventor said that an alkali was not to be used; he (Mr. Dresser) got the best results with ammonia, but it must never be used without bromide. He mixed one ounce each of amidol and potassium metabisulphite in ten ounces of water and prepared a ten per cent. solution of bromide and a five per cent. solution of potash carbonate. He preferred the carbonate at the latter strength, as a saturated solution varied with the temperature. For bromide work his developer was as follows :—

Amidol solution	16 drachms.
Carbonate solution, five per cent.	14 ,,
Bromide solution, ten per cent.	2½ ,,
Water	20 ounces.

A grey colour for uranium toning such as he employed could be obtained by using a saturated solution of common washing soda. Developing with amidol

required the shortening of the exposure as given for iron by about a fifth. It was better in all cases to use the amidol at full strength—that is, undiluted, and commence with a weaker solution of the potash or ammonia. The same formula was very good for lantern slides.

Mr. G. L. ADDENBROOKE had also experimented with amidol, which he found would not develop alone. Dealing with its properties as a developer with sulphite, he said that sodium sulphite was formed by passing a stream of sulphurous acid gas into a solution of the carbonate; but, as it was so weak, it only displaced the carbonic acid with difficulty, hence commercial sulphites usually contained alkali, so that a developer of amidol and sulphite contained an unknown quantity of sodium carbonate. It had been suggested, however, that it was desirable to make a developer of known constitution, and that could be done by the use of potassium metabisulphite, which was made by a patented process of supersaturation with sulphurous acid. There was thus a certain amount of free sulphurous acid present, which acted as a restrainer, and, although a mixture of amidol and metabisulphite would not develop by itself, it was well preserved. The same proportion as sulphite, down to equal parts, of metabisulphite to amidol answered well. Nothing could be more convenient to use than the formula given by Mr. Dresser, and he advised starting with a strong solution of developer, and trusting to extra quantities of bromide. The less time the plate was in the developer the better and cleaner the results. Amidol for negative work was as like pyro as it could be, although more energetic. Any one accustomed to use pyro could easily substitute amidol for it, and when it changed colour it did not deposit like pyro, the colouration being soluble throughout. It remained clear for hours without staining the film, and would answer well for dipping-bath development.

A CHEMICAL STUDY OF MERCURIAL INTENSIFICATION.

Mr. H. CHAPMAN JONES read a paper treating of the chemistry of the various forms of mercurial intensification. [This will be given *in extenso* in a future number.] He concluded by recommending the use of mercuric chloride followed by ferrous oxalate, as advised by him in January, 1890. Speaking of the elimination of hypo from the film, he advised the use of an acidified alum bath for the purpose, as it was practically impossible to remove it by simple washing, which would always leave enough to spoil many methods of intensification.

Mr. W. E. DEBENHAM said it was a very useful thing to have a definite account of the chemistry of mercurial intensification, but he regretted Mr. Chapman Jones had not extended his studies so as to include intensification with iodide of mercury and Schlippe's salt—a method which he (Mr. Debenham) preferred to all others. With several methods the image was changed by light; and with the cyanide method there was an alteration of the density ratios, unless hydrochloric acid was added to the mercury. Mr. Arnold Spiller said some time ago that with iodide of mercury no combination with the gelatine took place, so that the addition of hydrochloric acid was not necessary. Much greater increased density was obtainable with it than with ordinary methods of intensification. After the treatment with Schlippe's salt the image appeared to be thoroughly permanent. It was sometimes said that the method stained, and caused a deposit in the clear glass, but that was the case with all methods if the plate were not thoroughly fixed and washed, in which case it was not the hypo alone in the film that was objectionable. Photographers generally did not employ perfectly new fixing baths, so that a certain amount of silver was likely to be left in the film. Mr. Debenham showed a plate one half of which was clear glass and the other half a negative which had been intensified with mercury, iodide, and Schlippe's salt, and drew attention to the clear half, which was free from deposit.

Mr. CHAPMAN JONES, in reply, said he always fought shy of iodides and sulphides in intensification, as he found iodide intensifiers unreliable. A drawback to the use of Schlippe's salt was that, if it produced a thorough change on the image, nothing could be done with it afterwards, as it left a series of compounds which were awkward to attack. By his plan nothing but metallic mercury and metallic silver was added to the image, and they could do anything with it.

GAÏACOL.

The Hon. Secretary gave a brief précis of a paper sent by Colonel J. Waterhouse, in which the author confirmed the experience of Messrs. A. & L. Lumière (see "Continental Notes and News"), establishing the fact that the developing properties of gaïacol were due to its impurities. The author also stated that old carbolic acid had developing action, whereas new carbolic acid had not.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 5,—Mr. A. Haddon in the chair.

Mr. P. Everitt exhibited a photograph taken in a Skaife's pistolgraph.

Mr. H. Snowden Ward showed examples of gelatino-chloride printing by Mr. Hanna, of Auckland, New Zealand, who had sent them to this country to learn the opinions of English photographers as to their quality. They were considered excellent by the meeting.

The HON. SECRETARY drew attention to an article on "Spirit Photography" in the *Fortnightly Review* by the Rev. H. R. Haweis, quoting the passage relating to the young lady who was alleged to have discovered the face of her deceased lover on a "blurred" plate.

Mr. DRAGE said Mr. Haweis' contention was this: "May not a surface more chemically sensitive than the human retina be able to receive impressions of things which to us are invisible?"

The CHAIRMAN having recommended photographers to in future examine "blurred negatives" before rejecting them, the subject dropped.

PRINTING-OUT OPALS AND LANTERN SLIDES.

Mr. W. E. WOODBURY demonstrated the Paget Company's new printing-out opals and lantern slides, saying that their manipulation was practically the same as gelatino-chloride printing paper, they being coated with an emulsion of that character. In printing, as sharpness was so desirable, it was necessary to print in the sun, and always to keep the frame in one direction; otherwise, if it were turned another way, probably a double image would result. He exhibited a special printing frame for printing-out purposes, and said that, for toning and fixing, either the combined bath or the sulpho-cyanide, followed by fixing, could be employed. With the combined bath it was necessary to print a little deeper, as the image lost a little in that bath. The tones of the lantern plates were to be judged by transmitted light. In reply to a question, he said that he had not found the plates print out to a purple tone after having been kept for a few months; but with the combined bath the warmth of tone increased when the plate had dried.

Mr. Woodbury was thanked by the meeting for the demonstration.

THE SPEED OF PLATES.

Mr. A. COWAN described how the speed of plates was ascertained by Messrs. Hurter & Driffield's method, saying that for exposure a standard candle was employed, at the distance of a metre, and seconds for the measurement. For practical purposes, however, he placed the plates at a distance of two metres, because with eight plates there would be no error of exposure in the circle thus made. Eight strips were taken out of the middle of a fair-sized plate, placed in the slide in which they were to be exposed, and, with a pendulum swung before the eyes, the strips were gradually covered up, so that a series of exposures ranging from thirty-two seconds on the most dense parts of the strips to half a second on the lightest parts was given. A standard developer, for a given time at a constant temperature, was used, so that the conditions were always alike. In order to avoid reflections, he used the whole of the apparatus in a box, while a diaphragm was used in order that only the light from the candle should strike on the plate. Mr. Driffield, instead of the fixed frame with the strips, used a revolving disk with openings in it of different sizes at a certain distance from the candle, which made straight lines of different densities on the plate. The densities of the slips proceeded arithmetically, so that, taking two strips and superposing them at the point of correct exposure, an equal tint would result by the combination. Having described Messrs. Hurter & Driffield's method of measuring the densities by the ordinary slide-rule, Mr. Cowan went on to observe that, as the standard candle was not very certain, he always had a standard plate for comparative tests. He had found by experiment that one of his standardised plates was exactly the same speed after an interval of two and a half months.

Mr. JAMES CADETT had found a better mean of density with a slow plate than with a quick one, although there might be ten per cent. less emulsion on the ordinary plates than on the quick ones.

The CHAIRMAN asked whether, in burning the standard candle, the amount of wax consumed was weighed? The candle was only constant when consuming 120 grains of fat per hour. Did Messrs. Hurter & Driffield weigh the candle in their experiments?

Mr. CADETT, in regard to the relation of speed to density, said that when people compared two plates in the camera, and those plates had different density factors, the reading of those plates became very difficult indeed. He had recently sent some lantern and extra-rapid plates to a gentleman in order that he might read their comparative speeds in the camera. The result was a fatal one, as the lantern plates were made out to be four times quicker than they were. In such a case they might come to a point in the density where both plates were exactly alike, but at what part should the respective densities be read? People usually looked at that part having the very faintest detail. For a camera test negatives of equal density should be used, otherwise plates would be made out quicker than they ought to be. With negatives of equal density, the Hurter & Driffield reading would be exactly right, the density of the negative being calculated according to the amount of light it passed. With whatever standard light they used, they must read through the succession of densities in that part of the plate where correct exposure took place. The standard candle was a great trouble, but the system held good with a standard light. By trusting to the reading of the candle without a test-plate, errors of as much as twenty-five per cent. sometimes happened. All plate-makers should use the same test-plate, but who was to settle the point? Messrs. Hurter & Driffield had made a great discovery in the proper relation of density to speed. They were the first to show that there was correct period of exposure.

Mr. COWAN said he had undoubtedly obtained different readings with the variations of the standard candle. As many of them might like to know the standard developer he employed, it was as follows:—

Pyro	1 grain.
Sodium sulphite	12 grains.
Anhydrous carbonate of soda	4 ,,
Potassium bromide	½ grain.
Water	1 ounce.

Employed at a temperature of 70° for 7½ minutes.

The meeting then adjourned.

North Middlesex Photographic Society.—January 4, the first of a series of technical evenings for beginners was held, the subject being *Development*. The subject being treated in a purely elementary manner, the general body of members were not invited to attend. A fair number of gentlemen, among whom were several strangers, availed themselves of the opportunity afforded them. They each brought two exposed and undeveloped plates, and were, in their turn, taken in hand by Mr. C. Beadle, who was the instructor for the evening. He opened with a brief description of the various developers most generally in use, their advantages and failings, the correct method of compounding them, and of modifying them to suit the different exposures and subjects. He then questioned each gentleman as to the exposure given to the plates he had brought, and the general conditions under which it was taken, and advised him as to the best method of developing. He then sent him to mix the developer, and stood by while the plate was developed, giving advice during the process. The meeting was thoroughly successful, the gentlemen present expressing their gratification, and a desire to attend future meetings of the same character.

THE Annual Meeting of members was held on January 9, the President (Mr. J. W. Marchant) in the chair. The Treasurer presented his balance-sheet

which was the best during the Society's existence, and showed a sound financial condition. Mr. Pither gave a report of the results of the outings during the past season, and laid upon the table the Society's album, containing the selected pictures taken thereat. The certificate for the best collection of prints taken at those outings was awarded to Mr. McIntosh, the Hon. Secretary, and the second award, that of a view album, which could only be won by a non-member of the Council, was secured by Mr. A. J. Hewson. The annual report was then submitted by the President. He dealt with the satisfactory condition of the Society generally; the increased membership, the greater interest taken by the members in the meetings, as evidenced by the ready help given by them in the reading of papers and the opening of discussions; and especially dwelt upon the advance in the quality of the work shown at the late exhibition, as expressed by the judges. Reference was made to the affiliation scheme, and the advantages derived therefrom, and thanks were given to those gentlemen, not members of the Society, who had rendered assistance by their lectures. Votes of thanks were accorded to the officers for their past services. Mr. McIntosh stated that, finding himself unable to give the requisite time to the secretarial duties, he did not seek re-election. Balloting for the officers for the ensuing year was proceeded with, and resulted as follows:—*President:* Mr. J. W. Marchant (third consecutive year).—*Vice-Presidents:* Messrs. C. Beadle and F. Cherry.—*Council:* Messrs. H. Smith, Gregory, Walker, Wall, Gill, Mummery, Pither, W. Taylor, Golding, Wynne, Lathbridge, Treadway, and Goodwin.—*Hon. Treasurer:* Mr. F. W. Cox.—*Hon. Secretary:* Mr. George Gosling.—*Assistant Hon. Secretary:* Mr. F. M. Aynsley. Mr. John Humphries, F.S.A., who was president of the Society during the first three years of its existence, but who is now resident away from London, was unanimously elected an hon. member. Gentlemen desiring in any way to communicate with the Society will please address the Hon. Secretary, Mr. George Gosling, 13, Lausanne-road, Hornsey, N.

Harringay Photographic Society.—January 5, Inaugural Meeting.—The Chairman (Mr. Dudley Towers) showed the need was great for a society of this kind in this centre of photographic activity. It was proposed that a library be started, and that ladies be eligible for membership. The rules for the management of the Society were drawn up, and the following officers were elected:—*President:* Mr. D. Towers.—*Vice-President:* Mr. Bennett.—*Council:* Messrs. N. Watson and F. Bailey.—*Secretary* and *Treasurer*, C. Frith, 8, Cavendish-road, N., from whom all particulars may be had.

Rotherham Photographic Society.—January 6, Dr. Baldwin (President) in the chair.—The Annual Exhibition on the 7th and 8th of February was referred to, the Hon. Secretary announcing that Lady Abreda Fitzwilliam had consented to open the proceedings. The exhibition, although non-competitive in its character, promised to be most interesting, and photographically successful. An appropriate paper on *Preparing for the Exhibition* was afterwards given by Mr. E. I. Hubbard, Vice-President.

Sheffield Photographic Society.—January 3, Mr. B. J. Taylor in the chair.—The pictures and negatives sent in for the annual competition were fully criticised, and the prizes awarded to Mr. W. M. Toplis and Mr. J. W. Blackwell.

Correspondence.

ALUMINIUM MOUNTS.

To the EDITOR.

SIR,—Like your correspondent, Mr. Everitt, I have been much interested in the prices charged for aluminium mounts since their introduction, for, although the metal can now be had in the raw form very cheaply, there has been no corresponding fall in the mounts for lens. It would have been interesting had the weights of some of the mounts been given to show the cost per pound. With aluminium cast at 2*s.* 3*d.* per pound, its low specific gravity and its greater tensile strength permitting of a lighter cross section, I consider it practically as cheap as good brass for many purposes. But when I weighed a few lens mounts obtained from a *wholesale* source, I found the metal charged at from 50*s.* to 60*s.* per pound! and spun so thin as to exaggerate the comparison with brass, as if it were a precious metal, and to the great risk of damaging from denting or dimpling the true setting of good lenses.

There is no doubt a very heavy outlay on the part of those opticians who undertake to supply all their series of lenses in aluminium mounts. This must be recouped, and no one can blame them if buyers are willing to exchange gold for aluminium to save themselves carrying a few extra *ounces*.—I am, yours, &c.,

ARTHUR SEAT.

January 7, 1893.

To the EDITOR.

SIR,—The letter of Mr. Philip Everett in your last issue has touched a point which has probably puzzled many of your readers, and it would, perhaps, not be out of place to try to discover the cause of the anomalies mentioned by your correspondent. Something is probably due to the fact that the production of aluminium is still in the hands of a few companies who can control the market at their own sweet will, and it follows that in consequence of their operations, those of their customers who have been fortunate to secure their supplies during one of the low tides in the price can undersell the less lucky ones who are obliged to buy at high-water prices; but the principal cause is that aluminium is a very difficult metal to work. Pure aluminium or even ninety-nine per cent. is, for practical purposes, useless; it is too soft and inelastic to stand any strain, neither could it be turned or filed. The commercial aluminium, containing about five per cent. of silicon and iron, is better in all respects, except that it tarnishes more readily. The six per cent. copper alloy put on the market by the Nenhausen Company, is fifty per cent. better than either of these two as regards tensile strength; but its leaden colour and liability to tarnish are against it, besides that it is not much more easily worked. Some of the other alloys are very much superior in that respect. I have had some patent alloys, which could be worked as easily as brass, of a silvery-white colour, and, although somewhat lower in tensile strength than brass, they are, in point of elasticity and rigidity, quite equal to it.

A probable cause for the slow progress which the metal has made in its application to the commoner uses, apart from the question of price, is that the difficulty of working it hitherto has created a prejudice in the minds of the workmen, which time and experience alone will remove.—I am, yours, &c.,

J. V. P.

January 11, 1893.

TINTING MOUNTS.

To the EDITOR.

SIR,—Your editorial on the use of coffee as a stain reminds me of a modification of the same thing which I have found most useful, especially for brown platinum toned prints. Rough or hot pressed drawing-paper is a very suitable surface for mounts, but a pure white surface is not always suitable. I tried an infusion of coffee as suggested for tinting these mounts, but for my purpose the colour was too bright and obtrusive. I wanted to introduce a little grey into the brown, and for this purpose tried the addition of a little common writing-ink with success. A useful stone colour is the result tending towards brown or grey, according to the amount of ink added. My method has been to sponge over the mount with the solution, taking care that the sponge is not overcharged, and that an even surface moisture results. If the tint is not deep enough the process may be repeated after drying. The iron in the mixture may be objectionable for tinting the photograph itself, but it cannot harm if used for cut-out mounts. Some care and experiment is necessary to get a suitable mixture, which should be filtered before use. A very few drops of ink are sufficient.—I am, yours, &c.,

ALFRED WATKINS.

Hereford, January 7.

THE PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—I shall be much obliged to you if you will allow me space to inform the members of the Photographic Society of Great Britain that the figures opposite the names of Mr. Traill Taylor and Prof. J. M. Thomson, in the table at page 90 of our JOURNAL, have been accidentally reversed, and that Mr. Traill Taylor should have had six instead of two attendances credited to him.

I would also remind our members that nominations for the new officers and council should be sent in without delay, the 24th of this month being the last day upon which they can be received.—I am, yours, &c.,

CHAPMAN JONES, *Hon. Secretary.*

Photographic Society of Great Britain, 50 Great Russell-street, W.C., January 6, 1893.

THE LOUTH EXHIBITION.

To the EDITOR.

SIR,—I herewith enclose you Circular of Invitation for our third annual exhibition. I think we are the only Society that run an absolutely *free to the public* exhibition, without tickets of admission or some other check to the influx of the masses.

That it is appreciated by the people is clearly shown by the numbers visiting. The first year about 500 passed through during the five hours it was open. Last year, in the same space of time, 1000, out of a population of 10,000, availed themselves of the opportunity of seeing work by such workers as Messrs. Gale, Ralph Robinson, Bhedwar, P. Lange, Cyril S. Cobb, F. Sutcliffe, B. G. Wilkinson, Chamberlain, Wade, L. Meldon, Edgar Lea, Court Cole, Armatage, Smart, Wright, Pearson, &c.

This year we go in for two days, and hope to have even a greater success, as we fully expect to secure the kind support of many of the foremost workers of the present day.—I am, yours, &c.,

S. FRANCIS CLARKE, L.D.S.,

Hon. Sec. Louth and District Photographic Society.

Upgate, Louth, January 6, 1893.

A CORRECTION.

To the EDITOR.

SIR,—Permit me to call your attention to the fact that your report of the recent proceedings at Bloomsbury Hall is open to misconstruction, not only on account of the phraseology used, but for direct statements as to facts.

The closing paragraphs of the report are especially unfortunate for me, as I am there reported as speaking of Mr. Eastman as my "assistant"—obviously an impossible relationship.

I am sure that you, together with no small number of the 300 persons present at that time, will not fail to remember that, in my *impromptu* response to the address, I very particularly and specifically pointed out that Mr. Rider had given me far more credit than I was entitled to in connexion with any of the inventions owned by the Eastman Companies, and that in no sense could I be considered as entitled to any credit, excepting as co-inventor with Mr. Eastman of some of the earlier inventions.

I also at that time expressed most earnestly the hope that no misconception of the facts should become current, especially through the medium of the press.

As it is well known, I have been a resident of London *continuously* during the past seven years, and it is, therefore, obvious that my association with Mr. Eastman as co-inventor must have been limited to a very few of the earlier inventions, and this fact will be further borne out by reference to the titles of all the patents taken out for many years past.—I am, yours, &c., W. H. Walker.

London, W., January 9, 1893.

[Mr. Walker is quite correct. He certainly emphasised the part taken by Mr. George Eastman in the various schemes and inventions of the Company, and disclaimed his own sole action in such matters. Our report, instead of saying, "*assisted* by Mr. Eastman," should have read—Mr. Walker, *in conjunction with* Mr. Eastman, which would correctly have expressed the tenour of Mr. Walker's remarks relative to this.—Ed.]

"HALATION AND DOUBLE FILMS."

To the Editor.

Sir,—In reply to the opening remarks of Mr. W. B. Bolton in his "Note on Halation and Double Films" in your issue of the 6th inst., I should like to say that I think he must have somewhat misread my paper on "Multiple Coated Plates," to gather from it, or even continuing on the lines indicated, to conclude that it is impossible to produce a negative with clear shadows on a "Sandell" plate. I cannot find that I said, and I certainly did not intend to say, anything leading to such a supposition—in fact, quite to the contrary, I distinctly stated that if the correct exposure were given—that is, a full exposure for the shadows—then, so far as they were concerned, only the top film was used, and in its action differed nothing from that of an ordinary plate.

This being the case, there is no reason why the shadows should be rendered less clearly, or, indeed, in any way differently than by any one filmed plate.

And even where sufficient exposure has been given to affect the lower film in the shadows, the upper can be reduced till the desired amount of clearness has been obtained.

As to the historical inaccuracy that Mr. Bolton accuses me of, I will only say, without either admitting or denying the accusation, that had I, at the time of writing, had any idea that the article would be published, I should have assured myself of the absolute accuracy of any such statement, instead of trusting to the information of one whose authority on such matters I have never yet had occasion to doubt, for my own limited experience carries me back far short of the dates mentioned. I may draw attention to the fact that I did not say that Captain Abney was the first to discover or notice the causes of halation, my idea being rather that he collected the various suppositions that had been put forward, and by the aid of his own experiments, formulated them into a definite theory. If I am wrong in taking this view of the case, I shall only be too pleased to be put right.

With regard to the chromate of silver question, on which Mr. Bolton lays so much stress, I must still hold that Mr. W. K. Burton made something considerably more than a suggestion, though, perhaps, the less I say on this subject the better, for it verges on a question of priority, which has already been the subject of no little dispute, yet some light may be thrown on the matter by reference to a letter of Mr. Burton's which appeared in *Photography*, No. 208, page 702, and to his article in the The British Journal Almanac for 1888, therein alluded to.

In conclusion, I will only say that perhaps few have read with greater interest Mr. Bolton's remarks on the dual action of chromate of silver than yours truly, Gregor Grant.

The Tower House, Bexley Heath, January 9, 1893.

A VALUATION WANTED.

To the Editor.

Sir,—Would you give us your opinion as to the approximate value of goodwill and negatives of our business? The particulars are as follows: Business established eighteen years; business done this year, 850*l.*; profit, about 350*l.* to 400*l.*; number of negatives, about 70,000; size of town, 13,000, with good district, very little opposition (one very cheap man) besides ourselves; prices obtained as per list; eighty per cent. of business done is for cash. The rent is 30*l.* a year; taxes very moderate. Position of premises good, with ample accommodation.—I am, yours, &c.,

January 9, 1893 Seaside Photographer.

[Possibly some of our friends who have had experience in the valuation of photographers' businesses may be able to furnish an opinion.—Ed.]

Answers to Correspondents.

A. Muirhead.—We can add nothing to the information we have already given.

Jno. W. Spencer.—Since the date you name we believe that the firm in question has failed.

J. H. B. complains of a dishonest canvasser. Such a matter had better be referred to the police authorities.

F. C. Green (Chihuahua, Mexico).—Messrs. Hurter & Driffield have no doubt already sent you a copy of their pamphlet.

J. L. L.—We have had no opportunity of practically testing the apparatus but it is well spoken of in the American press.

John T. French.—Thanks for your letter relating to the South London Photographic Society's Exhibition, but we do not propose to reopen the controversy.

John Macallan.—The fault at first sight seems to be in the plates, but we cannot, except in one isolated case, discover any nucleus which would account for the transparent spots.

D. Avanzo (Antwerp).—The article by Mr. J. T. Hackett on "How to Make a Camera Bellows" appeared in the Almanac for 1876. This answers several other correspondents who have addressed a similar question to us.

Cymro Bach.—The precise distance at which the back elements of your cabinet portrait lens should be apart must be determined by experiment. If you make a ring a quarter of an inch wide, it will be found to be about the correct distance.

A. McDonald.—The subject has several times been referred to. Coal gas compressed in cylinders undergoes deterioration by keeping. Your experience is by no means exceptional. It will quite account for the batch of enlargements all turning out under-exposed.

J. W. C.—The bronze powder, with which the mounts are printed, is probably the cause of the spots. If the maker of the mounts cautioned you against what might happen, you have no cause of complaint. If you brought an action—even if you could prove the mounts were the cause of the spots—you would certainly lose it.

A. W. Curtiss.—If when using a single lens the illumination falls off seriously at the margins when a very small stop is used, remove the ground glass, place your eye at the side, and see whether the whole of the light from the lens reaches the side in an unobstructed manner. If it does not, let the distance between it and the lens be decreased.

W. A. B.—The yellow patches on the prints arise from imperfect fixation. Cold weather may have had something to do with it. When the fixing solution is very cold, a considerably longer time should be allowed for its action. Some of the prints have apparently been allowed to stick together, so that the solution has not had free action. The cause being pointed out, the remedy is obvious.

A Lancashire Lad.—So far as we have been able to learn, the principa towns in Australia are well stocked with photographers, and in most of them, if not all, competition is as keen there, both as regards quality of work and prices, as it is here. Probably, if you were to write to the Secretary of the Photographers' Benevolent Association, he might be able to give you more definite information.

W. A. P. and W. Benn ask for directions for making lantern slides by the wet-collodion process with a copying camera.—It is impossible in the limited space of this column to give any instructions that would be of service. Our correspondents should procure one of the several cheap manuals of photography published, say, twenty years ago. They all give full working instructions, and what is said on the process generally applies equally well to the making of lantern slides.

Thos. Carter.—See a leading article on the subject in the current number. We do not know the exact cost of a prism of the size mentioned, but it would certainly be many times that of a mirror. With ordinary care, a mirror will last a long time without requiring to be resilvered, though it may require to be repolished occasionally. To retain the instrument in good condition, it should be kept in a dry place, and protected as much as possible from the atmosphere when out of use.

H. H. Holden.—1. We cannot estimate the value of the gas-bags. But it would certainly be very little, even if they are in good condition, which is very doubtful. As they were the property of a travelling theatrical company, they are probably of inconveniently large size. Cylinders have quite superseded bags. 2. If the prints sent are the best the negatives will yield on albumen paper, they will not do at all, for platinotype bromide paper will suit them best. 3. It will certainly answer your purpose best to purchase the tissue ready sensitised. 4. There is little doubt that the picture is copyright. The publisher will, we imagine, help you, or, at least, give you some information as to the photo-engraver.

W. F. R.—Stereoscopic pictures may be taken quite well by mounting a small longitudinal table on the stand, and sliding the camera against checks at each end in succession. If the object to be taken be, say, over eight or ten feet away, then may these checks be parallel to each other; but, if it be close at hand, such as a vase of flowers within a few feet of the camera, then will it be well that the checks converge sufficiently to ensure the subject being in, or nearly so, the centre of the plate.

C. Williams says: "Last week I poured some boiling water into a very large porcelain dish to warm it before commencing to tone a batch of prints, and it cracked, and has since come in half. Can you tell me of any cement that will mend it for toning, fixing, and washing, hot water being sometimes used?"—We know of no cement that will fulfil these conditions. During very cold weather hot water should not be suddenly put into earthen dishes, or the result will be similar to that described.

A Correspondent, writing in reference to "F. E. G.'s" query as to sulphur on negatives last week, suggests that the sulphur may possibly be dissolved out by a solution of sodium sulphite. The same gentleman also raises a protest against Mr. A. R. Dresser's recommendation in a recent developing formula to employ saturated solutions of the alkalies. If our friend will turn to our report of the meeting of the Photographic Society of Great Britain on Tuesday, he will see that Mr. Dresser now advises solutions of a definite strength.

Xeno says: "I was shown some prints by one of my customers which were said to be platinotypes, but, from the price paid for them, and the time in which they were produced, I believe they are bromides. My competitor in this town, I am told by one of his late *employés*, regularly sends out bromides printed at night for platinums. Is there any ready test that will for certain detect this fraud?"—If a bromide print be treated with a solution of bichloride of mercury the image will disappear; with the same treatment a platinotype will be unaffected.

Shooter says: "A few weeks since I made a silver bath. I dissolved ten onnces altogether, and made a sixty-grain bath. I have now started using P. O. P., so I should like to know how to get as much of the silver back as possible. I only sensitised ten sheets in it."—The silver can be precipitated in the metallic state by placing in the solution a few strips of copper. But the more usual way is to throw down the silver as chloride by the addition of common salt or of hydrochloric acid, and then add the chloride to the stock of residues.

W. Stephens.—1. Although many rapid rectilinear lenses seem to be symmetrical—that is, having front and back lenses absolutely alike, yet some are not so, hence you must return them to their cells, first one and then the other being placed to the outside, in fact, reversing their position as regards each other, and by aid of a magnifier note the effect upon the ground glass. 2. The rounded or convex surfaces must always be placed to the outside of the cells. It is rare that lenses of that type are confined to their cells by counter screws; they are usually burnished in.

A. M. Z. asks "if there is much difficulty in accurately focussing pictures with hand cameras that require the distance to be estimated, the focus being adjusted by a scale of distances engraved on the camera?"—In reply: Some cameras are so accurately indexed that when the distance of the object is known a perfectly sharp focus may be relied upon when the index figure is set. We have tested this point with two such cameras in our possession, and find it to be so. Of course there may be some which are not so accurate, and with these it would be better to employ a ground-glass focussing screen.

M. B. S. writes: "In your 'Answers to Correspondents,' please advise me what I should do with my nitric silver printing bath, which has unfortunately got an overdose of carbonate of soda, so much so that in printing the paper is quite powdery on the surface; filtering has improved it only a little."—If an excess of carbonate of soda has been added, carbonate of silver has been precipitated. This will be again converted into nitrate of silver on the addition of nitric acid. Add nitric acid, drop by drop, till litmus paper is reddened. If the carbonate of silver has been filtered out, it is probable that the bath will require strengthening with nitrate of silver.

J. Barton writes as follows: "I have a lantern with four and a quarter inch condensers, and the lens is a No. 1 *carte*. When I enlarge a head and bust, or a vignette, out of a quarter-plate to 15×12, I get on all right, but when I try a quarter-plate landscape the corners of the pictures fall off fearfully from unequal lightings. I have always read that the lens that will take a negative the size of the one to be enlarged will do for enlarging it. The lens I use covers a quarter-plate beautifully. What can be wrong?"—The fault is not with the enlarging lens, if it will take a quarter-plate negative—and probably it will—but with the condenser, which is not large enough. No four-and-a-quarter-inch diameter condenser will evenly illuminate a full-size quarter-plate. To do that, one of not less than five and a half inches is necessary.

Stereopticus writes: "1. My stereoscopic lenses are three and a quarter inches apart, my eyes are two and a half inches apart; consequently the cutting and mounting glass stereoscopic slides present considerable difficulties, which are increased when copying in the camera. I want a ready means of making slides in the camera without cutting my negatives. By lessening the distance between the lenses, or preferably some other way, this ought to be easily done, but I do not at present quite see my way to it. 2. I want a new twelve-feet lantern sheet; which do you think the best and most serviceable—paper-covered or flatted in oil?"—1. Knowing "Stereopticus" to be an adept in making transparencies, we assume this to be the class of slides at which he aims. Three and a quarter inches apart is a fair minimum for the separation of the lenses on the camera for taking negatives; but, if the same lenses and camera are to be employed in transparency printing, it will be necessary to have them mounted so as to be adjustable as regards distance apart. 2. Both are good; some prefer the one and some the other.

West London Photographic Society.—January 17, Technical Social Meeting.

Messrs Spicer Brothers are thanked for their "Driquic" blotting case. The blotting-paper is exceedingly absorbent.

Photographic Club.—January 18, *Glass and other Fabrics for Dark Room Illumination.* 25, Annual Lantern and Musical Evening. 27, Children's Entertainment.

Kensington and Bayswater Photographic Society.—The subject of our next meeting, January 16, is *Development by Amidol*, by Mr. L. E. Morgan, and not as on the syllabus.

Brixton and Clapham Camera Club.—January 17, *The Hand Camera and its Use in Picture-making*, by Mr. W. Thomas. February 7, *The Optical Lantern with Special Reference to the Ether Light*, by Mr. B. E. Pinder. 21, *Stereoscopic Photography*, by Mr. J. A. Butler. March 7, Lantern Slides. 21, Annual General Meeting.

Huddersfield Photographic Society.—From January 1 this Society is amalgamated with that of the Huddersfield Naturalists' Society, under the title of the Huddersfield Naturalist and Photographic Society, with Mr. Alfred Clarke, of St. Andrew's-road, Huddersfield, as Hon. Secretary, to whom all communications should be addressed.

Forfarshire Photographic Exhibition, 1893.—This Exhibition is to take place in the town of Forfar in April. The exhibits will require to be there the end of March. Sir John Rigby, the Solicitor-General, is expected to open the Exhibition. The prospectus and rules will be ready about January 20. The show will be international and open to all, and there will be awards, which will be made by a Board of Judges consisting of two photographers and one artist of good standing.

The Louth and District Photographic Society's Third Annual Exhibition will be held in the Town Hall, Louth, on January 26 and 27. There are not any medals or other awards, the Exhibition being got up strictly for the advancement of photography in the locality. To secure that end, the Exhibition is thrown open on both days free to the public. The Society defrays all expenses, including carriage of all exhibits kindly lent. All pictures intended for exhibition must be mounted but not framed. Title, name, and address may appear on front of mount. Pictures must reach the Hon. Secretary, Mr. S. Francis Clarke, L.D.S., 8, Upgate, Louth, Lincolnshire, not later than January 23.

On Wednesday evening, January 25, the Photographic Club hold their Annual Lantern and Musical Entertainment (Ladies' Night) at Anderton's Hotel, when, as usual, a large number of admirable slides will doubtless be shown; and, as Mr. F. A. Bridge, the Hon. Secretary, is to be responsible for the musical portion of the programme, a treat in this direction may be safely anticipated. On the following Friday (January 27) the Club takes a new departure by providing a children's entertainment, to consist, we believe, of a selection of suitable slides, music, conjuring, ventriloquism, and other good things dear to the hearts of the juveniles. This entertainment (a happy thought in its way) is intended for the children of members and friends, and should be as successful as it will be novel.

FORTHCOMING EXHIBITIONS.

January 26, 27	.....	*Louth and District Photographic Society. Hon. Secretary, S. Francis Clarke, 8 Upgate, Louth.
February 1	.....	*Cleveland Camera Club. Hon. Secretary, J. J. Hallam, 11, Amber-street, Saltburn-by-the-Sea.
,, 7, 8	.....	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.
,, 14	.....	Durham City Camera Club. Hon. Secretary, R. Hauxwell, The Avenue, Durham.
,, 16–18	.....	*Woolwich Polytechnic Photographic Society. Hon. Secretary, W. Dawes, 145, Chesnut-road, Plumstead, S.E.
,, 18	.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb, 100 High Holborn, E.C.
March 1, 2	.....	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
April	.....	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.
,, 17–29	.....	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

JOURNAL OF PHOTOGRAPHY.

No. 1707. Vol. XL.—JANUARY 20, 1893.

ASSISTANTS AND THEIR SPECIMENS.

We have willingly opened our columns on many previous occasions to the complaints and representations of operators, retouchers, and others, of their having been robbed of their specimen pictures by the photographers to whom they had entrusted examples of work absolutely priceless to the sender. The heart of every honest man must burn within himself at the plain, straightforward accounts given by some of the writers referred to. Unfortunately, the class of man whose morality is of so low a grade—if it be permissible to establish degrees of mental turpitude—as to allow him to rob, in this heartless fashion, those able workers who reply to his advertisement, and, after having filched their goods, traded on their abilities, is utterly insensible to any appeal or reproach for his callous and nefarious treatment. The only way to treat him and his kind is by the strong arm of the law, which, more the pity, is often too slow for its strength. A short enforced retirement to study the intricacies of tarred rope, once applied, if such could possibly be brought about, would have more effect than pages of writing.

On this subject we feel more strongly than we care to put into words; but at the same time we feel bound to say that there has rarely been a more cogent instance of the value of the old proverb, "*Audi alteram partem*," than is afforded by the cases of wrong we are now considering. We had recently occasion to call upon a professional photographer, and, when ushered into his presence, were asked to excuse any violent language he might have been heard to use, for he was busy replying to advertisements, and much ruffled by the labour thrown upon him in consequence of the unbusinesslike mode in which the applications were made. "Yet," said he, "let me but lose or missend one single picture out of all this heap, and it will at once become the most treasured property of its owner, and there will be a howl of indignation from one end of the country to the other at the infamous way in which I am treating applicants for a post."

There can be no doubt that the photographs sent in reply to an advertisement, and the letters of application accompanying (or belonging to) them were of the most unbusiness-like kind. Beautiful photographs actually sent with no protection but a small piece of cap-paper tied with a piece of string; others well tied, but guarded from the sorter's stamp by nothing stronger than writing paper; others suitably and sufficiently packed; others, again, with small and large pictures placed higgledy-piggledy, and no guarding sheets between. A business-like man would at once reject an untidily got-up application if one of equal merit were to hand in which everything was neatly and securely put together. But, as this is merely by the way, not forming part of our especial object in writing, we pass on to the next point. Not only are pictures insufficiently securely packed and tied up, they are actually sent without any distinguishing mark inside, except perhaps a piece of paper marked "Portrait of self." Seeing that every one is a "self" at the time of writing, it is evident that something a little less vague would be desirable for identification. In the instance we were referring to, the photographer informed us that he actually had to guess by internal evidence whom certain of the lots of portraits belonged to. The postmark is not enough; more than one may be writing from the same town, and incontestably it is asking too much of the proprietor of any large establishment that out of a score or two, or three, or four applications he should be put in the position of being able to find the address or owner of a good proportion of the photographs sent only by submitting them to a rigid scrutiny and classification of postmarks, dates, handwriting, and so forth. What wonder if now and then some employers, of not over-gentle mien, do retaliate by pitching the unmarked photographs into the waste-paper basket! We do not uphold him in such a mode of dealing with them; we point out the possibilities.

Now, as such remarks as these lose some of their value if not made thoroughly practical, we offer the following advice to any one replying to an advertisement involving specimens being sent at the same time:—

Use some judgment as to the probabilities of the case, seeing it is notorious that specimens have been withheld by the receivers.

Let the producer of the picture or retoucher who sends samples of his work write his name legibly on every individual print, doing it on the face if he like, so as to avoid temptation to use it by others for dishonest purposes.

Let the parcel be well packed and covered by strong boards to protect it against stamping and damage in transit; post officials have no special regard to the contents of every individual package that goes through their hands. Let a very brief descriptive list accompany the prints, setting forth the number and style of prints, and the full name and address of their sender.

Do not send any original testimonial at the outset. Let the outer wrappers be in good condition, and be legibly readdressed (to the owner on the inner page, so that, when the advertiser returns the pictures to their various owners, the least labour may be involved). If it be assumed that an advertiser receives a score of applications, any one who has any knowledge of such things will say that, unless some such method as above

advised be adopted, a half-day's steady, continuous work will be absorbed by examining specimens finding out their owners' addresses, packing up and addressing the parcels again, not to speak of the possible courtesy of an accompanying "declined with thanks."

Finally, we advise that stamps for reply and redespatch be enclosed; they are not essential, and some employers do not look for it, but it is far safer.

In conclusion, we feel justified in saying that, if such a method of application here shadowed forth had been in general use, we should have heard less in time gone by of the robbery of specimens by advertisers.

NON-ALKALINE DEVELOPMENT.

Of late we have observed in foreign photographic journals more han one communication implying that, for the development of the photographic image on the haloids of silver in gelatine, tmany organic bodies recently experimented with were available which would answer the purpose when allied with an acid instead of a free or fixed alkali. It is, therefore, with singular opportuneness that we notice a paper contributed to the Proceedings of the *Société Française de Photographie* a few days ago by those indefatigable experimentalists, Messrs. A. & L. Lumière, which has a distinct and valuable bearing on the matter.

Messrs. Lumière point out that, while hydroquinone, eikonogen, and para-amidophenol, &c., require to be used in an alkaline solution, all organic developers are not to be similarly classed, and they quote Captain Abney as noting that pyrogallol, with the addition of sulphite of soda acidified by hydrochloric acid, or the acid bisulphite, will develop the latent image, while acidified hydroquinone does not possess that property. They recall the circumstance that they have already alluded to the fact that, while, in general, organic substances will not develop except in the alkaline state, in certain cases they found that the image may be brought out by an acid solution, and they now proceed to consider the relations which exist between the chemical constitution of the latter bodies and their property of developing either in neutral or acid solutions, rightly assuming that, besides being of theoretical, the subject is likely to be of great practical, interest, inasmuch as, during periods of heat, the gelatine vehicle would be less liable to attack by weak acid solutions than by those in which either the free or fixed alkalies are employed.

Diphenols, diamenes, and amidophenols, having only two hydroxyl or amide groups, do not, Messieurs Lumière find, fulfil the necessary conditions; on the other hand, substances having three groups of O H, or NH_2, are suitable for development in an acid state. Thus,

diamidophenol $C_6H_2\begin{cases}OH\\NH_2\\NH_2\end{cases}$; triamidophenol $C_6H_2\begin{cases}OH\\NH_2\\NH_2\\NH_2\end{cases}$

pyrogallol $C_6H_3\begin{cases}OH\\OH\\OH\end{cases}$; oxyhydroquinone $C_6H_3\begin{cases}OH\\OH\\OH\end{cases}$

and diamido-naphthol $C_{10}H_5\begin{cases}OH\\NH_2\\NH_2\end{cases}$

are suitable; the molecule, however, should not contain the acid group C O O H, substances containing it requiring the addition of a free or caustic alkali. The presence of C O O H in gallic acid destroys in some cases its developing powers, which Messrs. Lumière proved by effecting in that group methyl and ethyl substitutions when the resulting compounds, methyl gallate and ethyl gallate, were found to develop perfectly.

Amide groups NH_2 impart certain basic properties to the molecules in which they are contained, so that the influence of the acid C O O H on the developing power of bodies containing the amide is less energetic than in those containing hydroxyl, amidosalicylic acid, for example—

$$C_6H_3\begin{cases}COOH\\OH\\NH_2\end{cases}$$

developing with an alkaline carbonate, while pyrocatechic acid,

$$C_6H_3\begin{cases}COOH\\OH\\OH\end{cases}$$

requires a free alkali in order to reduce silver bromide. Hence Messrs. Lumière allege that, in order to arrive at the developing energy of an organic substance, it is desirable to understand not only the number and position of the hydroxyl and amide groups, but also the presence of the body, C O O H, and the basic influence of the NH_2 groups.

Messrs. Lumière conclude their paper by remarking that the substances containing more than two substitutions of O H or NH_2, and more especially those which already possess developing powers, and of which the molecule is free from the acid grouping C O O H, have a developing action either in neutral or acid solutions. Bodies so constituted, and which, besides, would be freely soluble in water, would appear to them to be henceforth preferable to other agents on those grounds.

Although the foregoing *resumé* of Messrs. Lumière's conclusions may seem at first sight to possess interest only to the chemist and the theorist, it points to some likelihood of the introduction of acid and neutral organic compounds for development, which may conceivably be of advantage to the photographer.

CHANGING BOXES *VERSUS* DARK SLIDES.

III.

Perhaps the best, as well as the simplest, application of the grooveless box system is one which, although not in the market, has stood the test of a season's use in the hands of its amateur maker, and, combining as it does the best points of the existing changing systems, may be worth description.

It consists of a plain grooveless box, which may be made to carry any convenient number of either plates or film-carriers. It is in the arrangement of the lid that the chief peculiarity consists. Those who are acquainted with Hare's changing box will be aware that as the sliding lid is moved from groove to groove the rigid top is followed up by a flexible portion, which packs away in the interior, and gives play enough for the slide to be passed over the full width of the box. In the arrangement to be described, this flexible portion is in duplicate, the top of the box carrying the jaws being movable in either direction, and when closed the jaws are in the centre. Immediately beneath the sliding top is a fixed under lid, covering the whole width of the box with the exception of a narrow slot at each end, just wide enough for the passage of a plate or film-carrier, as the case may be. When the box is "closed," that is, when the jaws are in the centre, the slot in the latter is effectually closed by the under lid; but, when the sliding top is moved as far as it will go in either direction, the opening in the jaws comes over one or other of the slots in the

Licenses will be granted on reasonable terms. See Advertisement on another page.

fixed lid, and communication is made with the interior. The changing box is thus practically automatic in its opening. The opening and closing of the slide is effected by means of a spring back acting in a very similar manner to Hare's changing slide. A catch is provided, by means of which the sliding lid is kept secure in the various positions it has to occupy.

In use the box works precisely as we have already described. One side is marked "out," the other "in." When a plate is required for exposure the slide is inserted in the jaws, and the sliding lid moved as far as it will go in the direction of "out," which is then in the uppermost position, and the top plate slides easily out of the box, the jaws of which are then closed. After exposure the process is repeated, the "in" side of the box being then uppermost, and the exposed plate is returned to the back of the stock.

To prevent the risk of re-exposing any of the plates, should a miscount occur, a piece of thin wood or millboard, the same size as the plates, but just too thick to pass through the slot, is placed behind the last plate or carrier, so that when the latter has been exposed the refusal of the "dummy" to pass announces the fact that the stock is exhausted. In order to guard against the possibility of a plate being taken out of or returned by the wrong opening, each is provided with a thin metal flap—which may or may not extend the whole length of the slot—which, held in position by a light spring, will open by the weight of the plate or carrier in only one direction, and these, being fixed in reverse position over the two openings, effectually prevent the plates being passed through the wrong aperture.

Finally, if double carriers are employed when the whole have been exposed once, an extremely simple arrangement permits the dark slide to be inserted in the jaws in the opposite direction and the reverse sides of the carriers can then be exposed. In this case, however, the safety flaps just mentioned must be removed at the time the box is charged, and it will be needful to bear in mind that the directions "out" and "in" bear an opposite signification.

We had nearly omitted to point out that in employing double carriers the dark slide must be filled with four separate back springs bearing on the corners of the carrier, instead of the usual central springs; and, as these are as easily applied, it is perhaps better to substitute them in all cases where thin metal carriers are used.

So simple is this arrangement that there is absolutely nothing to get out of order, and scarcely any room for making mistakes if a systematic numbering of the double carriers—should such be used—be adopted. It is equally adapted for glass plates or films, but will no doubt prove most useful with the latter, the box to carry fifty films in double carriers having a thickness of little more than an inch and a half.

The film-carriers employed in this apparatus have also the advantage of extreme simplicity and perfect efficiency, combined with lightness, cheapness, and the fact that they are within the power of construction of any one. They consist merely of narrow strips, say a little over a quarter of an inch wide, of thin metal bent in the direction of their length, so as to form a V section. These are cut to the length of the longer side of the film, or the direction in which it slides, and others about a quarter of an inch shorter than the other dimension. A number of pieces of opaque paper—ordinary brown paper answers perfectly—are cut the size of the films to be used, and these, "sandwiched" between two sensitive films, are bound together at the edges by the metal strips, forming one of the cheapest, lightest, and best carriers we have seen, the films lying perfectly flat, and being protected along all four edges. They may, of course, be used as single carriers if desired, and thin metal or cardboard may be used instead of paper for the opaque division if greater stiffness be wanted; but the metal edging forms a quite sufficiently rigid frame for all ordinary purposes.

We have seen another changing arrangement, in which a separate slide is dispensed with, or in which the slide itself forms the receptacle for carrying the films. In outward appearance, it closely resembles the slide of Hare's changing box, only thicker, and is provided with a changing bag attached to a sliding plate that fits into the end when a film is to be changed. When this is necessary, the bag is slid into position, and a spring catch is released, as in Hare's slide, which, however, opens *two* slots, out of one of which the exposed plate emerges, to be seized by the operator's fingers; and, after reversing the slide, it is reinserted at the back of the store, and another surface comes into position for exposure. There are numerous little details in the internal arrangements necessary to the smooth working of the affair that would require diagrams for their proper explanation; but the general idea we have given will enable any intelligent mechanician to construct such a changing slide.

We have described these forms of apparatus in the hope that some of our manufacturers may be induced to take up, and perhaps improve upon, the ideas, and thus supply the want of a really portable arrangement for carrying large numbers of cut films.

Photographers' Risks.—Photographers frequently incur great risks in the practice of their art. Often they will jeopardise their lives, sometimes unnecessarily, in positions that few would venture, in order to obtain a particular view or effect. Here is a case in point. Last week two photographers were taking views in a cave at Niagara Falls, when a huge icicle became detached and fell upon them, hurling them into a chasm below. After a time they were rescued and taken to the hospital. One is expected to recover. Of the other no hopes were entertained. It is to be hoped this may serve as a warning to over-venturesome enthusiasts in the art.

A Big Business.—It was stated in the evidence at the Folkestone Police Court the other day, *re* the Treasury prosecution in the "free portrait" swindle, that no less than eight clerks were employed in the business. This can be understood when from two hundred to three hundred letters were received daily. What do struggling photographers think of that? It appears that the police found nearly 2000 portraits on the premises. This represents the number of disappointed individuals who expected to receive a two-guinea picture for nothing. After the frequent exposure of the fraud during the past few years, some may be inclined to say "serve them right."

Sutton's Half-tone Process.—In the announcement pages of our present issue will be found two examples of Mr. Henry Sutton's half-tone process which our readers will remember we described in the JOURNAL for November 20, 1891, p. 737. In addition to rapidity and cheapness of production, these clichés are of a nature to admit of being printed with ordinary letterpress with fast-running machinery, which should prove a considerable boon to conductors of illustrated periodicals and those requiring phototypic reproductions expeditiously and at a low cost. It will be observed that the results, of which an excellent example is to be found in our ALMANAC, compare favourably in their artistic qualities with half-tone pictures obtained by other methods that have been employed for some time past.

Frozen Water Pipes.—In our last issue a correspondent details his experience of the effect of the frost on a porcelain dish. We fear, ere this, many of our readers have had a more costly one in the shape of burst water pipes. It is somewhat surprising at this age to find that the once popular idea, that the bursting of a frozen pipe takes place at the thaw, still prevails with some persons. It would be superfluous to tell our readers that the fracture occurs at the time of freezing, although it does not make itself manifest until the thaw. But it may be well to remind them that the fracture can always be discovered, and the injury repaired, before a thaw sets in. When a pipe is found to be frozen, it should be carefully examined throughout its length, when the burst, if any, will be easily seen, or even felt. If this were done, many annoying and costly floodings would be avoided.

A False Alarm.—At the conclusion of the meeting of the London and Provincial Photographic Association on Thursday, January 12, Mr. J. G. Hudson gave a practical demonstration of his Kolm magnesium flash-lamp, when several exposures were made by Messrs. Teape and Freshwater. In the course of the demonstration a considerable quantity of magnesium was used, so that a tolerably large volume of smoke resulted. To allow of its escape, the windows were opened, which, in conjunction with the unusually large and brilliant flame of the lamp, so alarmed a civic policeman that he blew his whistle, with the consequence that in a very few minutes three or four fire-engines, together with a fire-escape and a crowd of people, had assembled, under the impression that a conflagration had broken out on the premises occupied by the Association. The incident caused much amusement among the members and no little temporary alarm to the authorities of the hotel.

Strong versus Feeble Light.—There is a point in connexion with the sensitiveness of different materials to light that just now it may be well to direct the attention of experimentalists to, particularly those with the photo-mechanical methods. Some compounds are relatively much more sensitive in a strong light than they are in a weak one—that is to say, a proportionately longer exposure in a feeble light is not equivalent to a given one in a strong light. Notably is this the case with bitumen, so largely used in "process work," and bichromated gelatine in the other processes. With the former, in a weak winter light, several days' exposure will not bring about the same result that can be obtained in a few minutes in a bright summer sunshine. The same also applies to bichromated gelatine as used in collotype, photo-lithography, and other processes—a longer exposure in a dull light does not secure the same result as that obtainable in a bright one. Most carbon printers, for example, know that in a strong light the tissue is much more sensitive than albumen paper, but in a weak one it is very much slower. Sometimes, when the light is exceptionally bad, double the exposure will be required.

Recipes and Recipe Books.—One or more recipe books are usually to be met with on the shelves of most photographers; but, as many have discovered to their cost, not a few of the recipes as given are by no means to be relied upon, while some are nothing less than impossibilities in practice. This remark applies not only to cheap works, but also to the more expensive ones. The compilers of these works have in many instances adopted formulæ that have been handed down from generation to generation in older works, sometimes with printers' errors, without any kind of verification or comment. This should not be the case, for nothing is more annoying than, after taking every precaution to work strictly according to the recipe, that, in the end, the thing is impracticable. In a technical work now before us are six or seven different formulæ for French polish, a material often wanted by photographers. In these the proportion of resins to spirit vary from one ounce and a quarter to five ounces and a quarter to the pint. In some only two resins or gums are given, in others there are half a dozen, some of which are not even soluble in spirit—gum arabic, for example. It is not unusual in some books to find the same material under different names given in the same recipe.

WILLIAM BEDFORD.

With a feeling of sorrow, which we are sure will be shared by all our readers, we announce the death of Mr. William Bedford.

For some time he had not enjoyed robust health, this having been noted when, as President of the Bath meeting of the Photographic Convention of the United Kingdom, he so ably fulfilled the duties then devolving upon him. Mr. Bedford was a man who was universally esteemed, and was foremost in every good work appertaining to the welfare of photographers and the advancement of photography. For several years he was the Chairman of the Council of the Photographers' Benevolent Association; and with what honesty of purpose and assiduity he threw himself into the work of ameliorating the condition of his less fortunate brethren only those know who were associated with him in this beneficent institution, from which no worthy applicant for assistance has ever been sent away empty.

As a careful, pains-taking experimentalist Mr. Bedford had few equals, and when in his own singularly modest way he expressed an opinion on processes or methods based on his own investigations, it was felt by those who listened to him, with that deference which invariably attended his utterance, that they might be accepted as conclusive.

He was an active member of several Societies, including the Photographic Society of Great Britain, of which he has for several years been elected a member of the Council; the Photographic Club, of which he was a Trustee; the London and Provincial; an honorary member of the North London Society; and one of the active promoters of the Affiliation Scheme in connexion with the P.S.G.B.

Individually, he was an artist of great merit, and frequently was awarded medals at the higher class of exhibitions, the last being at the recent Pall Mall Exhibition. He received his education in the science of photography at King's College, the practical part being acquired in the studios of his father, Mr. Francis Bedford, the eminent landscape photographer who accompanied H.R.H. the Prince of Wales on his Eastern tour many years ago. He died of typhoid fever on Friday, January 13 last, aged forty-six years, and was buried at Kensal Green Cemetery on Tuesday, the 17th instant, amongst those assembled at the graveside to pay the last tribute of respect to him being several members of his family; personal friends; and employés, and Messrs. F. A. Bridge, F. P. Cembrano, jun., Alex. Cowan, R. Child-Bayley, W. E. Debenham, R. P. Drage, William England, E. W. Foxlee, H. M. Hastings, H. R. Hume, Alexander Mackie, E. W. Parfitt, John Spiller, J. Traill Taylor, G. W. Tottem, Horace Wilmer, &c.

The large circle of friends William Bedford had made and retained ensures wide sympathy for his wife and son, and for his aged and esteemed father, Mr. Francis Bedford, in their affliction. He will long be remembered for those amiable gifts of character which endeared him to so many, for it is safe to say that seldom in one man was there concentrated so much kindliness of disposition, courtesy, warm-heartedness and generosity, allied with those admirable qualities of mind which elicited the respect as well as the affection of his numerous acquaintances.

Our portrait, which was the last one taken of him, was reproduced for us by Messrs. B. Dellagana & Co. of Shoe-lane, at short notice.

Art Reproductions.—Seeing the extensive sale that photographic copies of some of the pictures in Continental galleries, and modern Continental paintings, command in this country, one is naturally led to speculate as to whether reproductions of the works in English galleries, as well as British modern works, would not meet with a similar sale if they were forthcoming. Of course we mean in the sizes and at the prices that the foreign productions are to be obtained here. It is often said that the British public generally do not care for art, but this, to an extent, is disproved by the fact of the large business done in the foreign copies. English publishers do not apparently care to issue reproductions of paintings in which they are interested in anything but large sizes and at high prices, and in the they are generally supported by the artists. Foreign publishers, on

WILLIAM BEDFORD.

Died January 13, 1893.

the contrary, issue several sizes, from cabinet upwards, printed in silver and carbon as well as collotype, and at popular prices. These pictures are available for either albums or folios, whereas the expensive English reproductions are only suitable for framing. In connexion with this topic we are given to understand by print dealers that the copyright in the popular German picture, *The Mock Tyrolese*' has proved one of the most profitable of late years. Copies of all sizes and by all processes have, for some years past, met with an extensive sale, not only in England and the Continent but also in America.

STUDIO HEATING.

Our esteemed Editor, knowing I have had considerable actual experience in this subject, and having asked me to give my views upon it for the benefit of any reader of the JOURNAL who may be contemplating adopting some one or other of the many methods recommended by persons interested or otherwise, I will do my best to carry out his wishes. So many studios being connected with dwelling-houses, it is natural that first thoughts would turn to the open fireplace, and I may say at once that I share the Briton's prejudice in favour of a good, hot, coal-fire; but it has certain disadvantages that render it at times the very worst heating medium possible. There are few chimneys which do not occasionally "smoke;" that is to say, the smoke, instead, of ascending the nice channel made for it, occasionally comes, instead in puffs into the rooms. This is annoying enough in a living room, but in a studio it simply means cessation of work for a long period afterwards; for it is difficult enough at this time of the year in the best weather to obtain a sufficiently clear atmosphere to enable one to take good portraits when the camera is any distance from the sitter, as for half or full-lengths. It is within the mark to say that, with a slightly foggy air to start with, no good negatives can be taken for an hour or two after one whiff of smoke, be it ever so slight, has come into the room. Hence, unless the chimney is known to behave perfectly—and how few have such a good reputation?—it will be better to eschew open fireplaces. Of course, if the draught be confined by restricting the open area of the grate by sheet-iron "blowers," or otherwise, there will be less danger of smoke. I have employed this plan with a very small fireplace, which I had specially lined with fire-brick, after finding the ordinary brick burnt out with a few weeks use. By using a blower coke can also be conveniently employed, which reduces risks of smoke to a minimum. There is always, however, the danger of the "boy"—ubiquitous when mischief can be done—exercising the usual carelessness when lighting the fire. One further reminder, and we may consider another aspect of the subject With open fires, even with perfect chimneys, there is always danger of smoke being blown down by the wafting of a lady's dress or similar cause. Those only who have experienced the ill effect of a slight amount of smoke in the air of the studio have any idea of the miseries it causes.

Far better are closed stoves, of which there is an infinite variety to choose from; but a good-sized slow-combustion stove, if room can be found for it, or a couple of them if the studio be a long one, is a very efficient mode of warming a studio. Their drawback is the unsightly flue or stove pipe needed for carrying off the products of combustion, though in this respect the makers are very accommodating, and nowadays construct them so as to reduce this disfigurement to a minimum by carrying the pipe downwards. This, however, implies a chimney near at hand to lead these portable flues into, and they also need a good draught, or the stove will not work. Further, there must not be lost sight of the pleasures of taking the pipes down periodically for cleaning, with the attendant dust, and dirt, and soot particles. When I had one of these in use, it was generally discovered that the flue wanted cleaning just when taking down the pipes would produce the utmost possible upset and inconvenience.

I have had personal experience of the building, in various places, of not much under a dozen studios, and if I built that number again I candidly say that I should be thoroughly averse to any method of heating that involved the slightest possibility of the entrance of smoke into any room where a portrait would have to be taken. It is very probable that throughout the country many a negative is produced with foggy characteristics all owing to the presence of smoky air, so slight as not to be noticed by the inexperienced, and for which defects the unfortunate plate-maker is blamed.

These smoke troubles are by no means confined to the fuliginous particles that escape from fires in the studio, for, if there be an open fire in adjacent dressing-rooms, any smoke wafts entering them will inevitably result in the ultimate contamination of the studio air. Indeed, one of the defects of studios situated over dwelling-houses is the liability to the entry of smoke from any room from basement to attic in which a fire is burning.

With the knowledge of all these possible defects, gained by painful experience, I advocate most strongly a system of heating by hot water. I built a very large studio more than twenty years ago and heated it in this way, and when, after seven or eight years' occupation, I left the premises I had the very same apparatus removed and set up in my next studio. They are in use now, apparently as good as the day they were first put in, and, I think, do not cost any more than—if as much as—I should have to pay with open fireplaces. The heat is produced in a brick furnace in the cellar, and the pipes traverse the studio, the dark room, a dressing-room, and my office, and there is never any complaint; sitters often say, "How comfortable the studio feels—just like a sitting-room." This is high praise, for one most important matter in professional portraiture is attending to the physical comfort of the sitters. Whatever the cost, it is money well laid out.

Every one, of course, will have his own preferences as to the particular kind of hot-water apparatus to employ. The one referred to is on what is known as the high-pressure system. The pipes are of narrow bore, the external diameter is only an inch and a half; there is no boiler, no safety valve, no water reservoir, all is self contained, and the last addition of water was about a wineglassful after over two months' constant use. The pipes for the high-pressure system are made of wrought iron, and so instead of the unsightly pipes of the more familiar kind occupying space and pulling premises to pieces when they are put into a series of rooms in a building already erected, there are merely these narrow tubes invisible in comparison with the others, which can be carried through room after room and requiring little more wall piercing than could be done with a good-sized auger.

I should like to say before concluding my remarks upon this branch of the subject that there is much to be gained by keeping the water hot night and day. In my own premises the fires are never allowed to go out during the winter; the furnace was lighted early last autumn, and, except for a few minutes occasionally while the slags are being raked out, has been burning ever since. The fire is banked up at night, and next morning is still alight, and studio, dark room, and dressing-room are at a most pleasant temperature however early work begins in the morning. What this means will be well understood by operators and others who, during such weather as we have lately experienced, come to cold rooms first thing and have to wait some hours before there is any real comfort.

I will conclude my remarks by reference to gas stoves, which are highly approved of by many. There cannot be two opinions as to their convenience, and, if sufficiently large, and supplied with gas through-pipes of large enough bore—a very unusual thing—they are efficient. They are also rather expensive when used at full power for large studios, there being usually such a considerable amount of ventilation, or air change, through the glass roof and otherwise. My own experience of this form of heating has been confined to dressing-rooms of late years. I have one of Fletcher's in use for that purpose, which can be turned on and off just as required, and thus is decidedly economical, and free from possibilities of my *bête noire*—smoke. It may be well to point out that the manufacturer named makes three types of gas fires, in which the incandescent materials are respectively asbestos fibres, hollow fire-clay balls, and corrugated iron, their economy of gas being most with the last named, and least with the first. There is, however, with the asbestos pattern power to turn the gas down—when full power is not needed—to a much greater extent than the others. In them, if the gas be turned too low, the flame passes down to the inner jet, and then lights, like a Bunsen with too much air supply. When that happens no value is obtained from the gas, and, what is still more important, this jet becomes coated with soot, the supply of gas is lessened, and if this lighting down be not noticed and continue for some hours, the

choking up of the jets is so great, and the efflux of gas so reduced, that it is with the utmost difficulty that when next required for use the burner can be lighted properly—the flame will shoot down and very little heat is obtained. I allude to this owing to my having seen gas fires in this condition; it was only a week or two ago that I was in a professional friend's studio whose burner was in the condition I describe without his being aware of the fact.

In concluding my brief survey, I can only say I hope some of my readers may gather useful hints from it; and, if I can throw light on any obscure point, I shall be happy to supplement it by details of personal experiences. G. WATMOUGH WEBSTER.

AMERICAN NOTES AND NEWS.

The Social Status of Photographers.—In the *Canadian Photographic Journal*, Mr. John Clarke recommends his brethren to adopt carbon and platinum printing, in order to impart variety to the contents of their reception-rooms, and bring them pecuniary success. He adds: "But the exhibition and judicious introduction of such pictures will do more, it will help to raise the tone of the establishment in which they are produced, probably a more valuable thing. It will be admitted, and it is true whether admitted or not, that photographers do not as a rule enjoy the social status to which they are entitled—are not, socially, on the plane of, say, the doctor, the lawyer, or the clergyman. It is true that a few who are commercially successful enjoy the social position that is an attendant on wealth however produced, but the great bulk of the fraternity are, in pull estimation, merely photographers. Much has been written about the status of photography, but photography itself is all right enough; it is the status of the photographer that needs raising, and anything that will act as a lever in that direction should be regarded with favour." The social status of English photographers, according to the foregoing reasoning, is higher than that of their Canadian *confrères*, inasmuch as here platinum, carbon, and other methods of printing only slightly in favour in America are largely practised. By the way, is not Mr. Clarke somewhat rash in assuming that platinum paper—or, indeed, any sensitive paper—will keep "indefinitely?"

Remedies for Over and Under-printing.—A method of treating prints which have been over or under-printed has been recently devised by Mr. J. Huntly, says *Anthony's Bulletin*. Those that have been over-printed are toned and fixed in the usual manner, and then immersed in a dilute solution of cyanide of potassium until reduced to the desired shade, when they receive a thorough washing in running water. Under-printed proofs are developed with hydroquinone in the same manner as a negative, and then finished in the ordinary way. The results obtained are said to be excellent, and we would advise our readers to make the experiment.

A "New" Ceramic Process.—According to the same journal, Mr. Geo. G. Rockwood, of New York, has recently invented a method for burning in photographs on glass which bids fair to become a very important one. "It is based on the property that gelatine possesses of becoming insoluble when exposed to light in the presence of a bichromate salt. Indestructible pigments are combined with the gelatine, and remain upon the glass after treatment with warm water, wherever it has been affected by the light, as, for instance, exposure under a negative. When dry, the glass is fluxed and placed in a kiln, and the pigments melted into its surface."

Anti-halation Plates.—Plates specially coated to avoid halation in interior work are being introduced by American manufacturers of dry plates. The M. A. Seed Plate Company have, it is said, such a plate on the market, and the Wuestner Eagle Dry Plate Company are also preparing a similar plate. On behalf of English plate-makers we here take leave to acknowledge the delicate compliment paid to them by our American friends in following the former's lead.

A Coin-controlled Stereoscope.—A patent (in the United States) has recently been taken out for a "Coin-controlled Stereoscope." The claims relate to the special construction and arrangement of parts for uncovering the object-glass, bringing the views into position, &c. Electricity, in conjunction with clock-work, is utilised as the motive power.

A Divided Interest.—"Watchman" in the *Beacon* writes: "I learn from *Wilson's Magazine* that one of its subscribers has long divided his attention between photography and grape-culture. I have known many who divided theirs between photography and the fruit of the vine, and my observation has led me to believe that, attractive as photography is, the grape, especially when it has been corn or rye, sooner or later ousted his colleague." Not always, we hope and believe, good "Watchman."

"A Useful Dodge for Aristotype Printers."—Mr. J. H. Reuvers, in the *Photographic Times Annual* for 1893, says: "Users of aristotype paper very often are annoyed in their printing by having some of the paper stick to the negative. If not successfully removed, an entire negative may thus be ruined. I have hit upon a dodge which removes the difficulty completely without injuring the negative in the slightest. Immerse the negative which has thus been marred in a hypo solution, and leave it there until the brown spots or streaks caused by the paper have entirely disappeared. Then remove the negative from the hypo bath and wash thoroughly by laying the negative in clean water, changing the water frequently. Do not allow the water to run on the negative, as it would remove the retouching. When the hypo has been removed from the plate by washing, remove the negative from the water bath and set it up to dry in the usual manner. If the process is accomplished with care, the negative will dry as perfectly as if nothing had happened, and the retouching even will not be marred." This reads like a very simple method of removing silver stains from negatives. Perhaps some of our professional friends will try and report upon it.

NOTES ON SILVER.

[American Journal of Science.]

Action of Ammonia.—Aqueous ammonia is supposed to be without action on normal silver, but this is not so; under favourable conditions, silver is gradually taken up by this solvent.

The first experiments were made with silver reduced from the nitrate by the action of sodium hydroxide and milk sugar. The silver was very carefully purified from any possible trace of oxide. Placed in contact with ammonia for a few hours, silver was taken up. Its presence could be recognised either by ammonium sulphide, or by adding a drop or two of hydrochloric acid, and then supersaturating with dilute sulphuric acid; a dense cloud of silver chloride forms, and this result can be obtained any number of times in succession by acting with ammonia on the same portion of silver.

A similar reaction was obtained with silver reduced from chloride by cadmium and hydrochloric acid, removing afterwards all traces of cadmium. Silver reduced in this way is liable to contain traces of chloride. These were removed by covering the silver with strong ammonia, letting it stand over night, and thoroughly washing out. This was repeated five times. From this silver, ammonia by twenty-four hours' contact always took up enough to give a dense white cloud when treated as above.

Portions of solutions obtained in the last-mentioned manner were evaporated to dryness over the water bath, and left brownish-black films. These were non-explosive, and therefore did not consist of silveramine; they yielded a large proportion of silver to acetic acid, leaving behind a little metallic silver. The ammonia, therefore, does not dissolve the silver as metal, but as oxide. The presence of a little metallic silver in the residue left by evaporation was probably due to slight traces of oxidable organic matter contained in the ammonia. This opinion was confirmed by the fact that the solution, when heated, acquired a transparent red colour.

It appears, therefore, that, in the presence of ammonia, silver has a tendency to oxidise, for when the silver was placed in a vial with an air-tight fitting stopper, filling it about half full, and was then completely filled with liquid ammonia and tightly closed, it was found that in twenty-four hours a mere trace of silver was taken

up. On the other hand, when the silver was placed in a flat basin and merely moistened with ammonia, more silver was taken up in five minutes than in the preceding case in twenty-four hours.

This action of ammonia in promoting oxidation recalls its behaviour with cobaltous salts and with copper. It is probably the only case in which silver is oxidised (at ordinary temperature) by atmospheric oxygen.

Action of Dilute Sulphuric Acid.—It is generally held that silver is insoluble in cold dilute sulphuric acid. Almost any form of silver, provided it is finely divided, is slightly soluble in sulphuric acid diluted with four or five times its bulk of water. With more dilute acid, different varieties of silver act very differently. The most easily attacked is that which is obtained by reducing the oxide with alkaline hydroxide and milk sugar; from this a distinct trace is dissolved by sulphuric acid, diluted with 100 times its bulk of water. From silver reduced from the chloride by cadmium, this very dilute acid takes up nothing.

Nitric acid, sp. gr. 1·40, diluted to ten volumes, and allowed to stand for an hour with finely divided silver, took up an extremely faint trace.

Hydrochloric acid, sp. gr. 1·20, was totally without action. The silver, after being well boiled with water to remove every trace of acid, dissolves completely in nitric acid.

Acetic acid has no action upon metallic silver.

Various Reactions of Normal Silver.

Normal metallic silver, even in a state of very fine division, does not abstract the slightest trace of nitric acid from perfectly neutral cupric nitrate obtained by acting on pure cupric sulphate with barium nitrate. After fifteen hours of contact, not a trace of silver had been dissolved.

But silver easily reduces cupric chloride with formation of purple photochloride. If the copper salt is present in slight excess, the silver is so thoroughly acted upon that nitric acid does not extract a trace of it from the purple photochloride.

Metallic mercury instantly reduces silver nitrate, but metallic silver takes chlorine from corrosive sublimate. The precipitate contains calomel and blackens with ammonia.

Silver in fine division slowly reduces a neutral solution of potassium permanganate.

Silver nitrate, as is well known, is reduced by ferrous sulphate or ammonia ferrous sulphate, the iron at the same time becoming peroxidised and the silver assuming the grey metallic form. On the other hand, silver powder rapidly reduces a netural solution of ferric sulphate. A solution of iron alum readily dissolves metallic silver without the aid of heat;* in a few seconds the solution strikes a blue colour with potassium ferricyanide, and if the iron alum is in excess the whole of the silver is dissolved. It has been before noticed that the reactions between silver salts on the one hand and iron salts on the other are to some extent reversible: the observations just described place the matter in a somewhat clearer light. With a view of ascertaining whether ferrous sulphate could be completely oxidised by argentic oxide, a portion of the ferrous solution was treated with successive portions of the oxide until the latter was no longer affected by it. But when this stage was reached the solution no longer contained a trace of iron, the whole of it had entered into combination with the silver. This combination is perfectly black, and may probably have consisted of the compound described by H. Rose as Ag_4O, $2FeO\ Fe_2O_3$, and obtained in the same way.

When ammonia iron alum is placed in contact with finely divided silver in considerable excess in a tightly closed vial, the solution, after a few days' standing, with frequent shaking acquires a deep red colour. This may last for a week or more. The solution then decolourises, and becomes greenish, but still contains abundance of ferric salt. Thus it appears that, although silver has a powerful reducing action on ferric salts, the action is self-limited, and ceases long before complete reduction is effected, for, after many weeks' contact in a closed vial, there are abundant indications of the presence of ferric salt, although silver has been present in large excess.

M. Carey Lea.

ESTIMATION OF OXYGEN.

[London and Provincial Photographic Association.]

In bringing before you such an out-of-the-way subject as the estimation of oxygen, we are chiefly influenced by the hope that it may be of some use to the large section of photographers who practise lantern work, and who use oxygen compressed in cylinders. That this oxygen may be of more than doubtful purity, was pointed out recently by Mr. Hepworth in a letter to *Nature*, and who had obtained results showing from 5 to 45 per cent. of impurity, which has also been the experience of one of us. We need hardly point out that not only has the amount of impurity present in oxygen a very bad effect on the light given out—when used for producing the lime-light—by cooling the flame, but also on the pocket of the lanternist, by his having to use more gas than he would otherwise have to do if the oxygen were pure.

Various Ways of Estimating Oxygen.

To estimate oxygen very accurately, complex apparatus such as Bunsen's, or modifications thereof, in which mercury is the trapping fluid, must be used, but for ordinary purposes Hempel's, or some such apparatus, in which water is the trapping fluid, may be employed.

The estimation of oxygen in a mixture may be carried out in several ways, of which the two most important are, first, by mixing the gas to be analysed with an excess of hydrogen, exploding the mixture by means of a spark from an induction coil, and measuring the decrease in volume. One-third of the contraction, due to the combination of the oxygen with the hydrogen, will be the volume of oxygen present in the original gas. Second, by bringing the gas to be tested into contact with a solution of pyrogallic acid and caustic potash, and noting the decrease in volume which occurs. The diminution in volume gives the amount of oxygen present in the original mixture, and the unabsorbed part the diluent.

We have chosen the latter method as being the most convenient and easy of manipulation, and it possesses the advantage that both pyro and caustic potash are well known to, and most probably on the shelves of all practical photographers.

We have bought a Hempel's apparatus to show how oxygen would be analysed in a chemical laboratory if the greatest accuracy were not needed, and also a modification designed for the use of lanternists.

The Hempel Method.

The Hempel consists of two parts—the one the measuring apparatus, and the other the absorption bulbs. The former consists simply of two glass tubes about three-quarters of an inch in diameter and eighteen inches long, connected together at their lower ends by india-rubber tubing. One tube is open at the top, and the other is closed by a glass stopcock and graduated. To start an analysis, the graduated tube is filled completely with water; when connexion has been made with a supply of gas, the stopcock is opened, and as much gas as necessary is introduced; the communication is then cut off, and the level is made the same in both tubes and the volume read. The object of making the level of the water in both the same is to avoid reducing to constant pressure. The graduated tube is then connected by means of capillary tubes to the absorption apparatus, which consists of two bulbs, joined together, one terminating in a capillary U tube. The bulb nearest the graduated tube, is filled with a solution of pyro and caustic potash in water. All the capillary connecting tubes and indiarubber tubes must be filled with water in order to eliminate errors. The following is the best proportion of pyro and caustic potash for the absorbing solution:—

Pyro	1 ounce.
Caustic potash	24 ounces.
Water	20 „

The gas under analysis, after being passed into the bulb, is brought into intimate and renewed contact with the alkaline pyro by constant shaking, three to five minutes being generally sufficient. The gas is then drawn back into the burette, and again measured as before; the decrease in volume represents the amount of oxygen in the gas. In order to make sure that no oxygen is left unabsorbed, it is again passed into the pipette, and if there is no decrease in volume on again measuring, the analysis is complete.

A Simple Plan of Estimation.

The other piece of apparatus we have here is of very simple construction, and could be procured at a small cost; or, if you have practised glass-blowing from the practical lessons given you by one of us, you could easily make it for yourselves. It consists of a tube, three-quarters of an inch in diameter, eighteen to twenty inches long, and drawn out at each end. To each end is attached a short length of indiarubber tubing, provided with a pinchcock. Beyond the lower pinchcock is another piece of glass tubing, which enables the tube of large diameter to be connected to a funnel, or other containing vessel, by means of indiarubber tubing of suitable size.

In order to use it, the tube is first completely filled with water

* The statement in the new *Encyclopédie Chimique* that heat is required and that the metal separates again on cooling (tome iii., cahier 15, p. 218) appears to be incorrect.

Connexion is then made with the vessel containing the gas to be analysed. Both pinchcocks are pressed, the one to allow the gas to enter, and the other to allow the water to escape. The lower end might, with advantage, be plunged into a tumbler or beaker full of water. As soon as the tube is full of gas, both pinchcocks are allowed to close the tubes, and the supply of gas disconnected. The funnel, or other convenient vessel containing the supply of pyro solution, is now, by means of the indiarubber tubing, connected, making sure that the tubing is completely filled with liquid. The bottom pinchcock is now opened, and if the reservoir of pyro be raised, a sufficient pressure will be obtained to force some of the pyro solution into the tube containing the gas to be tested. At once absorption of oxygen will commence; and, in order to facilitate this by increasing the surface of the liquid, the tube may be tilted or shaken, the pinchcock being opened occasionally in order to prevent too great a reduction of pressure inside, and thus cause a probable leakage of air into the apparatus, but this danger can be removed if the indiarubber tubing is wired on. When the absorption is complete, place the vessel of pyro, with the pinchcock open, so that the level of the liquid is the same in both tube and reservoir.

The tube must either have been graduated before, or, if only a few measurements are to be made, and the operator does not care to go to that trouble, the volume of the tube can be ascertained by completely filling it and measuring the contents in an ordinary graduated measure, then turn the tube upside down and fill with water up to the mark occupied by the unabsorbed gas.

The percentage of diluent can be easily obtained by dividing the volume of the residue in drachms or cubic centimetres by the original volume and multiplying by 100. Thus, suppose the volume of the unabsorbed gas to be 17 drachms or c.c., and the volume of gas operated on 80 drachms or c.c., then the percentage of diluent will be $\frac{17}{80} \times 100 = 1700 \div 80 = 21{\cdot}25$.

There are one or two precautions to be observed in using pyro and potash. First, it is no use to try and absorb oxygen with a weak solution of pyro; it must be about the strength given above. Secondly, it must not be used too often, or left exposed to the atmosphere, as after a time it begins to give off carbon monoxide, which would seriously vitiate the result of the analysis.

Results of Analyses.

The results of the analyses of various samples of oxygen, which have been obtained during the last fortnight are as follows:—

	N %	O %	
No. 1	15·5	84·5	Same maker at different times.
No. 2	39·4	60·6	
No. 3	43·1	56·9	
No. 4	43·8	56·2	
No. 5	25·4	74·6	
No. 6	7·0	93·0	Another maker.
No. 7	3·8	96·2	Made from chlorate and M_2O_2 at R.N.C. for limelight.

In conclusion, we hope that every one who uses a limelight, for whatever purpose it may be, will, if he wishes the light to be at its best and constant, take the small amount of trouble that is necessary in order to master the few details, so as to enable him to test the gas sent in, and, if it should contain more than a certain percentage of diluent, either return the gas as unsatisfactory or demand a reduction in the price, as, under these circumstances, not only is the article supplied bad, but apt to cause the user to acquire a bad reputation, which is of far greater importance than the cost of the gas.

We trust that the time will soon come when makers will guarantee that the percentage of purity is between certain limits, and then, if it is not, a remedy can be easily obtained. Salts of the precious metals are usually guaranteed of a certain percentage of purity, and, if any one took the trouble to analyse them, and found they were not so, we think he would be perfectly justified in seeking redress in a law-court. To issue as oxygen a mixture of air and oxygen, so that it contains thirty or forty per cent. of an inert and flame-cooling gas, is no better than the act of a publican who adds water to his beer and dilutes his whisky below what is allowed by Act of Parliament, and sells them as unadulterated. The one is certainly as much of a fraud as is the other.

F. B. Grundy and A. Haddon.

DISHES AND TRAYS.

It is not an impossible task, the repair of a broken porcelain dish; it must be a small one indeed that is not worth the trouble. A careless operator broke clean off one corner, the spout of course, of a 24×20 dish; this was very satisfactorily repaired with "coaguline." The parts should be carefully cleansed and hot, the hot cement applied to the edges, the latter then brought together, and while so held a second pair of hands may attach strips of gummed paper along the line of fracture; the paper, contracting as it dries, holds the piece very firmly at the most critical period, *during the drying of the cement*. To make the repair more certain and reliable and to prevent a mishap during use, the *outside* of the dish was at this corner taking in a good four inches outside the breakage, covered with a piece of stout linen, the same being applied with a *strong* solution of shellac in methylated spirit. The dish has, since this repair was effected, gone through some eight years of use.

For a breakage right across I should still use coaguline carefully, applied hot, the edges to be held with gummed paper. By the time union is considered perfect we can consider what best to do to make assurance doubly sure. If the dish were 15×12 or so, I should apply *broad tape* saturated with the shellac over the outside bottom and sides of the dish, putting it on in the same way as upholsterers affix the broad tapes to the seats of chairs, then all round outside, covering the *ends* of the cross pieces with a long strip of tape. I rather think this would hold the thing together. If preferred, we can, after cementing the pieces and bringing them together and drying, get made a shallow wooden tray, well put together at the corners, and big enough to hold the tray with a space of half an inch or so all round. Give it a good coating of the shellac varnish, and, when this is dry, mix plaster of Paris to a creamy consistence with water, adding the plaster *to the water*. As this stuff sets very quickly, we must make a rough estimate of the quantity required in order not to run short. The creamy plaster is run into the wooden tray, which it should cover to the depth of at least an inch; now lower the dish into the tray, one side or end a little in advance of the other, and, if enough of plaster has been mixed, the sides and ends will be comfortably filled, any excess running over, the plaster to be nicely bevelled off, and the whole allowed to set and get thoroughly hard. When quite set (and if made hot) it will be well to apply a good coating of the shellac varnish; the plaster, if dry, will absorb a good lot of this, and will be all the better for it.

On one occasion, while repairing a rather small dish in this way, I well soaped the bottom of the dish before dipping, so that, when quite set and hard, the dish was readily removed from the plaster bed; this latter was then well dried, and received three coatings of shellac varnish, and it made a very useful dish.

I have for some time now used almost exclusively *wooden* trays, three of which, measuring respectively 20×16, 22×18, 24×20, cost 16s., well made, dovetailed, and screwed. I gave them three coats each inside and out of the shellac varnish, and finally the insides received two coats of *enamel* paint, *bath* enamel preferred. They are carefully sponged out after use, and wiped with a damp leather. They are light, easy, and comfortable to handle, take up little space, and are likely to last for years.

J. Pike.

WINTER PHOTOGRAPHY.

Many of our amateurs (says *Anthony's Bulletin*) lay aside camera and tripod with the advent of the winter months, confining themselves to lantern work, bromide printing, enlarging, and the various other especially winter branches of the art. To these we would say, You are making a mistake; you are closing your eyes to Nature in some of her grandest forms; keen winds, Jack Frost, and even snow and ice, are well worth facing for the prizes that she offers at this time of the year.

When the leaves first begin to turn, and the green still predominates—enlivened here and there with a patch of yellow or red, or with edges just tinted, make an exposure, and see the increase of detail in the foliage that the picture will show. Are you near the water, where the rich warm browns of the sedge stand out in strong contrast to the still green foliage and grass? It is at these times more than ever that we long for the photographic millennium, a true reproduction of colour, obtainable with the same ease as the present monochrome results.

At this season of the year are visible huge banks of fleecy and ominous-looking clouds, infrequent at other times. Just before sunset these cloud effects are particularly fine, masses of brilliant colours, light and shade, that produce most desirable cloud negatives for printing in with such pictures as need it, and there are few that cannot be improved by treatment in this way.

There is a treatment of grounds known to landscape gardeners as "planting for winter effect" or "winter landscape." It consists in breaking the sky line or foreground with a judicious mixture of evergreen and deciduous trees. A landscape properly selected to produce an effect of this kind in the picture will be found a task worthy of the

skill of the artist. Bold, heavy masses of light and shade may in this way be utilised, while the delicate tracing of the leafless branches against the sky serves to remove what might otherwise prove too sombre an effect. Allow the white trunk of a silver birch to stand out sharply against some dark object in the background, while its upper branches are changed to dark slender threads against the high light of the sky.

It has fallen to the lot of many of us after a heavy snowfall to try an exposure, tempted by the glistening drops and icicles, the bright sunlight reflected with dazzling brightness from the snow-covered ground, and the trees overladen and bending far down under the weight of their burden. The first time we wait with impatience for the negative, but what a disappointment the first print brings us. "Nothing, with a few black specks floating aimlessly around in it," was a disgusted verdict once rendered by a disappointed worker, and one which seemed to describe the result remarkably well. Unfortunately, this is too often the case, and yet there is no good reason why it should be. Remember, that in a composition of any kind balance is needed and conditions must be carefully considered. It is unreasonable to expect that detail in the shadows can be obtained from an exposure sufficiently short to properly render the intense high lights of such a picture. Any object to appear clearly against such a background must be more or less in the nature of a half-tone or shadow, and to secure detail in it under such conditions without hopelessly over-exposing the high lights is an impossibility.

On the other hand, if the high lights are over-exposed and detail obtained in the shadows, these same high lights will be weak in the negative and appear as greys in the finished print. Now, grey snow is somewhat of an anomaly, save in our cities, when it is frequently black, and a picture representing it as such in bright sunlight is manifestly an absurdity and a failure.

It is by the careful study of our failures that we learn more than by our successes. Success must never come to be looked on as synonymous with perfection. As our experience grows, our ideal must expand with it. To-day's success must mean only something better than yesterday's attempts, otherwise we have reached the egotistical stage, and no sooner do we become thus perfect than we begin to retrograde.

But *revenons à nos moutons* and let us see what our first snow scene failure has taught us. Evidently strong sunlight is not permissible, and the balance between high light and shadow must be perfectly observed, letting the half tones and the blacks predominate in such a way as to remove that patchy unfinished look. To do this carefully they must be connected rather than isolated, and here Dame Nature steps in and beckons us to the recesses of her woods, by the side of some sluggish brook, rebelling against and half breaking its frozen bonds, with glimpses of mirror-like surfaces reflecting the overhanging boughs of brush and tree heavily laden with their ermine coat, yet preserving their graceful outlines, their under sides coming out sharp and distinct, as black lace upon a foamy surface.

That gnarled and knotted tree trunk, half covered in its white mantle, gives the requisite boldness to the right in the foreground, and serves to accentuate the feathery detail of the undergrowth, while the patches of dwarf hemlock, cropping up everywhere through the snow, break what would otherwise be a foreground of monotonous white.

Select a cloudy day for a picture of this kind, stop the lens down well, and let the exposure be ample, say, three seconds with *f*-32. It will be found advisable to reduce the amount of sky to a small proportion, that seen through the branches being all-sufficient. Grey snow, under circumstances such as these, will not be anomalous, and thus the correct rendering of the lights and shades is rendered easier.

There is something exhilarating about such picture-taking as this: the crisp biting air, of wonderful clearness after the storm, the almost absolute stillness, even footfalls are muffled in the snow, and the occasional sharp snap of a twig, breaks on the ear almost like a pistol shot. Warm clothing, thick gloves and rubber boots are necessaries which make all the difference between discomfort and a sense of defying the elements, and keeping dry and warm withal.

If you can find some bold masses of rock, with summits snow-covered and sides only slightly touched here and there, you will have an excellent opportunity for marked contrasts. Secure a surface which the water from the melting snow has darkened, and aim to secure the effect of looking into the sombre and unlighted depths of a forest from some point where a momentary rift in the vegetation overhead only serves to accentuate the gloom beyond. Be careful to avoid a few dark spots of rock cropping out from a snow-covered mass, otherwise the patchy effect will appear again, and the whole picture will be marred.

Let the summit be covered and the snow, patchy if you will, upon the dark background of the rock, or the few remaining leaves of some vine or creeper, together with its tendrils standing out in bold relief with the snow which they have retained upon them.

Isn't it nearly time that camera was unpacked, those rubber boots looked up, and some spot in the country (you need not go far to find what you want, especially if you live in this city) decided upon, where the next day off is to be spent? Try it once, remember the cautions we have given you, and see if the reward is not meet for the deed.

REVERSED NEGATIVES—AMIDOL.

There are some subjects touched on in the last issue of The British Journal of Photography on which I should like to state my experience. The question of reversed negatives is one that is bound to come to the front now that carbon printing and photo-engraving are becoming such important processes in the reproduction of negatives. I am very inclined to think that celluloid films will much facilitate the production of these reversals. I tried last summer printing on ordinary silver paper through celluloid negatives, and found the falling off of definition exceedingly small: indeed, quite insufficient for the purpose I had in view, viz., to produce a soft, slightly out-of-focus effect. Should, however, it be necessary for some reproduction processes that there should be *no falling* off of definition, it is easily accomplished by taking the negative through the film; if the lens is fairly stopped down, the loss of focus imperceptible, and, in any case, it only requires a slight turn of the focussing screw to set things right. I found the films perfectly free from blemishes, and the backs without the slightest traces of emulsion on them. I think there was a slight falling off in rapidity, and the image came up a little slower in development. The resulting negative could be printed as a reversed negative with absolute sharpness, or as an ordinary one with very little falling off in definition. There is another advantage in exposing films in this way, that there is no danger of the sensitive surface getting scratched by the shutter, as sometimes occurs, and, when printed on silver paper, there is no danger of staining the film.

I read with pleasure the debate on amidol, and particularly Mr. Dresser's experience, as he is such an authority on instantaneous exposures. He does not, however, say whether the formula he uses for these exposures is the same as the one he gives for bromide work. My experience with amidol, used according to the formula issued with it, does not agree with his. I find that amidol gives less detail than eikonogen, and altogether a harder negative; density comes quicker, but with patience I get as much with eikonogen.

George Mansfield.

NOTES ON SILVER CHLORIDES.

[American Journal of Science.]

Experiments made by J. J. Acworth* at the suggestion of E. Wiedeman showed that by heating silver chloride to a temperature of 220° C. it passes into a modification that was insensitive to light.

I think this change may be due to the complete driving off of moisture. Abney showed by a well-known experiment that silver chloride, when exposed perfectly dry in vacuo in a glass tube, was totally unaffected by light; but I have shown that fused silver chloride, poured into petroleum and placed in the sunlight without removing it from the liquid, was instantly darkened.

These three experiments taken together lead to the following conclusions:—

1. Silver chloride dry and perfectly isolated is insensitive to light. (Abney's experiment.)

2. The presence of atmospheric air does not restore the sensitiveness if the silver chloride has been absolutely dehydrated at 220° C. (Acworth's experiment.)

3. The presence of oxygen is not necessary or important for the darkening of silver chloride. The presence of moisture is not essential; its place may be taken by another substance capable of taking up chlorine. This follows from my experiment above mentioned.

There is no doubt that silver chloride retains the last portion of water with great obstinacy. I have frequently tried to dry silver chloride in hot air, so that it should lose nothing further by fusion, but never quite succeeded. There is always a loss, which may be roughly taken at half a milligramme, and from thence upwards to nearly one milligramme, in a gramme. When the water is thoroughly driven off, it is probable that the silver chloride is left in an insensitive condition. Acworth's experiments seem to show this.

So long as moisture is present the molecule of silver chloride easily

* *Wied. Referate*, 1890, p. 515.

breaks up, not merely by the action of light, but by the application of any form of energy. The part played by moisture in chlorine reactions is somewhat remarkable. It has been lately stated that absolutely dry chlorine has no action upon copper foil. As soon as a trace of moisture is introduced, energetic action sets in.

M. Carey Lea.

AMIDOL.

[Putney Photographic Society.]

Thursday, January 12.—Mr. L. E. Morgan, representing Messrs. Fuerst Bros., gave a lecture and demonstration on *Development with Amidol*. In a short preface Mr. Morgan claimed for amidol the following important advantages:—Good keeping qualities in its dry state, ready solubility, cleanliness during manipulation, great energy in bringing out detail without the addition of free alkali, power to give the necessary density, and absence of stain, even in prolonged development. Comparing amidol with other developers, he said that experienced workers might perhaps be prejudiced against it, as practically being a one-solution developer; they might think they were sacrificing some of the power which they possessed in older developers of readily modifying the proportions of the constituent parts to meet the requirements of varying subjects and of over or under-exposure. He would, however, prove that amidol also was quite capable of such modification—in cases of over-exposure, by using a weak solution and an extra quantity of bromide; for under-exposure, a strong solution and only a small quantity of the bromide. For uncertain exposures it was desirable to begin with a weak developer, and gradually increase the strength as occasion required. The ordinary stock solution (2 per cent.) is made up as follows:—

Amidol	10 grains.
Sodium sulphite, cryst.	100 ,,
Water	1 ounce.

This solution will keep well in full bottles, well corked, and although after a time it may discolour, it does not lose its developing power to any extent, nor does it stain the negatives or prints in any way. For use, dilute the stock solution with three to four times its bulk of water, 5 to 20 drops of a 10 per cent. solution of bromide of potassium being added for each ounce of stock solution. This diluted solution may be used successively four or five times without losing developing power to any extent. For his own use Mr. Morgan preferred to keep the following stock solution, which will keep for any length of time:—

Sodium sulphite, cryst.	1 ounce.
Water	20 ounces.

For use, 8 to 10 grains of amidol powder, and a few drops of potassium bromide (1 : 10) are added to 4 ounces of the above solution.

Mr. Morgan then proceeded to develop a negative which had purposely been given a somewhat short exposure, using the ordinary strength of developer; the image appeared in about thirty seconds, showing full detail in that time, development being allowed to proceed. The necessary density was obtained in about three minutes; the result was a brilliant and soft negative of a good printing quality. As showing the capability of amidol for developing bromide paper, he exposed a piece under a landscape negative and proceeded to develop with a solution of the same strength as that used for the negative. In this case also the result was extremely satisfactory, the tone of the print being very like a good platinotype. No clearing bath was necessary, and the manipulation throughout of the simplest. To prove that amidol is really a good all-round developer, Mr. Morgan proceeded to expose two lantern plates, giving the one an exposure of one minute, and the other six minutes, still using the same strength of developer, but in the latter case with an additional quantity of bromide he produced two very brilliant and satisfactory slides.

It was apparent as the demonstration proceeded that the members were agreeably surprised at the powers of amidol, particularly as the experiences of some of them with other developers recently introduced with great flourish of trumpets were of a disappointing nature, only confirming them in their preference for their old and tried friend, pyro. Mr. Morgan brought several bromide prints for inspection, but a portrait of a native of Morocco, a very fine enlargement by Mr. Gorin, and developed by him with amidol, showed most strongly that good results can be obtained with it without previous experience by an amateur, this having been Mr. Gorin's first attempt with the new developer.

A hearty vote of thanks to Mr. Morgan concluded an enjoyable and instructive evening.

[Kensington and Bayswater Photographic Society.]

Monday, January 16.—Mr. Morgan gave a demonstration on development of negatives, bromide paper, and lantern slides, by that chemical. He showed bromide prints from one negative which had received exposures varying from one minute to ten minutes, each of which was considered a good print. The leading points he claimed for this developer are its freedom from producing stain, when dissolved, either upon the hands or the plate or paper, though the crystals themselves, if allowed to remain in contact with the hands, will produce a brown stain.

Mr. H. E. Davis (of the Camera Club), who has largely experimented with the new developer, especially for lantern slides, gave his new formula for development (for warm tones only). He stated that he considered the ordinary formula used for the development of lantern plates by amidol made a too active developer, veiling the plate before development was complete. His practice is to use a *strong* developer *well restrained*. Thus:—

Amidol	160 grains.
Metabisulphite of potassium	2 ounces.
Water up to	20 ,,

This is the stock solution. Of this take half an ounce, and add to it 1 ounce of a 10 per cent. solution of bromide of ammonium, and water up to 2¾ ounces, then add a quarter of an ounce of a 10 per cent. solution of carbonate of potassium. This will develop twelve or fourteen lantern plates.

The following are the official instructions for the use of amidol:—

I.—*Concentrated Stock Solution.*

Water	7 ounces.
Sodium sulphite, cryst., pure	1½ ,,
Amidol	60 grains.

May be kept for a long time in full bottles well corked.

For use, mix one ounce of this concentrated solution with three ounces of water, and according to the make of the plates, add a small quantity, at most twenty drops, of potassium bromide (1 : 10). In this state the solution may be used four or five times successively, without much loss of developing power, but it is not advisable to leave the developer standing too long, nor to prepare more of it than necessary for the work in hand.

For landscapes, or strongly lighted subjects, the developer may be employed in a still more diluted form.

II.—*Two-Solution Developer.*

Water	20 ounces.
Sodium sulphite, cryst., pure	1 ounce.

This solution will keep for any length of time.

For use, eight to ten grains of amidol powder, and a few drops of potassium bromide (1 : 10) are added to four ounces of the above solution. To be saved the trouble of frequent weighings, keep a little horn or bone spoon for measuring the required quantity of amidol. To retard development, use a ten per cent. solution of bromide, and to accelerate it add a twenty per cent. solution of sodium sulphite. On very hot days, or for plates inclined to fog, it is recommended to add a few drops of citric acid (1 : 10). With normal exposures the image should appear in from eight to ten seconds, and be fully developed in about four minutes. Over-exposure is recognised by the immediate appearance of the picture, in all its details, as soon as the developer is applied, the deep shadows becoming veiled, and all more or less fogged. For over-exposure it is necessary to use a weak developer, and to increase very largely the quantity of bromide, using, in extreme cases, even up to one-quarter bulk of the amidol solution. In every case of unknown exposure it is advisable to begin with a weak developer, or one which has done duty before, and increase the strength, when, from first indications, it is found safe to do so. For under-exposures, a strong developer, or a large addition of the sulphite is recommended, and these also help to give greater density, which end may likewise be secured by prolonging the development. The degree of intensity is best judged of by transmitted light, remembering always to make allowance for reduction in the fixing process.

III.—*Special Developers.*

Solution A.

Water	20 ounces.
Potassium metabisulphite	2 ,,
Amidol	1 ounce.

This solution will keep for a very long time if well corked.

Solution B.

Water	20 ounces.
Soda crystals	2 ,,

Solution C.

Water	20 ounces.
Sodium sulphite, cryst., pure	4 ,,

Results similar to pyro may be obtained with

Solution A	10 parts.
,, B	6–10 ,,
Water	70 ,,
Bromide (1 : 10)	3 ,,

But this formula may be considerably modified, according to requirements; it is not, however, advisable to increase the quantity of alkali, for fear of inducing fog.

For over-exposed plates, add the solution B in the above formula little by little, until the desired effect is obtained, never exceeding the amount above prescribed.

Images of a softer character are obtained as follows:—

Solution A	10 parts.
,, B	20–40 ,,
Water	70 ,,
Bromide (1 : 10)	½–¾ part.

IV.—*Separate Developer.*

Solution D.

Water	20 ounces.
Sodium sulphite, pure cryst.	¾ ounce.
Amidol	2 ounces.

This solution keeps colourless for a long time in full and air-tight vessels. When opened it goes from yellow to red, which, however, does not affect the developing power, or colouration of plates.

Solution C.

Water	20 ounces.
Sodium sulphite, pure cryst.	4 ,,

For use take—

Solution D	5 parts.
Water	50–70 ,,
Solution C	20–30 ,,
Bromide (1:10)	1½ ,,

This formula also has the advantage, by gradually adding solution C, of controlling development up to the point desired, which is specially important for over-exposed plates.

As the image loses on fixing it is recommended to develop more strongly.

For Bromide Paper.

Both for prints and enlargements either of the above formulæ may be used, and the freedom from stains will prove of great advantage. With diluted solutions clear grey tones are obtained.

For Chloride Plates and Lantern Slides.

Transparencies of the blackest tones are developed with:—

Water	20 ounces.
Sodium sulphite, cryst., pure	1 ounce.
Amidol	40 grains.

Warmer tones are obtained through longer exposure and the liberal addition of bromide, even up to one ounce in the four ounce developer.

THE WEST KENT AMATEUR PHOTOGRAPHIC SOCIETY'S EXHIBITION.

This Society held its first Exhibition (members' work only) on Thursday 12th, at the Public Hall, Sidcup. The President, Mr. Andrew Pringle, opened the Exhibition with a short address. Mrs. Pringle then presented medals to winners. Class A—Lantern slides, set of twelve. Any subject. President's silver medal, E. J. Crowe; bronze, Gregor Grant. Class B—Enlargements. Vice-President's silver medal, E. Hawkins; Society's bronze, C. J. Crowe; diploma, G. I. Gill. There were a large number of entries in this class, and a very tough contest. Class C—Set of four prints. Society's silver medal, E. Hawkins; bronze, Gregor Grant. R. H. Pickell was awarded an extra special diploma for photograph of lightning flash taken June last. Class D—Not sufficient entries for an award. E. Hawkins very highly commended. The Judges were Messrs. Cembrano, Pringle, and Dresser. The programme of the evening consisted of a good selection of music, with lantern shows at intervals. Slides by Messrs. Carpenter, Edgar Lee, Pringle, Dresser, and members, were shown and much appreciated by audience.

ENLARGING APPARATUS AND THE ILLUMINANTS FOR SAME.

At the Manchester Photographic Society, on January 12, the President (Mr. Heywood) in the chair, Mr. H. M. Whitefield gave an address on *Enlarging Apparatus and the Illuminants for same.* At the outset he remarked that most of what he had to give the meeting had appeared from time to time in The British Journal of Photography, a source in which nearly all things photographic could be found. Assuming that daylight was generally not available to the bulk of amateurs, his remarks would be confined to artificial lighting of the negative. He passed in review the various methods suggested to obtain this object, most of which he had tried. The plans to obviate the employment of condensers, by rows of gas jets, magnesium wire, diffusion of the light by opal or ground glass, &c., he considered unsatisfactory, as not giving evenness of illumination, and gave uncertainty of exposure. The three-wick lamp, used with a condensing lens, was also faulty for the same reasons.

He considered the limelight the best, both for enlarging and reducing; but, for those who did not care to go in for this illuminant, he highly recommended the "albo-carbon" gaslight, as advocated by Mr. Traill Taylor some years ago. This was an invention to increase the illuminating power of gas for ordinary lighting purposes, and in its simple form consisted of a reservoir above the burner containing a supply of naphthaline, over which the gas passed before reaching the burner, taking up the vapour from the naphthaline, which was very slowly evaporated by the flame of the light itself, the result being a small bright light. To adapt this for working in an enlarging lantern, he added a second burner, placing the two jets one behind the other, with the flat sides towards the condenser. The flames must be separated just sufficient to prevent them joining. This arrangement gave a more solid light than a single burner. The whole of the flame was not required, and he enclosed the burners in a tin box having suitable air inlets at the bottom and a dark chimney at the top, a circular aperture, about three-quarters of an inch in diameter, being made opposite the brightest part of the flame and covered with a piece of glass. He found that the albo-carbon light was very actinic, and the difference in the exposure of a print as compared with that by the limelight was not as great as many might suppose (experiments given showed the advantage of the naphthaline very markedly), and the use of the light no more trouble than an ordinary gaslight.

Mr. Whitefield showed his enlarging lantern, which differed little from the usual form, and explained the necessity of having a condenser large enough to include the whole of negative without using the extreme edges of the lens, and practically demonstrated the working of the lights.

PATENTS COMPLETED.

Improvements in Apparatus for Changing and Focussing and Exposing Photographic Plates or Films.

No. 3680. Thomas Edward Heath, Oakbridge, North-road, Cardiff.—*December* 10, 1892.

This invention is intended principally to be used for that class of camera known as hand cameras, but it may be used for others. It enables a large number of plates to be carried in a very small camera, and the plates to be selected and exposed in any required order, and it allows a focussing screen being used when desired, and the focussing to be adjusted either to the picture shown upon the screen, or to an estimated distance, or to what is known as "fixed focus," and it also allows of an approximately equal exposure being given all over the plate, or a greater exposure being given to the foreground than to the sky, and I am enabled to use a rising front and swing back.

In order that my invention may be better understood, I will explain how I should apply it for taking the ordinary "quarter plates," and assume the lens to be a rapid rectilinear of four and a quarter inches equivalent focus. For this size I construct a rectangular camera box, which need only be about six and a half inches long, five and one-eighth inches wide, and seven and a half inches high, and yet it will carry about two dozen plates besides a ground-glass focussing screen. If a lens of longer focus be used the camera box must be longer, but then more plates can be carried. In the upper half of this camera box I have the exposing chamber. I fix a lens to the front wall, and at the back I have a door which is light-tight when closed. Along this exposing chamber travels an exposing frame which is carried by a base plate, which is pierced with a slot so shaped as freely to admit a sensitive plate. The sides and top of the exposing frame are grooved, so as to allow the plate to slide freely in and to hold it approximately in position. The base plate travels in suitable grooves, which extend from end to end on either side at the bottom of the exposing chamber. To the base plate I attach, at the front and at the back, bands of leather or other suitable material which may be stiffened by narrow strips of wood. These leather bands extend to the grooves on either side of the exposing chamber, and slide in them so that all light from the exposing chamber is excluded from the lower half of the camera box. In the lower part of the camera, and extending from very nearly under the back of the lens to nearly to the plane of equivalent focus, I have a store box, which is grooved on either side to hold the plates. For the size under consideration, the store box may be about three and five-eighths inches long, so that it will hold about twenty-four sensitive and one focussing plates. The bottom of the store box has a light-tight door, through which the plates are inserted.

The leather bands which pull the exposing frame to and fro are carried over suitable rollers all round the lower half of the camera box and below the storage box. The end of each band is here secured to a plate, and the two plates can be drawn together by a bolt or otherwise. The plates also carry pointers, which slide in a long slot at the bottom of the camera, and the bottom of the camera may conveniently be formed by doors hinged to each side, and leaving this slot when the doors are closed. Along the slot I have a marked and numbered scale which corresponds with the grooves in the store box, and the scale extends further, and is marked to show the position of the focussing screen. By pulling the pointers backwards or forwards, the exposing frame is moved in a like degree, but in an opposite direction, and thus any required plate can be selected, and if the camera is inverted it will fall into the exposing frame. The camera being then turned on its side, the exposing frame can be moved back to focus position. The ground glass plate can be selected, and the door at the back of the exposing chamber being opened, the picture can be focussed by moving the pointers backwards or forwards, the position of the pointers on the scale is then noted, the door

closed, the ground glass returned, and a sensitive plate inserted, and the pointers moved back to the position noted. This plan of focussing is only convenient when the camera is firmly held upon a stand—when it is held in the hand it is more convenient to use what is known as "fixed focus," or to estimate the distance of the principal object. For this purpose I provide a screw which passes through a bearing in the door at the back of the exposing chamber, which carries on its inner end a flat plate which is adjusted so that it will just make contact with the back of the sensitive plate when the latter is in the plane of "fixed" or equivalent focus, and the screw is screwed home on its bearing—and the distance of the object which is in exact focus when the screw has been moved through one—two three or more revolutions is found by experiment and noted for future guidance. The storage box must not extend so far as to be under the slot of the exposing frame when the latter is at equivalent focus—but below the focussing range must be a plane surface making a light tight joint. It is advisable to blacken about one-eighth of an inch on the top and bottom of the focussing plate, and to keep it in the nearest groove. The front of the camera which carries the lens is made so as to rise when required, sliding up in suitable grooves which may be notched at intervals to permit removal, and it has a circular recess cut in it in which works a thin disc with a drum on the middle to which two cords or wires are attached and wound in opposite directions. The disc can be revolved upon suitable bearings. The cords are carried down to opposite ends of a rocking lever passing freely through holes therein, and thence over guides to the end of a lever or trigger, which is attached at right angles to the rocking lever, and which extends a little below the bottom of the camera front. The cords are tied or made fast to the trigger in any suitable manner. I have a spring which engages in suitable catches to prevent the trigger being accidentally pulled over. The trigger may be pulled over by the finger or by a spring, or elastic band for rapid exposures. The disc is perforated, so that when the trigger is pulled fully to one side or fully to the other side the lens is completely covered, but between these points it is more or less open, and upon one side of the disc I shape the perforation so that the exposure is approximately equal all over the plate, whilst on the other side the perforation is so shaped as to give more exposure to the foreground than to the sky. If one side of the disc has been in use, and it is desired to use the other side—and the trigger is fully over on one side—the over is held firmly and the cords are untied, and the trigger can then be pulled disc (the cords sliding through the holes). Then the cords are pulled tight and again secured to the end of the trigger, when it will be found that the other half of the disc is now in use. There are suitable stops in connexion with the rocking lever or trigger which prevent its ever pulling the disc more than half a revolution.

The exposing frame may be attached to the base plate by suitable springs at each side, which normally keep it at right angles thereto, but allow of the exposing frame being pulled over to the front or to the back by suitable cords or other devices. I may have a set screw or other catch to prevent the leather band from moving when required. I have a slot in the top of the camera box with a sleeve attached lined with velvet, through which the diaphragms (which are pierced upon each end of a long flat plate) are let down into the lens, and there may be a loose apron secured to the back of lens to ensure perfect darkness. Films can be used in suitable sheaths as well as plates, and, if desired, plates can be used in sheaths, in which case the storage box will not require grooves, but to be covered at the top except for a slot at each end. The plate in its sheath being raised by a suitable lever, rack, or other device into the exposing frame, and, when used, returned by gravity to the other end. This does not allow the plates to be selected conveniently.

Improvements in or Applicable to Photographic Cameras.

No. 2879. George Howard Cricks, Woodford-green, Essex, and George Alfred Taylor, 53, Norcott-road, Stoke Newington, London. — *December* 17, 1892.

Our invention relates to photographic cameras, and comprises improved means for successively releasing a series of sensitised plates after exposure, and it also comprises an improved shutter.

According to the first part of our invention, the sensitised plates are carried in suitable frames, upon the exterior edges of which are projections designed to pass through slots formed in stops at the front end of the chamber in which the said plates are placed. The plates are pressed forwards towards the stops by a spring, but the slots in the said stops are so placed that the projections upon the frames cannot pass therethrough until the plates are shifted to the required position. In order to effect this movement of the frames carrying the plates, we provide a slide of the same thickness as the plates, and designed to be operated from the exterior of the apparatus.

When one of the frames is moved by this slide to bring its projections opposite to the slots, the spring presses the series of plates forward, the front plate falling into a receptacle designed to receive it.

Our improvements in lens' shutters comprise a sliding frame carrying the plate or diaphragm for closing the aperture of the lens. This sliding frame is normally retained with the shutter in a closed position by means of a spring, and is opened for the exposure of a plate by means of a rotating cam operated by clock mechanism, and arranged in conjunction with an escapement in such a manner that when the cam is released by the escapement it will make half a revolution to open the shutter, the closing thereof being effected by the spring. In conjunction with the cam, we provide a stop which serves to arrest the rotation of the cam when the shutter is open in order to enable the said shutter to be used for time exposures.

Improved Automatic Lock or Spring Catch for Folding Camera Tripod Stands.

No. 3226. Alexander Birnie, 118, Perth-road, Dundee, Forfar, N.B.—*December* 17, 1892.

This invention relates to folding tripod stands for cameras, its object being to retain the parts of each leg securely and firmly in position when unfolded for use, and also to allow of the said legs being readily folded up when desired.

In carrying out my invention I employ an automatic lock or spring catch, consisting essentially of a cross bar in combination with or part of a bent spring of suitable design, the whole being fixed to one section of the leg of the tripod stand. On the other and adjacent section of the leg is fixed a cross bar, with a recess for receiving the releasing knob of the spring when the two parts of the leg are unfolded—that is to say placed in line—the remainder of the spring, when it has passed the recess, springing out and catching the said cross bar.

Improvements in Burners or Jets for the Limelight.

No. 18,836. James Edward Anderson, 9, Crawford-passage, Farringdon-road, and Alfred Wrench, 50, Gray's Inn-road.—*December* 17, 1892.

This invention relates to burners of the kind used in magic lanterns for the production of the limelight. Such burners as hitherto usually constructed are provided with a spindle, upon which the block of lime used with the burner is adapted, to be raised and also rotated, and in some cases such burners are adapted to be adjusted bodily both vertically and laterally relatively to the socket, by means of which the burner is supported upon the supporting pillar, thereby avoiding the necessity of moving the said socket relatively to the pillar.

The means heretofore adopted for adjusting the burner relatively to the said socket have been defective, inasmuch as the vertical adjustment of the burner caused the spindle carrying the lime block to be moved more or less out of a vertical position.

The object of this invention is to provide for effecting the adjustment of the burner without affecting the perpendicularity of the said spindle.

In carrying out the said invention we employ a socket adapted to be fixed to the pillar in the ordinary manner, and having its upper end screw-threaded and provided with a nut. The burner proper is carried by a second socket, which slides upon the first-mentioned socket, and is acted upon by the said nut, a spring being placed between the second socket and the fixed socket in such a manner that when the nut is turned in one direction the burner will be moved downwards against the pressure of the said spring, and that when moved in the reverse direction the spring will raise the burner to keep the second socket in contact with the nut.

To effect the lateral movements of the burner, the rear side of a collar upon the second socket is provided with gear-teeth, with which a pinion carried in bearings upon the fixed socket is designed to engage, the said pinion having a knob or handle for operating it.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

January 12,—Mr. J. Hay Taylor in the chair.

Angle of View.

Mr. P. Everitt criticised the rule for finding the angle of view included on a given sized plate which Mr. Haddon states in an article appearing in the current Almanac. The rule is, with a given plate, to take its longest dimension, divide it by the focus of the lens, seek the corresponding or the nearest corresponding tangent, read off the arc, double, and that will give the angle included on the plate. He (Mr. Everitt) thought that Mr. A. Haddon was not altogether correct, as the angle would be determined by the centre of vision on the plate. Mr. Haddon should have taken the point of intersection nearer the margin. According to his (Mr. Everitt's) idea the rule should be to measure the furthest focus from the optical centre, divide by the focus of the lens, and then seek the nearest tangent and read off.

Mr. W. E. Debenham pointed out that the angle varied with the position of the plate in relation to the axis of the lens, hence he thought both Mr. Everitt and Mr. Haddon right.

Mr. HADDON maintained that the rule he had given was the correct one, and after some further discussion the subject dropped on the understanding that it would be brought up again.

THE ESTIMATION OF OXYGEN GAS.

Mr. HADDON read a paper, by himself and Mr. Grundy (of the Royal Naval College, Greenwich), on this subject (see page 39). At its conclusion, Mr. Haddon remarked, in reference to the tabulated percentages given, that, if one took oxygen diluted with only five per cent. of oxygen and mixed it with its own volume of atmospheric air, a result would be obtained just about the mean of Nos. 2, 3, and 4 in the table. A practical demonstration by the Hempel method, as described in the paper, was then given, the sample of oxygen tested being found to contain 6·9 per cent. of nitrogen, the oxygen being considered a very good sample. Another sample was then tested by the second method described in the paper, and found to contain 46·8 per cent. of nitrogen. Mr. Haddon claimed for both tests that they enabled one to estimate the purity of oxygen to within one or two points of its true value.

Mr. J. B. SPRAGE said that the tests used as technical analyses were all that could be desired. As regards the Hempel method he used an extra bulb, so that the atmosphere did not get in contact with the gas.

Mr. T. E. FRESHWATER always understood that oxygen made from chlorate of potash was much better than that made from common air, and gave a great deal more light. People who used compressed oxygen in optical entertainments often found it necessary to increase the pressure nearly double on account of its admixture with atmospheric air. There was a question of price, of course, as lanternists who could get a gas for a penny or three halfpence a foot would not use the chlorate of potash gas at a much higher price. Chlorate of potash fluctuated so much in cost that some oxygen-makers found that it made as much as 100*l.* difference to them in the course of a season, though there was no gas to come up to that made in an ordinary retort over a fire and carried into a bag. For experimental purposes, photographic or otherwise, if they did not mind the trouble of making and washing the gas, they would get better results with the chlorate gas than with that in cylinders; or if people did not care to prepare it, and would pay a little more for the gas, they would find it a very great advantage. It was remarked that with the Association's lantern people often said that they got a beautiful light. This was a great deal to do with the gas they used, which was a chlorate gas. He would like to ask Mr. Haddon the loss in percentage of light when using oxygen containing forty-six per cent. of nitrogen as compared with a gas only containing six per cent.?

Mr. HADDON had not studied that subject, but the light would certainly be very much inferior where the smaller quantity of oxygen was present; the nitrogen, of course, also pulled down the temperature.

Mr. F. A. BRIDGE had never tested oxygen but once, and that accidentally. He always used it for enlargements, drawing it from a gas-holder, the gas being prepared by the chlorate method. He was making some enlargements when his gas ran short, so that he refilled his holder from a cylinder of gas which he happened to have by him. He gave subsequent enlargements the same exposures as he had already made, but he found, upon development, that they were much under-exposed.

Mr. FRESHWATER asked if oxygen deteriorated by being kept in iron cylinders?

Mr. HADDON said, No. He also hoped that members would not run away with the idea that oxygen, kept for some time, would change into nitrogen.

Mr. THOMAS BOLAS said that all lanternists were indebted to Messrs. Haddon and Grundy for their paper and demonstration. The methods of testing were simple enough to any one who had had practice in handling gas apparatus, although, perhaps, people unaccustomed to that work might make failures in connecting. They could always verify their results by analysing samples of air.

In reply to a question from the CHAIRMAN,

Mr. HADDON said that both the samples of gas that Mr. Grundy and himself had analysed that evening were commercial samples. He might point out that they had checked the accuracy of the apparatus by analysing air with it, and it came out as containing twenty-one per cent. of oxygen. In reply to a question from Mr. BOLAS, he said that the chlorate gas could be got even purer than three per cent. of nitrogen.

Mr. BOLAS observed that there was, then, no excuse for the commercial maker in sending out oxygen with a higher proportion of nitrogen.

Mr. HADDON said the proportion of the latter should never ever exceed five or six per cent.

At the conclusion of the discussion a vote of thanks was passed to Mr. Haddon and Mr. Grundy.

Mr. Paget (of C. A. Rudowsky & Co.) exhibited samples of mica plates to be employed as supports for carbon transparencies.

Before the meeting closed Mr. J. G. Hudson exhibited and described his "Kolm" magnesium flash-lamp, by which both the intensity and the duration of the light are under the control of the operator, and, several groups of members having been taken, the proceedings terminated.

Hackney Photographic Society.—January 11, Mr. J. Traill Taylor presiding.—Messrs. H. Snowden Ward and W. Harvey were nominated for membership. Mr. Hudson showed a lantern-slide printing arrangement of design originally given by him, and Mr. R. Beckett handed round a Ross Concentric lens. The CHAIRMAN said the chief advantage of this was its extreme flatness of field. From the question box: "If a short and long-focus lens are both suitable for a subject, which is best to use?" The Chairman said for this time of year short focus was *perhaps* the best; at any rate, it would be for copying. Generally, however, a long focus was best for most purposes. Question 2: "Is there any difference in working solio paper in winter or summer?" Answer: "None." Question 3: "Can a bag (gas) that has got stiff be softened?" Answer: "Best to keep bags in fairly warm temperature." No other answer was forthcoming as to how to renew. Question 4: "Is there any advantage in using the Monocle lens?" Mr. HORSLEY HINTON said it depended what result was required. The word wanted properly defining. Mr. Grant thought it suitable for fuzzy pictures. The Chairman, however, did not quite agree. Mr. Dean showed a frame of lantern slides, and asked what was the best means of backing them in place of opal glass? The Chairman advised a mixture of collodion and ordinary spirit varnish. Mr. PAGET (of C. A. Rudowsky & Co.) explained their flash lamp, and stated that to obtain a continuous flame a double ball was necessary. The Chairman then called on Mr. Horsley Hinton for his paper, *Some Contributories to Artistic Effect*. Mr. Hinton at length went into the question of suitable frames, mounts, &c. Photographers nowadays thought too much of size of plate, and were afraid to use knife and scissors enough, so that often what would have been a good picture was spoilt by not taking out objectionable pieces. Among his remarks, he said he was looked upon as a champion of fuzzy effects, but must disclaim it. He could admire a sharply defined picture, and often used a small stop. A very great contributory was reflection. Too much hurry was the case nowadays. The Chairman asked what Mr. Hinton's ideas were about the hand camera. Mr. Hinton said it was to the camera proper what the sketch-book was to the artist. The Chairman said that, with respect to gilt frames, he had some pictures in common gilt frames, and which he preserved by the use of a solution of celluloid in acetone (amyl). In answer to a question raised about lantern slides, Mr. Hinton said the uncontrollable result produced on the screen stood in the way of their always being complete pictures. Mr. Hinton then summed up generally on remarks. He could not give a rule as to when pictures should be broadly treated—experience and judgment must decide that. The idea was to interpret nature as it appeared to impress one. Excursions were generally hurried over. It was more advisable to go, but leave the camera at home until details were fully thought out.

Leytonstone Camera Club.—January 11, Mr. A P. Wire in the chair.—Mr. TOM SYMMONS gave a lecturette, *Small* versus *Large Cameras*. In the larger sizes he thought that there were a number of drawbacks. First, the expense of the outfit; second, cost of materials; third, owing to the weight, the great difficulty in getting about. He, having had experience with large cameras, would not advise any beginner to exceed whole-plate; in fact, if only one camera to be purchased, that should be half-plate. The recent Exhibition had proved that enlargements were to be had from small negatives that were equal, and in some cases better than direct prints, owing to the facility of dodging and getting better effect in the process of enlargement. He next urged the great importance of getting the best of apparatus. In the discussion which followed the general verdict was in favour of small cameras.

Greenwich Photographic Society.—January 4, Mr. G. S. Criswick presided.—The Chairman announced that Admiral Sir R. Vesey Hamilton and Professor Reinold, M.A., had been elected honorary members of the Society by the Committee. Mr. E. J. WALL delivered a lecture on *Isochromatic Photography*. By means of an electric-light spectrum the use and effect of yellow screens of varying density was clearly demonstrated. Mr. Wall illustrated his lecture by many fine pictorial comparisons of his own results in isochromatic and ordinary photography.

Croydon Camera Club.—January 16, the President, Mr. H. Maclean, F.G.S., in the chair.—Upon his proposition, seconded by Mr. B. Gay Wilkinson, the following members were appointed Vice-Presidents:—The Honourable Sidney Herbert, M.P., and Mr. T. F. Edridge, J.P. Mr. Cembrano then proceeded to exhibit his Granada and Alhambra slides. These have already been described in our pages, and allusion has also been made to the happy and attractive items of archæology and history with which this lecturer intersperses his more technical remarks. Respecting the latter, Mr. Cembrano strongly criticised the contention that a slow plate should be used for interiors, he himself having obtained his results upon extra rapid ones. Considering that the views shown were all taken within the space of six winter days, it is obvious that, if slow plates had been employed, whatever other results ensued, only about half the negatives would have been secured in the limited time at the disposal of the operator.

Birmingham Photographic Society.—January 12, Annual Meeting, Sir J. B. Stone (President) in the chair.—The TREASURER reported an exceedingly gratifying condition of the finances of the Society, and drew attention to the fact that more new members had joined the Society in 1892 than in any previous year. The PRESIDENT, in the course of his address, said that the Birmingham Society had made for itself a permanent place among the public bodies of the town, and a foremost place among photographic societies. He pointed out the desirability of each member having some definite object in his work, and instanced the photographic survey of Warwickshire. A prominent Society such as the Birmingham Photographic Society could not, he said, skirk its responsibilities and obligations, and after explaining that, through the medium of sight, information was more readily conveyed than perhaps by any other means, he exhorted the Society to use to the full its power of educating those who had not the means of educating themselves by extensive free exhibitions of pictures, and by widened enterprise in connexion with the lantern entertainments. The following gentlemen were elected officers and members of the Council for 1893:—*President:* Sir J. B. Stone, J.P., F.G.S., F.R.G.S.—*Vice-Presidents:* Messrs. J. J. Button, J. T. Mousley, J. H. Pickard, W. Jones.—*Council:* Messrs. F. S. Goode, A. R. Longmore, E. Underwood, A. J. Leeson, Geo. Thomason, G. E. Miller T. Taylor, E. C. Middleton.—*Treasurer:* Mr. W. Rooke.—*Librarian:* Mr. W. S. Horton.—*Hon. Secretary:* Mr. James Simkins.—*Assistant Secretary:* Mr. Ernest Winn.

Bristol and West of England Photographic Association.—January 13, Annual Meeting.—Mr. H. A. Hood Daniel was re-elected President; Colonel Playfair and Mr. Ed. Brightman, Vice-Presidents; Mr. F. Bligh Bond, Secretary, with Mr. H. A. Hutchinson as Assistant Secretary; and Mr. W. Moline as Treasurer. The existing members of the Council were re-elected.

Shropshire Camera Club.—January 11, Annual General Meeting.—The following officers were appointed:—*President:* Mr. W. W. Naunton.—*Vice-Presidents:* Messrs. J. R. Greatorex, G. Ridlake, W. S. Buddicom, M. J. Harding.—*Council:* Messrs. W. Alltree, W. Bowdler, Dr. Cureton, S. L. Della Porta, R. J. Irwin, W. G. Preece, I. Pyefinch, F. W. Williams.—*Treasurer:* Mr. W. Barson.—*Hon. Secretary:* Mr. Martin J. Harding.—*Assis*

tant Secretary: Mr. W. Heath. A special vote of thanks was passed to Mr. Naunton for his valuable services as Secretary since the formation of the Club, and to Mr. Irwin for his services as lanternist. A Sub-committee was appointed to consider a scheme for acquiring permanent Club rooms, including dark room, and five new members were elected. The meeting was adjourned to the 20th inst. for the purpose of revising rules, &c.

Correspondence.

HALATION, DOUBLE FILMS, AND CHROMATE OF SILVER.

To the EDITOR.

SIR,—I have to thank Mr. Gregor Grant for his reference to Mr. W. K. Burton's article in the ALMANAC for 1888, which I find pretty well corroborates what I have already said. My own recollection of Burton's experiments with chromate of silver is that they date much further back; but I cannot at the present moment refer to them, but the article alluded to will for the present suffice.

In that article Mr. Burton himself says his experiments with chromate of silver as a preventive of halation "did not succeed," the chromate being reduced by the developer; and then proceeds to make what I believe to be merely a suggestion as to a method by which this result may be avoided, namely, soaking the plate before development in a weak solution of bromide of potassium. I conceive it to be a suggestion merely, for two reasons: first, because no actual statement is made that the experiment has been made; and secondly, because, if it had, the result seems scarcely likely to be any more of a practical success than before, though from a different reason.

Mr. Burton seems to have overlooked the fact of which he, of all men, is perfectly aware—the fact I alluded to in my previous communication as having been just pointed out by Captain Abney, that the soluble chromates destroy the effect produced by the action of light upon a sensitive film. If we imagine such a duplex film as that alluded to by Mr. Burton and Mr. Grant, silver bromide upon silver chromate, to have been exposed to light, we can readily believe that it will have an image impressed upon it; but it is not so easy to see how that image is to be developed, even by Mr. Burton's plan. The immersion in solution of potassium bromide will certainly convert the substratum of chromate into silver bromide; but, at the same time, it will, by double decomposition, form potassium chromate, which cannot but have full access to the overlying film of bromide of silver. What, then, about the image?

It is true that the bichromate is far more powerful in its destructive action on the latent image than the neutral chromate, on account of the loose atom of chromic acid, and it would be the neutral chromate that is formed under such circumstances. But the latter salt alone, and more particularly in the presence of a soluble bromide, is quite powerful enough to destroy any image with which it may be brought into contact. I should not like to say that it is impossible to obtain any sort of image by development under such conditions, but it seems quite impossible that a practically useful one could result. By using a very weak solution of bromide, and a great volume of it, so that the chromate would be converted slowly and a little at a time, the bromide film would be submitted practically to the action of a very feeble solution of potassium chromate, which might possibly not exert the full effect.

One other point I may note in passing. If the chromate film referred to by Mr. Burton is made in the same manner as that he recommends in another place as a substitute for ruby glass, namely, by adding silver nitrate and potassium bichromate to solution of gelatine to form an emulsion, from which the soluble matter is not subsequently washed, I am afraid there would be still further reason for failure. Even supposing the equivalent proportions of the two salts are so exactly hit that there is no excess of either, there would still be a soluble silver salt present in the form of dissolved chromate of silver. When the two salts just mentioned are mixed, neutral chromate of silver is formed together with nitrate of potash, and nitric acid is set free; and this latter dissolves a small quantity of the silver chromate. The experiment is easily made of adding silver nitrate in excess to solution of potassium bichromate, when, after the precipitate has subsided, the supernatant solution will be found to be highly coloured. A drop of the chromate solution will give a further precipitate of silver chromate, showing that the colour does not come from excess of that, but if the supernatant liquid is poured off, and treated with a solution of carbonate of soda until no further precipitate occurs, it will be decolourised, and the red precipitate will show that the colouration was due to chromate of silver held in solution by the liberated nitric acid.

If such a film were treated with an alkaline, or, indeed, any developer, it is not difficult to believe that reduction would occur without any question of exposure, and that may explain the first of Mr. Burton's failures, but does not affect the general question of the practicability of the plan suggested.

If any of the readers of the JOURNAL are desirous of testing this plan, the best way to proceed is to employ the neutral chromate of potassium in conjunction with nitrate of silver, the former slightly in excess, and to wash the emulsion so formed. Or carbonate of silver may be emulsified in the usual way—by precipitation and decantation before adding the gelatine—and then converting by means of chromic acid or bichromate of potash.

A still better plan was published by M. Paul Roy, of Algiers, some ten or twelve years ago for forming an emulsion of pure chromate of silver. It is based upon an alleged action of the soluble chromate in excess to precipitate gelatine in conjunction with chromate of silver. The process consists in dissolving one part of gelatine in 100 parts of water, to which ten parts of silver nitrate are subsequently added. When this is dissolved, a saturated solution of ammonium or potassium bichromate is added with vigorous stirring; the first result is of course the formation of chromate of silver, and when the soluble chromate is in excess, the gelatine in combination with the silver salt is said to separate, and may be washed and redissolved by heat.

I fully agree with what Mr. Burton says in the article I have referred to in regard to the probability of chromate of silver being found eventually to be a useful photographic salt. But I am afraid we shall have to find an altogether new developer first.

It was far from my intention to criticise Mr. Gregor Grant in a carping manner. My allusion to the impossibility of getting clear shadows with the double films was aimed at the theory propounded rather than the plates, and I must adhere to the belief that if such a "proper" exposure is to be given as to reverse the image of the more sensitive film, then there *must* be a deposit in the shadows.

Again, when Mr. Grant says that Captain Abney was "the first person to lay down any law," &c., and "the theory *just advanced by him*"—the italics are mine—was the reflection theory in fact, I naturally thought he meant it, and therefore gave the date of an earlier publication. Now, as he denies having stated that Captain Abney "was the first to discover or notice the causes of halation," I am in doubt as to how he came to be the first to "advance" them. Captain Abney has done a very great deal in connexion with the investigation of the various causes of halation, but, I repeat, Marlowe was the first to draw attention to reflection from the back surface as one of them.—I am, yours, &c., W. B. BOLTON.

January 17, 1893.

"KEEPING OF CARBON TISSUE."

To the EDITOR.

SIR,—Every now and then I see it stated that carbon tissue will keep about a fortnight after sensitising.

It appears, therefore, not to be generally known that it may be preserved, in good condition, for a much longer time if stored in a calcium tube.

I am using some to-day, received from the Autotype Company about the 2nd of December, which has been so stored, and is in the same condition now as when it came to hand.—I am, yours, &c.,

Watford, January 16, 1893. WILLIAM COLES.

OPTIMUS COMPETITION.

To the EDITOR.

SIR,—We have just received the enclosed awards for the Optimus competition, and shall be glad if you will announce them in your JOURNAL.—We are, yours, &c., PERKEN, SON, & RAYMENT.

99, *Hatton-garden, London, January* 18, 1893.

Class I.—Landscape, with and without figures. Sub-class A, The Haunted Cottage; sub-class B, White Star.

Class II.—Seascape. Sub-class A, Per-son-ray; sub-class B, Detective.

Class III.—Portraiture and Figure Study. Sub-class A, Mezzo; sub-class B, Joan.

Class IV.—Instantaneous Work. Lannul.

Having opened the envelopes bearing the above *noms de plume*, we find that the following are the successful competitors:—

Class I.—Landscape, with and without figures. Sub-class A, C. Field, West Bromwich; sub-class B, W. D. Welford, Birmingham.

Class II.—Seascape. Sub-class A, Mrs. M. E. Marriott, Liverpool; sub-class B, Charles M. Berry, Belfast.

Class III.—Portraiture and Figure Study. Sub-class A, John H. Gear, London; sub-class B, John Wickens, Bangor.

Class IV.—Instantaneous Work. James W. Morgan, Tunbridge Wells.

THE VENTILATION OF OPTICAL LANTERNS.

To the EDITOR.

SIR,—I read in last week's BRITISH JOURNAL OF PHOTOGRAPHY an article by Mr. T. N. Armstrong on the "Ventilation of Optical Lanterns," which refers to one at Edwards' establishment which was placed at his disposal. I would just like to call your attention to the following: The very lantern he refers to was made in White's workshops, to my design when I then

represented the firm in their sale shop. Now that the firm has no retail business, I on my own account, at the address below, make and use lanterns of the same kind. I may say that the lantern Mr. Armstrong refers to was made about two and a half years ago. There is not much in the idea further than that the bottom lantern is ventilated at the side. All the above facts are well known to Mr. Armstrong, but it is wonderful what some folks will do for a little favour.

Trusting you will see your way to correct such mistakes, and feeling sorry to trouble you over such little affairs, which are better corrected.—I am, yours, &c., JAMES MOIR.

77, *Renfield-street, Glasgow, January* 10, 1893.

A VALUATION.

To the EDITOR.

SIR,—Respecting the inquiry of your correspondent, "A Seaside Photographer," I should be disposed to say that, if there are no other considerations of weight beyond those mentioned in his letter, the business would be cheap at 1000*l.*, and if bought at 1100*l.*, the transaction would be fair on both sides.—I am, yours, &c., R. S. V. P.

January 17, 1893.

A BUSINESS MYSTERY.

To the EDITOR.

SIR,—How do the enclosed assimilate? I cut them out of two papers of last week.—I am, yours, &c., SCEPTICAL.

January 17, 1893.

[The following are the conflicting announcements to which our correspondent refers.—ED.]

From the *Stockport Advertiser*, January 6.

DAY AND ELECTRIC LIGHT STUDIOS.—Mons. Sauvy (of Paris) has just returned from his usual visit to Paris, and was successful in procuring a FIRST-CLASS FRENCH ARTIST, who will attend to the customers, as well as himself personally as usual, from 10 a.m. to 6 p.m. daily. 22A, King-street, Manchester.

From the *Manchester City News*, January 7.

MRS. KATE HARGREAVES begs to intimate to the public that she has purchased the entire PHOTOGRAPHIC BUSINESS of Monsieur Sauvy, 22A, King-street, Manchester. All the eminent Artists formerly engaged have been retained.

Mrs. Hargreaves can assure her patrons that the same high-class work will still be produced, and that the whole of the Negatives of Portraits taken at 22A, King-street are in her possession, and copies can be had at any time. Every branch of the business is under her personal supervision.

Mrs. Hargreaves draws particular attention to and invites inspection of her Speciality (recently introduced), viz., the highest class of Opal and Ivory Miniature Painting.

THE WEEKLY HALF-HOLIDAY.

To the EDITOR.

SIR,—The adoption of a weekly half-holiday, which has been occupying the attention of various trades for the past few years, is worthy the consideration of those engaged in the photographic business. When originating the movement in Glasgow and Paisley, we found that all the principal members of the profession acceded to the proposal, and strictly carried it into practice. As the spring is drawing near, it is expedient for a successful issue that those concerned interest themselves on the subject, and by their energies establish the movement, much to the satisfaction of those capable of recognising its advantages.—I am, yours, &c., BENJAMIN R. FAULKNER.

10, *St. James-street, Paisley, January* 14, 1893.

Exchange Column.

Will exchange 13*l.* single lantern for a 12×10 camera.—Address, FRANK LOBLEY, Hanley, Staffordshire.

Dallmeyer's 2B lens in exchange for centerlever enlarging lantern, eight and a quarter inch condensers.—Address, A. SIMMONS, 253, Westminster Bridge-road, S.E.

Exchange Thornton-Pickard's "Special" shutter, also "Cyclist" tripod, for Watson's half-plate turn-table and tripod.—Address, T. BERNARD, 101, Goldhawk-road, W.

Exchange six-inch Weston burnisher and burner, backgrounds, 12×10 camera and slides, flag, Pumphrey's telescopic stand, for anything useful.—Address, A. HOLLIS, Barrow-in-Furness.

WOOLWICH PHOTOGRAPHIC SOCIETY.—January 26, Lantern Night.

WEST LONDON PHOTOGRAPHIC SOCIETY.—January 24, *The Royal Palaces of England*, illustrated by lantern, by Mr. H. N. King.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical Meeting, January 24, at 50, Great Russell-street, W.C. *Photo-lithography*, a demonstration by Mr. W. E. Debenham.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

A. J.—Messrs. Hurter & Driffield's actinograph may be used for ascertaining studio exposures

AUGUST BAER.—We shall be very pleased to receive the communication. Thanks for the enclosure.

T. N.—The Vergara films are not made now. The Company has ceased to exist. The slides will have to be modified to take glass plates.

W. G.—We do not know the name of the publisher of Mr. Joseph Pennell's works. Your local bookseller would obtain the information for you.

HORACE JACKSON.—You may employ either of the two lenses as a single combination. The focus will be much longer and the covering power greater.

C. RAY.—Obtain what is known as masticated rubber, and no difficulty will be met with in its solution in benzol. Vulcanised rubber has been the cause of the trouble.

STOP.—There is no necessity to use a wide-angle lens for making lantern slides by reduction. Use a lens with a narrower angle (one of the rectilinear type), working at a larger aperture.

D. LEITCH.—So far as we are aware, no camera answering to the description of Dr. Marey's chrono-photographic apparatus is to be had commercially. The camera would have to be specially made.

NO. "49."—1. Citric acid has the double action of being a restrainer and of keeping the whites pure. 2. The new paper is probably twice or three times more rapid than the other rapid paper.

BOLL.—1. The studio will answer very well, but we prefer a direct side light in addition to the top light. 3. You may accept Mr. Brother's teachings as quite sound. Procure his book by all means.

A. R. TAYLOR.—Unless you can tell us the composition of the cement in question, we can give no opinion whatever as to the probable effect it may have on photographs. Its nature indicates nothing.

M. J. E. TILNEY.—Amidol is not employed for the purpose of developing under-printed images on chloride. Study two articles on the subject by E. Valenta at pages 247 and 279 of the last volume of the JOURNAL.

AT HOME.—We are not aware of any books having been published on the subjects referred to. *Carte* or cabinet portrait lenses will fulfil your requirements for rapid indoor portraiture under the conditions named.

LANSDOWN.—1. A good single lens, or, by preference, a doublet, will answer. 2. We do not know the nature of the head-rest mentioned. 3. See two formulæ for the P.O.P., page 794, in our ALMANAC for current year.

A SUBSCRIBER (Basingstoke).—If you can colour other photographs, we see no reason why you should not colour bromide priats. The same colours, whether oil or water, that are used for ordinary prints will do equally well for bromides.

A. E. W.—Your reading of the Act is quite correct, and, as you say, it is very unsatisfactory. The Copyright Act, as it stands, is very unsatisfactory indeed, and we fear that at present there is but a very small prospect of its being amended.

A. M. Z.—A little practice in judging of the distances when focussing with a hand camera having a focus scale will enable you to do so with sufficient accuracy for the purpose. There is no rule available. Both the hand cameras you name enjoy high reputations.

H. D.—1. A ten per cent. solution is one in which in every ten parts there is contained one part of the salt. 2. A view-finder, if constructed for the purpose, will show precisely what is to be seen on the ground glass. 3. There are no books published on such simple matters.

E. R. B.—If, instead of suspending the priats on a line to dry, they are dried in a blottiog-book, they will not curl up, and will be much more convenient for mounting. Greater distortion occurs from expansion, and the stretching of the paper in mounting, when the pictures are mounted wet than when they are mounted dry.

W. BARTLETT.—Slides such as those sent will not do at all for the lantern. The lights must be perfectly clear glass. In your slides they are represented by a thick veil of fog. Moreover, there is a decided trace of green fog. Better purchase commercial plates and get proficient with them, then go back to making your own.

A. LEACH.—1. Working in an experimental way with bichromated gelatine, there need be no fear of any harmful effects from the chromium salt. It is only with long and extensive working that any ill effects need be anticipated, and not then even if care be taken. 2. The films were probably over-dried, and too high a temperature used.

RODNEL.—The rooms where you witnessed the demonstration of enlarging are now closed, ths firoi having since ceased to exist. So far as concerns apparatus for enlarging, some notices relative to these have recently appeared in this JOURNAL. If you desire to know anything technically concerning enlarging appliances, we will be happy to give you any further information.

S. Bateman.—It has frequently been suggested to immerse albumen prints in a mixture of alcohol and glycerine to prevent their curling when kept unmounted. But we cannot recommend the method, inasmuch as glycerine has always a tendency to take up moisture, and that is conducive to fading. Roll the prints under very heavy pressure, and they will have little tendency to curl afterwards.

S. A. W.—As you have not a lens of the "rapid" type, the best amongst those you have for taking a large group will be the orthographic. As it is twenty-four inches focus, we should imagine it would cover a 15×12 plate with its full opening. Then it would be quite as quick, or, indeed, quicker, than a "rapid" of sixteen inches focus stopped down to make it cover that size plate with equal marginal definition.

Flexible.—Coiled-wire spring, suitable for a flexible chimney to convey away the smoke from a magnesium lamp, cannot be obtained in commerce, so far as we can learn. Solomon, of Red Lion-square, who first introduced such chimneys, had them made to order. Get a round rod of wood and wrap hard iron wire around it, and you will have just such a spring as we have in one procured from the late Mr. Solomon.

T. H. Price writes: "Kindly inform me if anything can be done to get oil out of a photographic print. Only a portion of the print is saturated with oil. I think from the smell it is linseed oil."—Pour a little pure benzol on the print, and allow it to soak for a short time, then blot off with clean blotting-paper, and apply more benzol and again blot off. Repeat the operations till the grease is entirely removed.

C. Ballard.—Evidently the plates were kept too long after they were prepared. Collotype plates should be used within two or three days of their preparation. It is not surprising, if they were kept for a fortnight, that they behaved as stated. After the plates are printed, and the bichromate washed out, they may be kept for months before they are printed from in the press. Possibly that is what you were told, and you have misunderstood the matter.

C. E. T. Tenby.—Prisms would certainly take up less space than mirrors. But why not fit the mirrors behind the lenses as you propose to do the prisms? That will do away with part of your difficulty. Any of the leading opticians would supply the latter to order. So far as we know, they are not mentioned in any English catalogues. The only quotation we can find is in the list of Steinheil & Son, Munich. There they vary in price from 4*l.* to 60*l.*, according to size.

R. A. M.—After an apprentice has served two years of his apprenticeship it seem a little unreasonable to expect him, after the usual business hours, to act the part of an errand boy in delivering pictures and parcels, and we are not at all surprised that he and his friends are beginning to rebel. Surely this employment is not teaching the young fellow the business his friends paid a premium for him to be taught. The friends would no doubt succeed in their threatened proceedings.

W. Pennefather (St. Austell) says that he is desirous of studying retouching in London during occasional visits which he has to make there on business, and asks for our guidance in recommending him the best course to pursue.—In reply: One could not do better than apply to Mr. Redmond Barrett, whose services as a teacher of retouching we, from the testimony and skill of many of that gentleman's former pupils, are happy to recommend. Mr. Barrett is also, we believe, instructor in retouching at the Camera Club.

T. A. Green complains that he cannot get the chloride of silver from the washings of prints to settle down. He says with the washings of paper of his own sensitising he has no trouble, but the difficulty is with the ready-sensitised and printing-out paper. We have heard the same complaint many times before. The best way is to add to the refractory residue, when it will not settle down after the addition of the salt, an ounce or two of nitric or hydrochloric acid, and then stir it up vigorously for several minutes. In a day or two after this treatment it will generally settle down.

A. B. (Belfast) writes: "I often see it in print, and often hear it stated, that the best slides for the lantern, and also for the stereoscope, are those by the old albumen process. Is this the case, and if so, why is it that the process is not worked more than it is, both by amateurs and professional slide-makers? If the process is as good as some claim that it is, why is it so neglected?"—The albumen process is undoubtedly an excellent one for transparencies, but it involves more trouble in working, and also requires more skill than other methods that are capable of giving excellent results. Hence amateurs fancy it is too troublesome for them, and professionals prefer the more expeditious process of wet collodion.

A. J. Henderson (Thames Ditton).—We cannot undertake to advise you as to the selection of particular makes of lenses, cameras, enlarging apparatus, &c. To this rule we make no exception. Consult a photographic friend in whose advice you have confidence, or, failing such, place yourself in the hands of one of the dealers advertising in this Journal or its Almanac, and state your requirements. With respect to your other questions: Messrs. Percy Lund & Co., Memorial Hall, E.C., or any dealer will supply you with all the books named. In our Almanac for 1892 is contained a series of articles for beginners. When enlarging with the lantern a bellows camera is not required. There is not necessarily any difference in quality between daylight and artificial enlargements on bromide paper. Their sharpness is dependent (1) upon the degree of sharpness on the negative; (2) upon accurate focussing of the enlargement, and (3) upon the qualities and proper use of the enlarging objective.

Aston Natural History and Photographic Society.—The numbers of this Society are increasing, but any who are desirous of becoming members are asked to communicate with the Hon. Secretary, Mr. Fred. W. Pilditch, 133, Wills-street, Aston.

Photographic Club.—January 25, Annual Lantern and Musical Entertainment (Ladies' Night). 27 (Friday), Children's Entertainment. February 1, *The Limelight and other Illuminants for the Lantern.*

Mr. H. A. Chapman, Photographer, of Swansea, who was elected to the Town Council twelve years ago and an Alderman three years ago, has been promoted to the Civic Chair of that town for the coming year. We congratulate Mr. Chapman on the distinction conferred upon him.

The Blackheath Camera Club will hold an Exhibition of Photographs and Photographic Apparatus in the Hall of the Art Club, Blackheath, on Friday and Saturday, March 3 and 4, when medals will be offered for competition in the following classes:—A (for members only): Prints, any subject by any process. B (for members only): Lantern Slides, any subject (set of four). C (Open): Prints—landscape, seascape, architecture, &c., any process. D (Open): Prints—portraiture, animal and genre, any process. E (Open): Lantern Slides, any subject (sets of four). F (Open): Hand-camera Work, any subject, taken with camera held in hand, not on tripod (sets of four prints). G (Championship): Any subject by any process, open only to pictures that have taken first and second-class prizes in any previous exhibition. Awards: Silver and Bronze Medals in Classes A to F, and a Gold Medal in Class G, will be placed at the discretion of the Judges. The Judges are Messrs. F. P. Cembrano, jun., George Davison, Andrew Pringle; and the Hon. Secretaries Messrs. Thomas B. Earle, The Cottage, Handen-road, Lee, S.E., and C. W. Piper, A.R.I.B.A., 46, Shooter's Hill-road, Blackheath, S.E.

Richmond Camera Club Conversazione.—The Richmond Camera Club, which last year held its annual *conversazione* in very modest fashion at the Cottage Hall, this year launched out in much bolder style, taking the Richmond Theatre Royal for the purpose on Monday, January 9. The venture was a distinct success, both as regards the numbers that attended (over 350) and the character of the entertainment that was given. A feature of the evening was the arrangement of the ground floor of the theatre, which we heard remarked by many visitors looked "quite like a drawing-room." The seats were removed, only a few velvet-covered stalls being retained and placed here and there in such positions as to allow free passage for those present to view the select exhibition of photographic work done by members of the Club, which was displayed on screens along the sides of the arena. Refreshments were served at two tastefully arranged counters under the gallery, which were partially curtained off from the main body of the theatre. From the neatly got-up programme we see that there were seven musical selections, sandwiched between four optical lantern displays, in which altogether some 180 slides were shown on a sixteen-foot screen at a distance of sixty feet from the lantern. For those whose memories go back to the Photographic Exhibition held in Richmond in 1889 in a part of the same building, the improvements arrived at during the intervening period, especially in the way of artistic effect, were very noticeable. The Mayor and Mayoress, many of the Town Councillors, and the *élite* of the neighbourhood, honoured the *soirée* by their presence. We are informed that H.H. the Duke of Teck, G.C.B., &c., has kindly consented to become patron of the Club.

FORTHCOMING EXHIBITIONS.

January 26, 27	.....	*Louth and District Photographic Society. Hon. Secretary, S. Francis Clarke, 8 Upgate, Louth.
February 1	.....	*Cleveland Camera Club. Hon. Secretary, J. J. Hallam, 11, Amber-street, Saltburn-by-the-Sea.
,, 7, 8	.....	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.
,, 14	.....	Durham City Camera Club. Hon. Secretary, R. Hauxwell, The Avenue, Durham.
,, 16–18	.....	*Woolwich Polytechnic Photographic Society. Hon. Secretary, W. Dawes, 145, Chesnut-road, Plumstead, S.E.
,, 18	.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb 100 High Holborn, E.C.
March 1, 2	.....	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
,, 3, 4	.....	Blackheath Camera Club. Hon. Secretary, C. W. Piper, 46, Shooter's Hill-road, Blackheath, S.E.
April	.....	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.
,, 17–29	.....	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

CONTENTS.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1708. Vol. XL.—JANUARY 27, 1893.

REPRODUCING NEGATIVES FROM PAPER PRINTS.

We have lately been retrying the old experiment of reproducing negatives, which have long been lost or destroyed, from prints that have been taken many years since, and the success attending the effort has been such as to warrant our bringing the subject before such of our less experienced readers as may not be aware of this method of reproducing a negative.

It is very curious that, in prints produced from some of these negatives, there is to be found *more* detail than is to be seen in the prints from which the negative was made. This is not difficult to understand when we consider that in a strong print —one obtained from an intense negative in which much of the finer details in the shadows had to be sacrificed, in order that the lights might not be altogether chalky, and thus get buried in the substance of the paper, presenting only a uniform blackness on the surface — such details are still found to exist if the print is examined when held against a strong light. Make a print on albumenised paper from any intense negative, continuing the exposure until nothing but the highest lights remain visible on the surface, and when held up against a strong gas flame, and viewed as a transparency, the details that are lost under examination by reflected light are still to be seen when the light is transmitted through it.

The print selected for making a negative of ought to be as vigorous a one as possible; and, from what has just been said, it will be seen that it is not an objection, but quite otherwise, that the deep shadows are clogged or seemingly obliterated.

The way by which the prints are removed from their mounts is to place them in lukewarm water for a few minutes, until, upon raising up one corner of the print from the mount, it is found to strip off. It is sometimes necessary to increase the heat and prolong the time of immersion to ensure this, as much depends upon the nature of the paste by which it was mounted. When removed, the back of the print must be carefully sponged, so as to remove any adherent paste. It must then be dried between sheets of blotting-paper.

The printing frame that is to be employed in reproduction must be fitted with a plate of stout and flat glass. On this the print is laid, face up, and a dry plate superimposed, face down, of course. It is not easy to indicate the exposure that should be given, but five seconds to a common gas flame with an ordinary slow plate proved ample in the last trial we made. A slow-acting weak developer has been hitherto preferred by us, but the selection of this depends upon the softness or the intensity of the print. When the negative thus made has been finished, it is ready for being printed from.

The method here described presents important advantages over the reproduction of a negative by the camera. By the latter nothing is copied but what appears on the surface, whereas the method advocated reveals what is concealed in the texture of the paper. We have one reproduction which forcibly illustrates this. The scene is one in the Maraposa Grove, California, and in the original print one portion is presented in such deep shadow as to reveal no detail whatever. It was first copied by the camera without showing more than was originally visible; but, when copied by transparence as described, a group of figures not hitherto seen in the print became plainly visible, and now forms an addition to the pictorial value of the print, more especially now that a lantern slide has been made from it sufficiently crisp and sharp as to betray no suspicion of its having had a paper origin.

Without having yet tried it, we can scarcely suppose that a print on a gelatine emulsion paper will show the same discriminative power in the burying of detail that one on albumenised paper will, seeing that in the former case the image is confined to the thin pellicle which contains the silver haloid, whereas in the latter the silver nitrate not only sensitises the albumen film, but penetrates beyond it—a fact that is easily proved by the stripping off of the albumen and observing the vigour of the image still visible on the denuded paper.

With a view to facilitating the printing and destroying granularity in the paper, we have rendered one-half of a precisely similar pair of stereoscopic prints translucent by Canada balsam varnish, allowing the other half to remain *in statu quo*, but have not found any advantage to arise. It may, however, prove advantageous with thick and uneven paper.

While on this subject, and correlative to the foregoing, we may remark on a useful application of the principle of producing a negative from a paper print with which, several years prior to the advent of modern dry-plate photography, the names of Valentine Blanchard and Claud Leon Lambert were associated. Given a negative imperfect from whatever cause, a print is produced from it which, when fixed and washed (it need not be toned), has the lacking detail put in with a pencil or a brush or the too dark shadows lightened by any of the reducing agents now so well known. This then forms a *cliché*, from which a negative is printed on finely surfaced paper, and which in turn, after further retouching if requisite, is employed as a negative to reproduce perfect impressions of the original. Some sixteen or eighteen years ago this system formed the means of producing many excellent prints, which were justly much admired. We mention this, as the method appears to have fallen into abeyance.

CHROMATE OF SILVER.

The question having arisen of the sensitiveness of chromate of silver or its power of forming a developable image, it may not be out of place here to state a few facts which seem, so far at least as our present knowledge goes, to set the matter at rest.

There are two chromates of silver analogous in their composition to the neutral and acid chromates of potassium, but it is the neutral or monochromate with which photographers will have more particularly to deal. This salt is formed when solutions of nitrate of silver and of a neutral alkaline chromate are mixed, or when carbonate of silver is treated with an acid chromate. It is also formed when bichromate of potash is added to a solution of nitrate of silver, but in this case nitric acid is liberated and a portion of the silver chromate remains in solution, owing to the solvent action of the free acid. The neutral chromate is insoluble in water, but is soluble in nitric acid, especially when hot, and particularly so in ammonia.

The acid chromate is formed when a solution of bichromate of potash, acidified with sulphuric acid, is added to one of nitrate of silver, or when carbonate of silver is acted upon by the same compound solution. It forms a reddish-purple precipitate, almost identical in appearance with the neutral chromate, but, unlike the latter, it is slightly soluble in water. A more detailed description of these salts will be found in an article on "Chromate of Silver and Chromates," at page 190 in our Volume for 1886, to which we must refer those who desire further information.

Up to the present time, chromate of silver has found little practical application in connexion with photography; one or two attempts have been made to use it as a stepping-stone to the formation of the gelatino-bromide emulsion, and an emulsion of the chromate itself was suggested some ten or twelve years ago by Mr. W. K. Burton as a means of forming a substitute for ruby glass for the dark-room window, and also, as will be seen from recent correspondence, as a preventive of halation. In connexion with the first application, it was pointed out that the chromate emulsion films were of little actual use in daylight, owing to the fact that, being sensitive to strong light, they quickly darkened, and soon became too dense to transmit light, and from this it came to be imagined that the chromate of silver was itself sensitive to light.

This, however, is not the case, so far, at least, as we have been able to discover, the discolouration that takes place being really due to the action of light upon the bichromatised gelatine of the emulsion. As all our readers are aware, the soluble chromates and bichromates in the presence of organic matter are sensitive to light, one of the results being a visible image due to the reduction of the chromic salt. Thus ordinary paper, floated in a strong solution of bichromate of potash and dried, becomes sensitive to light, forming a brown image on a yellow ground, which only requires washing in water to "fix" it or render it permanent. If the paper is sized with gelatine, the sensitiveness will be greater, and the colouration proportionately deeper. Solutions of gelatine, gum, dextrine, glucose, sugar, or other similar organic substances in combination with chromic salts, also darken under the action of light, or even spontaneously, and it is to this action alone that the deterioration of the ruby-glass substitute must be attributed, we think.

If, to a solution of gelatine, bichromate of potash and nitrate of silver be added, a deep red emulsion is formed, the pigment being chromate of silver; but, in addition to the silver chromate in suspension, there will also be a minute quantity in solution, owing, as we have shown, to the presence of free nitric acid. If the equivalent proportions of the silver nitrate and bichromate have been pretty closely adjusted, such an emulsion will not possess a very high degree of sensitiveness—that is to say, it will not discolour or darken very rapidly, owing to the very small quantity of *soluble* chromate present, though that small quantity is sufficient to cause it to change eventually. Moreover, the fact of there being a salt of silver also in solution forms another cause of instability; but, if, as is most likely to be the case, an excess of bichromate has been used, then the sensitiveness will be very materially increased, and a comparatively short exposure to daylight will produce an appreciable change of colour.

It will be readily understood, therefore, how it is that an emulsion of this kind darkens under the action of light; but, if before it is spread upon the glass it be "washed" in the same way that a negative emulsion is, to remove the soluble salts, although the appearance of the resulting film is in no way altered, it will be found to have practically lost its tendency to change under the action of light—to have, in fact, lost its sensitiveness. We say "practically," because the absolute desensitising will depend upon the thoroughness of the washing.

In other words, what we wish to convey is that chromate of silver, *per se*, is insensitive to light, or, at any rate, incapable of forming a visible image. The experiment is easily made without the trouble of forming an emulsion by floating paper upon a solution of nitrate of silver, and, after drying, refloating on bichromate or, preferably, neutral chromate of potash, and subsequently washing very thoroughly to remove all excess of either salt. It is important that the paper in the first instance and the water used be free from soluble chlorides, otherwise chloride of silver will be formed, and may lead to false judgment. If the layer of chromate of silver be thoroughly freed from soluble matter, and be clear of silver haloids, the paper so prepared may be exposed under a negative without producing any trace of an image. If, however, any traces of chromic salts remain in the paper, more or less discolouration will occur, and, if an excess of silver should have been used, a similar result will accrue.

So far we have only dealt with the capability of chromate of silver for forming a visible or direct image; let us now turn to the question of development. It is an easy matter to say that it is sensitive if we only knew how to develop the image formed; but what we have particularly to deal with now is whether with our known methods of development it is possible to produce an image. So far, we have not found it possible.

For the purpose of experiments made some years ago, and which we have repeated quite recently, an emulsion of pure silver chromate was prepared. In order to avoid as far as possible any secondary action that might arise from the action of silver salts or excess of chromic salts on the gelatine, the emulsion was made with precipitated carbonate of silver converted into chromate by the cautious addition of a weak solution of chromic acid, followed by washing in distilled water. For all practical purposes the film of chromate of silver thus obtained was as pure as could be.

So far as actual trials were concerned the results were identical, and afforded no opportunity of varying the conditions under which they were made. With every kind of developer used, including the most recently introduced, the chromate was blackened, whether exposed or not. Further than this, the same result followed the employment of plain

solution of pyro, without any alkali whatever. In fact, chromate of silver is reduced without exposure to light by any of the developers in ordinary use.

Acting on the suggestion originally made by Mr. Burton, and referred to in the recent correspondence on the subject, the experiment was made of converting the chromate into bromide of silver before development, but with little better success. Before development the films were immersed in a solution of bromide of potassium of the strength of half a grain to the ounce until the red colour of the chromate was completely discharged, and the developer then applied in the ordinary way. The result was invariably the same, the film appeared absolutely insensitive, no matter what exposure was given, and it was only on the application of an abnormally strong solution—sufficient to produce fog—that any result in the way of development could be obtained.

It is, of course, possible that with other forms of development—acid silver, for instance—a better result might be obtained; but, looking at all the circumstances, we are scarcely encouraged to hope so. At any rate, for the present we may rest content that chromate of silver is of no practical use as a photographic agent.

PHOTO-PLASTIGRAPHY.

A few weeks since, it will be remembered, we devoted a descriptive article to a new style of sculpturesque portraiture by an American artist. Although there is but a comparatively small demand for that class of picture in this country, there is, we believe, a greater demand for it in America, also in some parts of the Continent. Seeing that statuesque portraits are still being produced here as well as abroad, and that, notwithstanding their frequent incongruities, they meet with a certain degree of favour, it is not inopportune to consider whether or not genuine statuettes would not, at the present time, meet with commercial success if they were forthcoming.

It will possibly be new to many of our readers to learn that veritable statuettes—bust and full-length—were produced commercially by photographic means in the earlier days of photography. The first process—that of Mr. François Willéme, of Paris—was patented in this country just thirty years ago. We well remember seeing at the time some really very fine examples of the work, alike in Parian, plaster of Paris, and bronze, that were made by the inventor himself, and also by the late Mr. Claudet, of Regent-street. Mr. Willéme's process was this:—

The studio in which the negatives were taken was circular, and about thirty feet in diameter. In the centre was a raised polygonal platform with twenty-four faces, numbered consecutively from one to twenty-four. In the centre of this platform the sitter was posed. Round the studio were placed twenty-four cameras, one exactly opposite each of the faces of the polygon. A negative was then taken, simultaneously, or as nearly so as possible, with each of the cameras on wet collodion, so that twenty-four different views of the sitter were obtained. The negatives were then numbered according to the face of the platform from opposite which they were obtained. These negatives completed the actual photographic portion of the work.

The statuette was made in the following manner:—On a block capable of being rotated on its axis was placed a cylinder of soft modelling clay. This block waspolygonal in shape, and its faces were numbered from one to twenty-four; in fact, it was an exact counterpart in miniature of the platform on which the sitter was posed. At a certain distance from the clay was fixed a ground-glass screen, upon which the enlarged image of one of the negatives was projected by mean of an enlarging camera. One of the sides of the block, whose number corresponded with that of the negative, was then brought opposite the image. The outlines of it were then gone over with the tracer of a pentagraph furnished with a cutting style or knife, which cut a corresponding outline in the clay. Then a second negative was taken, this time by preference one obtained at right angles or nearly so to the first, the clay being rotated to the corresponding number, so that the cut then made by the style would intersect that previously made, by which a wedge-shaped piece of clay was set free, and could then be removed. This operation was repeated with all the negatives in turn, so that in the end a perfect transcript of the contour of the sitter was obtained. All that now remained to be done to complete the statue was to touch out a few of the hollows and scrape away the trifling edges left between the various incisions made by the cutter of the pentagraph. Instead of projecting the image on to a ground-glass screen, it was sometimes thrown on to white paper or card, and the outline then traced with pencil. This tracing was then used with the pentagraph instead of the ground-glass image. When the clay model was obtained, any number of duplicates could be produced in plaster of Paris, Parian, or bronze in the ordinary way. As illustrating the practicability of the process, it may be mentioned that Mr. Willéme used to supply a full-length statuette, fifteen or eighteen inches high, for three hundred francs, equal to twelve pounds English.

A couple of years after the date of Willéme's patent Mr. Claudet patented another method of working. In this method the pentagraph was dispensed with, the enlarged image being thrown direct upon the modelling clay, and then manipulated by hand. The clay was fixed on a rotating table, as in the process just referred to; but it was capable of being moved backward or forward by means of a slot, as required. Thin plates of metal were placed in the clay, upon which the outlines of the figure could be seen as the clay was cut away. Such are the brief outlines of, at least, two practical methods of producing sculptures by photography, and others will suggest themselves to the ingenious.

At the time these processes were introduced only wet-collodion was in use for portraiture, and all familiar with its working know quite well the difficulty there would be in obtaining a couple of dozen negatives with long exposures from the different points of sight at the same time, particularly in hot weather, when the plates will only keep a few minutes after preparation. No such difficulties would be encountered with dry plates. Twenty-four cameras were formerly employed; but if the platform upon which the sitter is placed were a turntable, and he were posed on its axis, one camera could practically be made to answer the same end, provided it were rotated for the different views. Two cameras might, however, be found more convenient in practice. In this case they might be placed so that they were opposite alternate sections of the platform. The exposures could be made simultaneously by one operator with pneumatic shutters. The cameras would be furnished with repeating backs carrying, say, half a dozen quarter-plates each, so that two slides for each would suffice for the twenty-four negatives, supposing that number were required.

Some portraitists, suffering from stagnation of business, often sigh for a novelty or new style in portraiture. Here is a style which, though it cannot in any way be termed new, would cer-

tainly now be novel to the public generally, and it requires very little outlay for its practice in any ordinary studio. It may be said that photo-sculpture when introduced did not prove a commercial success. That is true, but the same may be said with regard to other things in connexion with photography on their first introduction, though they have proved successful later on. It may be well to mention that at the time photo-sculpture was introduced the *carte-de-visite* furore was at about its full, and only small pictures that could be put in albums were entertained.

As regards cost. Of course, statuette portraits cannot be produced so cheaply as paper pictures; but there is no reason why a sculptured portrait should not be very profitably supplied for the same price as that usually charged in good establishments for well-finished enlargements, while duplicates could be supplied for infinitely less than duplicates of finished enlargements.

The Proposed New Central Photographic Institution.—We are informed that considerable progress has taken place in the preliminary discussions necessitated by the suggested formation of a new broad-based photographic club or institute, several meetings of the originators having been held. At the present moment a very strong and representative committee, counting some of the foremost men in all departments of modern photography, is in process of completion, of which a meeting is to take place at an early date. We understand that the attitude of the principal London Societies, and of large numbers of photographers, is distinctly favourable to the scheme.

Photomicrographic Stereograms.—An alleged novelty in stereographic photographs was described by Dr. Hausemann at a recent meeting of the Berlin Physiological Society; he stated that he had obtained photographs of microscopic objects which, when placed in a stereoscope, gave the impression of solidity. They were produced, he said, by taking one photograph of the object in focus for a given level, and then a second photograph at a different level, the two when united in the stereoscope giving the impression of solidity. This method, among several others, has long been employed by us in producing micro-stereo-photographs, and ought to be well known to attentive readers of this Journal, seeing that it has been published more than once.

Absorption of the Sun's Radiations. — Professor Langley and others have, during their investigations of the solar radiations, come to the conclusion that "the heat reaching us from any point of the sun's limb is only about half that reaching us from its centre; but the Astronomer Royal for Ireland and Mr. W. E. Wilson have been engaged upon a farther investigation of the sun's rays, and have almost proved that the sun's own atmosphere absorbs fully one-third of the sun's heat. To fully sustain their argument, the two named astronomers suggest the use of photography. They would have photographs taken from time to time through an entire sunspot cycle, and all reduced in a precisely similar manner, from which deductions could be drawn as to any real change in the absorbing power of the sun's atmosphere, and change of condition in the sun's surface, which would be entirely lost in direct observations, owing to our atmosphere varying so continually in its optical properties.

The Eclipse of April next.—M. de la Baume Pluvinel has made a communication to the Astronomical Society of France indicating the points he considers of most importance to be investigated during the period of the shadowing. The ever increasing prominences, he says, can be studied any time, and therefore should be left alone, and the brief moments put to other uses. The corona is most important, and should be photographed to show its general aspect with various exposures; its spectrum also should be photographed. Several plates should be used, as, owing to the various degrees of brightness of different parts of the corona, it will be impossible to obtain all the details in one exposure. He recommends isochromatic plates for the spectrum work. Mr. Lockyer proposes to obtain a special image with each portion of the spectrum by using an objective prism which would give monochromatic rings. Instantaneous photographs are wanted to possibly set at rest for ever the problem of the "reversing layer."

The Electric Light in Practice.—The cost of producing the electricity is the one cause why its use for illuminating the sitter is not almost universal in large portrait studios; but it is true that the continual progress of discovery has already resulted in cheapening electric lighting, and a communication to the Institution of Civil Engineers by Mr. J. Emerson Dowson on *Gas Power or Electric Lighting*, is one of the most practical contributions to the study of its cost and practicability yet brought forward. We need not here quote his paper beyond giving the conclusions he arrives at, the following being a summary: — "1. When town gas was used for driving the engines of an electrical station, the consumption was about fifty per cent. less than the volume of gas required to give the same amount of light by ordinary burners. 2. When town gas was used neither boiler nor firemen were required, and there were no ashes to be removed; less space was needed; no accumulators were required, except such as might be necessary to equalise the load of the engines, and to provide for a small amount of storage. The engines could be worked in the most crowded districts, close to where lights were required, and where boilers were not allowed. 3. When 'generator gas' was used, the consumption of fuel under a full load would be at least fifty per cent. less than with steam power, and the loss due to steam boilers not being fully worked could be almost entirely avoided."

LECTURES ON PHOTOGRAVURE.

In connexion with the affiliation of Photographic Societies with the Photographic Society of Great Britain, we are happy to announce that two lectures, together with a practical demonstration of photogravure or photo-etching on copper, will be delivered by Mr. Herbert Denison (of Leeds), at Bloomsbury Hall, Hart-street, Bloomsbury, London, W.C., on Friday, February 17th, and Friday, February 24th, at 8 p.m., when Mr. J. Traill Taylor will preside.

The syllabus of the first lecture is as follows:—General introduction and the principles of the process; appliances and materials required; the negative; the reversed transparency and its preparation for the printing of the resist; printing the resist; and that of the second lecture:—*Résumé* of first lecture; preparation of the copper plate; laying the ground; fixing the ground; transfer of the resist to the copper; development of the resist; drying off; protecting the margin; the etching; finishing and retouching the plate; pulling a proof. A practical demonstration will be given of each step in the process after the verbal description.

Admission to members of affiliated societies is by tickets, to be obtained beforehand from the Hon. Secretary of their Society, one shilling the two lectures. Non-members will be admitted, by tickets obtainable at the doors, or on application to Mr. R. Child Bayley, Assistant Secretary, P.S.G.B., 50, Great Russell-street, Bloomsbury, W.C., two shillings and sixpence for the two lectures. Bloomsbury Hall is within two minutes' walk of the British Museum, Mudie's Library, and the Bloomsbury Tramway Terminus.

There are now, we believe, something like thirty societies affiliated to the parent Society, and during the past year a joint committee, of which the late Mr. William Bedford was one of the most active members, has been constantly at work in the endeavour to ascertain the best means of giving beneficial effect to the scheme. It will be remembered that members of the affiliated societies were conceded admission to the Society's Exhibition at reduced rates; that several of the papers read at its meetings were placed at the disposal of bodies affiliated; and that other minor advantages were either promised or bestowed. The lectures on photogravure about to be delivered are the further outcome of the desire of the affiliation committee to confer

advantages of a practical nature upon members of societies that have supported the parent society by seeking affiliation to it.

The opportunity of witnessing a practical and complete demonstration of photogravure does not often occur, and the present one therefore should be seized by all those interested in the subject. We appeal to members of affiliated societies and to our readers generally to support by their presence the two to be given next month, which we hope will be so successful that they will be but the forerunners of many practical demonstrations on other subjects.

A SEASONABLE PRINTING PROCESS FOR AMATEURS.*

In the matter of pigments the amateur can avail himself of the finely ground and carefully prepared artists' colours in tubes, but on a large scale, in such an establishment as the Autotype Company's, it is necessary to grind the colours on the premises, and this, together with their thorough mixing in large quantities of gelatine, absolutely necessitates costly and extensive mechanical arrangements. Again, the coating of the continuous rolls of tissue can only be performed by means of elaborate machinery, whereas the amateur may in a single evening coat sufficient paper or tissue to last him for a very long while, and with no more complicated arrangements than a sheet of plate glass and a levelling stand.

One word of caution may be offered to any of your readers who may embark in the preparation of tissue for carbon work, namely, that the samples of gelatine that are sold for emulsion purposes, and which answer best when so employed, are *quite unsuited* for our present purpose. It cannot be too strongly borne in mind that the treatment such gelatines undergo during the process of manufacture in order to harden them, confers upon them the very opposite characteristics to those required for carbon work, where a perfectly soluble and yet sound gelatine is a *sine quâ non*. Many of the artificially hardened gelatines become spontaneously insoluble in contact with bichromates, or may even be actually precipitated, and the employment of such can only lead to the most complete failure. Nelson's photographic gelatines Nos. 1 and 2, and their No. 1 Flake, are suitable kinds, but the "X Opaque" of the same makers, together with most of the foreign brands specially made for emulsion work, are to be shunned.

Beyond the careful and thorough diffusion of the finely divided pigment throughout the mass of gelatine, and the subsequent straining through swan's-down or similar material to remove accidental particles as well as air-bubbles, there is no special care required in the preparation of the tissue. The paper employed may receive some little attention, as it is important that it be readily penetrable by water, without partaking too much of the bibulous character. The various papers sold for photographic purposes will answer well, but are of unnecessarily good quality for the purpose. A stout and fairly good sample of printing paper will serve every purpose; but highly surfaced and sized papers should be avoided as not permitting the free access of the water to the under side of the film in development.

In coating with the pigmented gelatine it is only necessary to thoroughly damp the paper and squeegee it on to a sheet of levelled plate glass, removing all superfluous moisture. A measured quantity of the coloured gelatine is then poured on and allowed to set, after which the sheet is tacked by two of its edges to light laths, after the style of a map, and hung up to dry, which it will then do without much cockling or distortion. It is absolutely impossible to give any definite proportion for mixing the coloured gelatine, as the pigments themselves vary so considerably, and actual trial is the only safe plan. The best course to adopt is to first mix a quantity of colour to the desired tint, using as the basis liquid Indian ink or China ink and any of the more permanent of the tube colours to produce the modification of tone. Then, having prepared a solution of gelatine of the strength of from eighty to one hundred grains to the ounce, add the colour gradually until the correct depth has been obtained. It will probably be necessary to prepare, sensitise, and develop one or two sample pieces of tissue before the exact depth is reached, but there is in this process as in others considerable latitude.

I do not advise the preparation of sensitised tissue for the reason already given that it keeps too short a time. Besides this, in the absence perhaps, of very perfect drying arrangements, if the operation should be, in consequence of the presence of excessive moisture in the atmosphere, a protracted one, the presence of the bichromate would very probably lead to partial or total insolubility of the tissue before it was ready for use. The unbichromated gelatine, however, runs no such risk, and the operation of drying it after sensitising is a far shorter one than the original dessication.

That tissue making is not a particularly difficult process is proved by a series of prints that were shown to me a few days ago, the production of an amateur on home-made tissue. Compared with duplicates in silver the carbon prints were in every case superior, although the negatives were all of them fairly good ones for silver printing.

W. B. Bolton.

* Concluded from page 20.

JOTTINGS.

Thank you, Mr. H. M. Whitefield, for your handsome acknowledgment that The British Journal of Photography is a "source in which nearly all things photographic can be found." The high falutin', in which some recently established photographic journals are fond of indulging, and by which alone they exist, looks very funny to old students of photographic journalism, who must derive great amusement from the frequency with which, in those papers that are constantly telling their unsophisticated readers that they never publish intelligence after their contemporaries, items of photographic news are reproduced weeks, months, and sometimes years after their original appearance in these pages. More than one of your contemporaries not only conveys your matter, but also the style of it; and, as for the genial journalist who a year ago accused you of copying his "side headings," and more recently said that the Almanac imitated his annual in the matter of illustrations. I am sure he would not have said such things had he known what was done in photographic journalism long, long before he entered it.

The Editor's warning as to the danger to health lurking in the careless use of mercuric chloride should be laid to heart by photographers, who, however, I should like to point out, when employing it for intensification purposes, have no need to immerse a greater portion of the hands than the finger tips in it. This reduces all danger to the minimum. I have, nevertheless, watched photographers, when using a tolerably large volume of the solution, place their hands as freely in it as if it were merely plain water, and not attempt to dry them afterwards. I do not know how surgeons treat their hands after they have had them in a mercury solution, but not long since I was present in the laboratory of a friend who was conducting some experiments necessitating the sterilisation of the substance he was working upon, and after the hands had been bathed in the mercury they were carefully dried and then rapidly passed through a gas flame to "sterilise" the hands and possibly to remove the last traces of mercury.

There are undoubtedly some good points about the piece of apparatus for developing plates in a vertical position without the use of a dark room which Mr. Alexander Watt describes; but the fact, that such a system is useless except for correctly exposed plates, at once places it out of court as regards practical utility, except, of course, to the experimentalist, who works on different lines and for different objects to the average professional or amateur photographer. Until we have all learned to expose our plates with absolute accuracy, such attempts to obviate the necessity of using a dark room must naturally be just so much wasted labour. As regards vertical development, however, I think that, if ever I desired to employ it, I should not search further for the necessary piece of apparatus than one of those grooved vertical porcelain baths to be had of the dealers. These, I believe, are made to hold three, six, or a dozen plates, and would answer just as well for developing as they do for fixing or washing.

Reading all that has been written about amidol—or, at least, a considerable part of it, for to an old hand a new developer on

paper will only go down in homœopathic doses—one conclusion is irresistibly forced upon me, and that is, that, after all, pyro has outlived the rivalry of hydroquinone, eikonogen, and para-amidophenol, and takes rank as the standard developer by which newer substances must be judged. I have submitted amidol both with and without alkali to a series of trials, but save and except that it is extremely energetic in cases of under-exposure, cleaner in working, and conserves its power for a longer time than other compounds, I can discover no advantage in it over pyro and ammonia sufficient to justify the abandonment of an old friend where it gives satisfaction. At any rate, for negative work I can get all that I require with the latter, and so long as that is the case I shall not relinquish its use. For bromide work, however, amidol is, I think, superior to iron, as I find it does not clog the shadows, gives a nicer colour, and requires no subsequent acid bath.

I have often wondered whether any practical advantage could be taken of the phenomenon of shearing stress—that is, the fact that the application of a developer to a plate of gelatino-bromide of silver which had received mechanical pressure produced reduction to the metallic state, and more recently, on the publication of Mr. Carey Lea's experiment proving that great mechanical pressure alone suffices to darken the silver salt, the same thought occurred to me. There seems to me to be some feasibility of utilising the idea for reproduction purposes, and I commend it to the attention of experimentalists.

I should like to know why (1) Mr. Henry Crouch believes that ordinary cameras are being gradually superseded by the hand camera, and that sooner or later the former will be a thing of the past. (2) Mr. A. R. Dresser believes that stopping down the lens does not increase the definition for enlarging purposes, although it may appear to do so. (3) Mons. Sauvy has resumed business at Manchester, and advertises the fact, when "Mrs. Hargreaves" also advertises that she has bought the business. (4) Retouching by electricity is regarded by some men as practicable. (5) Whether, judging by the financial success of the "free portrait" scheme, there are not more fools than Carlyle imagined in the population. (6) Why Mr. Horsley Hinton does not like his friends to say that he believes in "nothing but photographs put confusedly out of focus, printed on exceedingly rough papers, and in a reddish brown colour, fallaciously called sepia;" and (7) why (by the kindness of the Editor) I have received several letters containing all sorts of painful threats against

COSMOS.

FURTHER NOTES ON METOL AND AMIDOL.

Journal of the Photographic Society of India.)

I HAVE not been able to work much more with metol and amidol, but the following few notes in continuation of those in last month's *Journal* may be of interest.

METOL.

Metol, I find, seems to work best with potash carbonate, but it has a decided tendency to give veiled images, and may require a little bromide to give the best results. The stock metol solution with sodium sulphite keeps well, and it is altogether a clean developer.

The electrolysis of metol solution presented some peculiarities, and made up as a developer with carbonate of lithia it has shown itself more active in evolving hydrogen than any other developing agent yet tried except ferrous oxalate. I have not yet been able to try a metol-potash solution in the voltameter.

A solution of metol at 1 to 200 of distilled water was electrolysed in a tube voltameter with platinum electrodes, using 4 gravity cells giving a fairly constant current of half an ampère under a pressure of 4·4 volts The current through the voltameter at starting was about 10 milliampères, with a pressure of 2·8 volts; but after about 10 minutes it sank to 6·5 milliampères, with a pressure of 2·3 volts, and remained steady at that for the next 20 minutes. The yield of hydrogen was about ·3 c.c. in 5 minutes; ·5 c.c. in 10 minutes; ·1 c.c. in 20 minutes; and about 1·5 c.c. in 30 minutes. A purplish substance formed round the anode, colouring the solution in the oxygen tube and working out into the body of the solution, which at the end of the experiment was of a purplish brown inky colour.

With silver electrodes the result was very different. The current through the voltameter at starting was about 8·5 milliampères, with a pressure of 2·5 volts, and in about 30 minutes it had slightly increased to 8·75 milliampères with a pressure of 2·55 volts. The yield of hydrogen was greater than with platinum electrodes, being about 3 c.c. in 5 minutes; ·7 c.c. in 10 minutes; 1·3 c.c. in 20 minutes; 1·9 c.c. in 30 minutes. In this case the solution round the anode and in the oxygen tube remained quite clear, while the purple substance was formed about the base of the cathode, discolouring it and the solution in the hydrogen tube. The anode was covered with a pulverulent deposit of silver, and very finely precipitated silver was also diffused in the solution. In both cases the hydrogen formed a brownish froth at the top of the hydrogen tube, and it was difficult to estimate the amount of gas liberated. A second experiment with a battery of three dry cells gave a similar result.

A solution of metol and lithia carbonate—

Metol	1
Lithia carbonate	2
Sodium sulphite	10
Water	200

was electrolysed with platinum electrodes, and a current from 4 gravity cells. The current through the voltameter at starting was 35 milliampères with a pressure of 3·25 volts, and remained fairly steady. In 5 minutes 1·8 c.c. of hydrogen were given off, and in 15 minutes 6 c.c., which is a very much larger proportion than usual. Some gas was also given off from the anode, but not in measurable quantity. The hydrogen was frothy as before. After 15 minutes the solution was only slightly yellow. The anode was surrounded by a deep yellow solution, and the solution in the oxygen tube was yellow. In the hydrogen tube it was quite colourless.

AMIDOL.

A plain solution of amidol at 1 to 200 of distilled water was electrolysed with platinum electrodes and a current from 4 gravity cells. At starting the current through the voltameter was 10 milliampères with a pressure of 2·1 volts, which decreased to 9 milliampères and 1·75 volt in 30 minutes. The yield of hydrogen was ·5 c.c. in 5 minutes; 1 c.c. in 10 minutes; 1·8 c.c. in 20 minutes; and 2·3 c.c. in 30 minutes; about ·5 c.c. of gas was also evolved from the anode. The anode was stained brown, and the solution turned a deep claret colour. No decolourising action was noticed in the hydrogen tube.

With silver electrodes and the same battery and general arrangements, the current at starting was 23 milliampères with a pressure of 3·1 volts, and at the end of 30 minutes it was 19 milliampères with a pressure of 3 volts. Hydrogen was given off more freely than with the platinum electrodes, the yield being in 5 minutes ·6 c.c.; in 10 minutes, 1·3 c.c.; in 20 minutes, 2·4 c.c.; and, in 30 minutes, 3·5 c.c. No gas was set free from the anode. The anode was covered with a compact deposit of dark purple on the outside and greyish inside, which separated afterwards in flakes, probably an oxychloride.

The cathode was quite clean. The solution was very dark but clear, and no decolourising action was noticed in the hydrogen tube.

It may be noted that, if a solution of amidol be added to a solution of silver nitrate, a thick white deposit as of chloride of silver is at first thrown down, but the solution speedily takes a rich crimson colour, and the precipitate is redissolved, silver being reduced.

The voltameter used on the above experiments consits of a glass vessel holding about 4 ounces of solution, closed at one end with a cork about 1¼ inch in diameter. The electrodes are of platinum or silver about ⅜ inch wide, 1 inch long, and about 1 inch apart, the wires from them passing out through the cork below. The gases are collected in graduated measure glasses divided into tenths of a cubic centimetre.

The galvanometer used is one of Edelmann's absolute unit galvanometers reading up to 12 volts with 1000 ohms resistance, or to 12 milliampères with 100 ohms resistance; with 10 ohms resistance up to 120 milliampères, and with 1 ohm resistance up to 1200 milliampères. It also has a separate shunt of 0·1 ohm resistance, by which stronger currents can be read up to 12 ampères, and an extra resistance of 9000 ohms, which enables pressures up to 120 volts to be measured. I find it a very useful and convenient instrument, and it is quite portable.

COLONEL J. WATERHOUSE, I.S.C.,
Assistant Surveyor-General of India.

ON THE PRODUCTION OF BLACK AND WHITE NEGATIVES BY MEANS OF ARTIFICIAL LIGHT.

I.

AT some time or other it generally falls to the lot of most workers, be they amateur or professional, to copy a subject in black and white, such as a manuscript, engraving, a page of printed matter from a

book, or some other similar subject. With expert workers, such as those having experience in the production of negatives for photo-mechanical work, this is at all times an easy matter of accomplishment, for, as a rule, they being conversant with the working of collodion (a process especially suitable for this class of photography), the work offers no difficulty; but among the great army of non-expert workers, even including professionals, collodion work has been discarded long ago, the aroma of which is now but seldom felt even in studios. It is the dry plate, the dry plate on all hands, for all purposes, no matter how little such be suited for many of the commissions a professional may have to execute. Many have been the attempts, therefore, on the part even of experienced workers, to utilise gelatino-bromide for black and white work, as against the undoubted claims of collodion when properly understood. Nor have plate-makers been slow to recognise the importance of catering specially for this class of work, the outcome of which has been that at least one firm has for a considerable time placed on the market a very excellent plate for photo-mechanical purposes. . There is, however, a very wide range of work outside that of photo-mechanical in which it is desirable that black-and-white negatives of special features be produced, such as the copying of black-and-white subjects for the purpose of producing lantern slides for lecture sets or the reproduction of such subjects by printing on bromide or platinotype, the latter in either paper or textile fabric, whereby an amateur may experience much pleasure in prosecuting such work by means of a gelatino-bromide dry plate, provided certain well-defined lines are followed in their manipulation. In making these remarks, I do not wish any one to imagine that I in any way advocate the use of gelatino-bromide for this branch of photography in preference to collodion. I am a true lover of my silver bath, and with me such is always kept in a working condition (and a very handy thing it is to fall back upon on many an occasion); but there is no use blinking the fact that not one amateur in 500 knows anything about collodion work, and until such time as we have schools of photography, or the heads of our large amateur associations arrange for regular courses of instruction in this and many other almost forgotten branches of our science, it is not likely they will know much about it; for I fear professionals are fast "keeping much up their sleeves," as the saying goes.

To such workers, therefore, as are desirous of producing black and white negatives by means of gelatino-bromide, I offer the following suggestions, and they are the result of much close study on my part, and, I believe, point out, as good if not the best, lines to follow when it is desired to copy black and white subjects by means of gelatino-bromide.

Undoubtedly some of the first considerations, when undertaking this work are: What are the best source of illumination to employ; and, what is the best method of using such in lighting the subject it is desired to photograph? A worker having no practical experience may very likely imagine that, to obtain the best results, it is necessary to employ daylight for the exposure of the plate; but, although daylight is in many ways preferable to artificial light when following most branches of photography, experience has shown me that quite as good results are to be obtained by a well-arranged system of artificial lighting as is possible with daylight. I desire, however, to qualify such assertion to this extent —that there is undoubtedly a limit to which artificial lighting is applicable. In cases where such work as the copying of large maps, plans, and framed engravings of very large size are concerned; there is no doubt that better or more even illumination is obtained by means of daylight than is at all possible by artificial light, but it seldom happens that amateurs or non-experts have such extreme sizes to deal with. The more commonly met with sizes will run from about four inches up to fifteen, and such are perfectly capable of being dealt with by a system of artificial lighting. Having said so much may be accomplished by means of artificial light, a student would do well to give some thought to a few very important factors in the matter of what is the proper amount of light to employ, or in other words, to understand thoroughly the difference between the *intensity* and *quantity* of light he is to use.

I sometimes think that there is not sufficient notice taken by workers of the difference which exists between these two important factors when practising photography in many of its branches. Somewhat recently I happened to remark to a gentleman that as regards the quality of the resulting picture it mattered a good deal whether the exposure was made with the aid of a bright light and a small stop, or a weaker light and a larger stop, the exposures being calculated correctly for the different stops. My friend could not see that there would be any difference, say, in the case of taking two negatives of a landscape, alike in every other respect as regards colour, &c., but different in light. Suppose the first negative was made at a moment of bright illumination, and a stop of small dimensions inserted in the lens so as to give a correctly timed exposure in so many seconds; while in the case of the other plate the lighting of the view was say, four times weaker, to make up for which a stop just double the diameter was employed, so as to make equal exposures, the plates, of course, would or ought to receive equal impressions as regards the light that reaches them.

This is a very commonly accepted theory, but the fact is that the results are by no means the same as regards the quality of the picture obtained. In the one case the picture is obtained by an intense light stopped down, and in the other case by a less intense light with less cutting off. Let any worker try a few experiments in this line, and he will not be long in finding out that very different results are obtained, according to the nature of the light employed in conjunction with different stops.

With some workers the knowledge of such difference obtained by this means is taken advantage of in their style of working, and here we have just a one very important factor that must be taken into consideration when making black and white negatives, or, in other words, negatives that are strong in contrast. When, therefore, it is desired to gain the utmost amount of contrast possible, so far as the lighting of the picture is concerned in conjunction with the employment of a certain stop, the light should be of the utmost intensity in the first place, and a small stop used so as to gain contrast.

Of course, the reverse of this is the employment of a weaker light and a larger stop, the result being less contrast.

Of the different methods of lighting such subjects, numerous have been the trials made, some advocating the burning of magnesium ribbon, some paraffin lamps, others common house gas. I don't know, however, if other workers' experience in any way agree with mine. As regards magnesium, I always found it troublesome and messy in a greater or lesser degree, and by no means so easily controlled as the working by means of house gas, and therefore I discarded it entirely for a *distinctly practicable* method, the first essential of which is certainty in the results obtained, with the utmost comfort in its use. In common house gas we have all that is required, provided a proper arrangement of burners be provided, and these so fitted as to permit of their being placed easily in a desired position in front of, or to the side of, the work that is to be copied.

Of the various forms of gas burners, perhaps as yet no more useful form has been provided for good, sensible, hard knocking about than the ordinary Argand pattern, such as give a light equal to about sixteen candle power. With four of such attached conveniently to ordinary gas pipes, much may be done in the way of conducting photographic operations even on a large scale. For smaller work two of such will be found ample.

In utilising such burners, a very convenient method to follow is the attaching of them to an upright stand in such a way that the lights can be elevated or lowered at will. Any one can easily make such an arrangement themselves. The first necessity is a good baseboard to carry the burner. This is easily made by utilising a piece of board one inch thick by six inches square; to the centre of this baseboard screw an upright support eighteen inches high, having a thickness of half an inch and width of three inches. Right down the centre of this upright support cut out a slot so that the stem of the gas burner will slip up and down easily. The burner is clamped and held in position on this upright by means of two wooden collars, kept tight by a small bolt and nut. It does not take much ingenuity or trouble to rig up an arrangement of this sort. My own apparatus is home-made, and I can testify to the perfect manner and comfort with which it works.

To the end of the pipe on the burner is attached a length of rubber tubing, which brings the gas from any convenient source. The great advantage of this arrangement is that the lights can be placed in any desired position, up or down, or to the sides. I fit on to each burner a reflector made of plaster of Paris, in form similar to the opal cover of a microscope lamp. This has several advantages over every other form of reflector I have ever met in with, and works admirably.

On a future occasion I shall describe more in detail the manner in which these reflectors are made, for they are well worth the small amount of labour and trouble it takes to construct them.

T. N. Armstrong.

AMIDOL.

I note what Mr. Mansfield asks in your paper of the 20th inst., and so answer it, and give my opinion on amidol.

I stated, when I spoke on amidol at the Photographic Society of Great Britain, that I could not speak with any authority on the use of amidol for negative work, as I had not had a chance to give it a fair trial, only having used it two or three times, but that for very fast exposures I had found it work very well in the few trials I gave

it. I do not use the formulæ that are sent out by the makers, as I did not like them, and much prefer the formulæ I use; and, again, they distinctly stated that no accelerator is necessary, and I have found just the reverse, as the formula I use for amidol I find works best with carbonate potassium, carbonate soda, or ammonia, and for very fast exposures, so far, I have found that either carbonate potassium or ammonia works best.

The formulæ I use are as follows:—

No. 1.

Amidol	1 ounce.
Metabisulphite potassium	1 „

Mix and make up to 10 ounces.

To use with this, I make up the following:—

No. 2.

Carbonate potassium	1 ounce.
Water	5 ounces.

No. 3.

Carbonate soda	1 ounce.
Water	5 ounces.

No. 4.

Bromide	10 per cent.

No. 5.

Ammonia (·880)	1 ounce.
Water	2 ounces.

And use the various accelerators as required, as I, for one, am quite sure that a one-solution developer cannot give good results, as one wants to alter the strength of the developer according to exposure given.

The way I use the formulæ given is as follows:—

For instantaneous work (one-hundredth to two-hundredth of a second).

Amidol (No. 1)	1 drachm.
Carbonate potassium	40 drops.
Water	1 ounce.

The image will appear at once (if it is there), but requires some time (ten to twelve minutes) to get up the density. After image is well out I add twenty drops more of carbonate of potassium, and if *very* much under-exposed go on adding carbonate of potassium (No. 2) till the developer turns quite black; and, although developer may turn black, it will not stain the plate, but on *no* account must it be used again after potassium has been added to that strength. I have tried to fog a plate with amidol by increasing the accelerator (potassium), but have not been able to do it; if the potassium was added little by little, say, five minutes apart, but if you add an excess at once it will fog.

When using ammonia with amidol, it requires a good lot. I begin as a rule with—

Water	1 ounce,
Amidol	1 drachm,
Ammonia (No. 5)	4 to 5 drops,

and add ammonia as required. I have added up to forty drops without fogging.

I use no bromide if I think the plate is under-exposed much, but if the exposure has been over the $\frac{1}{100}$th I use a little bromide, as amidol works so much better with it.

I was hoping to be able to say for certain what I thought of amidol for negative work, but the weather has been so bad I have had no chance to get any negatives. I have found it work well, as I said before, with what few instantaneous shots I have been able to get (skating views), and studio work; but, so far, I have not managed well with it for negatives that have been over-exposed (although I knew they were so), and cannot recommend any one to give up eikonogen for amidol, although I believe it is quite as good, but being fond of eikonogen for negative work I shall not give it up in a hurry.

For slides amidol works well, but I gave my experience with it in an article elsewhere, so there is no need to repeat it.

For bromide papers I consider nothing can touch amidol, as I am astonished at the certain results one can get, not spoiling one enlargement out of a dozen with the development. The chief point one has to consider is not to over-expose if possible, as one can get as *good* results on bromide papers with amidol (formulæ I use) as with iron, and only have to give one quarter the exposure. I have now had about three weeks' steady work at enlarging and developing with amidol, and so can speak with certainty as to the results to be got, and, what is more, I can show them. When I first used amidol I worked with formulæ sent out by the makers, but found if you over-exposed you were sure to lose the picture, and so gave it up for that reason; and also the developer would not keep, but turned a dark brown in a week or ten days, which I did not like, so set to work to try amidol with metabisulphite of potassium, and can safely recommend it to every one.

The formula I use for my enlargements is the one you published as given at the Photographic Society of Great Britain, but it makes little difference if you vary it a little; but on no account make it weak, or you will get grey tints and not good blacks. For good blacks one must use a *strong* developer and a short exposure. To give an example, I have just been enlarging up to 15 × 12 from part of quarter-plate with limelight and portrait lens, working at *f*-6 on Eastman rapid bromide, with a fair negative, *not* thin, but a good silver printing negative. I only gave ten seconds' exposure, and it was fully exposed.

The formula for bromide paper is—

No. 1.

Water	3 ounces.
Amidol	3 drachms (or 2½ least).

No. 2.

Carbonate of potassium	2 drachms.
10 per cent. bromide	30 to 40 drops.

and if the image does not come up fast enough add more of No. 2.

I think these few remarks may help my brother amateurs, and I can only say I shall be glad at any time to help any of them along if able by any answers I can give to questions they may ask, and some future day I hope to be able to write with some certainty on amidol for negative work.

A. R. Dresser.

BROKEN DISHES.

Apropos of that broken dish of your correspondent "Old Collodion," and the answer to correspondent "C. Williams," to repair broken photographic earthenware dishes—if they are anything of the kind of size suggested by "Old Collodion," say for 24 × 20—is an absolute impossibility. The material of such dishes, and, indeed, all dishes of the class indicated, not being thoroughly fused, as old china, glass, or porcelain is, remains in a state of tension, and when broken it will be found that an absolutely close joint is impossible, the material itself shrinking or changing shape, and so preventing a true joint. In this case the strongest jointing material I have had experience of is the zinc white sold in tubes by artists' colourmen. Before using it try whether the edges of the break adhere to the tongue or otherwise absorb water in any degree. If so, saturate its desire for damp by coating the edges with the thinnest photographic varnish once only. After this is quite dry, plaster the edges of the broken dish with the oil zinc white, press them together as firmly as possible, and set to dry in a warm place. Clean off the surplus in about a week after, and let stand for another week. This is the strongest way I know of mending (for use) a broken dish.

W. H. Davies.

DETERMINATION OF PLATE SPEEDS.

I.

Those who remember with what a flourish of trumpets Warnerke's sensitometer came before the photographic world will probably have reason to think that history repeats itself, and very quickly too, if we may judge by current events. I have referred to the Warnerke instrument by way of reminding my readers of how exultingly we hailed this little invention as the very ideal and perfection of a speed-measuring system, for had we not at last hit upon a "standard light," and had we not got a perfectly graduated screen? The standard light was soon found to be utterly fallacious; and, as for the screens, why I have now in my possession a couple of screens which to the eye differ in densities by twenty-five per cent.! So one event in photographic history has been the complete discrediting of the results shown by the Warnerke sensitometer, and we shall probably not have long to wait before we see a similar fiasco.

Let me say here that no one would more appreciate a really reliable system for measuring the speed of plates than myself. My love of instruments of precision causes me to delight in the delicacy and beauty of such apparatus as is employed for minute and exact measurements in the kindred sciences—electricity, for example—and it has occasioned many a longing in my mind when I have seen with what exactness and nicety measurements can be made by other scientific appliances, whilst in photography we have none. Whether it will ever be so, I cannot venture to predict; but, when we consider the varying factors with which photographers have to contend, it would almost seem hopeless that our dreams could ever be realised,

because, to begin with, we are about as far off the realisation of a standard light as ever we were, and until we can hit upon a *standard that shall be equivalent to daylight in its properties* it appears to me almost wasting time to attempt to construct any system for measuring the speed of plates if reliable accuracy and incontrovertible readings are to be obtained. I hold that to submit plates to any artificial light with the object of ascertaining their speed is tantamount to arguing upon false premises. As ninety-nine per cent. of our plates are subjected to exposures (within a camera) with daylight as our illuminant, it appeals at once to our common sense as being wrong to attempt first to ascertain the speed of those plates by any standard in which an artificial light is the prime factor.

Various attempts, more or less crude, have been made to reduce daylight to a standard by the use of comparatively insensitive surfaces, which, when exposed to light, will assume a tint more or less rapidly; this tint has then to be compared or matched with some arbitrary or fixed tint, and the time occupied for the attainment of similarity is taken as a measure of the light force, and forthwith made a factor. But I am sure I need scarcely appeal to the older race of photographers, who have already seen such things come and go, to receive their confirmation of my view, that such rough and inexact appliances (in which it is at all times possible to multiply the error ten times or a hundred times) can never be seriously put forward with the hope that we could recognise them as even approaching what we seek in a standard.

When the unreliable readings of the Warnerke sensitometer became apparent, our plate-makers quickly relinquished the issue of plates bearing any actinometer or sensitometer number, and a pretty general return set in to the older nomenclature, which held good during the earlier years of gelatino-bromide photography. It is almost needless to repeat what those names were, but I may just give a few of them, viz., "Ordinary," "Medium," and "Instantaneous." With some variations, such as "Landscape," "Studio," "Rapid," "Extra Rapid," "Special Rapid," "Drop-shutter," &c., these terms have remained in vogue, it being deemed ample description to apply some one of these to the two or three rapidities of plates issued by most makers. I think the use of the terms twenty times, thirty times, or sixty times —meaning those many times the speed of wet collodion—have nearly died out, and, for all practical purposes, the relinquishment of the Warnerke sensitometer numbers has resulted in the adoption of such appellations as serve the requirements of distinguishing the use of the plates; for instance, any one who uses various rapidities of plates will feel that, when he exposes, say, "Ordinary" plates (of any good brand), he will employ them on such subjects, and give them exposures which would be likely to yield him results of a satisfactory nature, not requiring the use of quicker plates. The description given to their plates by makers of good brands is such as probably fills every present requirement; the name fairly indicates its speed, and, in the absence of any other reliable method, is actually preferable to misleading numbers.

Some few weeks ago I noticed a statement that six plate-manufacturers had adopted the Hurter & Driffield method of determining the speed of plates. Probably I need not recapitulate here what that method is; the statement, however, created some surprise, in which I share. I think I do not stand alone when I say that I do not concur with the general accuracy of the "Investigations" of Messrs. Hurter & Driffield. With the method they adopt to ascertain the speed of plates I am decidedly at issue, and for the reason I gave above, viz., that I consider it is based upon wrong premisses. However, an opportunity presented itself whereby I could devote the requisite time to carry out a series of experiments, and I was enabled to enter upon the inquiry with deliberation. I ascertained from the dealers that only two makes of plates could be had marked with the speed numbers according to the Hurter & Driffield method. I obtained plates marked 37, 80, 95, 100, 135, and 140, with which I forthwith commenced my experiments.

The basis upon which I began is as follows :—

Daylight exposures, in a twin-lens camera, on such a subject as should embrace deep shadow, and therefore require a long exposure. Each exposure checked (to verify accuracy of lenses and stops) by placing the competing plates first right and left, and then left and right.

Development effected in most instances by a normal developer, such as the maker recommends for his plates. Large quantities of normal constituents of developers were mixed (forty ounces at a time), in order to obtain uniformity as far as possible. The subject contained high lights, as well as abundance of shadows, but necessitated an exposure of from thirty to sixty seconds, at *f*-16, according to the day. In every case exposures were given that would ensure the shadows remaining clear up to the very end of development, even if that was necessarily prolonged to give the slower plate every chance. The pairs of plates were developed together in one dish, where the developer would permit, and the principle acted upon was that of allowing a slow or sluggish plate time to go on developing until such times as that function was exhausted; in other words, getting the most out of every plate.

The method of employing a twin-lens camera is probably less open to error than any other. For the purposes of this experiment Messrs. Ross & Co. furnished me with a pair of portable symmetricals, which were specially selected, and adjusted so that their foci and their stops should be identical. Before using them I carefully measured the stops, to assure myself of their accuracy, and I am prepared to speak with certainty of their exact performance. As most of the experiments were duplicated (alternating right and left), any inaccuracy would be checked.

Before I describe the nature of the experiments, I had better mention that, in competitive experiments such as these, when we come to develop pairs of plates of different makes, it is frequently found that one make of plate will start much before the other; indeed, it is not unusual to see one plate well out before the other starts. There is nothing in this disadvantageous or the contrary, as it is the final result that has to be looked for, and the condition of things, when both plates have stopped and all there is to come has been obtained, then has to be estimated. Inexperienced developers might jump at the conclusion that the plate which springs up first is the quicker plate; but this is by no means so, often it is the very reverse.

G. F. Williams.

THE HAND CAMERA AND ITS USE IN PICTURE-MAKING.

[Brixton and Clapham Camera Club.]

On this subject there seem to be the most absurd misconceptions abroad, among both the non-photographic public and a large number of those practising photography. It appears to be assumed immediately one leaves off using a tripod, the millennium has come; and no matter what the subject, conditions of time, light, or plates, &c., every exposure can satisfactorily be made in fractions of a second fearful to calculate, and the results turned out in one unbroken string of successful negatives, from which prints may be produced that, for freshness, beauty, and truthfulness to nature, will outrival, or, at any rate, hold their own, side by side with pictures produced by any of the best methods in monochrome.

This is a state of things which may hereafter be brought about, but it will be far away in that dim and distant future when, perhaps, Lord Lytton's *Coming Race* are dabbling in the black art.

The Hand Camera not a Toy.

Now, I propose to-night directing a few remarks to the *real work* to be done with a hand camera; and if any among you look upon it merely as a toy, to be taken out to shoot off a few plates with, I am going to try and convince you that just as good pictures can be done, and *are* being done with it as with cameras worked on a stand. With certain classes of work excepted, as, for instance, *interiors*, and, in fact, just those kinds of work that require a more or less prolonged exposure, when, of course, a tripod, or some arrangement for holding the camera is absolutely necessary—and I do not agree with those who claim that the hand camera is superseding the so-called ordinary camera—each method of working has its uses, and so it will remain until the *speed race* has placed in our hands a workable plate, capable of being taken into the dim, mysterious cloisters, and of such a speed as to be sufficiently exposed with a second or less. This time has not quite arrived yet, and the tripod will still remain with us. Personally, I fail to see any pressing reason to wish its early demise; there is room and work for both.

Various Classes of Hand Cameras.

I do not think we should be spending our time with profit by going through the long list of hand cameras now on the market, and considering the details of their construction or methods of working; any of the trade lists will fully describe them, and, in case further information is desired, the makers of any particular one would be certain to make every possible point in favour of his camera absolutely clear to intending purchasers, with, perhaps, some favourable points it should possess thrown in.

There are, broadly, two classes of hand cameras—one in which the plates are held in a magazine, and the other in which ordinary dark slides are used, neither being the best method, but simply one of convenience.

When one speed of plate is used, and rapidity in working desired, then the magazine form is convenient; but if plates of different speeds were taken out to be used as circumstances required, then the dark slides would undoubtedly answer better. It is a matter each worker must decide for himself which system will be most convenient, it making

absolntely no difference to the quality of the results as pictnres whether the plates are carried in a magazine or ordinary dark slide.

I will show you one example of each system, and would only observe I am claiming nothing for either of them as to their being better or worse than others of a similar character, but merely use them to show you the broad difference between the rival systems.

The Important Points.

Briefly, the important points in any camera intended for use in the hand are first and foremost (1) the lens, (2) the shutter, (3) the focussing arrangements, (4) the finders; and then you have this further question, whether plates or films are to be used. And on this I have nothing to say to-night beyond that it is a matter each must again decide for himself, there being very substantial points in favour of films both on account of their small weight and convenience in packing, and if used in a roll-holder, one cannot close one's eyes to the fact that it certainly is of enormous advantage when perhaps you have tramped ten or fifteen miles out into the country or along the coast, to have the means of making from fifty to one hundred exposures instead of being limited to twelve, or, at most, twenty, as when using plates. On the other hand, the very advantage offered by being able to make a number of exposures (in excess of those under ordinary circumstances made when using the camera and tripod), and done with so little trouble, has been one of the weakest points about hand-camera work, and is largely responsible for the mass of utter rubbish produced by it.

The Lens.

This is the most important item about the whole apparatus, if you intend, as many of us would, that one lens only should be used, and used on all classes of subjects that may have to be dealt with. Then it is of vital importance that the quality of such lens should be of the very best The question arises, Which is the very best?

The hand camera will undoubtedly be used upon subjects of varied character—marine, landscape, figure, and subjects in which buildings appear, and in which it is desirable that straight lines should be kept straight, and not appear as if they had been keeping Christmas festivities up not wisely, but too well. It is certainly an advantage, in my humble judgment, to use a good rectilinear lens.

I am aware many workers advocate the use of a single lens for general landscape work, and, although I am far from saying the rectilinear lens is absolutely necessary, I myself fail to see any quality possessed by a single lens that is not equally possessed by the rectilinear; and one does find very marked advantages possessed by the latter type—one instance among others, in dealing with architectural subjects, or anywhere straight lines appear; and hence I would prefer the rectilinear, and in my own work have, during the last eighteen months, used exclusively one of Wray's, of which I cannot speak too highly.

Whichever kind is used, there is the question of its focal length to be considered, and here I am at arm's length with those who insist upon the necessity of a lens of short focus being used in hand cameras. I fail to see any sound reason for departing from the same rule that applies when using a camera on a stand for the purpose of picture-making—that the lens should not be of so short a focus as to reproduce a view otherwise than as seen in nature by the human eye when looking at it under normal conditions.

It appears to me the best results all round will be got by using a lens on a quarter-plate, or 5×4 camera, of five to six inches focus, my own being five and a half inches, used on a quarter-plate.

Then there is the diaphragm to be considered, and here another advantage arises in using a lens of the character just named—Wray's, working up to full aperture of *f*-5·6—and, although it is not often necessary to use it at that large apertnre in my own practice, for reasons that appear later on, still it is an advantage that costs nothing to keep, and now and then is the means of allowing a picture to be obtained that could not otherwise be enccessfully done. It is needless to say the Iris form of diaphragm possesses distinct advantages over the older form, allowing, as it does, of quicker changes being made, and, what is of not less importance, by its sticking to the lens closer than a brother, prevents you finding, when too late, that the stops have preferred stopping at home.

The Shutter.

The forms of this are innumerable, but the important characteristics for it to possess are that of being easily adjusted to different speeds and working without vibration.

Whether it is in front of the lens, between, behind, or immediately in front of the plate in the form of a blind, personally I care not a jot. The Thornton-Pickard time and instantaneous shutter answers all my requirements.

The Focussing Arrangement.

This is an arrangement the need for which is by some hotly contested, but, althongh a so-called fixed-focus camera does away with any trouble and need for jndgment in this direction, and at first, in using one, allowing of alteration in focus, there are some sad mistakes made in judging distance, yet it is a difficulty that must be faced, and by care and practice overcome, like many others, when one desires to get the best possible results under all circumstances.

Whatever the arrangements be—whether by lever, as in the one present, or by rack and pinion—it should be in such a position as to be easily got at and attended to, in case, as often happens, of a change being required in a hurry. Needless to say, it should be correctly scaled, if the focussing is done to distance.

Finders.

And now there is only one more feature in connexion with the camera I need allude to, and at the commencement I do not hesitate to say a camera is, for the purposes of being used as a means of procuring pictures, practically useless unless it contains some efficient kind of finders. It is asserted by some they are needless, a great nuisance, and quite unnecessary.

With every respect I say it, anything more misleading cannot well be imagined.

That you may quickly be able to point the camera and lens so as to insure the object—say, a man or woman walking—shall be on the plate, one can understand; but, without wasting time over it, *finders are absolutely* necessary if you desire to ascertain that your main object of interest takes its proper position, and that the whole composition is properly balanced—in fact, there is no difference in arranging and composing a picture, whether to be copied with a camera held in your hand or used on a tripod, it requires the same care and constant attention.

It would be equally absurd to say that a ground glass was nseless and of no assistance in composing a picture when using a camera and tripod.

Any hand camera to be of use needs good finders (which, by the way, are, as most if not all of you are aware, simply small camera obscuras). There should be either one or two, so that you can see at once how the picture looks both upright and horizontal. They should give you just so much of the view as will be taken in by the lens taking the photograph, and no more. They should also be well sunk in so as to render it possible to see the image easily on the small ground glass.

They are better if covered with a lid, as in one shown, that can be raised partially or as desired, and forms a very effective screen.

One more thing about the finders. They should be as *large* as possible, so as to be more easily seen.

There is nothing further about the apparatus itself I can usefully occupy time in describing. I pass by swing backs, rising fronts, levels, side swings, and all the hundred and one other things you find on cameras nowadays, half of which are rarely used, and the purpose of the others as often as not misunderstood. That they are some of them useful, more especially the swing back when doing architectural work, one knows; but in the hand camera, although in theory they would be equally necessary, in practice that is not so, and, to sum up, it should be as light as possible without sacrificing strength, it ahould be compact, it should be simple in its movements, and certain in its action.

The Kind of Plate to Use.

Turning from the apparatus to its use, the first thing to settle is the kind of plate to use. At present I, for one, do not feel disposed myself to throw over the glass support for films for various reasons. Mr. Butler could suggest one or two, and I know our friend Mr. Goldby has made some wonderful discoveries with them in the shape of new stars and planets and comets, but he fails to appreciate their true value. When they in their eccentric fashion are found on his negatives starting out of mountain sides, and the comets wandering up and down the plate in an altogether unaccountable fashion peculiar to such things, he objects, and perhaps most of us would do likewise; and, although films have been very much improved of late, yet glass snpport stands the favourite, and it will be of such plates I shall say a few words, at the same time my remarks being equally applicable to films.

This question of plates is a matter in which different workers appear to follow paths widely apart. Some, and among them being names well known as successful hand-camera workers, advocate the using for general purposes plates of about the same rapidity as Ilford Ordinary. This may be all right during the short period of the year (May to August) when the light is at its best, but even then I don't find they are by any means rapid enough when used on subjects containing any great amount of shadow. Of course, if they can by any means make certain of sufficient exposure being given to all subjects as they arise, then by all

means use a comparatively slow plate, since the development is much simpler and the cost quite fifty per cent. less than that of plates of extreme rapidity; and, all things being equal, perhaps the average results obtained from slow plates would be higher than when handling more delicate ones. *But*, and here's the rub, can we get full exposure on the bulk of subjects such as I am dealing with to-night (examples of which are before you in form of prints, and later on some will be shown you through the lantern) on ordinary plates?

RAPID PLATES TO BE PREFERRED.

I think not, and from inquiries made of those with whom I have come in contact, I am certain the greater number who use the hand camera successfully wisely provide themselves with a plate rapid enough to meet all reasonable calls that may be made on them in, say, a day's work; and, after all, if you use plates a trifle quicker than are absolutely necessary for *some subjects*, yet the remedy is so simple, either to stop down a little or quicken the shutter. I used this last year mostly the Mawson plate, and some of the Lumière; and, as you will observe from the prints and negatives, the subjects are of a varied character, and were taken at times ranging from four a.m. to eight and nine p.m. You may find traces of slight under-exposure, but none of the frantic results you would expect from over-exposure, when I tell you a smaller stop than *f*-11 was rarely used, and the average exposure given about one-tenth to one-fifteenth of a second, and in developing them they were done eight or a dozen at once in a large dish, and dealt with on the assumption that if wrongly exposed it erred on the side of under rather than over-exposure, having a dish of strongly restrained pyro developer at hand to bring up density, and as each negative came fully out in detail they were, if requiring it, transferred to the second dish and left till complete, this method being a revival of the old wet-plate method—detail first and then density.

It may be taken as pretty safe advice that, as regards speed of plates to be used in May, June, July, and perhaps early part of August, good results may be looked for with a plate of similar speed as, say, Ilford Rapid. I only mention that make of plate because it is so well known and forms a good standard to judge by. During the remaining portion of the year I would strongly advise a good plate, and by that I mean one rich in silver, and just as quick as can be got; this is, I ought to say, when using a camera of the magazine form. Of course, if using one with ordinary slides, then plates of two or three speeds are available, and can be used as desirable.

That it is useless placing these very sensitive plates in the hands of beginners goes without saying, and it is equally true that, with rare exceptions, it is worse than useless to place the hand camera before them and expect any other result than failure. W. THOMAS.

(To be concluded.)

LIQUID AIR.

WRITING of Professor Dewar's recent experiments on the liquefaction of air, the *Times* says:—

"Liquid oxygen, until quite recently, was a curiosity produced in quantities of a few grammes, too small and too evanescent to admit of any exact and systematic examination of its properties. Professor Dewar produces it by the pint, and demonstrated its more obvious physical properties—its beautiful colour, the blue of the sky, its high magnetic quality, and its characteristic spectrum—with as much facility as if he had been dealing with water. But all this, simple as it perhaps looked, has only recently become possible, and that through a very beautiful discovery of Professor Dewar's, possessing equal practical and speculative value. Liquid oxygen, boiling at 182° below zero, is at ordinary temperatures [always in a state of violent ebullition, which, in the first place, means very rapid dissipation, and in the second interferes seriously, and for many purposes fatally, with the determination of its properties. The double problem, therefore, was to find some means of preventing the waste of a costly liquid and of obtaining it in a state of quiescence suitable for experiment. All the ordinary non-conducting devices proved useless; but the problem was solved by the discovery, that by surrounding the vessel containing the liquid with a very high vacuum the influx of heat from outside could be reduced to one-seventh, as was proved on Friday by actual measurement of the escaping gas, or by other refinements not shown on Friday, to a yet lower point. The result is liquid oxygen at a temperature below its boiling point, tranquilly and slowly evaporating, as water evaporates at moderate temperatures. No ordinary vacuum is of any use. It must be a high vacuum, and Professor Dewar has given a new significance to the phrase; for he has produced vacua measurable in hundred-thousand-millionths of an atmosphere, and by means which exhaust the largest vessels more quickly than the mercury pump exhausts the smallest.

"Many remarkable phenomena were shown on Friday, but none was more worthy of attention than the little bulb of liquid oxygen, something between a walnut and a golf-ball, which hung in a clip upon the lecture table. It was filled and hung up at an early period of the lecture, and it remained four-fifths full at the close. If a conjuror had made his appearance with a large vessel of boiling water and a brisk fire beneath, and if in that water he had boiled for half an hour a piece of ice as big as a golf-ball without reducing it by more than one-fifth, every one would have been vastly astonished. But the little bulb full of liquid oxygen was far more wonderful. The difference of temperature between the conjuror's ice and his boiling water is 100° Centigrade. The difference between the temperature of Professor Dewar's bulb and the air of the theatre was not less than 210° Centigrade. Yet, though that scorching blast necessarily had free access to the oxygen in one direction, the liquid was so perfectly protected by its vacuum jacket as to retain that relatively high degree of permanence.

"Not only is liquid oxygen rendered thus susceptible of complete and leisurely examination, but it becomes a valuable means for pursuing further research. It was shown that atmospheric air can be condensed into a liquid at ordinary pressure by the cold of liquid oxygen boiling under the air-pump. Liquid air, which was also shown in quantity produced by other means, enables us to effect a further reduction of temperature, and, therefore, an approach to the solution of the tremendous problem of liquefying hydrogen. A gas which occupies weight for weight nearly fifteen times the volume of air, and requires for liquefaction a temperature twenty degrees or thirty degrees lower than the lowest yet produced, obviously offers difficulties of an unusual kind. If they are ever overcome, it will be due to the great advance we have just described in the methods of storing and manipulating liquid air.

"An interesting illustration was given of the essential difference between a liquid and a gas of identical composition. Air liquefies as a whole, the liquid containing oxygen and nitrogen in the normal atmospheric proportions; but, when the liquid is allowed to boil, it follows the laws of mixed liquids, the nitrogen with its lower boiling point distilling off first, and showing no appreciable admixture of oxygen until half of the mass has evaporated. It was also shown by various experiments that liquid air behaves in the magnetic field and in the spectroscope simply as diluted oxygen. Its colour is to the beautiful blue of oxygen as the watery sky common in this country to the azure we see through breaking clouds after a storm."

COMPOSITE HELIOCHROMY.

[Journal of the Photographic Society of Philadelphia.]

THE following is an extract from the report of the Special Committee appointed by the Board of Directors of the Photographic Society of Philadelphia, September 1, 1892, to take into consideration the advisability of some form of recognition by the Society of Mr. Ives' work in connexion with composite Heliochromy:—

"Mr. Ives' system of colour photography, which he has named 'Composite Heliochromy,' consists—

"1. In the production of a triple photograph or chromogram, one image of which represents, by its light and shade, the effect of light from the object upon the fundamental red sensation, another the effect upon the fundamental green sensation, another the effect upon the fundamental blue-violet sensation, in accordance with the Young-Helmholtz theory of colour vision, and the actual measurements by Maxwell and Abney of the relative power of different spectrum rays to excite the respective fundamental colour sensations.

"2. The optical superposition of the three images of the chromogram, either by means of a triple optical lantern, or in a table instrument known as the Heliochromoscope, in which the image of the red sensation is seen by red light, the image of the green sensation by green light, and the image of the blue-violet sensation by blue-violet light, but with the three blended together to form a single image, which reproduces the light and shade, and colours of the objects photographed.

"The triple photograph is made by a single exposure, on a single sensitive plate, and from a single point of view, by means of a special camera of Mr. Ives' invention, in which the incident light is divided by the partial reflection and partial transmission of light by transparent mirrors, ingeniously arranged to secure the projection of the three images on a single plane, with identical perspective. The sensitive plates employed are sensitive to all the visible spectrum rays, which are made to act in the production of the three images in proportion to their power to excite the respective fundamental colour sensations. This result is accomplished by filtering the light which goes to each image through a selective colour screen, which has been adjusted by experiment in photographing the spectrum itself, to secure in the spectrum photograph a density curve corresponding to the graphic curve of the same sensation in Maxwell and Abney's diagrams. The adjustment of such a camera can only be made by a scientific expert, familiar with the laws of optics and the use of the photo-spectrograph and the photometer; but when the adjustment is once made the successful operation of the process is brought within reach of any skilful amateur photographer, no more operations being necessary than for the production of an ordinary negative and lantern slide.

"The Heliochromoscope is a neat table instrument, containing the

same system of reflectors as the camera. By its use the chromogram is seen as a single picture, reproducing the natural colours as readily as a stereogram is seen in the stereoscope reproducing binocular vision.

"The first suggestion of composite colour photography was made, we believe, by Henry Collen, of England, in 1865, and improved upon by Du Hauron and Cros, in France, in 1869 and after, but without recognition of certain principles of colour vision, the application of which Mr. Ives holds to be essential to success. Mr. Ives has been charged with making claims that are unfair to Du Hauron and Cros; but a careful examination of his publications upon this subject has satisfied your Committee not only that he has stated the claims of his predecessors in this intricate and not generally understood field of research, fully, clearly, and fairly, but he has repeatedly given the references to the original publications of Collen, Du Hauron, and Cros, in order that the accuracy of his statements might be readily verified, and has stated his own claims so clearly that if his predecessors had had the same ideas the facts could readily be proved. On the other hand, we have been struck by the fact that writers who have charged Mr. Ives with unfairness have, themselves, either through ignorance or with intentional unfairness, failed either to describe his process or to state his claims, and have ignored altogether points of difference which Mr. Ives has insisted upon, for reasons which he has given, as being absolutely essential to success.

"The following is a brief statement of Mr. Ives' claims, which he has communicated to this Committee:—

"1. 'A triple photograph, one image of which represents by its light and shade the effect of light from the object upon the fundamental red sensation, another the effect upon the fundamental green sensation, another the effect upon the fundamental blue-violet sensation. This claim dates from November 21, 1888 (*Journal of the Franklin Institute*, January, 1889), previous to which date no one else had made photographs answering to this description, or recognised the principles involved. Such photographs are obtained by a method of precision in accordance with actual measurements of the effect of different spectrum rays upon the separate fundamental colour sensations.' (United States Patent, No. 432,530, July 22, 1890.)

"As bearing upon the above claim, Mr. Ives points out that making photographs 'through red, green, and violet glasses,' or 'by red, green, and violet rays,' as finally recommended by Du Hauron and Cros, is either positively and fatally wrong, or else the names of colours are used in such an indefinite sense that the statements have only a vague meaning, indicating no definite principle or system of colour selection, and that nobody working with such vague ideas ever accomplished anything of value.

"2. 'A camera producing the triple photograph on a single sensitive plate, by a single exposure, from one point of view.' (United States Patent No. 475,084, May 17, 1892.)

"It is a well-known fact that many unsuccessful attempts were made to devise such a camera, and that several provisional patents were taken out for ideas that failed to accomplish the desired result.

"3. 'The Heliochromoscope, the only successful device for optically recombining the three images of the chromogram to form one image on the retina of the eye, reproducing the colours.' (United States Patent No. 475,084, May 17, 1892.)

"Mr. Ives also points out that it is important to recognise that his system makes photographs by the action of all visible spectrum rays, but shows them by means of three kinds of spectrum rays only, and that nobody else saw the necessity for such a procedure, although no other is possible in accordance with the modern theory of colour vision.

"It is further claimed that the above-mentioned improvements have—

"1. Solved the problem of reproducing the natural colours by photography.

"2. Simplified the procedure so much as to make it possible for any good photographic operator to make the photographs, when supplied with the special camera, even if he have no knowledge whatever of colour science.

"It appears to this Committee that Mr. Ives' claims are sustained, not only by argument and references, but also by his exhibition of results, which may fairly be said to be wonderful improvements upon anything obtained by his predecessors. In fact, while the results obtained by Du Hauron and others are described as crude and unsatisfactory, Mr. Ives shows, by his process in the Heliochromoscope, reproductions so perfect that it is sometimes difficult to realise that one is not looking at a reflection of the object itself, instead of a photograph.

"Mr. Ives has pointed out that the results have one defect, which exists in all photographs, as has been already indicated, although it is less noticeable in the absence of colour. This defect, as has been said, is an increase of contrast in the middle shades of the picture at the expense of both ends of the scale. Ordinary photographs are relatively too flat in the high lights and wanting in detail in deep shadows, and in the colour photographs the colours are apt to appear somewhat bleached out in the lighter shades and too dull in the shadows. This defect is not noticeable in reproductions of some subjects, but quickly attracts attention in others. For instance, a bright sky will in some instances not be as blue in the reproduction as its own reflection in a body of water, because the greater light intensity of the sky itself produces the effect of bleaching out by over-exposure. Since this is the result of a defect inherent in all photographic processes, it should not be charged against the system of colour selection.

"It is also stated that delicate shades of colour will go wrong in the high lights when the sensitive plates are unevenly coated, especially if the coating be thin. The remedy is obvious, and lies with the plate-makers.

"In conclusion, your Committee submit that, in view of the great importance of the results achieved by Mr. Ives, the Society of which he has long been an active member should use its influence to secure to him just recognition for his scientific labours. To that end we recommend the adoption of the following:—

"Resolved, That the Board of Directors recommend to the Society the adoption of the following preamble and resolutions:—

"Whereas Frederic E. Ives, of Philadelphia, has, by the application of his new principle in composite heliochromy (dating from November 21, 1888), made a practical solution of the problem of recording and reproducing by photographic means the colours of nature; and

"Whereas Mr. Ives has, not only in this connexion, but in many other ways, notably in the field of photo-mechanical printing processes, orthochromatic photography, and optical projection, made distinguished contributions to the progress of the art and science of photography; and

"Whereas the Photographic Society of Philadelphia is incorporated for the special object of increasing and diffusing 'the knowledge of those natural laws which relate to the action of light, and particularly to promote improvements in the art of photography;' it is therefore

"Resolved, That, as a special recognition of the eminent scientific labours of Frederic E. Ives, a gold medal is hereby awarded to him by the Photographic Society of Philadelphia."

RYE AND WINCHELSEA WITH THE CAMERA.

Under the auspices of the Hastings and St. Leonards Church Institute, a lecture on the above subject was delivered in Hastings on Tuesday evening, January 18, by Mr. Algernon Brooker, Hon. Secretary to the Photographic Society there. Notwithstanding the severity of the weather, there was a large audience, the hall of the Brassey Institute being quite filled. The lecture was illustrated by the exhibition of about 150 photographic lantern slides of very fine quality, both technically and pictorially. Having conducted his audience through some very charming scenes by way of the Cliff-road to Winchelsea, taking Fairlight and Pett on the way, the lecturer dived into the ancient history of the old seaports, and was able to put on the screen several slides bearing on his subject, which showed the great pains he had taken to unearth the antiquities of the ancient township. Dealing with his subject from a pictorial point of view, Mr. Brooker then showed that the locality offered great possibilities as a happy hunting-ground for the photographer, with artistic instincts. Some of his pastoral scenes were very beautiful, and, as pictures, are equal to, and in some cases surpassing, some of the most highly honoured work of our best exhibitions.

PHOTOGRAPHIC SOCIETY OF IRELAND'S EXHIBITION.

The Exhibition included, in addition to the work of the members, a large number of photographs by English and Scotch proficients in the art. The Exhibition was substantially divided into five classes:—(1) Enlargements; (2) Landscape views; (3) Lantern slides; (4) Hand-camera work; and (5) Historical or archæological subjects (exclusively confined to Ireland). In the class for enlargements the silver medal was awarded to Mr. Victor Smith for a fine enlargement from a quarter-plate print. The second place and bronze medal was won by Mr. Inglis for two excellent enlargements, 15 × 12. They were most admirable photographs of Foley's *Burke* and *Goldsmith*. Mr. L. R. Strangeways, M.A., was commended. In the section for views, Mr. George Mansfield, J.P., President of the Society, obtained the silver medal, and the bronze medal was given to Mr. John A. C. Ruthven. The centre picture of this group, *Kilchurn Castle*, is, says a local critic, one of the most faultless and exquisite photographs possible to conceive. The suggestion of atmosphere, the singularly fine gradations of light and shade, and the perfect realisation of the perspective, combine to make this little print one of the gems of the collection. In the class for lantern slides Miss White won the silver medal, second place being secured by Mr. Joseph Kelsall, of Killiney. For hand-camera work the silver medal was awarded to Mr. A. W. Geddis, and the bronze to Mr. J. White. In the archæological class, Mr. L. R. Strangeways came first for photographs taken by the aid of the magnesium light at Lough Crew, county Meath, the subject being rude stone carvings. The bronze medal was gained by Mr. A. A. Geddis for a set of photographs taken at Monasierboice and Mellafont Abbey.

There was a very good collection forming the Loan Gallery. This included some flashlight photographs by Mr. John Stuart, of Glasgow, who also sent in large portraits of Bishop Dowden and Professor Blackie. The Autotype Company sent in very large reproductions—one of Ludlow Castle and one of Durham Castle being especially good. Messrs. Morgan & Kidd contributed a large full-length portrait of Miss Mary Anderson

and a bust of Sir Edwin Arnold. Mr. Richard Keene, of Derby, also contributed some very interesting examples. The Eastman Photographic Company contributed an enlargement on their bromide paper and studies on glazed paper. Mr. Gambier Bolton showed a very good photograph of the lion in the London Zoo. Mr. Walsh, of Belfast, had a nice collection of views of Irish antiquities; and Mr. Werner, of Grafton-street, and Mr. Robinson, of Grafton-street, were also amongst the contributors. The *Freeman's Journal* and *National Press* Company exhibited the different processes of producing a zinc illustration block.

During the week lantern exhibitions were given to a large audience each evening, the lantern being ably managed by Mr. J. Carson, C.E., and very interesting slides by Messrs. Ruthven, Geddis, Inglis, Strangeways, and Smyth were thrown on the screen, the yacht series of Messrs. Inglish and Smith evoking much admiration, and Mr. Strangeways' "Ignition and Fruition" unbounded merriment.

Some fine slides lent by Messrs. Hastings and Cembrano, many of them recalling scenes in the Photographic Convention of 1892, were given, and one evening was devoted to medical and scientific work, when many medical gentlemen were present to see Mr. A. Pringle's unique collection of microscopic slides.

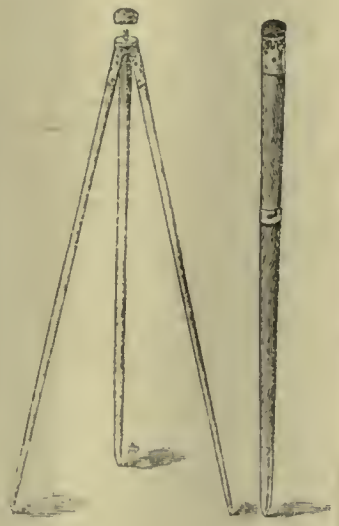
Among exhibitors of lenses and apparatus were Messrs. Ross & Co., Taylor, Taylor & Hobson, Gotz, Mayne, Robinson, Curtis, and Lonsdale Brothers.

The Exhibition Committee are to be congratulated warmly on the success of their undertaking, which, financially and otherwise, has surpassed their expectations.

THE EYE AND THE CAMERA.

Before the Dundee and East of Scotland Photographic Association on Thursday, January 19, a paper was read by Dr. M'Gillivray on *The Eye and the Camera*, in which after comparing the structure of the eye with that of the photographic lens and the mechanism for focussing in both cases, he went on to speak of colour blindness. He recommended strongly the adoption of the tests approved by the Royal Society, and urged the necessity for railway and marine officials being carefully examined with a view to discovering whether they were affected with the disease. He held that all lads entering the service of railway companies should be subjected to a rigorous test of their eyesight, and that at stated intervals they should be medically examined to discover whether their sight was becoming impaired. He pointed out the extreme danger of employing drivers, signalmen, or steersmen who were suffering from colour blindness. One of the chief symptoms of tobacco blindness was that the patient was unable to distinguish red and green, the colours used on railways and at sea. The disease might be acquired in a few weeks, and there was no class of men more given to smoking and more afflicted with colour blindness than signalmen or steersmen.

The Blackfriars Alpenstock Walking-stick Tripod. — The Blackfriars Photographic and Sensitizing Company are issuing a handy stand in the form long known as the Alpenstock. The three legs are closely jointed, and are readily opened by removing the ring at the centre which binds them, and the metal ferule at their base. The stands are extremely light, compact, and rigid, and are made in two sizes, 38½ and 49 inches.



London and Provincial Photographic Association.—February 2, *Calculation of the Angle of View*, by Mr. P. Everitt. 9, First Technical Lecture of the Series, *The Lens*. 16, *Demonstration of the Air Brush*, by Mr. W. H. Harrison.

At the Llandudno Police-court last week two respectably dressed young men, named Vincent Johnson, *alias* Brunker, and Leopold Geoffrey Harding, were committed to the assizes on a charge of obtaining money by false pretences, viz., by advertising for sale in The British Journal of Photography a camera for the sum of 5*l*.

Our Editorial Table.

The Paget Company's Frame for Printing out Opals and Lantern Slides.

The special frame which the Paget Company have provided for use with their printing-out lantern slides and opals has many points of great excellence. The negative is held in position on a glass bed by means of four adjustable screw catches, various sized negatives below that of the maximum being available. The opal, or transparency, is then placed in position in another frame, being held thereto by a revolving circular catch, contact and registration being secured by the second fitting on to four small uprights and clamped down with the usual springs, so that it may be moved, and the progress of the image watched with the certainty that on again being placed *in situ* no doubling of the image will result. The system in our hands has answered admirably.

Fallowfield's Double Glass Petroleum Lamp.

Mr. Jonathan Fallowfield has brought out a really neat and convenient dark-room lamp, the nature of which will be seen from the illustration. The burner is an Argand, and gives a bright flame by aid of a yellow chimney with contracted neck. Overtopping this is a ruby chimney, which is capable of being raised when a flood of yellow light is desired—a position shown in the cut. The lamp is well made, and cannot fail to prove useful.

The Magnesium Company, 7, Auckland-road, Battersea Rise, S.W., have submitted to us a sample of what they designate "Smokeless Magnesium Dust." On making trial of it we find that it ignites readily, gives a clear bright flame, and emits less smoky fumes than any other sample that we have tried. This latter quality will be appreciated by all flashlight men.

Messrs. Percy Lund & Co., Memorial Hall, have courteously favoured us with a neatly bound volume of their *Practical Photographer*, being all their monthly issues of last year. It contains numerous illustrations.

We are indebted to the Scovill & Adams Manufacturing Company, New York, for a handsome Office Calendar for 1893, got up in that ornate style characteristic of the calendars issued by them for several years past.

"SPIRIT" PHOTOGRAPHY.

A lecture on this subject was delivered by Mr. F. B. Chadwick before the Cardiff Amateur Photographic Society at the meeting on Friday evening last. The lecture, which was listened to with great interest, dealt with the scientific aspect of the question, and maintained that, if only one case of photographing the "Spirit" could be indisputably proved, it ought to be sufficient, however easy and numerous the counterfeits, to awaken the interest of the photographic world. It was a mistake to suppose that the various authorities that would be quoted were ignorant of the methods of imitation—quite the contrary—and that this alone should be a guarantee of their ability to guard against fraud and deception in their experiments. Illustrations were then given from experiments with various mediums, notably Mrs. Mellon, Mr. Duguid, and quotations from authorities such as Mr. Alfred Russell Wallace, Mr. William Crookes, F.R.S., and various American scientists, and concluding with quotations from several of the last numbers of current literature, expressing anticipations of a near future when the photographic art would play an important part in solving the most stupendous question of human life and existence.

One of the interesting features of the evening were the albums kindly lent by Mr. James Burns, the Editor of the *Medium and Daybreak*, containing a large number of suitable photographs illustrative of the subject.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 30	Camera Club	Charing Cross-road, W.C.
,, 30	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 30	Richmond	Greyhound Hotel, Richmond.
,, 31	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 31	Hackney	206, Mare-street, Hackney.
,, 31	Halifax Camera Club	
,, 31	Lancaster	Springfield Barracks, Lancaster.
,, 31	Leith (Annual)	165, Constitution-street, Leith.
,, 31	Paisley	9, Gauze-street, Paisley.
,, 31	Rochester	Mathematical School, Rochester.
,, 31	Warrington	Museum, Bold-street, Warrington.
February 1	Edinburgh Photo. Society	38, Castle-street, Edinburgh.
,, 1	Photographic Club	Anderton's Hotel, Fleet-street, E.C.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

JANUARY 24,—Technical Meeting, Mr. T. Sebastian Davis (Vice-President) in the chair.

Before the formal business of the meeting commenced, the Chairman made reference to the great loss the Society had sustained by the death of Mr. William Bedford, who was a member of the Council.

PHOTO-LITHOGRAPHY.

Mr. W. E. DEBENHAM read a paper on *Photo-lithography* (this will appear in a future number), which he supplemented by a practical demonstration of the process. He showed various examples of negatives suitable for it, as well as transfers, stating that wet collodion was recognised as the best for the former.

The CHAIRMAN, in reference to the lithographic stones used, said that, forty years ago, a kind of magnesium limestone came from Germany, and it had been found that the character of the stones somewhat modified the nature of the prints, their various uses depending upon the extreme fineness of the outline to be impressed on the stone, which he presumed would apply in the ordinary practice of lithography. It occasionally happened, after printing a certain quantity of impressions from the stone, that the ink filled in the intermediate spaces between the lines, which would become clogged. He used turpentine to obtain the original fineness.

Mr. DEBENHAM had never found any difficulty with regard to the selection of the stones. In answer to Mr. Bolas, he said he obtained the roller he was then using from Albert in 1877, and it had not deteriorated. In reply to Mr. Archer Clarke, he said he did not think photo-lithography was suitable for tint subjects. It was suitable, however, for pen-and-ink subjects, which was the nature of the pictures he was then reproducing.

Mr. J. D. ENGLAND said he diluted the lithographic ink considerably with turpentine, and rubbed on with a sponge, and then afterwards with a piece of cotton wool he rubbed off as much of the ink as possible.

Mr. T. BOLAS thought Mr. Debenham had got hold of all essentials, and had emphasised the points between success and failure. People did not realise how small a quantity of ink should remain on the transfer; the image should show through the ink. One point, however, might lead to a little difficulty. Commercial transfer ink was sometimes pigmented comparatively highly, and others comparatively little, and one must allow for this. A highly pigmented surface would possibly darken all over. It was scarcely possible to rub off the ink so completely that there was not enough for the transfer. There were more failures from putting on too much ink than from all other causes.

Mr. ENGLAND showed results on gelatine plates which he considered suitable for photo-lithography.

Mr. DEBENHAM thought them fine results, but he himself recognised wet collodion as the best.

A vote of thanks was passed to Mr. Debenham for his paper and demonstration, in acknowledging which Mr. Debenham took occasion to thank Mr. G. Ruthven for the assistance he had given him in the practical work that evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 18,—Mr. A. Mackie in the chair.

THE LATE MR. WILLIAM BEDFORD.

The CHAIRMAN made a brief reference to the late Mr. Bedford, who was a member of the Association, remarking that there was nobody in the photographic world so well liked.

Mr. T. E. FRESHWATER, in moving a vote of condolence with Mrs. Bedford and the family, said that the late Mr. Bedford was one of the best men for listening to anything that was said to him. In him the Photographers' Benevolent Association had lost a great friend.

Mr. W. E. DEBENHAM, in seconding the motion, said that there was no one in photography so much esteemed as the late Mr. Bedford.

A NEW JET.

Mr. R. R. BEARD, in exhibiting his new jet, said that its novelty was the improvement of the cut-off and regulating arrangement of the gases, which is effected in the following manner:—In place of the usual two taps, one tap of a special construction is substituted, the shell of which has the two supply and delivery tubes to the mixing and Y chambers respectively, to either mixed or separate burners, as usual. The plug of the tap lies horizontally, and has a projecting lever at right angles. In both ends of plug of tap are fitted screw-down valves, one for each gas, oxygen and hydrogen. With these valves the supply of gas is regulated to burner. Having regulated the gases, they can be cut off entirely by raising the lever of plug; a small adjusting screw is attached to the shell, which arrests the movement of plug, and therefore any amount of by-pass can be left on. It will be seen that this arrangement takes the place of the ordinary four-way dissolver, having a decided advantage, as the whole is constructed in the jet itself, and can be got at outside the lantern, and there being no wheels or delicate parts to get out of order, or separate pieces of tubing, making unnecessary joints. Also the gases are regulated by the fine-threaded screw-down valves. The mixing chamber is of the most modern pattern, having discs alternately perforated at edges and centre, thereby ensuring perfect mixing. The nipple is large and taper. The jet-holder is likewise improved. In place of the usual round tube, with the boss and thumbscrew—so unsatisfactory, owing to the pins of trays seldom fitting them—a pear-shaped hole is made, the thumbscrew binding, as it were, the pin into the wedge, thus forming a triangle of forces so necessary to make rigid. The position of this is adjustable to suit the various sizes of lanterns, the jet being made the maximum length. The lime-turning arrangement is fitted with screw gearing; this enables the rod to be parallel with the tubes, and any alteration in position does not interfere with working of gearing.

AN ELECTRIC RETOUCHER

Mr. H. Snowden Ward exhibited Messrs. Anthony's electric retouching pencil, in which an ordinary retouching pencil was held in suspension by a spiral spring, actuated by a small electric motor, and guided by the hand. The pencil has a slightly eccentrical motion, making a series of arcs on the negative. It had been in practical use in several studios for some time, the opinion being given that the work of retouching could be got through much more rapidly with it.

The meeting concluded with a display of lantern slides, among which were several of various electric discharges taken by Mr. A. A. Campbell Swinton by means of an induction coil, and showing most beautiful markings, also several slides of composition subjects by Mr. Benham, in which a number of skeletons were posed as boxing, taking tea, singing, &c., with very humorous effects.

North London Photographic Society.—January 17, Mr. Douglas in the chair, adjourned general meeting, held at Canonbury Tower.—The agenda paper contained only routine business. The officers and council for the year were finally agreed upon. *President:* Mr. J. T. Taylor.—*Council:* The Rev. E. Healy, and Messrs. W. Bishop, J. Brewer, J. Douglas, and E. W. Parfitt.—*Curator:* Mr. W. Few.—*Hon. Secretary:* Mr. W. T. Coventon, 59, Highbury-park. The members present were well pleased with the accommodation obtained in the above-named historical building. In addition to the rooms specially allotted to the Society, the members may use the reading-room, known as "The Compton Oak Room." This apartment is wainscoted with finely carved oak from floor to ceiling, and is a very perfect and interesting specimen of interior decoration of the age in which it was executed, viz., the latter end of the sixteenth century.

North Middlesex Photographic Society.—The first Lantern Night of the new session, was held on Tuesday, 24th inst., at Jubilee House, Hornsey-road, about ninety members and friends partaking of the fare. Slides were shown by various members. The advantages of the affiliation scheme to the Photographic Society of Great Britain was further demonstrated by the loan of a splendid collection of slides which evoked considerable applause, the flower studies of Mr. Carpenter and the cloud effects of Mr. Dore being particularly admired, and afforded the members present a standard up to which to work. The next meeting will be on February 13, when a demonstration by Mr. H. M. Smith, of the Eastman Company, on *Enlargements*, will take place.

Harringay Photographic Society.—January 19, Mr. C. Watson presided.—The following gentlemen were announced as being patrons of the Society:—Rev. W. Frith, F.R.G.S., and Messrs. Valentine Blanchard and Charles W. Hastings. A vote of thanks was passed to Mr. C. Frith for the interest he had taken in the Society since its formation.

Hackney Photographic Society.—January 17, Mr. G. Hankins in the chair.—The Treasurer gave a short account of the finances respecting the recent Exhibition. The Hon. Secretary showed some smokeless powder of the Magnesium Company, Battersea, which was tried in Messrs. Rudowsky's lamp. Comparatively, there was great advantage over ordinary magnesium powder, as it seemed to clear very much, Mr. Beckett observing that firemen were not necessary, as recently they were at London and Provincial. Mr. Paget was thanked for his attendance with the lamp, and was informed by Mr. Beckett that their retouching desk (electric), which he was requested by the Society to try and report on, did very materially save time, and gave a very fine stipple, which he thought advantageous. The Hon. Secretary showed Marion's eikonogen cartridges, and the form they were sending out cartridges of hypo and thionine. Mr. Carpenter showed Rendell's lantern-slide printing frame, and a box lid with a ground-glass plate in, to view lantern slides through. From the question box: "What would be the probable exposure at *f*-8 for snow scenes?" Mr. Grant said he would give a full exposure, and use very little pyro. Mr. Herbert Smith held the same opinion, but said judgment was required. Mr. Deane and Mr. Gosling had recently taken some snow pictures, and had given ten seconds, *f*-32 slow plate, and reported a pretty correct re-

sult. Mr. R. Beckett said the exposure would depend very much on the lighting. The Chairman then called on Mr. S. J. Beckett for his paper on *Lantern Slide Colouring*, but, as the evening was somewhat advanced, he was unable to deal very fully with the subject. He thought very little attention had been given, generally, to this interesting subject, and expressed, in a concise and lucid manner, the way to colour slides, choice of colours, materials, &c., after which, slides he had coloured were put through the lantern and commented on by him. Birds were frequently made of dust spots on the plates, and so helped to hide what sometimes would be a fatal defect to an otherwise good plate. Colours looked to the naked eye more bright than when shown through the lantern.

Richmond Camera Club.—January 16, Mr. Davis in the chair.—Mr. G. W Ramsay read a paper entitled, *A Comparison of Different Printing Processes.* After a short historical sketch of the evolution of modern printing processes, and a few remarks upon combination printing, Mr. Ramsay proceeded to notice in detail the principal makes of paper, both for printing out and for development, now in the market, showing specimen prints on every variety. He summed up his "comparison" by quoting the toper's judgment on whiskeys—"All are good; but some are better than others."

Brixton and Clapham Camera Club.—January 17, Mr. W. H. Harrison in the chair.—Mr. W. Thomas read a paper on *The Hand Camera and its Use in Picture-making* (see page 57). The Chairman said that it was an excellent paper, and that the pictures shown upon the screen were of unusual artistic merit. Cameras without rising and falling fronts might usually do in tolerably level country, but in mountainous regions, and occasionally elsewhere, rising and falling fronts were a necessity. He also advocated the use of a lens of long focus; the rule was that the focus of the lens should be of the same length as the distance at which the print would be most liable to be viewed by the eye to give a good recognisable picture of the original scene. He also advised the use of a single lens where possible, and so avoid two reflections from the surfaces of the glass. When a photographer went out with only one small camera, it should be a stand camera primarily, and a hand camera secondarily. Messrs. Butler, Coade, Dockree, Goldby, and Haward took part in the discussion, one point being the necessity for finders, upon which opinion was divided.

Croydon Microscopical and Natural History Club (Photographic Section).—January 20.—The "1893 Convention" Slides were shown. These have been brought together by the Devon and Cornwall Camera Club, in view of the fact that the next Photographic Convention of the United Kingdom is to be held at Plymouth in the summer. In addition to the general views of the town, and of the principal places of interest in the neighbourhood, to which excursions would probably be arranged, there was an interesting series of some of the prehistoric remains—stone crosses, cromlechs, cairns, &c.—so numerous in Devon and Cornwall, concerning which the several theories that have been put forward to account for their erection were lucidly explained by the President (Mr. Lovett).

Leicester and Leicestershire Photographic Society.—January 17, Annual Meeting, Mr. J. Porritt (Vice-President) in the chair.—The following gentlemen were elected as officers for the ensuing year:—*President:* Mr. J. Porritt.—*Vice-President:* Mr. A. Wilson.—*Council:* Messrs. F. Pierpoint, G. Bankart, S. Partridge, F. Jolliffe, and J. Cook. *Hon. Treasurer:* Mr. A. Wilson. *Hon. Secretary:* Mr. H. Pickering, High Cross-street. On January 20, an adjourned meeting was held, when it was decided to present the Hon. Secretary with a lantern and a pair of interchangeable lenses of long and short foci, as a small token of the appreciation of his past services and the courteous and indefatigable manner in which he has carried out the arduous duties of this office from the earliest days of the Society. It was also decided to hold a two-days' Exhibition, on March 22 and 23, in the Co-operative Hall; the Exhibition to be free, and non-competitive in its character, when we hope, in addition to the members' work, to secure the kind support of many of the ablest workers of the day. The President announced that Mr. S. B. Webber, of Bromley, Kent, had consented to read a paper on *Isochromatic Photography* at their next meeting, February 8.

FORTHCOMING EXHIBITIONS.

February 1	.....	*Cleveland Camera Club. Hon. Secretary, J. J. Hallam, 11, Amber-street, Saltburn-by-the-Sea.
,,	7, 8	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.
,,	14.....	Durham City Camera Club. Hon. Secretary, R. Hauxwell, The Avenue, Durham.
,,	16-18	*Woolwich Polytechnic Photographic Society. Hon. Secretary, W. Dawes, 145, Chesnut-road, Plumstead, S.E.
,,	18.....	Holborn Camera Club. Hon. Secretary, F. J. Cobb 109 High Holborn, E.C.
March 1, 2	.....	*Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas, Leytonstone, Essex.
,,	3, 4	Blackheath Camera Club. Hon. Secretary, C. W. Piper, 46, Shooter's Hill-road, Blackheath, S.E.
April	.....	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.
,,	17-29	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

* Signifies that there are open classes.

PHOTOGRAPHIC CLUB.—February 1, *The Limelight and other Illuminants for the Lantern.* 8, Members' Open Night.

Correspondence.

BALL PROGRAMMES BY PHOTOGRAPHY.

To the EDITOR.

SIR,—We have thought it might interest yourself and your readers if we sent examples of a recent application of photography to the festivities of the season.

An artist friend or brother of the house where a dance is to be held supplies a pen-and-ink sketch about 6 × 4 to reach us on the morning of a given day, and on the following morning fifty or 100 copies reduced to programme size are in his hands for attaching to the dance list.

Though such orders are executed in so short a time, it is obviously better to allow forty-eight rather than twenty-four hours in case of postal delays.—We are, yours, &c., J. MARTIN & Co.

4 *and* 3 *Park-villas, New Southgate, London, N., January* 23, 1893.

AMIDOL FOR LANTERN SLIDES.

To the EDITOR.

SIR,—My attention has just been called to a letter in your issue of the 23rd of December, 1892, by the Rev. E. Healy, in reference to the use of amidol for lantern transparencies. I must apologise to the writer for having overlooked his query.

If he will refer to my paper in the ALMANAC, he will see that my remarks are suggestive and tentative, and give those results which in practice I have found the best. Mr. Healy can easily vary the proportions and find if his experiments prove me to be somewhat in error.—I am, yours, &c., HENRY E. DAVIS.

Camera Club, January 18, 1893.

P.S.—Metabisulphite should be six parts, not three parts as quoted by Mr. Healy.

LOUTH PHOTOGRAPHIC EXHIBITION.

To the EDITOR.

SIR,—Thinking you would like to see the progress our list of promised exhibitors is making, I have pleasure in sending it, to date. Of course, there are yet several days to send in, so it may yet be extended. It is as follows:—

Messrs. J. E. Austin, H. S. Tonkins, G. Lewis, Paul Lange, A. G. Tagliaferro, Bernard Alfieri, Lewis Meldon, Edger G. Lea, A. R. Dresser, H. P. Robinson, B. G. Wilkinson, jun., J. C. Thompson, A. Taviner, Adam Diston, Karl Greger, Ralph Robinson, S. N. Bhedwar, J. D. Pearson, H. W. Bennett, Alfred Maskell, Ernest Spencer, Thomas Mansell, A. L. Spiller, H. Symonds, Elliott & Son, G. Davison, W. B. Post, Charles Reid, Richard Keene, M. J. Harding, F. Seyton Scott, J. Chamberlain, A. Burchett, A. Horsley Hinton, Birt Acres, W. B. Cassingham, F. J. Bright, Frank Howard, Lyonel Clark, E. Calland, W. Scorer, and A. Debenham.—Yours, &c., S. FRANCIS CLARKE, L.D.S., *Hon. Sec.*

8, *Upgate, Louth, Lincolnshire, January* 20, 1893.

COATING WOODEN DISHES—REMOVING SILVER STAINS.

To the EDITOR.

SIR,—With reference to Mr. J. Pike's suggestion for using enamel paint for coating wooden dishes, mentioned in his article on "Dishes and Trays" in last week's JOURNAL, I should be glad if you or he would answer the following queries with reference to same:—1. Would it be safe to, and would the paint stand, the following solutions being used in the dishes (not in the same dish, of course): hypo, ferrous oxalate developer for bromide work, or dilute solutions of acid and water? 2. Would not the coatings of shellac varnish be likely to make the paint liable to crack, and therefore peel away? I have several wooden frame dishes, with glass bottoms, that I find it somewhat difficult to keep water-tight, and thought that, if the paint would have no deleterious effects on above solutions, it would be a good thing. If, therefore, you will insert my queries or a reply in the correspondence column, I should esteem it a favour.

With reference to "A Useful Dodge for Aristotype Printers," I have often found the method described, viz., "to immerse a negative to which paper containing silver has stuck in hypo solution direct," one of the simplest methods of removing silver stains from negatives—in fact, I think it is the only method that is desirable. The chief point to observe in this method is that the negative is not put in water before the hypo, especially where the paper has stuck, as in that case it only releases more of the silver out of the paper, which is absorbed by the gelatine films, making the stain larger than if put straight into the hypo. Like all other remedies for accidents, it is not always as efficacious as one could wish, but in practice I have found it the simplest and safest course to pursue in the circumstances.—I am, yours, &c., HARRY W. NEWTON.

Sefton House Studio, Bridge-road, East Molesey, January 23, 1893.

P.S.—Should the negative be varnished and get stained, the varnish can be removed without affecting the retouching, provided the spirit is allowed to work spontaneously, and no rubbing resorted to in the way of helping it, and the negative then placed in the hypo as described.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPH REGISTERED:

Graystone Bird, Bath.—*Grand transformation scene.*

EXCHANGES next week.

J. SALT.—Received. We note the contents of your letter.

P. HALL.—We have no recollection of the catalogue referred to.

S. B.—Ivory for miniature painting may be obtained of artists' colourmen.

A. WERNER.—Thanks for the enclosure, of which we have utilised a portion.

J. J. MCQUILLAN.—We do not give opinions on particular makes of cameras.

F. & A. HILL.—We have not received either of the Societies' reports to which you refer.

F. HALL.—Treat the cloth stained with bichromate of potash with a solution of sulphurous acid.

W. A.—You can register the design for the mount. It would not be the subject for a patent, which would be more costly.

J. C.—Ordinary water colour, blended to match the tone of the picture, is the only thing required for working up bromide enlargements.

SNAP-SHOT.—A lens working with an aperture of *f*-16 is not quick enough for very rapid exposures at this time of the year, even with the most sensitive plates.

S. WOOLTON.—The cause of the prints sticking in burnishing is that they were not sufficiently dry. Lubrication will not protect too damp prints from injury.

DR. H. ZERENER.—Many thanks; we do not think, however, the matter would be of sufficient interest to our readers to warrant us in accepting your kind offer.

J. THOMPSON.—The print, and not the negative, must be registered at Stationers' Hall. It is not imperative that the word "registered" should be printed on the photographs.

W. B. HARRINGTON.—*Modern Dry Plates* (by Dr. Eder), published by Piper & Carter, is the only other English work, beside Abney's, which deals with the subject exclusively.

BITUMEN.—1. The book is published by the author, at St. Louis, U.S.A. 2. Mirrora suitable for the purpose may be ordered of those who make the silvering of glass a speciality.

LIONEL HARTMAN.—We would suggest a radius of about eight inches. The lenses are correctly placed in the drawing. Fix them with an interval of two inches between the curved surfaces.

HARROLD.—Colours for spotting prints that are to be burnished have been advertised in the JOURNAL, by different makers, during the past few months. It is against our rule to recommend any particular maker's goods.

C. W. H.—The changing box strikes us as likely to work extremely well in practice, and we therefore advise you to protect it before offering it to any trade house. We cannot recommend any one particular firm.

G. PARKER.—All particulars with regard to the sending of exhibits to the Chicago Exhibition can be obtained at the offices of the Society of Arts, Adelphi. We can, however, tell you that it is now too late to apply for space.

A. COUSINS.—Ordinary shellac, whether in its natural state or bleached, when dissolved in spirit, is always turbid. The insoluble portion will, however, settle down if time be given; or it may be filtered out by the usual methods of filtration.

R. E. A.—The first patent in connexion with the platinotype process has expired, but subsequent ones were taken out. How many of these are still in force we cannot say. The register at the Patent Office is the only reliable source of information.

A. Z.—As you sent the money with the order, and cannot get the pictures after waiting a month after the time they were promised in, and no reply to your letters, enter an action in the County Court for the money paid and the value of the negatives.

ANXIOUS ONE.—Messrs. Percy Lund & Co., of Memorial Hall, E.C., publish *The Practical Ferrotyper*, which might suit you. The materials for ferrotype work may be had of Mr. Jonathan Fallowfield, Charing Cross-road, W.C., and other dealers.

R. MILLER.—In copying a painting the point to be considered, with regard to the lens, is not the size of the original, but the size of the copy. If the reproduction is to be, say, twelve by ten, a lens that will cover that size plate will suffice, no matter whether the original be thirty feet or three feet.

RADINGIE.—A sixteen-inch focus orthoscopic lens will certainly answer for a 5×4 hand camera; but care will be required in the adjustment of the focus, this being ao to a far greater extent than with the short-focus lens. We cannot advise you any farther unless we saw the orthoscope in question.

METHYL.—Messrs. Jones & Mason, Regent Wharf, Copperfield-road, Mile End, are methylators from whom you can obtain the old spirit by permit.

B. J. R.—We can suggest no improvement in the design for the studio. It might, however, be made three or four feet longer with decided advantage. Ordinary twenty-one ounce sheet glass will do quite well. "Colourless" glass would be more expensive, and very likely would become yellow by the action of light.

ESSEX.—1. So far as we can see, neither the paper nor the toning formula are at fault. It is the negative that is the source of the trouble. It is of much too feeble a character to give prints that will tone to "a strong black colour." If you require black tones from that class of negative, the only way to obtain them is to print on bromide paper. 2. The negatives are too thin for platinotype. 3. The same remark applies to carbon.

W. E. asks: "Can you give me any idea of the exposure necessary in Madeira during March and April as compared with those on the Italian lakes during the same months?"—Subject to the presence of light, fleecy clouds, which are likely to be present over the Italian lakes, you would find a shorter exposure necessary in the latter case than at Madeira, where, however, on bright days, "instantaneous" exposures, as we are aware, are practicable.

PARISIAN AMATEUR.—If the focussing telescope is adjusted for one sight, it will not do for another and different sight without separate adjustment, a the personal equation is introduced. It will then require a supplementary eyeglass through which to view the image. A suitable way to obviate all difficulty would be to make the eye tube travel in a jacket attached to the camera, and engrave thereon a few marks representing long, medium, or short-sighted, then tightening the jacket when the adjustment was made. This would meet every difficulty.

G. W. C.—The proposed studio will do quite well for working on a small scale if the new addition be carried three or four feet further out to the westward. If made according to the sketch, after four feet or so of the direct side and light are stopped off, there will only be about four feet available for the illumination of the sitter. The addition we suggest should not be glazed. No glass will be needed in the south side. Have pale blue or green curtains to draw at the sides, and blinds to pull down from the roof. Make the whole of the west end a plain background.

MUNICIPAL TECHNICAL SCHOOL, MANCHESTER.—A series of lectures on photography will be given at the Whitworth-street Branch, Room C, of this school, by Mr. W. T. Wilkinson. Course 1 is devoted to elementary photography, and commenced on Wednesday, January 25, 1893, 7 to 8.30 p.m. Course 2 embraces photo-mechanical processes of photography, and commences on Friday, January 27, 1893.

ON Wednesday evening last, January 25, the Photographic Club held its Annual Ladies' Night and Entertainment, when, in addition to the display of a large number of excellent slides by members, some capital vocal and instrumental music was discoursed by Miss Minnie Kirton, Mr. A. F. Kipps (piano), Mr. F. A. Bridge, and Mr. M. C. Gaze. A large company assembled in response to the Club's invitation, and a thoroughly enjoyable and successful evening resulted.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A meeting of the Committee was held in the rooms of the Photographic Society of Great Britain on Friday last, Mr. Mackie in the chair. Before opening the business of the meeting the Chairman feelingly referred to the death of Mr. William Bedford, the Chairman of the Committee, which had occurred that morning. An application from a photographer who had previously been assisted by the Committee, but who had only been able to secure odd jobs during the winter, and who was again in difficulties, was considered. The sum of 2*l.* 10*s.* was granted, and the Secretary was also instructed to pay the applicant's rent for several weeks if that should be necessary. A second application was from a photographer who had been in business thirty years, but now incapacitated by blindness. Application for a grant to assist in refurnishing part of his house, so that his family might eke out a subsistance by letting furnished apartments. The sum asked for was granted, subject to the statements being verified and references satisfactory. The case of an applicant to whom a loan had been granted some time ago, and repayment of which was overdue, was discussed. From investigations made, it seems as if the defaulter was attempting to evade repayment. The Secretary was instructed to pursue the inquiries further, and, if it appeared that the defaulter was now able to pay, to take immediate legal proceedings for recovery. The report and balance-sheet were discussed, and the Secretary was instructed to call the annual meeting for February 3.

JOURNAL OF PHOTOGRAPHY.

No. 1709. Vol. XL.—FEBRUARY 3, 1893.

STEREO-MICROGRAPHY.

There are indications that on the Continent the highly useful and attractive system of photographing microscopic objects as stereoscopic slides is likely to be once more brought to the front.

The superior attractiveness of binocular over monocular microscopes is evinced by the immense numbers of these that are now made. We do not, however, purpose here to institute any comparison between these two methods of microscopic examination, but shall at once assume the desirableness of seeing on an enlarged scale and by photographic agency these minute objects in all the solidity of nature.

Imprimis, a micro-stereograph does not by any means imply that a binocular microscope must be employed in its production, for some of the most effective of these pictures we have seen have been obtained by the usual instrument having a single barrel—nay, for most purposes it is to be preferred. Again, there are many organisms so exceedingly minute as to render it difficult to conceive of them as capable of being photographed under circumstances conducive to showing stereoscopic effect, any more than they would be amenable to direct visual binocular examination under a microscope bearing what may be termed an excessively high power.

The conditions under which a microscopic stereograph must be made are identical with those of an ordinary binocular picture, such as a portrait or view from nature, and the methods applying are similar in both cases, size of appliances alone excepted. The one, however, is an enlarging, and the other a reducing, method. Both pictures must, in either case, be taken from a slightly different point of view, with a single exception to which we shall presently allude.

One method, and a very simple one it is, for making a micro-stereograph is to place a cap over the front lens of the microscopic objective, which we may assume to be one of an inch or less in focus, one half of this cap being cut away, so as to allow the light from the object to be transmitted by either one side of the objective or the other, according to whether the cap is rotated to one side or the other. This will give dissimilar views of an object, which must be photographed by two successive operations. According to the distance of the sensitive plate from the objective, so is the magnification; but on this merely elementary topic we need not dwell, it now being well recognised by all. The pair of enlargements thus obtained, when printed and mounted side by side on a card, present true stereoscopic relief when viewed in a stereoscope.

The defining power of a microscopic objective differs altogether from its penetrative power. Take a well-mounted object possessing depth and transparence, such as the head of a crane-fly, with which, as a test-object for this special purpose, we have of late been conducting several experiments. With an inch power we see the *front* of the eye, but fail to discover the *back*. With a two-inch objective the performance is more satisfactory as regards this quality, while with a still lower power we see both front and back. By sufficiently stopping down the one-inch objective we reduce its angular aperture to such an extent as to enable us to see both front and back of the insect's eye, and this is the condition we require for a stereoscopic photograph of this object.

Observe now the image shown in a common monocular microscope, and the following anomaly will be apparent. Having noted the relative positions of the front lines of the eye with those of the back, shift the light a little from one side to the other without disturbing, even in the slightest degree, the microscope in any other respect, the relative positions of object and the lens remaining the same; when, behold, the relative positions of the front and back of the eye are changed. Taking advantage of this, pictures having a true stereoscopic effect may be most easily obtained by the very simple expedient of a slight motion from side to side of the concave mirror by which the object is illuminated, this, of course, being done previous to the making of the second exposure. This method was well known to a few of the *habitués* of the now long extinct Photographic Society of Scotland thirty years ago, but we much doubt that it has long been forgotten.

The conditions for micro-stereography with a monocular microscope are also fulfilled by a system we described in 1877, and which, together with other methods, we brought before the British Association of that year. It consists in having fitted to its main stage a super stage capable of being influenced by the mechanical adjustments of the instrument and also of oscillating from right to left within a limited sphere, for which purpose the slide-holder is pivoted in such a manner that the axis of motion nearly coincides with the object to be photographed.

A picture having been obtained of the object when in one position, the oscillating stage is tilted in the opposite direction, and a second photograph obtained. These two form a pair which, when combined in the stereoscope, show the object in all its natural solidity.

It will readily approve itself to the reader that, with regard to this latter method, the oscillating motion must be slight and the microscopic objective of very small angular aperture; else, if the object be large, its sides will be lacking in sharpness.

In another article we shall treat of methods of making stereo-micrographs by binocular projection.

RETOUCHING AND VARNISHES.

A CORRESPONDENT, whose letter we publish in another column, puts a query which, no doubt, has often required an answer during the practice of other workers. He wishes to know how to prevent the retouching from moving when the retouched negative is varnished. The question is by no means so simple a one as at first would appear, and the reply will necessarily not be devoid of complications.

First, let us take the mode adopted by the best workers in actual practice, which we believe we are safe in saying is to work upon the gelatine film itself before varnishing. Where the amount of pencilling is slight, the fine grain of the unprepared negative usually gives sufficient tooth to enable the pencil to bite without extraneous aid. Where the extent of retouching needed is beyond slight tints, it becomes requisite to prepare the surface. Some workers use a solution of gum arabic, or other similar substance, for the purpose, but by far the larger proportion use one or other of the various "mediums" that are advertised for sale, or they make their own—a terebinthinous solution of some resin being the standard formula. There are hundreds of formulæ to be found in photographers' note-books, no doubt each believed to be better than any other owing to its possessor being familiar with its working. There are also many different makes issued by dealers, and, of course, it is no part of our work to recommend one or other of them, or decide upon the merits of rival makers. We will simply present our readers with a recipe given to us in 1874 by one of the best and one of the earliest retouchers in this country. We have given copies of it to many workers, who have expressed their satisfaction with it, the prevailing opinion being that the resin should be in larger proportion; that, however, is a mere detail, which each can manage to settle for himself. The recipe is as follows:—

Gum dammar	30 grains.
Venetian turpentine	6 „
Rectified turpentine	4 ounces.

Dissolve a little to be rubbed on the negative, and the surplus wiped off with a pledget of cotton wool after a few seconds. At the date that the above was communicated to us, the gelatine plate was a thing of the future; hence it will be seen that the medium was intended to be used upon the varnish. We may say, however, that (when made stronger) it has been in frequent use for working direct upon the gelatine.

We will assume that a negative has been fully worked upon after the manner intimated, and that it is necessary then to varnish it. *En passant*, we may repeat advice often given by us, namely, that every negative from which more than one or two prints are needed should be varnished, otherwise silver stains are so very liable to make their appearance. If the above medium be used, the experimenter need have no fear whatever of the retouching shifting or becoming blurred when varnished with ordinary alcoholic varnishes and by heat. If, however, a needlessly thick and sticky medium be used, there will be danger of its being dissolved and the retouching floated out of its place. To this extent our correspondent's query is replied to. But, when the retouching is performed upon a varnished negative, troubles set in and multiply fast. Many will say, "What is the need of varnishing?" and it may be at once said that its advantage is only apparent when a large number of prints are needed, or when the negative has to be stored away for future use when required. Under other conditions we would say decidedly, "Leave varnishing alone." The drawback in printing from a retouched negative not protected by a second coating of varnish, is that the combined friction from the paper placed in the frame to print and the necessary brushing or dusting to keep the surface clean, abrades and gradually removes a portion of the work, till at last its delicacy is quite lost.

When the question of varnishing is to be faced, difficulties arise quickly. Many use liquids, with benzol as the solvent, and with a suitable resin the plan is good. But some photographers strongly object to the use of benzole in any form, from an objection, first to its smell, and secondly, to the danger of fire its presence gives rise to. As for ourselves, we have tried methods of protecting the retouching in such a way as to render possible the giving a second coat of alcoholic shellac varnish, so as to involve the smallest amount of trouble in routine work. We have tried collodion, solutions of gelatine, spraying with sundry liquids devised to protect the first varnish from being softened and dissolved, and so causing the pencilling to shift or run. We are not in a position to say that any of the methods tried have been invariably successful; for, just when we have come to the conclusion that our plans had succeeded, a number of plates having been varnished and the work left intact, we have found a fresh plate, apparently identically treated, quite spoiled, through the softening of the varnish and the running together of the pencilling. Hence, although, beyond the objectionable benzole varnishes, we have had successes, they have not been so uniform as to warrant our recommending a particular process to our readers. We have still further experiments in view, the results of which we hope to communicate at some future period. Meanwhile, no doubt, our readers would be pleased to have the experience of workers who find themselves able to revarnish a retouched negative with ease and satisfaction.

The 1893 Convention.—The date of the 1893 Convention, which is to be held this year at Plymouth, has been fixed for the week commencing July 3 next.

An Invitation.—The Hon. Secretary of the St. Louis Camera Club writes:—"If any of our English cousins should happen this way on their visit to the World's Fair at Chicago during the coming year, we trust that they will remember that our 'latch string always hangs on the outside,' and they can rest assured that we will do our best to make their stay in St. Louis a pleasant one."

Painters versus Engravers.—Photographic engravers frequently get into disagreement with artists in the reproduction of their works. Usually the work has to be done to the satisfaction of the painter, and he is often a "faddist," and has strange ideas as to how his different colours should be rendered in monochrome. Often a misconception of terms as used by the painter and the engraver exists, and this sometimes leads to unnecessary alterations, to the serious deterioration of the work, in order to conform to the painter's ideas.

Provisional Specifications.—Over 24,000 provisional specifications for patents were accepted last year, but possibly not one tithe of this number will be further proceeded with. A provisional specification only costs a pound, and many are lodged with no idea of the patent ever being completed, but merely to use the term for advertising purposes. This remark applies to photography as well as other things. When a provisional specification is lodged, which may be done for anything, no inquiry or investigation is made as to the originality or the practicability of the alleged invention for which protection is claimed. As a proof of this, it came out in evidence in the case of Wells, who stands charged with fraud, that

during the last few years he has filed no less than 192 specifications, though he only completed one patent. A patent can be obtained for almost anything in this country, unless it be opposed on the sealing. Such is not the case in most other countries.

Another Fatal Accident from Ether.—In September last, we referred to an accident that happened in Paris at the house of a photograph enameller, through the breaking of a bottle containing collodion, by which several persons lost their lives. The vapour from the ether, mixed with the atmosphere, reached a light, and then exploded. A very similar accident has occurred in London, though, fortunately, here only one life was lost, but there were some narrow escapes. The facts, as stated at the inquest last week, are these. One evening the enameller and his wife heard a hissing noise in a cupboard where a bottle of ether was kept. This was found to be the vapour from it escaping, and presently, so it was stated, the bottle exploded. A lamp on the table was at once extinguished, and the wife commenced to wipe up the spilt ether, when its vapour must have become ignited by the fire in the grate, and thus set fire to the unfortunate woman's clothing. In all cases where ether is spilt, as we pointed out when referring to the first accident, burning lights that are low down should receive attention before those above, because the vapour from ether is so very much heavier than the atmosphere. Many modern photographers and their assistants, who use collodion for enamelling prints, are not fully aware of the dangerous nature of this material when exposed to only a moderate heat. Ether boils at a temperature of 98° F., and gives off inflammable vapour at all temperatures. If a little ether, for example, be poured in the palm of a warm hand, it will boil at once. Ether and collodion for enamelling should always be kept in well-stoppered or corked bottles, and stored in the coldest place available.

Chromo-photography.—Several times during the past few years it has been our by no means pleasant duty to call attention to the general backwardness of mechanical photography in Great Britain, as compared with most other countries. It is true that considerable advance has been made here of late, yet it must be admitted we are still behind. Notably is this the case with colour work, which is now advancing rapidly abroad. It will be remembered that a couple of years ago a number of very fine examples of chromo photographs, from different parts of the Continent, were on exhibition at the rooms of the Photographic Society of Great Britain, and others at more recent shows. Now they are to be seen plentifully enough in the shop windows of London and all large provincial towns, but they are all of foreign production. It may be mentioned that chromo work has been produced here, but only in small sizes. The majority of the pictures now in the market are of large sizes—twenty inches and upwards—for framing, and we are told they command a ready sale, though their prices are high. If this be so, no better proof of the commercial value of this branch of the art is needed. Photographic copies of paintings by the best artists are in demand all over the world, but there is no question that if they were in the exact colours of the originals they would have greater value. It has been said that some of the photographic chromos in the market are too highly coloured, but it must be borne in mind that the majority of them are from modern foreign paintings, and that Continental artists, as a rule, are more lavish with brilliant colours than are English painters.

Official Photographers.—It has on several occasions been suggested that an official photographer should be attached to certain public institutions—such, for example, as the British Museum—whose business it would be to take from time to time such negatives as might be required by the authorities, or for outside purposes. Quite recently the subject has again been mooted, and, so far as departmental requirements are concerned, the thing may be highly desirable; but it may be a question if the desirability extends beyond that. The British Museum is now provided with a studio and dark rooms, which are at the service of any one desirous of making copies of any of the objects included in the Museum by making formal application to the authorities. This system, so far as we are aware, works well as regards the public. But will what has before been suggested and has again been mooted—an official photographer who will produce negatives at a fixed price for those who require them—work equally as satisfactorily? This is open to question. A negative that will be an excellent one for some purposes may be just the reverse for others. Under the present arrangement, a photographer can go and secure a negative suited to his particular requirements, although it might be considered an inferior one from some standards; but this end may not so easily be attained if there is an official photographer to do the work. Even now authorities are divided in opinion as to how an ancient manuscript should be reproduced—whether as it is in its present, and often dilapidated, condition, or as it was when in its pristine state. Paleologists say the former, while others, in the interest of historical students, say the latter. Ancient documents have been reproduced both ways, the negatives being taken specially for each purpose. If an official photographer be eventually appointed, the privileges publishers and the public now enjoy in the matter of copying the objects in the public collection should in no way be curtailed.

Coloured Lantern Slides.—A well-painted slide, of modern production, is only seldom to be met with. We mean such as those of the highest class that used to be produced some twenty or thirty years ago by skilful artists, and for which a what would now be considered high price was charged—half a guinea and upward. Photography, we know, has had much to do with this. The subject of lantern-slide colouring was, however, brought before a recent meeting of one of the suburban societies, and it proved an interesting one. Those who are in the habit of attending lantern exhibitions, at which the audience is composed more of what may be termed the general public than photographers, know quite well how slides in colour are usually received, although they may be very inferior in quality. There is no reason why the colouring of photographic slides should not receive more attention than it has hitherto done on the part of amateurs. In an ordinary slide we obtain all the fine detail and truth of photography; but when such a slide is coloured, however skilfully that may be done, it can never equal, in purity of colour, one that has no photographic basis. In a coloured photographic slide, the colour has to be seen with the photograph imposed upon it, whatever colour it may be, and this gives it a more or less muddy appearance. In fact, a coloured lantern picture is precisely equivalent to a photograph coloured from the back, such as those called "Crystoleums." This trouble might be partially met by making the photographic image exceedingly thin, and not of the usual photographic tint—say, in pale yellow, blue, green, &c., according to the subject. The carbon process lends itself to this end. Here we should secure all the truth of the photograph, and the artist a greater value in the colour he applies.

HAS PYROGALLIC ACID BEEN DISPLACED?

In the presence of numerous new developers, such as rodinal, amidol, eikonogen, &c., the question whether pyrogallic acid has been altogether displaced has been repeatedly raised.

This question has already been answered several times in favour of pyrogallic acid, as by W. J. Stillman (*Photographic Times*, November 25, 1892), and, again, in *Photographische Mittheilungen* for December (p. 283), where side by side with the mention of the newest developers, various practical workers emphasised the pyrogallic acid developer as the best.

I have often and repeatedly worked in the Imperial Technical College with the most varied developers old and new, and have unreservedly recognised the claims of the new developers—the so-called amidophenols, which give pictures without addition of carbonate of soda—in cases where instantaneous plates are to be developed, where, generally, a rapid effect is desired.

For such purposes the amidophenols will be welcome, especially to the amateur, as well as sometimes in portrait work where short exposures are desirable and no great density of the plate is necessary.

On the other hand, experience has shown that the pyrogallic acid developer possesses more universality of application. According to the amount of alkaline carbonate added, it can be made to work softly and rapidly, or slowly and hard. The density can be increased to a degree unattainable with the new rapid developers, so that, in all my colour-sensitive exposures where I developed plates with pyrogallic acid and with amidophenols for purpose of comparison, I abandoned the latter because the density progressed only to a certain degree and then remained unaltered, while I could push it to any desired extent by the use of pyrogallic acid. There can be no doubt that amidol develops more quickly, but the action of pyro can be accelerated by addition of more alkali or potassium carbonate, while with the amidophenols such additions may readily cause fog.

For the rest, slower development is in no way detrimental; as a matter of fact, it is emphasised as an advantage of hydroquinone, because the development can be more easily watched.

At the same time the pyro developer has the advantage over hydroquinone that it remains active at low temperature. In separate solutions (alkali by itself and pyro with sulphite of soda in another vessel) it keeps for weeks, and, under a layer of vaseline, even for months.

On the large scale, therefore, I use the pyro developer exclusively, and resort to the other developers only when speed is a desideratum, or a case of under-exposure is concerned, or for certain interim exposures.

My solutions are prepared as follows:—

No. 1.

Distilled water	500 ccm.
Sulphite of soda, cryst.	100 grammes.
Sulphuric acid, conc.	8 drops.
Pyrogallic acid	14 grammes.

The pyrogallic acid is added only when the other constituents have been perfectly dissolved.

No. 2.

Distilled water	1000 ccm.
Carbonate of soda, cryst.....	50 grammes.

To prepare the developer, one volume of No. 1 and two volumes of No. 2 are mixed together.

The potash developer, which works much more rapidly, I use seldom, although it is preferable for instantaneous exposures. In the case of normally exposed plates I add, as a rule, three drops of ten per cent. potassium bromide solution to each ounce of the mixed developer.

For the potash developer I take twice as much of potash as of soda for the soda developer. I prefer the latter the more because the soda keeps unchanged in well-stoppered bottles, while potash very readily deliquesces. Sulphite of soda should also be kept in tight-closing vessels, and not in paper parcels.

It has been long known that several plates can be developed one after the other with a mixed pyro developer.

I am accustomed, however, to employ a fresh quantity of the solution for each plate. The low price of pyrogallic acid justifies the slightly increased expense.

It has also been known for several years that softer negatives can be obtained by dilution of the developer with the half or an equal volume of water.

H. W. Vogel, *Prof.*

PHOTOGRAPHING PAINTINGS BY ARTIFICIAL LIGHT.

[London and Provincial Photographic Association.]

In photographing paintings by artificial as by any other light, some of the things most important to be observed are the avoidance of reflections which would dim the shadows, and, so far as possible, to avoid bringing into prominence the irregularities of surface of the picture. The general principles of lighting the subject to be copied, and particularly that of the angle at which light should fall upon the picture, in order to escape interferences from both the causes mentioned, have been dealt with in a paper (*Avoiding Reflections and Granularity in Copying**) read before this Society in 1884, and published in the journals of December 19 in that year. There are some points, however, in connexion with artificial lighting that should be particularly noticed.

* The British Journal of Photography, vol. xxxi. p. 808, and Photographic News, vol. xxvii. p. 104.

The Angle of Illumination.

When photographing a picture of moderate size by daylight in a studio of fair dimensions, the difference of angle at which the various portions of the picture receive the light falling upon them need not be great. With artificial illumination it will often be thought desirable to economise the light by bringing it near the picture, and then the various parts will receive the light at very different angles; so much so, that it may be difficult or impossible to so arrange it that some part shall not suffer from either reflections or a lighting up of the prominences caused by irregularities of surface. With oil paintings particularly, there is a great liability to the reflection from the side of each irregular elevation of surface that is inclined towards the source of light, and which has been mentioned in the former paper as the blankety texture sometimes seen near the top of a copy, or along the edge which is nearest the light. It was pointed out that reflection occurs when the angle of incidence of light falling on any part of a picture having a glossy surface, is such that the returning angle will fall upon the lens. It was shown also that the angle must not be taken merely from the general surface of the picture, but from the inclined surfaces of the irregularities existing upon it, and that this consideration involves having the source of light at a greater angle from the axis of the lens than would otherwise be necessary.

The Source of Light should be as far from the Picture as practicable.

When working with the light near any but a very small picture, two kinds of difficulty arise. In the first place, as the light must not be close to the lens, on account of the reflections that would be introduced, but must come from a considerable angular distance, it is obvious that the part of the picture nearest the light will receive more illumination than the opposite side. This difficulty may be minimised where the direction of light will not interfere with the painter's intention, by a second light from the opposite side. Another difficulty, however, is, that with a near source of light, the angle at which it falls is very different at different parts of the picture, so that, if we get a sufficient angle at the side nearest the light, the illumination will fall very obliquely indeed upon the opposite side. All this points to the desirability of having the source of light as far removed from the picture as is reasonably practicable. The two considerations which will permit of a nearer approach of the light are, first, a small size of picture to be copied, and, secondly, though not to so great an extent, a greater distance of the lens from the subject. This end is secured by using a lens of long focus compared with the size of plate, and this is also desirable for another reason—*i.e.*, that the image will be in a flatter field, and so much stopping down will not be necessary. The main objection to a distant source of artificial light is the length of exposure that would, with some illuminants and in some subjects, be necessary, and hence, no doubt, compromise will frequently be tolerated.

Various Lights.

The necessity for placing the light near the picture and the difficulty arising therefrom, only come into play (except for limitation of space where no large room is available) when the photographic activity of the light is low. Where the electric arc is obtainable, the difficulty ceases, and on various accounts with such a light available I should prefer to instal a copying establishment with that, rather than with day light, especially in London, where we are so much dependent upon weather and season. Magnesium light is also good if a chimney can be fitted to carry off the fumes. With any artificial light (except the magnesium flash) it is easy to interpose a glass to intercept the rays that should be cut off by the yellow screen in orthochromatic work, a plan which obviates any optical interference with the working of the lens, and does not necessitate specially optically ground glass of the colour required.

Paraffin Illumination as Compared with Day Light.

A source of light everywhere obtainable, and one which will suit most amateurs, and be quite sufficient for copies from small paintings, especially water colours and such oi paintings as have not much yellowed by time, is that given by paraffin or gas light. Light of this character may be used without a coloured screen, and gives about the same result as the use of a moderate yellow screen in the lens with daylight illumination.

I have here a few photographs illustrating the copying of paintings by a paraffin illumination as compared with daylight. The light used was the lamp from an ordinary three-wick lantern of the sciopticon

kind. The condenser was removed on account of the image of the flame which it gives. The distance from the flame to the picture was about forty inches. The lamp was first placed nearly in the line of the camera, and gradually removed to one side until the reflection first visible on the side nearest the lamp had disappeared. The photographs A to G, representing a female head and a quantity of flowers, are copied from a print in colours, fairly representing a water-colour drawing in photographic power, whilst those marked M and onwards are from an oil painting about twenty years old, and pretty well mellowed in tone.

The plates used were of an ordinary commercial make, and for the orthochromatic series Ilford isochromatics of the instantaneous brand. The lens used was one of Suter's extra rapid aplanatics, full aperture, equal to No. 2 on the universal system for exposures.

The exposures given were, for the female head and flower subject, three seconds by day light for both kinds of plates, sixty seconds for ordinary plate and yellow screen, and twelve seconds for the orthochromatic plate and yellow screen. For paraffin illumination the exposures were: ordinary plate, four minutes; ditto, with yellow screen, one hour; for the orthochromatic plates, thirty seconds sufficed without the screen, and four minutes with it.

For more ready comparison of the results, I have put them into a tabular form:—

		Exposures. Representation of water-colour drawing.	Oil painting, somewhat mellowed.
Day light..	Ortho. plate	3 seconds ..	20 seconds.
	Ordinary plate	3 „ ..	20 „
	Ortho. plate with yellow screen	12 „ ..	80 „
	Ordinary plate with yellow screen	1 minute ..	6 minutes.
Lamp light	Ortho. plate	30 seconds ..	30 „
	Ordinary plate	4 minutes..	4 hours.
	Ortho. plate with yellow screen	2 „ ..	30 minutes.
	Ordinary plate with yellow screen	1 hour.	

The same screen was used for day and lamp light, but in the latter case it was placed in front of the lamp; and, with day light, in front of the lens. The use of colour-sensitive plates is very strongly indicated for lamp-light exposure on account of their much greater rapidity in that case, as well as for truer rendering of the blues and yellows.

Advantage of Lamp Light over Day Light.

An advantage of lamp light (even with an ordinary plate) over day light, unless a deeply tinted screen is used, is seen in the clearness and brightness of the copies of the oil painting. In the day-light reproductions (without screen) the whole surface seems to be covered by a mistiness, which is almost absent in the lamp-light copies. The explanation is that the colours of the painting have been so yellowed by time that their photographic effect is very much less than their effect on the eye. The reflections from the surface of the picture are not affected by this yellowness, and, being disproportionately strong, disguise in the photograph the work of the painter. It is on this account that it has been justly observed that the orthochromatic methods (by which expression coloured light and coloured screens are included as well as specially sensitised plates), the cracks and surface disfigurements of old pictures, so very evident in reproductions by other means, are now no longer so obtrusive.

The figures given in the table must be taken as representing the exposures actually given, which were only approximately correct. The ordinary plates exposed to lamp light would, in several cases, have been the better for even a more lengthy exposure than was given.

Ordinary Paraffin Lamps may be used.

When a "lantern" lamp is not at hand, ordinary paraffin lamps may be used. Two of the larger kind of tin-back lamps, placed one a little higher and behind the other, may be used on one side (generally the left), and one on the other side. With a smooth surfaced water-colour or fresh painting, very fair results may be obtained in this way.

I have not thought it desirable to go into the question of many sources of illumination. The general principle is the same, but, with such lights as magnesium or the electric arc, yellow screens will have to be used as with day light; but conveniently between the illuminant and the picture, instead of in the lens. Reflectors or weaker lights may also be used on one side, or below the picture, if without them the grain or irregularities show otherwise than the artist intended.

There are, I believe, many, especially amateurs, who have paintings of which they would like to have photographs, but who cannot spare day-time for the work. For such subjects as have been indicated I hope some will find pleasure and success in working with artificial light.

W. E. Debenham.

P.S.—One point I omitted to mention until reminded by a question. The lamp-light copies of the oil painting, on plates of both kinds, came out of full intensity, and in fact, if anything, required reducing, whilst the day-light copies of the same subject without screen required a considerable amount of intensification.

DETERMINATION OF PLATE SPEEDS.

II.

The first score or so of my experiments were directed towards ascertaining whether the spectroscope would enable any clue to be obtained of slight differences in sensitiveness. As the spectroscope reveals the sensitiveness to coloured rays, and, as we know very well that any or all plates are too sensitive to violet, indigo, and blue, if our investigations are not in the direction of ascertaining sensitiveness to green, yellow, &c., the spectroscope will scarcely be as reliable as side-by-side camera exposures, especially when examining plates by different formulæ. I therefore begin at the first of the camera exposures. I will distinguish the two makes of plates examined by the letters x and z.

No.	Experiment.	Result.
18.	Pl. x, speed 135 / „ x, „ 95 } *f*-16, 30 secs.	Identical negatives as to detail; 135 gave rather more density.
18a.	Repeated.	The same in every respect as above.
26.	Pl. x, speed 100 / „ x, „ 80 } *f*-22·6, 30 secs.	The pair of negatives as exactly alike as it is possible to make them. Theoretically, the 100 plate ought to have shown 25 per cent. more exposure.
26a.	Repeated.	A similar pair of identical negatives.
27.	Pl. x, speed 135 / „ z, „ 80 } *f*-16, 60 secs.	The x plate shows about 10 per cent. more exposure than the z plate. Theoretically, the 135 plate ought to have shown 60 per cent. more rapidity.
27a.	Repeated.	The above confirmed. Error in speed, 50 per cent.
28.	Pl. x, speed 80 / „ z, „ 80 } *f*-16, 60 secs.	The x plate showed 10 per cent. in advance of the other. Theoretically, they should have come out alike.
28a.	Repeated.	The above exactly confirmed.
29.	Pl. x, spd. 37, *f*·16 / „ z, „ 80, *f*-22·6 } 60 secs.	The x 37 plate shows 10 per cent. more exposure. Theoretically, as the 37 plate had just double the exposure of the 80, it ought still to have been behind in the ratio of 74 to 80, or 7½ per cent. slower. The combined differences show an error of at least 15 per cent. in estimating speeds by two makers.
29a.	Repeated.	Exactly similar result.
30.	Pl. x, speed 100 / „ z, „ 80 } *f*-16, 60 secs.	The 100 plate has about 10 per cent. in its favour. Theoretically it should have showed a mean difference of 22½ per cent. It proves that two makers cannot agree in their determination of speed, and this remark applies also to No. 28.
30a.	Repeated.	As above. Had both plates been equally coated, probably their speed would have been alike.
32.	Pl. x, speed 140 / „ x, „ 100 } *f*-22·6, 60 secs.	A pair of identical negatives. Theoretically, there should have been 40 per cent. difference, but there is not 1 per cent. discoverable. So alike are they that they might have been out of one batch of emulsion, density and detail being exactly alike.
32a.	Repeated.	Perfect accord with above. 40 per cent. error.

No.	Experiment.	Result.
33.	Pl. x, speed 140 } *f*-22·6, 60 secs. „ x, „ 80 }	The pair of negatives differ by 10 per cent. only. Theoretically the difference ought to have been 75 per cent. in favour of the higher speed plate. Practically the error in speed determination in this case is no less that 65 per cent.
34.	Pl. x, speed 140 } *f*-22·6, 60 secs. „ x, „ 95 }	The pair differ by under 10 per cent. Seeing that the difference should have been nearly 50 per cent., it proves that here again there is an error of 40 per cent.
34a.	Repeated.	Exactly confirms above.

I might go on enumerating several other examples of these enormous discrepancies, but am sure it will suffice if I instance errors of from ten per cent. to sixty-five per cent. to convince my readers that there is something alarmingly wrong in this new-fangled method of determining the speed of plates. I refer for one moment to the experiments, and I point out Nos. 18, 26, 32, 33, and 34. These, it will be noticed, are comparisons of speed of *one make of plate*, which I have called x. What do these experiments show? That 37 is under-estimated by about twenty per cent.; that 80 and 100 only differ by ten per cent. in speed; and that between 95 and 140 there is really only about ten per cent. in favour of the 140, while 100, 135, and 140 are for all *practical* purposes alike in speed.

During my treatment of the plates in this series of experiments, of which the foregoing are a few selections, I have been much struck by the great influence the thickness of the coating has upon the final result. For aught one could tell, some of the plates might have been coated from the same batch of emulsion (although bearing different speed numbers), the real or apparent difference consisting of a thicker or thinner coating. Again, some of the plates started under the developer sooner than others, without, however, causing any distinguishable difference in result at the finish. Any one who has had much experience in emulsion-making will bear me out when I say that a difference of one or two per cent. of gelatine in two similar emulsions will account for this.

I have no space at my disposal to discuss here the rights or the wrongs of the method known as that of Hurter & Driffield for determining the speed of plates. At the moment it does not concern the purport of these remarks; all I intended to show is the utter unreliability of the system, and to prove that such speed numbers are fallacious and deceptive. I have shown that the half-dozen speed numbers of a given maker resolve themselves into two, or at most three, rapidities. For any other or rougher purpose than that of determining the speed of plates, possibly the method might be found suitable; for instance, it might tell us what were the proportions of particles of carbon in a carbon print, but it will not do for plates. Probably I shall give my reasons for this anon.

G. F. Williams.

A CHEMICAL STUDY OF MERCURIAL INTENSIFICATION.

[Photographic Society of Great Britain.]

In January, 1890, I read a paper before this Society *On Control in the Density of Negatives* (*Photographic Journal*, New Series, xiv. 40), and therein described the action of mercuric chloride upon a silver image and of ferrous oxalate upon the bleached image. The effect of sodium sulphite, instead of ferrous oxalate, was also shown, so far as the character of the resulting image is concerned. Since that time I have further studied the changes taking place during mercurial intensification, and I beg to lay before the Society those of my results that are of practical interest to photographers. I have obtained further evidence that the action of mercuric chloride upon metallic silver gives a double salt, and not a mere mixture of silver and mercurous chlorides, which, with other matters of a purely chemical interest, will probably be published elsewhere.

The action of mercuric chloride upon the silver image is perfectly definite, but in practice it is found difficult, if not impossible, to prevent the mercury salt from combining with the gelatine when it is employed in a plain solution, and to prevent this it is usual to add a little hydrochloric acid. The small amount of acid generally used—and it cannot be increased, or frilling will result—is very desirable, but it should be applied with the mercuric chloride, and not afterwards, because, in the absence of mercuric chloride, it is liable to affect the bleached image. Hydrochloric acid, when strong and hot, dissolves out all the silver and half the mercury from silver mercurous chloride, leaving half the mercury in the metallic state, thus:—

$$2AgHgCl_2 = Hg + HgCl_2 + 2AgCl.$$

If the acid is weak, the silver chloride remains almost entirely with the mercury, and the effect is practically a loss of mercury. This change, however, cannot take place in the presence of excess of mercuric chloride; therefore the acid generally added to the mercury solution employed for intensification is harmless to the image.

It has been suggested to add ammonium chloride to the mercury solution, presumably for facilitating the solution of the mercuric chloride. This addition is not to be recommended, because mercuric chloride is quite soluble enough in water alone, and ammonium chloride, if it should have opportunity to act upon the bleached image in the absence of mercuric chloride, would lead to a loss of mercury. Its final effect, when hot, is to dissolve out two-thirds of both the silver and the mercury, leaving the rest in the metallic state. There is not the same safeguard in the use of ammonium chloride that there is in the case of hydrochloric acid, because large quantities may be present without injury to the film, and, as it is unnecessary, it is better to avoid the possibility of irregularity that results from its use.

I have investigated the action of several reagents upon silver mercurous chloride to elucidate the changes that take place when the image, after bleaching it with mercuric chloride, is blackened by the various methods that have been proposed.

Action of Sodium Sulphite.

In the previous paper the action of sodium sulphite was expressed thus:—

$$4AgHgCl_2 = \underbrace{3HgCl_2 + 2AgCl}_{\text{Dissolved by the sodium sulphite.}} + Ag_2Hg.$$

To this I can now add the statement that the mercuric chloride dissolved forms mercuric sodium sulphite, thus:—

$$HgCl_2 + 2Na_2SO_3 = Hg(NaSO_3)_2 + 2NaCl.$$

The silver chloride is doubtless changed into sulphite, which is dissolved by combination with sodium sulphite, but the proportion of the sodium salt required is not so certain as in the case of mercury. One molecule of silver chloride appears to require, as a minimum, about four molecules of sodium sulphite to dissolve it, but practically more must be used to avoid secondary changes.

The action of sodium sulphite may therefore be written:—

$$4AgHgCl_2 + 7Na_2SO_3 + xNa_2SO_3 = 2Ag + Hg + 3Hg(NaSO_3)_2 + Ag_2SO_3, xNa_2SO_3 + 8NaCl.,$$

where x is equal to seven or more. The large quantity of alkaline sulphite necessary to dissolve the silver chloride doubtless leads to the leaving of silver chloride or sulphite in the image when an insufficiency of sodium sulphite is employed. This may account for the thinning action of hypo upon an image intensified with mercury and sulphite which has been observed, though I have never myself noticed this effect.

As stated in my previous paper, if the sodium sulphite solution, with the salts that it has dissolved, is allowed to remain in contact with the metals left as residue, the mercury in the residue will dissolve, and metallic silver will take its place; but, if intensification is carried out in the ordinary manner, this action is not likely to take place.

It may be remarked in passing how greatly inferior sodium sulphite is to sodium hyposulphite as a solvent of silver chloride. The figures given above indicate that, taking the two crystallised salts, the former is only about one-third as efficacious as the latter, weight for weight. But this proportion must not be relied upon too implicitly for practical purposes, because a considerable excess of the sodium salt must be taken in both cases to avoid secondary changes, and it is probable that a larger excess is needed in the case of the sulphite. Nor does this comparison include any difference in the rapidity of action of the two salts. It appears that sodium sulphite acts more slowly than the other, and that, for this reason also, a greater excess of it would be desirable if it were to be used for practical purposes as a fixing agent.

In the continuation of the investigation of the action of sodium sulphite, I have been ably assisted by my colleague, Mr. W. Kirman to whom I offer my best thanks.

Action of Sodium Hyposulphite.

Sodium hyposulphite rapidly blackens silver mercurous chloride, and, if an excess of it is used from the first, the change is of a simple, character, and may be expressed thus:—

$$3AgHgCl_2 = Hg + Ag + 2AgCl + 2HgCl_2.$$

That is, one-third of each of the metals is left in the metallic state, the two-thirds being dissolved. The silver chloride is, of course, changed into the double hyposulphite, as is well known, but there is no sufficiently definite information about the hyposulphites of mercury

to enable one to state in what form it is dissolved. If the sodium hyposulphite is not in excess from the first, then sulphides of the metals are produced, and also sulphuric acid, which causes the precipitation of sulphur from the solution. By prolonging the action of the hyposulphite, the metallic mercury dissolves precipitating silver from the solution.

Action of Potassium Cyanide.

Potassium cyanide in solution blackens silver mercurous chloride with great readiness, and gives, like sodium hyposulphite, one-third of each of the metals in the residue. Its action may be written thus:—

$$3AgHgCl_2 + 8KCy = Hg + Ag + 2KAgCy_2 + 2HgCy_2 + 6KCl.$$

But the action of the resulting solution upon the residue is different from that observed in the previous cases, for the metallic silver dissolves precipitating mercury.

Potassium cyanide is of no use as a follower to mercuric chloride in intensification, on account of the rapidity with which it attacks both silver and mercury when they are so finely divided as they are in gelatine films. It is probable that it was to avoid this solvent action that potassium cyanide was first saturated with silver cyanide, and this addition certainly does prevent the loss of image, but it also profoundly alters the reaction that takes place.

Action of Potassium Silver Cyanide.

Potassium silver cyanide is produced by adding silver cyanide (or silver nitrate) to a solution of potassium cyanide until there remains an excess of silver cyanide which the solution is unable to take up. The use of such a solution, after mercuric chloride (or bromide) has often been commended, since H. J. Burton described the process in the *Year Book* for 1873 (p. 97), and it gives a vigorous intensification of a good black colour with the minimum chance of staining, or like trouble. Mr. Burton very wisely and properly recommends this method for negatives of line subjects only, but others have since applied it to negatives of all sorts.* I have been bold enough, however, to condemn such intensification of half-tone negatives, chiefly because the prolonged application of the blackening solution thins the image. Some time ago I pointed out, and Messrs. Hurter & Driffield have subsequently confirmed my observation, that reduction of the image by such a process changes the character of its density gradation. But, even if there were no change of gradation, the reduction following the intensification leads to uncertainty, and the perfecting of technical photography demands the elimination of uncertainty. I am now in a position to condemn this method of intensification more emphatically, because also of the composition of the resulting image, and because of its want of uniformity.

The primary action of potassium silver cyanide upon silver mercurous chloride may be expressed thus:—

$$AgHgCl_2 + KAgCy_2 = Ag + AgCl + HgCy + KCl.$$

The residue contains, therefore, as metal, all the silver originally present, and to this has been added an equivalent quantity of silver in the form of chloride. This result is highly desirable, and, if only we could stop here, the method would be worthy of the highest appreciation, because it would only remain to reduce the silver chloride, and the image would be of pure metallic silver in double the quantity first present. But there are secondary reactions which appear to be inseparable, or, at least, inseparable with any degree of certainty, from the primary change.

The silver chloride, by reaction with more potassium silver cyanide, is replaced partially by a double equivalent of silver cyanide, thus:—

$$AgCl + KAgCy_2 = 2AgCy + KCl;$$

and the silver chloride that remains holds to itself some of the mercuric cyanide so tenaciously that prolonged washing only slowly removes a part, the remainder resisting, apparently, any amount of washing.

The residue, therefore, consists of the metallic silver originally present, with silver chloride, silver cyanide, and mercury cyanide. By prolonging the action of the potassium silver cyanide, the silver chloride and the mercuric cyanide will decrease, the silver cyanide will increase, and the metallic silver will tend to dissolve. By prolonging the washing, the mercuric cyanide will decrease. Thus one cannot tell what may be finally present, and the composition of the images of different negatives intensified by this process cannot be expected to be identical. The image itself is not permanent; it is affected by light. It is obvious that this method of intensification may be repeated on the same negative, but this is scarcely an advantage, because one application of the process is likely to give too much density.

Sodium hyposulphite thins the intensified image, leaving only the metallic silver, and it appears that it is possible in this way to remove all that the intensification has added to the image. But it would not be well to rely too much upon this, because finely divided silver is readily attacked by alkaline cyanides, and there might, therefore, be an accidental loss of metal.

Action of Alkalies.

Ammonia readily blackens silver mercurous chloride, and the general idea appears to be that the silver chloride is dissolved, and that mercurous ammonium chloride remains. This is not the case, for, though some silver is dissolved, the greater part remains in the residue. I have not yet completed my examination of this reaction, but my results point to the probable production of two compounds in varying proportions, namely, $NH_2AgHgCl$ and $NHAgHg_2Cl$. Almost the whole of the mercury remains in the residue.

Caustic soda immediately blackens silver mercurous chloride, replacing chlorine by oxygen, but the action is very difficult, if not impossible, to complete. It is, without doubt, the silver chloride that is so tardily affected. The residue consists of mercurous oxide, silver oxide, and silver chloride. If the alkali is allowed to absorb carbonic acid by exposure to the air, mercury will be dissolved.

Sodium carbonate acts more tardily than caustic soda, and dissolves a considerable quantity of mercury.

Practical Conclusions.

Whatever methods of intensification may suffice in occasional emergency, I submit that we should have, for regular use, a method that works in an exact and definite manner, that can be allowed to proceed to completeness without the possibility of any other change setting in to make the final result uncertain, one that does not produce too great an increase of density, and that leaves a permanent image of simple and definite composition, which can, if necessity arises, be treated for further intensification, or other effects, with the same facility as the original image. This is the more important, because it is impossible to be sure of getting the density required by simple development when various subjects have to be photographed under various conditions. It is also impossible, without falsifying the gradation, to develop too dense, and afterwards reduce to the desired condition. By the use of mercuric chloride, followed by ferrous oxalate, the conditions stated are realised, and I do not know of any other intensifier of which this can be said. Since I drew attention to this matter three years ago, the method has been varied by one and another in the replacement of the ferrous oxalate by alkaline developers. This change is not desirable, because of the uncertainty introduced as to whether or no the alkali has produced its characteristic change to a certain extent. Ammonia leave an image of a complex and variable composition, and sodium carbonate has a tendency to dissolve mercury; therefore, allowing that oxides as well as chlorides are reduced by the developer to the metallic state, the presence of any alkali makes the change uncertain.

I believe that any photographer who takes the trouble to master the few difficulties that attend the use of mercuric chloride, followed by ferrous oxalate, will be very loth to use any other method for half-tone negatives. The two chief precautions necessary are to eliminate the hypo that remains after washing before treating the negative with mercuric chloride, and to wash away the excess of mercuric chloride before using the ferrous oxalate. The first is done by a few minutes' soaking in an acidified alum solution; and by applying the ferrous oxalate in a dull light, such as is used for manipulating carbon tissue and printing-out papers in; if a little mercuric chloride is left when the ferrous oxalate is added, its only effect will be to retard the blackening of the image.

Chapman Jones, F.I.C., F.C.S.

* Since writing this paper, Mr. H. J. Burton has kindly informed me that the cyanide method of intensification was told to him twenty-four years ago by an operator working at the British Museum, who learned it from another operator. Mr. Burton adds that "the method was worked in this way. A portion of the ordinary fixing bath of cyanide of potassium was put into a glass measure, and a little of the intensifying solution added, and this was poured over the negative after treatment with mercury bichloride. Finding that, if the cyanide of potassium was in excess, the action was irregular, I prepared it in the manner published by me. For many years I have been in the habit of adding to the solution, after the whole of the cyanide of potassium has combined with the silver, a small piece of hyposulphite of soda. This addition gives the negative an intense black colour instead of an olive black." So far, therefore, as I have been able to get at the facts of the case, it appears that the cyanide method of intensification ought to be called Burton's, and not Monckhoven's, if any name is to be attached to it.

THE HAND CAMERA AND ITS USE IN PICTURE-MAKING.*

The Causes of Failures.

It needs a good photographer to use a hand camera with any proper measure of success, but this is just what you have a considerable number of among the members of this Brixton and Clapham Camera Club; and to such of you as may take up hand-camera work this year, and I trust to see some who will, and if used intelligently, I can promise you much pleasure, and, I am bound to say, some disappointments, but that will not be unexpected by those who have had any experience with the camera and tripod, as, even with this method—allowing time for consideration in all the stages up to actual exposure—yet failures are many with most of us, and when working the hand camera, it will soon dawn on any one taking it up for the first time, that the conditions are very different—requiring a quick and decisive judgment as to what to take and what to leave, the proper moment to let the shutter fly, and, what often is of equal importance, a strong self-control, in order to hold back from letting it go just too soon. All this sounds formidable, and yet it is soon acquired by practice, and expenditure of a little thought over the *pros* and *cons* of the whole thing.

I am afraid we amateurs give far too much time and attention to dashing up and down, making exposures *ad lib.*, but very little time to sitting quietly and working out in our own minds not only what have been our successes, but, what is of infinitely more importance for future advancement, what are the *causes* of our failures. Whether they be technical or pictorial failures, we might often spend a little more time over them with profit, and, if not understood at the moment, put them away, and afterwards something may turn up to explain the cause, and so enable one to guard against similar mistakes occurring.

This question of failures is looked upon with different opinions by different people. The ruler of my household entertains strong opinions on the matter, and whenever I am just getting a choice collection gathered, she makes a rapid calculation of £ *s. d.* they represent, which calculation is generally of a generous nature, no stinting about it, and is a sure sign that at their next visit the dustmen are certain of finding a richer harvest of glass than usual (it may be some of you have a guardian angel ministering over you in a similar fashion).

Find a Good Plate and Keep to it.

In leaving the question of plates, let me strongly advise all in doubt to tackle a good sound plate, and, having once found a suitable one, stick close to it. "*It is better to deal with a rogue you know than one you don't know*," so goes the old saying, and, striking out rogue and substituting plate, makes it a sound bit of photographic advice. So much for the question of plate. It must be good, and rapid as possible if only one kind is used. It might be expected something ought to be said respecting colour-sensitive plates, but, beyond what is generally known of them and their special uses, we need not trouble to-night. They are useful, and of assistance when dealing with work having much yellow or red, as landscape in autumn, and may be of assistance in dealing with skies containing much blue, in contrast to light, fleecy clouds, and where any fog is about, but for ordinary work they are by no means an absolute necessity.

Having disposed of the apparatus, how to use it is the next matter to claim attention. Any one commencing hand-camera work will, on becoming possessed of one, naturally be eager to try it; and, although it would be better to sit down and look the thing over for yourself, and arrive at a correct understanding of the purpose and working of its different parts—in fact, thoroughly make yourself master of its mechanism—yet no great harm will come from rushing off and trying it at once, beyond, perhaps, spoiling a few plates and indulging in the luxury of a few mild observations on some people's stupidity, especially hand-camera makers, and then sitting down and going through the directions and looking over the camera, and finding the fault was all your own, and which materially adds to your satisfaction *sometimes*.

Studying the Camera—Some Reminiscence.

This question of studying the camera and its working is a matter of far greater moment than at first would appear. The whole movements (if it have any) must be so understood and practised that they become a kind of second nature, and it is also necessary to work with system; for instance, it is better to change each plate immediately after the exposure, and then at once set the shutter ready for the next picture. By this means you avoid exposing twice on the same plate. After a little practice, it is done mechanically and as a matter of course, and there is no trouble on that score. I remember in my early working a hand camera going off one afternoon to Greenwich and taking the boat to Blackfriars for the purpose of getting barges sailing. Well, it was a day in the week when even barges seem to go on strike, and the result was only one was met the whole way; but it was a beauty, and, after getting everything ready while she was in the distance, I fixed myself in the bow of the steamer and waited. It is exciting work sometimes this waiting. You cannot tell which side you will pass her on, and the element of uncertainty makes it enjoyable enough when things come right. On this occasion I had judged matters correctly; the distance between us was rapidly narrowed; one look at shutter and focussing lever, to see both were set right, and then the camera was held up, the picture composed on the finder a second, and the barge was near enough. And what a picture! The sun shining brilliantly behind the top sail, throwing masses of dark reflections in the water, relieved by touches of glittering light. The moment had arrived! Shutter released, and much joy reigned in the breast of yours truly.

The safety shutter inside camera was next to do its duty while setting shutter again, and on tenderly proceeding to carry out the necessary movement, I found it had faithfully been doing it all along. Never having been opened, and not having been coated with a sensitive film outside, but a good coat of black varnish, the picture had passed away, and its shadow also, instead of remaining on the trusty plate eagerly waiting behind that blackened door to receive it. I studied that camera in the evening in a desperate mood, *but to some purpose—that mistake never has happened again.*

Work with System.

Study the mechanical arrangements of your hand camera and work them with system, always doing the necessary movements immediately after each exposure, and rid yourself of one trouble—*uncertainty*—and leave your mind free when called upon to arrange and take a picture. You will find, if aiming at the best results, you require every atom of undivided attention devoted at the moment to securing the picture desired, whether it be animals (human or otherwise), marine, or pure landscape.

The knowledge of, and command over, your instrument is a matter of grave importance, and cannot be neglected without paying the penalty of frequent and needless failures. Hand-camera work is difficult enough, and to obtain good technical results is not the simplest thing in the world; it behoves one to do everything possible to minimise the chances of failure.

Well, we have got it all off by heart, and after putting some plates in, out we go into the park or lane, and, behold, some sheep are being driven along. A good light, suitable surroundings—everything promises well. We choose our standpoint, all being ready, shutter being set, &c., we wait until they are getting near enough, and then the question is, Where shall we hold the camera?

Where shall we Hold the Camera?

There are two things we must be certain of. First, holding it without movement during exposure; and, secondly, so that we can see the finders plainly. Now, where is the position most likely to succeed in both these points? After trying all methods, I prefer holding it to one's chest (like this); it enables you to see the finders perhaps better than in any other position; you are able to get a firm hold of the apparatus, and by holding your breath during the short time taken up with the exposure, run little or no risk of movement.

There are other ways advocated—under one's arm by the side. This method, personally, I do not like, as I cannot get so clear and convenient a view of the finders. You may now understand my reason in advising that finders should be as large as possible; it is a matter you will find have a serious effect on your results if not attended to. One last word. Great and unremitting care is needed in holding the camera steady, movement of a slight character being sufficient to spoil what otherwise might be a perfect production. It is almost entirely a question of practice and care.

We will assume, please, you saw the composition on your finders satisfactorily, and made the exposure, and probably repeating the operation on other subjects. And, now we are back at home, and, naturally enough, desirous of seeing the wonderful results this new method of working is to give us, so for the the dark room and the developer. What is this to be?

The Developer.

Personally I must confess at present to sticking to the dirty but useful old friends, pyro, ammonia, and bromide, and the use of a little common sense. I should not presume to talk to you about development, many of of you having, no doubt, forgotten more than I ever knew upon the subject; but this, and this alone, I may say respecting development of

* Continued from page 59.

hand-camera plates. Go for the detail, and keep back density—that can always, and at any time, be obtained. Having got out such detail as may be desirable, then go for density.

I have tried within the last few days flashing out the detail by using amidol stock solution diluted to six times its bulk with water, and one drachm of ten per cent. ammonia added as accelerator—getting density by using stock solution full strength afterwards. This promised so well that I shall experiment further with it, trying other alkalies, and redeveloping with pyro and ammonia for density.

Whatever developer is used, the method should be the same—detail first and then density, and thus produce negatives worthy of platinum or carbon printing. On this question of printing, the thanks of all amateurs are due to Mr. Willis for placing in our hands such a delightful process as his new cold-bath platinum paper, which is simplicity itself to use, both in printing and developing, and the results obtainable charming. I can strongly recommend any and all of you who may not have done so yet to try it.

The notion entertained by many that negatives produced when working rapid exposures are only suitable for gelatino-chloride emulsion, and that class of paper, is quite erroneous. Use a rapid plate, develop for detail and then density, get a good cold-bath platinum print, and you have something to look at with pleasure now and in after years if you are lucky enough to be able to keep it.

(To be concluded.)

A VISIT TO MESSRS. MORGAN & KIDD'S COLLOTYPE WORKS AT RICHMOND.

On January 30 a large number of members of the London and Provincial Photographic Association accepted the invitation of Mr. F. de P. Cembrano, the President of the Richmond Camera Club, to witness a practical demonstration, to the members of the latter Club, of collotype, under the superintendence of Mr. R. L. Kidd and his manager, Mr. Berghaff. After a very courteous welcome by Mr. and Mrs Kidd, and inspection of many fine examples of the work as exhibited in the showrooms, all adjourned to the large new building adjoining, the aspect of which (filled as it was with a magnificent plant and machinery, comprising all the latest improvements, and all the machines at work, under the guidance of a large staff of busy workers) went far to prove the assertions of some of the gentlemen present that Messrs. Morgan & Kidd, by their business enterprise, had placed themselves well abreast of anything of the kind in existence in this country.

In introducing the subject to the gathering, Mr. Kidd gave the following description of the working of the process:—

"An ordinary quarter-inch plate glass is ground on one side with the finest emery powder. It is then thoroughly cleaned, and well washed with water to get rid of the emery powder. When dried, it is coated with a substratum composed of solution of beer and silicate of soda: some prefer sugar and water instead of beer, but our experience is that beer is preferable. The beer should be slightly warmed before mixing it with the silicate of soda. Without the substratum the printing composition would not adhere to the plate glass.

"After the plate is carefully coated with the substratum it is then placed on a plate-rack, and allowed to dry spontaneously. When thoroughly dry, it is washed in clean water for a quarter of an hour, and then placed again to dry as before.

"It is then put into the drying oven, perfectly levelled, and heated up to about 120° Fahr. It is then coated with a bichromated solution of gelatine and water, which must be of the same temperature, viz., 120 Fahr. This must be done with the greatest care to avoid dust particles, and secure a perfect and even coating. It is now left to dry for about two hours in a uniform temperature, which should not exceed 125° Fahr., care being taken to avoid draught or any unevenness of the drying, which would cause markings to appear in the printing of the plate. There are some workers who dry them in a temperature of 150 Fahr., but our experience is that this temperature is too high, and the results are inferior; the higher the temperature the coarser the reticulation or grain will be, and this would interfere with the delicacy of detail.

"We may point out that the printing from a coarse-grained plate is much easier than from a fine-grained plate, though the results are inferior. The coarse-grained plates are more used for commercial printing, as a much greater number of prints can be pulled from the plate. The finer-grained plates are adapted for high-class illustrations.

"There are many formulæ, and every collotyper has his own pet formula; there are a great number published in the various photographic papers.

"A formula which will give good results by carefully working is as follows:—

Middle hard gelatine	100 parts.
Water (distilled)	1000 ,,
Bichromate of potassium	22 ,,

"Some workers prefer bichromate of ammonium instead of the potassium salt; in this case only twenty parts of bichromate of ammonium should be taken.

"When the plates are thoroughly dry they are allowed to cool down gradually and are now ready for exposure in contact with the negative, which must be reversed, except where the reversal of the image is of no consequence.

"The negative is placed in an ordinary printing frame. The collotype plate is then brought into contact face to face with the negative under heavy pressure, and exposed by day or electric light in the ordinary way. The right exposure is known by examining the image through the back of the plate glass until all details show in a light brown tint.

"After the exposure is completed the plate is washed in clean water until all the bichromate has disappeared. This is known by the absence of the well-known yellow tint of the bichromate salt.

"It is then allowed to dry spontaneously at an ordinary temperature. When dry it is ready for the power machine or hand press, but it is advisable, if possible, to keep the plate about two or three days; the gradation and half tone would be found more perfect.

"After placing it in the printing press it is necessary to moisten the printing surface with a solution of glycerine and water, which is generally called the etching solution. The parts where the light has not acted the gelatine will absorb more moisture; where the light has acted the gelatine has more or less hardened, and will resist the etching solution. It is kept on the plate about fifteen minutes, and then taken off with a sponge and blotting-paper. The plate is then inked up with a gelatine or leather roller charged with stiff, greasy ink, similar to the lithographic process. The parts where the gelatine has absorbed the etching solution now refuse to take greasy ink, whereas in the parts upon which the light has acted the gelatine surface has hardened, and made them more or less insoluble. They will not absorb the etching solution, and will readily take the greasy ink; in fact, the greasy ink is repelled more or less in exact ratio to the amount of light acted on the plate, hence we obtain an image in all the graduations true to nature.

"A considerable number of impressions can then be taken off the plate, but after each print the plate must be inked up again; and from time to time a fresh application of the etching solution is needed, otherwise the plate would gradually lose its power of repelling the ink. The printing part of the process requires a great amount of skill and experience to secure the finest results."

At the conclusion of Mr. Kidd's address the various details of the process were all gone through in a thoroughly practical manner, from grinding the plate glass with emery to coating the plates with substratum, the drying of same in the large, accurately levelled drying chambers, the coating with the bichromated gelatine, and the printing by means of negative films stripped from the glass. The films having been previously coated with a solution of three ounces Coignet's gelatine to twenty ounces water, with ten drops glycerine added, stripped very readily from the glass plates (especially prepared for stripping by Messrs. Morgan & Kidd). The electric light was used for printing, after which the etching process was gone through and various wrinkles explained.

Great stress was laid on the necessity for proper inking, Mr. Kidd stating that very many proofs were taken sometimes before a perfect result was obtained, but when the right effect was gained a very large number of impressions could be pulled without any variation in quality. He pointed out that, for specially fine work, the hand machine was most suitable; but, when using thoroughly good negatives, best results could be obtained by the larger machines, and as many as 100 impressions per hour could be produced when everything was in good working order. The leather rollers were used for inking the plates, and the gelatine roller for working the ink well over the impression.

At the conclusion of the demonstration Mr. Cembrano called on every one present to testify their thanks to Mr. Kidd for his hearty reception of them that evening, and for the large amount of instruction every one had received.

Mr. W. E. Debenham, on behalf of the visitors from the London and Provincial, endorsed Mr. Cembrano's remarks as to Mr. Kidd's kindness, and remarked on the public spirit shown by Mr. Kidd in making everything appear so clear and straightforward. Nothing at all appertaining to the process seemed to have been withheld, thus strongly contrasting with other so-called demonstrations, where an inquirer, seeking for real information, often had to go away no wiser than he was before.

Mr Kidd, in reply, said how pleased he was to have imparted any information that evening, and how gratified he was to observe the attention that had been paid to the various details by all present. He would, however, venture to remind gentlemen that, with all the instruction they had received that evening, perfection in the process could not be attained without a considerable amount of practice.

A NEW EXPOSURE TABLE.

Messrs. Elliott & Sons, of Barnet, are issuing a system of exposure tables for use with their plates, of which they say: "One of the leading features is, that we give four small illustrations of typical views, lettered respectively A, B, C, and D. A is a distant view without dark objects in foreground; B is also a view with distance, but there is heavy foliage in foreground; C is a near architectural subject; whilst D represents a moderately well-lighted interior. Portraits out of doors would require the same exposure as C, whilst portraits in ordinary rooms would require about the same exposure as D. The tables are calculated for stop *f*-32,

but an additional table is given showing at a glance comparative exposure for any other sized stop. To use these tables, all that is necessary is to compare the subject to be photographed with the illustration, note the letter marked on picture that appears to correspond with view, also note time of day and year; then, referring to Table 1, under group of columns headed with corresponding time of day, follow down the column headed with letter on illustration similar to view, until the line marked with required month is reached, when the approximate exposure will be found."

TABLE No. 1.

Showing approximate exposure for any given time of day and year for "Barnet" ordinary plates, with stop *f*-32, in bright sunlight. To find exposure for any other size of stop, see Table 2. A, Distant view without dark objects in foreground; B, Distant view with heavy foliage or dark objects in foreground; C, Near architectural subjects, or portraits out of doors; D, Well-lighted interiors or portraits in ordinary rooms.

Directions.—Compare subject to be photographed with illustrations, note time of day and month, refer to Table 1 under group of columns headed with corresponding time of day, follow down the column headed with the letter on illustration similar to view, until the line marked with required month is reached, when the approximate exposure will be found.

PLATINOTYPE UP TO DATE.

BEFORE the Bristol and West of England Photographic Association, on January 27, Mr. Ed. Brightman in the chair, Mr. Buchanan Wollaston, of the Platinotype Company, gave a demonstration of the working of the new cold bath paper, showing the great advances on the old hot bath process. The old paper could only be kept a few months, while the new cold process paper in proper calcium tubes will keep for a year, and the Company had some which had kept perfect for twenty-three months, being longer than any other printing paper.

A great advantage is the wide latitude in printing, so long as the paper is not under-printed, as even in a very much over-printed proof the result is quite under control by the help of glycerine in the developer. Moreover, a print can be artistically developed from a poor negative, by local manipulation. A complete black-and-white print (for copies of maps or plans) is obtained by the addition of a few drops of oxalic acid in the strong normal developer. Printing is carried out until the details in the highest lights are just visible in well-gradated negatives, and consequently printing is deeper than with the old hot bath paper. As long as any curl remains in the undeveloped print, after removal from the calcium tube, the paper is dry. The development with normal exposures of prints and normal solution takes thirty to forty seconds, but by adding glycerine and diluting solution with water, development can be much slower if desired. However long the print may be left in the developer, the image will not be damaged, but the acid clearing must be more thorough. No means of destroying the image except hot *aqua regia* has yet been discovered, and this proves permanency. The prints can be developed by immersion, by brushing developer on, and even by one's fingers rubbing the solutions on, as touching any part of a print prematurely with developer leaves no mark on finish of development. With plain strong oxalate developer, inky blacks and cold tones are obtained. By diluting developer with two parts of water, slightly warmer tones. By taking one part of oxalate solution, one part of glycerine, and two parts of water, and brushing solution on, much warmer tones. While by rubbing glycerine all over print first, and still further diluting the oxalate glycerine solution and using brush, the richest and warmest tones are obtained.

To keep print flat during development, pour glycerine on a vulcanite slab or sheet of glass, rub all over, and place print face upwards on slab, smooth down, and it will stop there. Should the sky print through with a thin negative, rub the sky and other high lights in print with glycerine, brush on developer as usual, and the whites will be pure after clearing in acid baths. Hydrochloric acid (which must not be "commercial," but water-white) is better than citric acid, as the latter is hard to wash out of the paper. Platinotypes print three times as fast as albumen in summer time, and twice as fast in winter. Thin negatives should be printed under pale-blue glass, and this produces bright, plucky prints. To get brilliancy, keep solution in motion with brush on print, and blot off after clearing and washing. To secure breadth in a flat print, brush foreground over with strong solution, middle distance with weaker, and far distance with still weaker solutions. To get soft effects from a hard negative, take one part water, and nineteen parts glycerine, paint over print, which will absorb water, and develop as usual. In this way half-tone can be secured from a negative which has none. The glycerine must be free from an admixture of citric acid, as sometimes what is sold as pure glycerine by chemists has as much as thirty per cent. of citric acid in it. The acid wipes out the image as the clearing bath would if print were placed in it before development. Pictures dry a little darker than they appear when wet, and this should be allowed for at the end of development.

LOUTH AND DISTRICT PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Louth and District Photographic Society's Exhibition was opened on Thursday afternoon, January 26, to the invited guests of the Society, when there was a large attendance. The arrangements were carried out by the Hon. Secretaries, Mr. S. F. Clarke and Mr. Herbert C. Bentley, who were materially helped in their arduous duties by several members of the committee. The pictures represented all departments of photographic skill. In addition to a large non-competitive exhibition, to which most of the best-known photographers of the day contributed, there was a members' competition for which Mr. S. F. Clarke announced that thirteen members had entered. The Judge's awards were as follows:—Silver medal (given by Mr. Mark Smith), Mr. H. S. Forman; 2nd prize, Mr. E. H. Forman; 1st certificate, Mr. Herbert C. Bentley; 2nd certificate, Mrs. Fawssett. Mr. E. J. Wall, the editor of the *Amateur Photographer*, who acted as Judge, added the following to his award:—"The average quality of the work was decidedly high, and if the other two prints by 'Ominon' (Mr. O. Burdett) had been equal to *A Rift in the Clouds* (another of Mr. Burdett's) the set would have been very near the first best."

The Exhibition is said to have been a great social and photographic success, the chief credit therefor being due to Mr. and Mrs. S. F. Clarke, whose efforts on its behalf were unremitting.

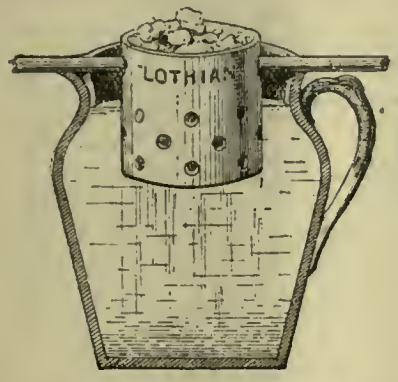
Our Editorial Table.

The "Reliable" Ventilator.

Mr. Henry Jones, 11, Albion-street, Coventry, has sent us a sample of a ventilator he has introduced for fixing in photographic dark rooms for keeping up a supply of fresh air, much needed in some of the little stuffy places in which many photographers are compelled to work. It consists of a mill-board oblong case about a foot in length, an inch in thickness, and three and a half inches in width, with a row of holes on the two opposite sides permitting free ingress and egress of air without the possibility of light being transmitted, this being ensured by a longitudinal division piece inside. It is attached to the door or a partition in the dark room by flanges at each end, a space being cut in such to correspond with the holes in the ventilator. He recommends that one should be fixed near the ceiling and another near the floor.

The "Lothian" Rapid Solution Jar.

Mr. A. H. Baird, 15, Lothian-street, Edinburgh, sends us a new rapid solution jar he is making. Its principle is similar to that brought before the London and Provincial Association some time since by Mr. W. M. Ayres, who, as a practical man, advocated it strongly



Mr. Baird's jar is of white porcelain, perforated with holes in sides and bottom, and is of such dimensions as to be easily suspended in the mouth of a jug or jar of water, as shown in the diagram. To use it, all that is necessary is to place therein the crystals, such as hyposulphite of soda, that are to be dissolved, and lower it into the water. One cannot speak in too high terms of the utility of this simple piece of apparatus.

Messrs. Thomas Illingworth & Co., the enlargers, who have lately removed from West Hampstead to more commodious premises at Willesden, have sent us a view of their new house. The picture is a good example of Messrs. Illingworth's technical skill.

Messrs. C. & W. Wimpey, of Goldhawk-road, of whose artistic floral and landscape backgrounds for enlargements we have previously spoken in a favourable sense, have submitted to us a specimen of their work in water-colour painting on ivory from photographs. The results are charming and artistic.

RECENT PATENTS.

APPLICATIONS FOR PATENTS

No. 963.—"Improved means for Colouring and Tinting Photographic Prints. E. Hooker.—*Dated January* 16, 1893.

No. 989.—"Improvements in regard to Washing and Draioing Racks for Photographic and other purposes." F. T. Parsons.—*Dated January* 17, 1893.

No. 1000.—"A Photographic Hand Camera." H. Gamwell and C. Gamwell —*Dated January* 17, 1893.

No. 1065.—"Improvements in Coin-operated Photograph Machines." P. van W. Welsh and W. F. Freeman.—*Dated January* 17, 1893.

No. 1151.—"An improved Photographic Camera." G. I. Spalding and R. L. Hawkins.—*Dated January* 18, 1893.

No. 1192.—"Improvements in the production of Photographic Images." H. K. Tompkins.—*Dated January* 19, 1893.

No. 1195.—"Improvements in Grooved Metallic Strips for Boxes for Carrying and Storing or Packing Photographic Plates and other Plates, and for other like purposes, and in the method of, and tools for, making the said Grooved Metallic Strips." W. H. Dugard and G. H. Dugard.—*Dated January* 19, 1893.

No. 1581.—"Improvements in and relating to Photographic Cameras." W. Watson.—*Dated January* 24, 1893.

No. 1684.—"Improved Coin-freed Apparatus for Exhibiting Photographs, Pictures, Advertisements, and the like." F. J. Cocks.—*Dated January* 25, 1893.

No. 1696.—"Printing Photographic Plates." E. A. Basebe.—*Dated January* 25, 1893.

No. 1965.—"Improvements in and relating to Frames for Holding Plates or Films in Photographic Apparatus." E. A. Veltch.—*Dated January* 28, 1893.

,, 11	Hull	71, Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

January 26,—Mr. Walter D. Welford in the chair.

The Hon. Secretary read a letter from Mrs. Bedford thanking the members for their expression of sympathy with her and her family in the death of Mr. W. Bedford.

Platinum Toning on Ilford "P.O.P."

Mr. Lorrimer drew attention to the following remarks in the January number of *Photographic Scraps*:—"We have frequently expressed an opinion that P.O.P. prints toned by this method were not satisfactory in result. There was an absence of purity in the whites, and a general degradation over the whole print that we did not admire, and which seemed to us to indicate a general stain rather than a deposit of platinum on or in substitution for the silver. We tested prints made by every formula which has been given for platinum toning, and found *that absolutely no platinum was deposited on the image*. Prints made by others were tested in the same way with the same result." Mr. Lorrimer went on to say that he had exposed some pieces of the Ilford printing-out paper to light until they were thoroughly bronzed, and, having washed them, placed them in a platinum toning bath, and subsequently treating the print with nitro-hydrochloric acid, obtained a precipitate of platinic chloride, which showed that platinum must have been on the image.

Mr. A. Haddon inquired whether there was a possibility of the platinum being substituted for the silver. The Platinotype Company were not able to use gelatine for sizing their paper in consequence of the combination of platinum with the gelatine, one-fiftieth of a grain being sufficient to give a deep shadow over a square inch. Most probably there was not half that amount deposited on the whole of the print. It was extremely difficult to substitute platinum for silver. In boiling down residues, they might have a certain combination of potassium chloride and platinic chloride which might escape detection.

"Photographing Paintings by Artificial Light."

Mr. W. E. Debenham read a paper on this subject (see page 68), showing

several prints from negatives made by the light or an ordinary petroleum amp.

In the course of the discussion which followed,

Mr. W. H. BARNES said that for copying paintings it was sometimes advantageous to use a medium isochromatic plate in preference to the rapid, the question of time being not of much importance.

In reply to a question, Mr. DEBENHAM said he did not advise taking old oil paintings from a different point of view to what they were painted, unless one could have sufficiently powerful light to get a great distance from them.

Mr. BARNES said the colour of the yellow plate used was most important, as it made the light so much slower. He would recommend a plate of a selected yellow-red tint.

Mr. P. EVERITT observed that some samples of yellow glass acted in different proportions compared with gas and artificial light.

Mr. R. BECKETT asked whether different glasses should be used with different paintings?

Mr. DEBENHAM thought the same glass was required throughout. As to the disadvantage of two lamps for lighting the picture, a painter painted so that his picture looked all right from the side in which he had painted. He had often used two or three ordinary tin-backed lamps, and the common oil obtained from the oil shops at sixpence a gallon. He did not recommend having more light on one side than on the other of the painting, but he would get such a distance off as to obtain even illumination all over. Many people got better results by artificial light than by daylight.

Mr. ARCHER CLARKE said he had found a tendency to under-expose oil paintings by daylight, and thought that with some pictures the lumps of paints would show as black shadows in the print, and therefore he considered a light both sides advisable.

Mr. J. S. TEAPE asked Mr. Debenham whether he obtained proper density by development alone?

Mr. DEBENHAM replied that he did not at all require to intensify negatives made by artificial light.

After further discussion the meeting terminated.

Hackney Photographic Society.—January 24, Mr. Charles W. Hastings in the chair.—Mr. Carpenter presented a number of his lantern slides to the Society. Mr. Reynolds presented the Society with an album. Both gentlemen were thanked. Mr. LEWIS MEDLAND then gave a lantern lecture on the Zoo. The lecturer explained that the slides were nearly all from hand-camera negatives, here and there supplemented by drawings of animals by Buffon, which (latter) caused great amusement. A composite picture of a lion in Epping Forest was funny. All kinds of animals were spoken of by Mr. Medland, who has travelled a great deal, and consequently the lecture was the better rendered. When at the Zoo, Mr. Medland was especially favoured, and has been successful in obtaining some capital negatives of the animals there and of some now dead and gone; such as Jumbo and Sally were shown. The lantern was manipulated by Mr. A. S. Newman, assisted by the Hon. Secretary. From the question box—1: "Can Alpha paper be toned after fixing and drying?" It was said that Mr. Howson, at a previous meeting, said, "Yes, it could be." Question 2: "Is it necessary to varnish a negative previous to retouching?" Mr. R. BECKETT said, "Do all the retouching, and varnish after, then mend any defect on the varnish."

West London Photographic Society.—January 24. The evening was devoted to Mr. H. N. King's paper on the *Royal Palaces of England*, illustrated by over 100 lantern slides, the quality of which evoked great admiration. Owing to the greatly increased pressure of business on the time of the Hon. Secretary (Mr. Bennett) he has been obliged reluctantly to resign office and Mr. W. S. Rogers (Assistant Secretary) has taken over his post, Mr. J. Stein filling the post of Assistant Secretary. Mr. Rogers' address is 13, Addison-road, Bedford Park.

Bath Photographic Society.—January 25, Mr. Austin King (President) in the chair.—Mr. W. PUMPHREY gave an illustrated lecture on the Channel Islands. By way of preface he said his photographic slides were all reduced in the camera (wet collodion) from half-plate gelatine films. Only by the means adopted he thought it possible to secure some of the pictures to be shown. He then proceeded in his well-known felicitous style to display and explain a number of pictures representing views on four of the principal islands, some of which were obtained with difficulty and some personal risk.

Liverpool Amateur Photographic Association.—January 26, Mr. A. J. Cleaver (President) in the chair.—Fifteen new members were elected. The President announced that a series of lectures and demonstrations had been arranged, which would take place every Thursday until the middle of April. Two prints were exhibited by Mr. Rogers, a member of the Association, showing the great difference obtainable from the same standpoint following out the principle of tele-photographic lenses. Messrs. Ross's twin-lens hand camera was exhibited and fully explained by Messrs. Sharp and Hitchmough. The prizes gained at the 1892 annual competition were presented to the successful members.

Newcastle Photographic Association.—January 24, Annual Meeting, Mr. Alexander S. Stevenson, J.P. (President of the Association), presiding.—Mr. Thompson, in the absence of the Treasurer, submitted the financial statement, which showed that the balance in hand at the beginning of the year was 3*l.* 18*s.* 9*d.*, and, after paying out during the year 31*l.* 16*s.* 6*d.*, there is a present balance in hand of 5*l.* 9*s.* 6*d.* The report was adopted. The Hon. Secretary (Mr. Edgar G. Lee) read the annual report, which stated that the Council again had pleasure in being able to congratulate the members on the continued and increasing prosperity of the Association, the membership now standing at 168, being an increase of forty as compared with the previous year. The meetings, both outdoor and indoor, had been much more numerously attended. The acquiring of new premises at the Art Gallery undoubtedly constituted one of the most important events in the history of the Association, and the Council hoped that, with the increased facilities for useful work which it now possessed, the Association would continue to progress in the future. Outdoor meetings had been held at Stocksfield, down the Tyne, and Naworth and district, and on the whole were well attended. The Council, in conclusion, expressed their extreme regret, in which the members would join, at the loss the Association would sustain by the removal of the President (Mr. Stevenson) from the district. The report was adopted. The result of the election of officers was then announced as follows:—*President:* Mr. J. Pattison Gibson.—*Vice-Presidents:* Messrs. Alexander S. Stevenson, J.P., L. Sawyer, M. Anty, and H. G. Ridgway.—*Council:* Messrs. W. Parry, W. P. Brewis, J. Watson, J. H. Robinson, G. L. Snowball, T. O. Mawson, J. Kirkwood, L. Williamson, W. E. Cowan, and G. Hall.—*Treasurer:* Mr. Frederick Park.—*Secretary:* Mr. Edgar G. Lee.—*Assistant Secretary:* Mr. James Brown.

Tunbridge Wells Amateur Photographic Association.—January 26, Annual Meeting, Mr. E. R. Ashton in the chair.—The Treasurer presented the accounts, and the Hon. Secretary read the report, both of which were satisfactory. The following gentlemen were elected officers for the ensuing year:—*President:* Mr. F. G. Smart.—*Vice-Presidents:* Rev. A. T. Scott, Messrs. E. R. Ashton, and George Lewis.—*Committee:* Messrs. J. W. Morgan, A. W. Pearson, and E. Catchpole.—*Auditor:* Mr. W. E. Brampton.—*Treasurer:* Mr. B. Whitrow.—*Secretary:* Mr. Joseph Chamberlain. The CHAIRMAN then said he had a pleasant duty to perform. They were all agreed that the time had arrived when they should recognise the valuable services the Secretary (Mr. Joseph Chamberlain) had rendered the Association, and he had much pleasure in handing him a gold watch on behalf of the members as a mark of esteem for the indefatigable way he had conducted the arduous duties of the office. The SECRETARY said he wished to thank them all for their handsome present, and for all the kind things the Chairman had been good enough to say about him. He was very proud to feel that anything he had done for the Association should meet with such unanimous approbation. The watch in years to come would remind him of the kindness and consideration he had met with from all the members, and he thought there were few Societies so fortunate in having a patron like Sir David Salomons and a President like Mr. F. G. Smart, who took so much interest in the actual working of the Association, and which was one of the main secrets of its success, coupled with the great cordiality that existed between himself and the other officers, to whom he tendered his best thanks for their kind co-operation in the work which had been carried out, and he again thanked them for their kind present, which he should always value. It was a gold keyless watch, having the recipient's monogram on the back, and on the dome was engraved, "Presented to Joseph Chamberlain by the members of the Tunbridge Wells Amateur Photographic Association in recognition of his valuable services as Hon. Secretary, 1893," and it had a Kew certificate, having been tested there. Letters had been received from Sir David Salomons, regretting his inability to be present, and from the President, and all regretted the cause of his absence, and wished him a speedy recovery to convalescence.

Edinburgh University Photographic Society.—A meeting was held in the Secretary's room, Bristo-street, on the evening of January 20, at which Dr. LOGAN TURNER delivered a technical lecture, illustrated by slides and the lantern. The subjects were: Series 1, comprising surgical cases from the patients; 2, microscopic slides; and, 3, naked-eye specimens. At the close he was awarded a hearty vote of thanks.

FORTHCOMING EXHIBITIONS.

February 7, 8	.....	Rotherham Photographic Society. Hon. Secretary, H. C. Hemingway, Rotherham.

FOX TALBOT'S PHOTOGLYPHIC PROCESS.

To the EDITOR.

SIR,—My attention has been called to a notice of my father's photoglyphic process at page 506 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the present year, from which it would appear that a fact which I published in 1878 has failed to become generally known. This was the latest and best method which he devised for producing a grain, or, as he termed it, "an aquatint ground." The earliest method was by the use of crape, as described at page 513 of the ALMANAC, which I think he termed a photographic veil. The powdered resin was an improvement on the crape. There were other methods tried, but the one to which I

refer was within my knowledge, though not published by him. He must have devised it after taking out his last patent, and would not allow me to divulge it, under the impression, I suppose, that it might possibly be included in some future patent. I took the earliest possible opportunity of making it known after his death, which opportunity arose in my having to complete for Messrs. Low & Co. the Appendix A of the second edition of the translation of Tissandier's *Handbook of Photography*. At page 372 of that Appendix, after noticing the powdered copal or resin method, I said, "This method of producing a ground, however, was uncertain and troublesome, and was superseded by a much better and very ingenious method, discovered since the enrolment of the specification in 1858, and never yet published. Common resin and camphor are dissolved in chloroform in proportions which may be varied. At the same stage of the process as before, namely, when the plate bearing the photographic image is removed from the copying plate, some of this solution is poured upon it. The chloroform immediately evaporates, leaving a film of resin and camphor on the surface of the gelatine. The plate is then warmed over a spirit lamp, which causes the camphor to evaporate, leaving the resin in minute particles adhering to the surface of the gelatine. This method ensures a much more even distribution of the resin than the former."

According to the greater or less proportion of resin to camphor, the ground was, I believe, coarser or finer. There were occasional small explosions of the camphor vapour during the plate-warming. You have yourself seen the best results of the photoglyphic process of date 1866, and I doubt if those results could have been obtained without the employment of the above method. Also, my father's latest practice was to employ, not steel, but copper plates, and to have them afterwards coated with steel. I am not sufficiently familiar with the present use of photographic words to know whether a *cliché* would be understood to mean a positive transparency in contradistinction to a negative. It is, of course, essential in the photoglyphic process that the exposure should be under a *positive* transparency.—I am, yours, &c., C. H. Talbot.

Lacock Abbey, Chippenham, January 29, 1893.

DETERMINATION OF PLATE SPEEDS.

To the Editor.

Sir,—Mr. G. F. Williams, in his article on this subject last week, goes out of his way to attack the accuracy of actinometers similar to the one associated with my name.

Allow me to point out that, as far as I am aware, such actinometers *never have been* "seriously put forward with the hope that we could recognise them as even approaching what we seek in a standard," the standard referred to being an exact light standard for a standard speed system.

The purpose for which such actinometers have been so extensively and successfully used for the past three years is to estimate the value of daylight falling on the subject as a guide to the length of exposure to give a plate. For this purpose hundreds of practical photographers, including some well-known names among the "older race of photographers," have found the use of a bromide of silver actinometer far more reliable than the old rough and inexact method of estimating light by the eye, aided with experience.

A very small amount of investigation shows that sunlight, as it reaches the earth, varies in its properties from time to time quite as much as many artificial lights vary from average sunlight. It is plain to me that an artificial light will have to be used if a standard system of speed determination is desirable, and I should be the last to advocate the use of an actinometer in this connexion. With a reliable standard light the amount of light received by the plate should certainly be judged by the standard of time, and not by the readings of an actinometer, which, however accurate, would be a useless complication.

Of course, this artificial light should be as alike as possible in its spectrum to average sunlight.

Mr. Williams' statement with regard to supposed errors caused by the use of actinometers, that "it is at all times possible to multiply the error ten times or a hundred times," is absolutely untrue.

If an actinometer is used as a guide, either for time of exposure or for speed of plate, and there is an error in the estimation of light of, say, 25 %, the resulting error in the time of exposure, or in numerical speed of plate, will be 25 %, no more and no less, unless error from some other source is introduced.

Surely it is unnecessary to point out that an error of one second in a four-second exposure, is identical in value with an error of ten seconds in a forty-second exposure, and the same thing applies to speed numbers.

I do not think Mr. Williams does justice to the importance of Messrs. Hurter & Driffield's investigations. It is very easy to pick out the weak parts in their method as now applied (I have done it several times), but it is only right to recognise that they were the first to point out the way in which the graduation sensitiveness of a plate could be ascertained, and their method, although perhaps in some other form, is certain to be utilised in the standard method of the future.

It will, in my opinion, be necessary to recognise that the quality which we sum up in the word "sensitiveness" is a complex one, and cannot be accurately expressed by one numerical value.

Just as Warnerke's system made the mistake of presuming that the *density-giving* speed of a plate is all we want to estimate, so Hurter & Driffield wrongly presume that the photographer only wants to know the *graduation* speed of a plate.—I am, yours, &c., Alfred Watkins.

Hereford, January 28.

THE PHOTOGRAPHIC SOCIETY'S LATE EXHIBITION.

To the Editor.

Sir,—Permit me to register a complaint as to the management of the late Exhibition of the Photographic Society of Great Britain of your city. The circular sent out promised that wall space for foreign exhibits would not be charged, but that the Society would *frame* and *hang* such exhibits free, and then return them after the Exhibition closed. My own experience will be, doubtless, concurred in by the many whose photographs were treated in a manner similar to that accorded mine. On arriving in your city, I naturally called at the Exhibition to see the display, and draw my shortcomings by comparison with the work of better photographers than myself. Imagine my feelings to find, after searching a long time in company with a friend, my pictures thrown loosely in a so-called portfolio with numerous other foreign contributions, and the whole lot so fingered and thumbed over as to be a disgrace to any collection. To add insult to injury, instead of returning my contribution in the wooden case in which they were sent well packed with tissue separators, I received them from the Express Company roughly tied together with a piece of cord, and the edges of the cards all broken and cut, thus finishing the ruin so well in hand when I left them in London. Performances of this kind are not apt to induce foreign contributions, particularly on the part of those who, like myself, attended the Exhibition and witnessed the manner of "*framing* and *hanging*" the Society performed.—I am, yours, &c., Robert E. M. Bain.

515, *Pine-street, St Louis, January* 16, 1893.

EXHIBITION RULES.

To the Editor.

Sir,—Recent events and discussions have conclusively demonstrated the great need which exists for reform in the rules of photographic exhibitions. Photographers of all schools are agreed that the system of classes, and the distinction between amateur and professional, are arrangements both undesirable and unnecessary. Yet each new prospectus which comes to hand reveals the same antiquated rules; only one exception has come under my notice, viz., the rules of the Fillebrook Athenæum Exhibition, with which I have the honour to be connected. We are, therefore, so to speak, pioneers in this direction, but I am convinced that it will not be long before our example is generally followed. The encouraging letters which have come to us, quite spontaneously, from several well-known workers, and the numerous applications for entry-forms, show that the new principles meet with general approval, and prophesy for us a most successful show. This being the case, one is inclined to wonder why other exhibition committees have not adopted similar conditions. It would certainly be interesting to know the reasons for their reluctance to relinquish the old traditions.—I am, yours, &c.,

Leytonstone, Essex, January 30, 1893. Joseph W. Spurgeon.

WOODEN TRAYS AND PORCELAIN DISHES.

To the Editor.

Sir,—In reply to Harry W. Newton, I have used all the solutions named without any "peeling off." I may add, the preliminary varnish coating should be more to satisfy the absorbent qualities of the wood used—*not* to leave a bright surface—*one* coat of enamel might do if this could be laid on evenly. The way to make the trays of *permanent* use is, however, to see them properly rinsed out every night after use, being put away *dry*.

With regard to the *glass* bottom trays, my experience is limited, but shellac varnish mixed into a thin paste with prepared chalk and run well round the edges might answer; melted paraffin wax may be used with advantage.—Yours, J. Pike.

Leicester, January 30, 1893.

To the Editor.

Sir,—Mr. H. W. Newton will find paraffin wax ironed well into the wood, using a heated smoothing iron for the purpose, much better than varnish or paint.

Large trays can also be lined with ordinary oil cloth of the white marble kind. Glue with the woolly side next the wood, fold the corners, and don't cut the cloth. Let the edges of the cloth lap over the outside of the ends and sides, fastening them with a row of tacks.—I am yours, &c., Williams Kennan.

35, *Dame-street, Dublin, January* 30, 1893.

To the EDITOR.

SIR,—As I have for years gleaned much useful information from the JOURNAL and THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, let me explain for the benefit of your readers how I repaired a valuable porcelain dish. These dishes are only lightly glazed, and are not hard baked, and may be drilled with the tang of a three-square file; and the way to commence to mend such a dish is to first make up a good fire, let the dish lay in front until it gets quite warm, then smear the edges with Prout's elastic glue, get all as hot as possible, and bring the parts together, and keep them so until quite cold and set. Now make the tang end of a file in the form of a drill, harden this, do not temper, press the point into the dish, and it will be found to cut easily through the enamel; use a little water. Work this drill gently until a hole is bored quite through the dish. The boring is sooner done than one would think. Now make another hole at the other side of the crack, then take a bit of copper wire, soften by getting it red hot in the fire, and pass this through the two holes, and gently make a twist on the under side of the dish. Do this wherever it is needful. This having been accomplished, take a hot poker, not hot enough to burn the elastic glue, but to melt it into the holes and cracks. Having made it waterproof and wired the parts together, let all get quite cold, then gently scrape off the surplus elastic glue, and your dish will, if it has been mended with judgment, last, as mine has done, for years. Elastic glue may be bought at ironmongers, leather dealers, &c., and is known as Prout's Elastic Glue, 1*d.* and 2*d.* per stick.—I am, yours, &c.,

J. H. AINLEY.

426, *London-road, Lowfields, Sheffield, January* 30, 1893.

THE BENEVOLENT.

To the EDITOR.

SIR,—Will you allow me space to state that, although the Committee of the Benevolent arranged at the last meeting reported to hold the Annual Meeting on February 3, it has been found impracticable to do so? The Annual Meeting will therefore not be held till Monday, February 20. The usual notices will be sent to all subscribers.—I am, yours, &c.,

Memorial Hall, E.C. H. SNOWDEN WARD, *Hon. Secretary.*

AMIDOL.

To the EDITOR.

SIR,—I have had my attention drawn to a mistake in the amido formula I gave at the meeting on January 10, at the Photographic Society of Great Britain. I do not see how I managed to miss it, as it was very careless on my part not to notice it, as the formula as given would not work, so I want you to please publish what I say. On page 95 of the Society's *Transactions* it says carbonate potassium (5 per cent. solution), but what I said, or, anyway, intended to say, was potash solution, 1 to 5, viz.:—

Potash carbonate	1 ounce,
Water	5 ounces,

which is very different, being a 20 per cent. solution. I can only say I am sorry I did not see the mistake, as it has led those trying the formulæ all wrong, for which I am to blame for not speaking plain.—I am, yours, &c.,

A. R. DRESSER.

Springfield, Bexley Heath, Kent, January 31, 1893.

ELECTRIC LIGHTING FOR RETOUCHING.

To the EDITOR.

SIR,—I, and no doubt many other readers of THE BRITISH JOURNAL OF PHOTOGRAPHY, was very much interested in the article by Mr. R. W. Harrison, on "Retouching with the Incandescent Light," on p. 826 of your issue for December 23, 1892. Can any reader inform me what the cost of a thirty-two candle-power lamp, complete with suitable battery, &c., for working it? also how many hours the battery would be likely to keep the above light going; the cost of having it recharged; also how long the lamp would last if used for, say, four hours a day?

I should also like to know if Messrs. Anthony's electric retouching pencil can be bought in this country, and what is its price; also where is it to be obtained, for, from what is stated upon p. 62 of THE BRITISH JOURNAL OF PHOTOGRAPHY for January 27, 1893, it appears to be much appreciated in several studios.—I am, yours, &c., J. T. HACKETT.

The Victoria Studio, Albert-street, Fleet, Hants, January 31, 1893.

THE NEW METHYLATED SPIRIT AND SILVER PRINTS.

To the EDITOR.

SIR,—After having used for a great many years ready sensitised albumen paper without any trouble, I have been blessed since about one year with the now universal trouble, I think, blisters. As different cures appeared in your esteemed JOURNAL I have tried them, but without any certain results up to date except with one, and that is alcohol. I have tried hot water without any good. I did not try boiling water, as, however an amateur can use it, it is rather out of the question for a toning of over 100 10×8 or 12×10 prints. I have tried borax in hypo with some fair results for some short time, but then found it only a cure for very small blisters, but not for large ones.

I was told a few drops of ammonia in hypo would cure; but no. The only good result was obtained with the new methylated spirit. 1. Now what I want to ask you is, Do you not think that this methylated spirit may in time act injuriously to the print? The smell remains even after the print is mounted, and then another trouble sets in. When dry there appears on *some parts* of the print some very dirty marks, a kind of skim (or scum) as if touched with very dirty hands. These marks disappear almost altogether when rubbed off very hard with the hand. 2. What is it? 3. Will it injure the print?—I am, yours, &c., A. LEVY.

4, *Avenue Pinel, Asnières* (*Seine*), *January* 29, 1893.

PHOTOGRAPHING AT THE CHICAGO EXHIBITION.

To the EDITOR.

SIR,—As a good many inquiries have been made as to the regulations under which photographs can be taken of the grounds and buildings of the Chicago Exhibition, I should be much obliged to you if you would give publicity to the enclosed communication, which has been forwarded to me by the Chief of the Foreign Affairs Department of the Exhibition.—I am, yours, &c., H. T. WOOD, *Secretary.*

Society of Arts, John-street, Adelphi, London, W.C., January 30, 1893.

[Copy.]

"WORLD'S COLUMBIAN EXPOSITION, DEPARTMENT OF FOREIGN AFFAIRS,
WALKER FEARN, CHIEF.

"*Chicago, U.S.A., January* 14, 1893.

"*Sir Henry Trueman Wood,*
"*Royal Commission of Great Britain for the World's Columbian Exposition.*

"DEAR SIR HENRY,

"Replying to your letter of November 23, receipt of which was acknowledged December 12, I have now to enclose a copy of a communication, dated January 11, which I have just received from the Secretary of the Ways and Means Committee, and which gives the information you desire.

"Faithfully yours,
(Signed) "WALKER FEARN."

[Copy.]

"OFFICE OF THE WAYS AND MEANS COMMITTEE.

"(*R.*) *Chicago, January* 11, 1893.

"*To the Honored Walker Fearn,*
"*Chief, Foreign Affairs.*

"DEAR SIR,

"In reply to your communication of December 12, will say that same has been considered by the Ways and Means Committee, and I am instructed to inform you that at present no one is permitted upon the grounds to take photographs except the Official Photographer of the Exposition, and such persons as may care to use hand cameras which are fitted with single lens, and take pictures upon a plate not to exceed 4×5, and provided that they shall pay to the Exposition the sum of $2·00 per day for said privileges.

"The Exposition proposes to operate under this organization until the 1st of May, and it is not likely that it may be continued during the Exposition.

"The Official Photographer will be very glad to take pictures of such views as he may be requested by outside parties. These parties, of course, to pay for same at uniform rates, which have been established.

"Very respectfully,
(Signed) "S. A. CRAWFORD, *Secretary.*"

VARNISHING RETOUCHED NEGATIVES.

To the EDITOR.

SIR,—Can you tell me the best way of preventing the retouching from moving when it is varnished?—I am, yours, &c., IN A FIX.

[This subject is referred to in a leading article.—ED.]

A DEVELOPER QUESTION.

To the EDITOR.

SIR,—Mr. F. Miall gives, in the 1893 ALMANAC, a formula for a soda developer, thus:—

Anhydrous sodium carbonate	1 ounce.
Sodium sulphite	1 ,,
Water	20 ounces.

And ½ to 1 grain pyro to each ounce of above.

Surely the carbonate should not be *anhydrous*, one ounce of which is equivalent to 2·70 ounces of soda crystals! The usual soda developers—such as that recommended by the Ilford people, for instance—contain one ounce of *soda crystals* in twenty ounces of developer, whereas Mr. Miall uses, apparently, nearly three times that proportion of the accelerator,

i.e., he uses the equivalent of 2·70 ounces soda crystals against the usual one ounce.—I am, yours, &c.,

JOHN H. HIELD.

54, Dartmouth Park-road, N.W., January 25, 1893.

ANOTHER VALUATION.

To the EDITOR.

SIR,—The given particulars are 70,000 negatives in eighteen years, or about 4000 negatives a year. Expenses are about:—

			£
400 dozen dry plates, say,	... ...		45
£375 Cabinet at 15*s.*	5000 cabinet mounts	)	30
£475 Cartes at 7*s.* 6*d.*	15,000 carte ,,	)	
£850 (as given)			
35 quires sensitised paper	... ...		22
Six cheap workers, viz..	*s.*		
1 Negative Retoucher	30		
1 Printer	15		
1 Lady for waiting-room	15		
1 Lady Spotter ...	15		
1 Assistant Operator...	30		
1 Boy	5		
52 weeks wages at	£5 10	... ...	286
Rent and taxes (cheap) ...	... ...		40
Small expenses 1*l.* per week	... ...		52
Chemicals: gold, hypo, pyro, &c.	... ...		30
Paper, books, cardboards, &c.	.. ..		20
Yearly refurnishing	... ...		40
Coal, gas, water, &c.	... ...		20
Expenditure	... ...		585
Alleged business done	... ...		850
			265
Worth given by "R.S.V.P." = 1100*l.* at 4 per cent....			44
Real goodwill	... ...		221
Leasehold ...	... ...		?
Negative value, two years reorders, about		... ...	100
Valuation of fittings, stock, and furniture		... ...	?
Real value ...	... ...		?

Or, a business that does not pay is not worth a goodwill.—I am, yours, &c.,

OPERATOR.

January 23, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange 800 *carte-de-visite* mounts for a eight or nine-inch condenser.—Address L. WARD, 2, Station-road, West Croydon.

Will exchange eight-inch gas burnisher as good as new for whole-plate camera.—Address, J. BENNETT, 38, James-street, Swansea.

Wanted to exchange two microscopes (Dollond's) for 12×10 outfit.—Address, J. G. PAGE, 8, Richmond-gardens, Shepherds Bush, W.

Exchange 10×8 burnisher by Rock, Sheffield, for 5×4 rapid rectilinear.—Address, J. TAYLOR, 19, Castle-street, Dufftown, Banffshire.

Will exchange BRITISH JOURNAL OF PHOTOGRAPHY, over seven years, for half-plate or larger camera.—Address, T. MUIR, 43, Nethergate, Dundee.

Harlwich's *Photographic Chemistry* in exchange for Taylor's *Photographic Optics*.—Address, J. A. C. MURRAY, 3, Nightingale-terrace, Sutton, Surrey.

Wanted first-class lantern or hand camera for Halse's ten-guinea medical electric battery.—Address, ARTHUR PEARCE, 11, Waterloo-crescent, Dover.

Biunial (four-inch condensers), portrait lenses, dissolver, and jets, gas bag, &c., exchange for camera or lenses.—Address, H. ALLBRIGHT, 135, London-road, Croydon.

Stove, powerful and handsome, suit studio or public building, cost £20*s.*, exchange for half-plate camera, or photo sundries.—Address, H. ALLBRIGHT, 135, London-road, Croydon.

Will exchange burnisher, nine-inch roller, for a rolling press, or will make enlargements and finish in oil or black and white for same.—Address, A. HAMILTON, Artist, Kingsdown, Bristol.

I will exchange a 5×4 quick-acting portrait lens by Ross for a 7×5 optimus eurryscope, iris diaphragm.—Address, WILLIAMSON EMSLEY, Whitelands, Little London, Rawden, near Leeds.

Will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY from April 1890 to end of 1892 (141 numbers) for plain background or burnisher.—Address, C. GODFREY, 23, Lucas-road, Penge, S.E.

Will exchange an eight-keyed flute (by Monzani), silver keys and fittings, for a cabinet portrait lens by good maker.—Address, H. & A. FLOATE, Photographers, 330, High-street, Stratford.

Exchange for a 4D Dallmeyer lens equivalent value of the following lenses:—2B Dallmeyer; 1A Dallmeyer wide-angle lens, patent; a Grubb patent landscape lens.—Address, McISAAC & RIDDLE, Studio, Oban.

Will exchange large rapid 10×8 portrait lens for 9×7 Optimus Euryscope lens with Waterhouse stops, or 7×5 as as above with Iris diaphragms. Specimen of work sent.—Address, J. R. SMITH, Photographer, Little London, Rawdon, near Leeds, Yorks.

Wanted, instantaneous shutter to fit hood one and a half inches, pneumatic, Thornton-Pickard preferred, sound, in exchange for THE BRITISH JOURNAL OF PHOTOGRAPHY, 1892, unbound.—Address, B. BURSLEM, 2, Windsor-road, Kingston-on-Thames.

Will exchange a nearly new Russian iron magic lantern, with travelling case, fittings for oil or limelight; also French cabinet portrait lens, good for large heads, for Lancaster's half-plate 1892 or 1893 instantograph set.—Address, W. BOND, Bank Plain, Norwich.

Will exchange Harrison's patent head and body rest, and Scholzig's graduated bust vignette background and stand, both new, for half-plate Instantograph, or other outdoor set. Good pocket revolver taken.—Address, J. MAGEE, 30, Parma-crescent, Lavender Hill, S.W.

Camera 15×12, conical leather bellows, reversing swing front, three double dark slides, book form; exchange for first-class 10×8 camera, all movements, long extension, and three or four double dark slides.—Address, J. T. PICKLES, Hebden Bridge, *vid* Manchester.

Will exchange THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACS for 1869, 1870, 1875, and from 1877 to 1891; *Carbon Printing*; and Burrows & Colton's *Retouching*, for *Materia Photographica* and Burnbank's *Photographic Printing Methods*.—Address, R. MCF. MURE, 35, Underwood, Paisley, N.B.

Wanted, whole-plate Ross's or Dallmeyer's Universal rapid-symmetrical or rapid-rectilinear lens, in exchange for first-class whole-plate camera, square bellows, long extension, as new, three double slides, and tripod, total worth 5*l.* 10*s.* or 6*l.*—Address, J. T. PICKLES, Hebden Bridge, *vid* Manchester.

Wanted, safety bicycle, in exchange for magic lantern (four-inch condenser), balustrade and pedestal, four plate-glass shelves and brackets (brass), cork flower stand, cabinet burnisher, oak specimen frame, and three volumes of THE BRITISH JOURNAL OF PHOTOGRAPHY, 1890-91-92.—Address, H. MANISTRE, 5, Ithyl-street, Kentish Town, N.W.

Cabinet lens, by Derogy, two and three quarter inches in diameter, seven inch focus, exchange for Dallmeyer's 1e long; interior background, new, for another interior or good plush curtain; Ross's 10×10 camera, long focussing screw, for posing chair, two or more backs; traveller's Multum in Parvo walking-stick, patent, for pedestal or balustrade.—Address, J. HORTON, Central Studio, Caroline-street, Cardiff.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPH REGISTERED:

T. S. Hicks, Sheffield.—Photograph entitled, *John Bull and his Pal.*

G. S. D.—A single lens can be used in the manner and for the purpose you describe.

E. M.—The electric retouching desk can be obtained of Mr. C. A. Rudowsky, of Guildhall-chambers, E.C.

QUX.—We have had no experience in that class of business. Better consult some one conversant with the practical working of the system.

J. H. BOWMAN.—Mr. E. Dunmore has an article on "Lantern-slide Colouring" in this JOURNAL for November 4 last (see Supplement, page 10).

WM. FENTON JONES.—Metol is not, so far as we are aware, on sale in this country. Possibly Messrs. Fuerst Bros. would procure you a small quantity from Germany.

T. MOLTEN.—The most rapid lens for lantern-slide negatives is what is known as the instantaneous stereograph. It is a modification of the Petzval lens, and has an aperture of about *f*-3½.

MAY (Ayr) writes: "Would you kindly tell me in your learned correspondence the first day of spring in England?"—According to the almanacs, the first day of spring in England is March 21.

PRINTER.—Possibly Mr. Buchanan Wollaston's remarks on the subject in the present number of the JOURNAL will assist you. We have not heard of any previous complaints of granularity with the new paper.

SANDOWN.—Any view that is taken direct from nature can be made copyright, notwithstanding that it may have been photographed scores of times from the same spot and each of the photographs made copyright.

A. PEARCE.—We cannot account for your failure. We do not think there is any advantage in the use of recrystallised carbonate. Give us fuller details of your method of working, and we may be able to assist you.

A. J.—1. The addition of Venice turpentine to starch used for mounting is not likely to act injuriously on the photograph. 2. The frames can probably be had from Marion & Co., or any of the other dealers in photographic goods.

E. GOODFELLOW.—If, upon the addition of a little permanganate of potash to the water, the red colour of the permanganate is converted to one of brownish hue, then is the water contaminated with organic matter, and not fit for drinking purposes.

A. BEN asks: "Can you tell me how to put the gilt line on the outside of cut mounts, usually about a half an inch from the opening?"—The gold is put in with a ruling pen charged with gold paint. Gold paint ready for use is supplied by all artists' colourmen.

G. W. ANDREWS.—You had better get a manual of the carbon process, such as that issued by the Autotype Company. That will give you the information required. Having got a general idea of the principles of the process, you will then have no difficulty in producing carbon pictures.

ANXIOUS.—By no means go to South Australia, where we have reason to believe things are in a bad way. Possibly you would find South Africa a better locality in which to secure photographic or picture-frame-making employment. Ask your doctor if the climate would be suitable.

O. OSBORNE.—As cochineal colours, such as crimson lake, &c., are fugitive by exposure to light, and they were used in matching up the tint for spotting the prints and working up the enlargement, the fading, or changing of colour, after six months' exposure in the show-case, is fully accounted for.

J. H. G.—Eighteen or twenty inches will be a suitable focus for such a lens as you need. Not knowing the focus of your 9×7 lens, we cannot give you the measurements desired. With reference to the electric queries, Whittaker & Co. publish several cheap works devoted to this topic. Write for a list.

C. H.—One of the best papers to be had for the purpose—that is, the best an amateur can obtain in small quantities—is Whatman's or Hollingworth's rough drawing-paper. They have not exactly the surface of the sample enclosed, but the papers themselves are otherwise better suited for photography.

E. GREGSON writes: "Could you inform me of a recipe for imitation of ground glass for studio top and sides—one that can easily be cleared off in winter? I am very much troubled with the sun."—Make a mixture of starch paste and whiting, and stipple over the glass with that. It can easily be removed with water at any time.

RALPH.—1. What you say is perfectly correct. Every one knows that a clear white sky in a lantern slide is better than badly put-in clouds, hence there is no necessity to insert your letter. 2. Enlarged portraits, if they exceed life size, are very unsatisfactory. 3. Make an enlarged negative, and print either in carbon or platinotype.

CARPATHIAN.—We think that either of the cameras mentioned would suit your purpose quite well; but if we recollect aright, "A" is not adapted for a roll holder. Your supply of lenses is quite sufficient for every purpose. These is no difficulty in producing enlargements from films, any more than from glass negatives. We have always used No. 2.

LEGAL.—So far as we are aware, there is no special law relating to photographic studios. If premises are taken on a repairing lease, and a photographic studio is part of them, of course that is included, the same as the others, unless there is any special agreement to the contrary. If there is any dispute in the matter, better submit the agreement to a solicitor, as all is dependent upon its wording.

H. A.—1. If you will refer to page 776 of this JOURNAL for December 2 last, you will see we have an article dealing with cresco-flyma. 2. Hydrofluoric acid may be obtained of operative chemists; it is a common-enough article. 3. A saturated solution of hypo cannot be expressed in definite proportions, as the amount of salt the water takes up varies with the temperature. When the water will dissolve no more salt, then is the solution saturated.

D. MCKENZIE asks what amateurs usually charge their friends for portraits? He says he often takes the portraits of his friends, and they ask him for copies, and wants to know how much to charge so as to make a little profit on the work for his trouble.—In reply, amateurs make no charge whatever to their friends; if they did they would cease to be amateurs and become professionals in disguise, such as is our correspondent. In arranging his charges, he should be guided by the price lists of *bonâ-fide* professionals of his neighbourhood, with whom he appears to be competing.

P. SMITH says: "I am an old amateur, and am tolerably familiar with wet collodion, with which I was able to take very fair negatives. I have recently gone back to that process for lantern slides, though I never made any by it before. I get on very well, but the slides, when dry—they look all right while wet—are more or less opalescent in appearance. It is not fog. Can you suggest a remedy?"—This appearance is by no means uncommon. It can entirely be got rid of by varnishing the slides with ordinary negative varnish. They will then be the same as they appeared while wet.

A. W. NEAME says: "I am only an amateur, and was called from home for three weeks the day after making up a new acetate toning bath. When I went to use it a few days ago, the sides of the bottle were covered with a dirty, bronze-like coating, and there was a muddy deposit at the bottom of the bottle, and the prints will not tone with an hour's immersion. No prints had been toned in the solution, so the paper could not have injured it. Why is it in this condition?"—The reason is that the gold has, by some means or other, become reduced to the metallic state. Impure water, an imperfectly cleansed bottle, &c., may be the cause. A long exposure to light will also bring about a reduction of the gold.

COUNTRYMAN writes: "I have been consulted about supplying a dozen enlargements, 15×12, of a deceased person, one of a group on a little glass positive. They will require a great deal of working up by an artist to make them at all good, and this, I fear, will make them too costly for me to secure the order. I can make the enlargements myself, but it is the finishing that troubles me. Can you give me the benefit of your advice?"—We should suggest that an enlargement be made, say, twenty or twenty-four inches, and this be well finished by an artist. From this a negative should be made the size required, then the prints would require no work upon them. It is quite possible that some of the friends of the deceased would purchase the finished enlargement.

THOS. LAMBELL writes as follows: "Can you give me any information with regard to the enclosed print, and how I can restore it and about a dozen others like it to its original condition, which was that of an ordinary albumen print? The facts are these. A customer of mine, who has been travelling on the Continent, brought home a number of views mounted on cabinet cards, and I undertook to take them off and remount them in a scrap album. Three or four dozen came off all right as usual, but about a dozen, after soaking with the others, became opalescent in appearance like the enclosed, and, as you see, this hides the detail. These particular prints I noticed before I put them into water seemed to have a more artificial gloss than albumenised prints usually have. Any hints you can give will be appreciated, as I fear I shall get into trouble with my customer."—The print in question is not a silver one, but a collotype on "surfaced paper" that has been glazed with an aqueous solution of lac. The only treatment we can suggest is to remove the old glazing by soaking the prints in spirit, and re-glazing or varnishing them.

WEST LONDON PHOTOGRAPHIC SOCIETY.—February 7, Technical Social Meeting.

PHOTOGRAPHIC CLUB.—February 8, Members' Open Night. 15, *Home-made Apparatus.*

MR. WILLIAM TYLAR has removed to new premises at 41, High-street, Aston, Birmingham.

MESSRS. O. SICHEL & CO. have removed to new West End show-rooms at 47, Oxford-street, W.

WE also announce the death of Mr. Henry Dixon, the well-known photographer of Albany-street, in his seventy-third year.

WE are sorry to learn of the death of Mr. John Harmer, of Littlehampton, who for many years past was a frequent contributor to this JOURNAL and its ALMANAC.

HACKNEY PHOTOGRAPHIC SOCIETY.—February 7, Ladies' Night; *Amidol demonstration and Prize Slides.* 14, *Photographic Chemicals*, by W. H. Sodeau. 21, *Lantern-slide Colouring* (adjourned), by S. J. Beckett. 28 *Prize Slides.*

LEYTONSTONE CAMERA CLUB. — February 8, Lecturette, *The Optical Lantern: its structure and its uses*, by Mr. A. P. Wire. 15, Demonstration, *Lantern Slides and how to make them*, by Mr. H. E. Farmer. 22, Members' Lantern Evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—February 9, First Technical Lecture, *The Lens.* 16, *Demonstration of the Air Brush*, by Mr. W. H. Harrison. 23, Annual Musical and Lantern Entertainment. Ladies' night. Mr. J. Traill Taylor in the chair.

THE premises at Kingston-on-Thames, lately occupied by the Fry Manufacturing Company, will be sold by auction at the Southampton Hotel, Surbiton Station, by Messrs. Maddox & Son, at four for five o'clock on Wednesday, February 15.

MESSRS. ARTHUR SCHWARZ & CO. inform us that from this date they are the sole agents for the products of the photographic department of the Actien-Gesellschaft für Anilin Fabrication, Berlin, who are the manufacturers of Dr. M. Andresen's developers—eikonogen, rodinal, and diamidophenol.

ON Friday evening last, January 27, the Photographic Club gave an entertainment to the children of members and friends, which was numerously attended by the small people invited. The bill of fare included slides humourous and otherwise, singing, pianoforte-playing, ventriloquism, conjuring, &c. all of which gave unmitigated delight to the audience, each member of which, on departing, was presented with a parcel of sweets contained in a box having the form of a hand camera.

THE LONDON COUNTY COUNCIL AND BILL-POSTING.—The action taken by the London County Council in reducing the height of posting hoardings to twelve feet has had a widespread and disastrous result, and at a recent meeting of the Manchester branch of the Amalgamated Society of Lithographic Artists, Designers, and Writers, and Copperplate and Wood Engravers, it was resolved "That this meeting is of opinion that the restriction made by the London County Council is calculated to do a serious injury to business not only in London, but in many large establishments outside London."

WE are informed that the National Association of Professional Photographers will hold their second annual meeting at the Grosvenor Hotel, Manchester, Thursday, February 9. Chair to be taken at 7 p.m. by the President for the year, Mr. Thomas Fall of London. The Council will meet at 2 p.m. same day, and same place. Only members whose subscriptions are paid up are privileged to attend and take part in the proceedings. Important matters will be laid before the meeting, which it is hoped in the interests of the profession will be a large and influential one. Communications to be addressed to the Secretary, D. J. O'Neill, 47, Charlotte-road, Birmingham.

THE annual *conversazione* of the *employés* and friends of Messrs. George Mason & Co. took place in the Assembly Rooms, Glasgow, on the evening of Wednesday, 25th ult. With Mr. Mason as chairman, whose ability in a social function of this kind is well known, with Mrs. Mason's kind help and the aid of an energetic Committee, the success of the reunion was assured. "All went merry as a marriage bell." The music was excellent, the floor in magnificent order, and the forty couples who tripped the light fantastic till well on in the morning left with a decided sorry-to-part-happy-to-meet-again feeling. Songs were given during the evening by several ladies and gentlemen, Mr. J. L. Cox excelling himself in the delivery of "True till death" and "A warrior bold."

VALUE OF GOODWILL IN PHOTOGRAPHIC BUSINESSES.

An inquiry appeared in our correspondence columns a few weeks ago as to the value of the goodwill in a business at the seaside. In reply thereto one correspondent, on the data given, values it at from one thousand to eleven hundred pounds —or equivalent to about the stated profits for three years. Another correspondent estimates its value, practically, at *nil*. The discrepancy is great. Three years' purchase certainly seems a very high estimate for the goodwill of any photographic business at the present time, and we have little doubt that many photographers would be only too glad to dispose of their businesses on much easier terms than these.

The correspondent who gave the low estimate, last week, quotes figures, in a businesslike way, to substantiate his idea of the profits on a return, as stated, of 850*l*., and it must be admitted that he has not been over-liberal in the matter of expenses—wages in particular. The salaries of a lady for the reception-room and a printer, for instance, are only put down at fifteen shillings a week each, and a boy at five shillings. The computation leaves about 220*l*. only as profit—about the salary of a really good operator. If this return be accepted, it shows that the goodwill is not worth buying, as the profits do not exceed the salary a purchaser would receive as an *employé*.

Since the query first appeared we have made some inquiries amongst those we consider competent to give an opinion on the subject, and we find a great diversity of ideas amongst them. One and all, however, agree that, for an ordinary portrait business, anything like a three years' purchase would be quite out of the question, and that one year's profits, in the present depressed state of the profession, would, in some cases, be too much, and in others the stock, plant, furniture, &c., at a valuation, would be quite sufficient. One gentleman went so far as to say that there was really no marketable goodwill in a portrait business, as it depended entirely upon the artist himself. He asked where is the goodwill in the business of an R. A., although he may derive a large income from portraiture? The same might be said with regard to a medical practice. That is entirely dependent upon the doctor himself. Still there is a goodwill in a doctor's practice, but it is always estimated much lower than many other businesses—if a medical practice may be styled a business. With a business in marketable commodities, say a grocer's, for example, its success depends as much upon the *employés* as the principal, hence the goodwill in it is of a somewhat more substantial character than it is either in a medical or a photographic one. In estimating the value of a medical practice, we believe it is generally taken to be equal to from a year to a year and a half's receipts, but then it is usually arranged that the seller still continues nominally as a partner for a considerable time, to introduce the purchaser to the connexion. This system of transfer has also, in some instances, been followed in photographic businesses, though it is by no means general; but, where it is done, a far more liberal sum may well be paid for the goodwill than where it is not done.

As regards the value of photographic businesses, there is no actual standard to go by, and what businesses have realised in the past cannot be taken as a criterion, for it must be admitted that they are not, proportionately to the returns, worth now so much as they were some few years ago. Competion is keen, and prices are lower, while labour and material remain much as before. Hence more business has to be done to make a corresponding profit, and this involves a larger working capital. In calculating the worth of an old-established business, an average of the profits for the previous three or five years is usually taken; the last year is, however, really the most important for the purchaser's consideration. If its gross returns and profits are less than the preceding ones, it indicates that the trade has fallen off. If, on the other hand, it shows an increase, then it has greater value than in the other case. It is obvious that a declining business is proportionately less valuable than an increasing one, be the returns what they may.

In buying a business, the way it has been conducted should always be considered. It often happens that an enterprising business man starts a concern in a small provincial town, and, during two or three years, does an excellent trade and makes a *bonâ fide* good profit, as the books prove; but during the time he has by his energy, so to speak, exhausted the business —the inhabitants of the place have become so well stocked with portraits that only a limited number more will be required for years to come, particularly if the so-called club system has been a feature. This some purchasers have found out to their cost. Some businesses in pleasure resorts are largely dependent upon extreme energy for their existence, such as intercepting visitors and excursion parties in waggonettes and like conveyances on their way to neighbouring places of interest, photographing them, and then submitting proofs of the picture on the return journey, and thus obtaining orders for copies at a low price. A business of this kind, worked on what we have heard termed the "high pressure system," is not equal in value to one the returns of which are secured solely from sitters visiting the studio. Neither are the negatives so obtained so valuable as regards their demand for future copies.

Here is another point for purchasers' consideration. In

some country businesses, particularly branch ones, their management has largely devolved on the operator. Now, if such a business be disposed of, and, say, the operator opens one on his own account in the same town—not an unknown circumstance—the value of the original one will be greatly depreciated. A photographer when selling a business is usually bound by agreement not to be engaged in another within a certain radius; but that does not, of course, apply to any of his *employés*, and some of those may be better known amongst the customers than the principal himself.

In former times the stock of negatives was always an important item in a valuation, but we are told that they, except in the case of publication pictures, are not proportionately of the same value now, as photography has become so much more general and less costly. Therefore people, ladies especially, instead of ordering from old stock negatives, now prefer to have fresh sittings in more modern costumes. In the case of deceased sitters, too, it is usually the last-taken portrait that is preferred. All this tends to depreciate the value of stock negatives. Except in the case of celebrities, an old photographer remarked to us that a stock of negatives which had been taken over about two or three years may now almost be considered a white elephant, as they were scarcely worth the storage, and the glass they were on is worthless. A business in a quiet country town, which is entirely dependent upon the residents, is, of course, on a different footing from one at a fashionable watering-place, where its main support is derived from visitors.

In the foregoing remarks no attempt is made to fix a standard for the goodwill of photographic businesses; neither has allusion been made to what will be obvious to all as to the continued success or otherwise of a transferred business, namely, the relative merits of the vendor and buyer as artists, photographers, and last, though not least, as business men. The object has been to point out a number of collateral circumstances that should be taken into consideration in estimating the value of a photographic business in which portraiture is the principal feature. Our columns are open for further discussion on the subject.

STEREO-MICROGRAPHY.—II.

In the previous article on this subject last week we confined ourselves to the production of micro-stereographs by successive operations, and, without anticipating what we have yet to say, we may observe that the system is much simpler than can be adopted by any binocular means, although the latter possesses the advantage of simultaneous exposure. As, in viewing an object in a binocular microscope, only one-half of the light transmitted through the objective reaches each eye of the observer, so, in the simultaneous methods now to be described, no more than half of the light will reach the sensitive plate.

Probably the least complex of the various systems to be noted is one which, on an exceedingly minute and totally inverted scale, is analogous to the Wheatstone stereoscope. It is a method by which the two photographs may be taken either simultaneously or successively. It consists in mounting two small mirrors at a right angle to each other, and placing their point of junction in as close proximity to the posterior element of the object-glass as the mounting will permit. The light from the object on the stage, instead of passing on in direct lines, is deflected—one half to the right and the other half to the left, where the focus is received on the sensitive plate. The adjoining cut shows the principle of the arrangement.

We have not thought it necessary to draw the camera itself, or the stages; suffice it to say the former is merely a long, square, wooden box, to the centre of which is affixed the object-

glass, a quarter-plate dark slide fitting each end. We had the frame which carries the mirrors made so as to be capable of being withdrawn, for the twofold purpose of cleaning the polished faces of the mirrors when dusty and also of examining and placing the object by direct vision from above. To this end we had a hole cut in the top of the box in which to insert the tube of the microscope with its eyepiece. This was for facilitating the arranging and lighting of the object; the focussing was, of course, effected on the obscured glass of the cameras.

Although the arrangement here described permits of the simultaneous photographing of an object, this is really not at all necessary, as the subject will remain still *in perpetuo*, while with a good lamp a considerable period must elapse ere there is any change in the lighting.

Respecting the construction of the mirrors, which need not each exceed the dimensions of a postage-stamp, we have made them in three different ways—first, of speculum metal, which we cannot recommend on account of the time involved in giving them an absolutely flat and polished surface. However, if any one chooses to do so, let him in using this metal make allowance for grinding away a more or less considerable portion around the edges to allow for marginal error, for unless one is familiar with such optical work as involves the grinding and polishing of prisms, or with the polishing of flat steel in connexion with the watchmaker's art, in both of which the marginal rounding of a flat surface is avoided, errors arising from such rounding, although not readily detected by the eye, will seriously affect the accuracy of the enlarged image.

We succeeded better by silvering the surfaces of a small rectangular prism of exquisite flatness, and using this as the reflectors, but eventually decided upon forming an obtuse wedge by cementing two plates of flat glass and silvering them. This is what we recommend in preference to other reflectors for this purpose, and it does not require the services of a skilled optician in its construction.

Pieces of optically worked glass can be obtained at the philosophical instrument makers or through any firm who supplies that trade. It is not necessary that the glass be thin, but it must be flat. One edge of each piece must be bevelled by rough grinding, so that when the two are placed in V-fashion, and cemented together, the junction shall present a fine edge. The silvering of this is effected in the way so often described in the Almanacs of this *Journal*.

We have tried other methods for producing stereoscopic photographs, including the employment of the prisms and systems of Nachet, Wenham, and Stephenson, but have so far found the balance of advantages to lie with those now described.

"Given away with a Pound of Tea."—The *Birmingham Daily Mail* of Saturday last contains the following paragraph:—"The system of present-giving has been in operation in Birmingham tea shops for a long period, and various improvements in the system have been tried by enterprising proprietors. Quite the most original variation, however, is the one recently introduced by the manager of a large shop in the centre of the city. In lieu of the stereotyped vase or cradle, this original individual places his customers before a camera, and in due course well-finished vignettes are forwarded to them."

A New Bunsen Burner for Alcohol.—Herr G. Barshell has devised a new burner as above, which gives a higher temperature than that given by the gas-burner of this pattern. It is supplied through a tube from a reservoir placed about a yard higher than the burner, the supply being regulated by a screw-tap just below the air holes. It consists of a thick-walled tube fitted into an iron foot, the tube being divided horizontally into two parts. The lower part is filled with a metal network, and serves to vapourise the spirit. Just above the division are air holes similar to those in an ordinary Bunsen. A piece of wire gauze in the upper part of the tube assists in the production of a steady flame.

Strength of Acetic Acid.—Although this chemical does not occupy in many studios the important position it held in the old wet-collodion days, it is still of the greatest value in photographic work, and a ready means of estimating the strength of a particular sample would be useful. It is customary with the glacial acid to state its specific gravity; but we must point out that this is an entirely misleading method, for the specific gravity of solutions of the acid increases with the strength only up to eighty per cent. With still greater concentration the gravity begins to fall instead of rising. To overcome this difficulty, Herr E. Nickel takes the specific gravity as usual, then dilutes with water, and retakes the specific gravity. If it rises, the higher value must be assumed to be correct, but, if it falls, the lower.

Photographic Atmospheric Absorption.—Professor Schaeberle has been making investigations on the very important question as to the extent to which our atmosphere absorbs the sun's rays at various heights of the sun. His memoir on the subject is being published by the University of California, but meanwhile, has issued a table, which we append, giving the final results. The absorption is expressed in photographic magnitudes, and must be added to the unknown atmospheric absorption at the zenith.

Zenith Distance.	Photo. Absorption.	Zenith Distance.	Photo. Absorption
5°	0·00	50°	0·44
10°	0·01	55°	0·56
15°	0·04	60°	0·71
20°	0·07	65°	0·89
25°	0·11	70°	1·12
30°	0·16	75°	1·45
35°	0·21	80°	1·94
40°	0·28	85°	2·68
45°	0·35	90°	5·00

How to Use a Bunsen.—It is singular to notice how few of the many experimenters in the habit of using this popular burner are acquainted with the proper mode of using it. In the first place, we may say that the cheapest form in which it is sold is of very limited use, for the great value of the burner is in its economy; but it cannot be economically employed unless there is power to lower the flame when needed. This lowering cannot be done beyond a certain point unless the air holes are supplied with an adjustment for cutting off a portion of the air supply. The secret of use is to reduce the air supply as the gas is lowered; then, if there be insufficient air, the flame will be white; if the air is in excess, the flame will "blow down"—that is to say, ignite inside the tube at the point where the gas issues—under which circumstances it is useless. It should then be extinguished for a moment, the air supply lessened by the regulating band that encircles the air holes, and relighted. This is a simple thing, but by no means generally known.

Photographic Drolleries.—Some of our older readers will remember the rage there was some quarter of a century ago for depicting such subjects as a man shaking hands with himself, carrying his head on a plate, and suchlike apparently superhuman appearances, the effects being obtained by making two exposures on one plate by means of a pair of hinged shutters meeting in front of the plate. Our ever-lively contemporary, *La Nature*, published a year or two ago engravings from photographs of similar effects produced by other means, and a week ago had two pages of illustrations from still other photographic vagaries of the kind. We have a man wiping a sword, and just in front of him a decapitated criminal, whose head lies on a block; next is a headless body, with knife in hand, surveying, if it were possible, a table bearing a head on a plate; in another we find a man wheeling a barrow holding the head only of a giant; still another has a full-length representation of a gentleman in outdoor costume bottled up in a huge glass bottle, and so on. The chief difference between the old and the new mode of producing these effects lies in the use of a black background for the most important portion of the subject, which thus permits of an exposure being made a second time without fogging the first impression, though the sitter may have moved away entirely, and perhaps reseated himself opposite the place occupied by his first pose. For the rest, the writer states that the system employed is that of a deep natural black obtained by the open door of a darkened space, combined with screens cleverly arranged within the camera between the lens and the plate. This, he says, is the surest means of obtaining the desired effects with the greatest sharpness and without the junctions being visible. The screens should be placed from about an inch and a quarter to an inch and a half from the ground glass in the last folds of the camera bellows.

A "WELL" DEVELOPING DISH.

In these days of "one-solution" developers used over and over again for a succession of plates, there are many ways in which we may with advantage modify the old system of development, and one of the first is in the style of dish employed. The old form of dipping bath has been recommended in place of the dish; but, while almost its only advantage is the smaller surface of liquid it offers to the atmosphere, it is clumsy, and, owing to the necessity of a dipper is inconvenient in actual use. The "well" dish or bath, sometimes used in the old wet-plate days in place of the dipping bath for sensitising large plates, possesses numerous advantages over the ordinary dish at present used, while it is free from the faults already mentioned, being little bulkier than the vessel it is intended to supersede, and requiring no dipper.

There were two forms of the dish or bath in question, in one of which the "well" portion stood at a considerable angle with the rest of the vessel, the dish proper; and this, though it may possess some points of advantage as a sensitising bath, is, like the dipping bath, a clumsy contrivance for developing. The other form, which is to be preferred, consists of a flat dish somewhat longer than the plate it is intended for, and having the lengthened portion at one end covered in, so that, when the dish stands upon one end, a well is formed, in which the solution rests.

The advantages of this form of dish are numerous, and a few may be briefly enumerated. In the first place, if the same quantity of solution has to be used for several plates as is now the fashion, it is surprising how rapidly it decreases in bulk in pouring backwards and forwards into the measure from an ordinary dish, whether after development is complete or in order to examine the negative. With the "well" dish it is not necessary to pour the solution out at all, the dish is simply placed on end in the sink or other convenient position, where it may rest until required for another plate, and the negative lifted out to be washed and fixed. If constructed with a glass bottom, the negative may be examined for density by simply turning the dish up to the light, the motions required in examining the image and

recovering it with the solution being so quickly performed that there is far less chance of fogging the plate from exposure to the atmosphere and oxidation than when the solution is poured off into a measure, and there is no loss.

And then advantage in the rapidity of motion will be found in other than the one-solution system of development when it becomes necessary in cases of over-exposure or the reverse to modify the developer; the dish is tilted, the necessary quantity of bromide or alkali, as the case may be, is dropped into the well and the solution returned in a wave over the plate almost in less time than it could safely be poured into the measure in the ordinary way. Many similar points might be urged in favour of the well if it were necessary, but these seem sufficient to recommend it.

The fact alone of there being no diminution in the quantity of solution used, except to the extent of what clings to the surface of each plate, must add considerably to the uniform character of the results obtained. It would be idle to attempt to argue that the action of the solution is identical in the case of successive plates, since the very process of development reduces its energy, and adds to the quantity of restrainer it contains after each plate. Starting with a quantity of solution little more than sufficient to cover the plate, the loss of bulk when using an ordinary dish renders it necessary to augment the quantity with fresh solution after each development, and in this manner each operation is performed with a mixture of utterly unknown proportions. But where there is no loss, and consequently no necessity for fresh additions, the action of the solution may be expected to change in a regular manner; that is to say, it may be anticipated that each successive plate, supposing the exposures to have been equal, will take a little longer time to appear, to show its detail, and to gain density, than its predecessor. This being so, the operator knows perfectly well what to do, without any feeling of uncertainty as to whether the plate is under or over-exposed. With the well dish, and a fairly liberal volume of solution to commence with, the best possible chance is afforded of successfully developing half a dozen, or even a dozen negatives, with the least expenditure of material.

Until this dish becomes an article of commerce, for so far as I am aware it is not so at present, it will remain with those who wish to adopt it to use the home-made article, and fortunately it is not a thing that will severely task the skill of any ordinary amateur mechanic. Many photographers I know, both amateur and professional, already construct their own dishes from a variety of materials, including paper, cardboard, metal, glass, and wood, but for present purposes a combination of the two last seems the most suitable.

The sides of the dish should be of quarter-inch baywood or mahogany, dovetailed at the corners; the bottom of glass, and the covered portion forming the well, may be of any sort of thin wood prepared for fretwork. The corners should be preferably dovetailed, or, if that be beyond the skill of the amateur joiner, the ends may be let into a rebate in the sides and secured by means of screws. A deep rebate should be made to receive the glass bottom, deep enough for the glass itself, as well as a fillet of wood a quarter of an inch deep to secure it in place, and to allow the glass to stand clear of the table when in use. The cover of the well is simply laid on and fixed with small screws.

The woodwork if dovetailed should, of course, be put together with glue; but, if the rebate joint is made, it will be better to use white lead mixed with a little dry red lead, the whole thinned down with turps to the consistency of cream. The same may be used for putting in the bottom, and also for rendering the joints of the well cover water-tight. If the framework be put together first so as to find the proper places for the screw holes, it can be taken to pieces, the joints cemented and screwed together again, at once forming a perfectly water-tight junction.

Before, however, finally screwing together, the wood should be thoroughly impregnated with paraffin wax by repeatedly rubbing it in, holding the wood to a hot fire in order that the wax may be absorbed, or the paraffin may be cut in shreds and rubbed in with a hot flat iron. After the dish has been put together, the whole of the inside woodwork, and especially the joints, should receive one or o coatings of thick shellac varnish, the first being allowed to dry thoroughly before applying the second; or two or three coatings of good Brunswick black slightly thinned with turpentine may be applied in the same manner, and to the outside as well.

As regards dimensions, much will depend upon taste, but for convenience and symmetry combined, if the well be about one-fifth the total length of the plate and the depth of the dish be arranged so that it will hold the requisite quantity of solution comfortably, the conditions will be fulfilled. For instance, for $7\frac{1}{2} \times 5$ plate the dimensions I adopt are length nine inches, width six inches, depth one and three-eighths of an inch, the well cover extending one and a quarter of an inch all inside measurement. It is an additional convenience if a strip of glass is cemented across the bottom, inside, to form a rest for the negative and prevent its slipping into the well when the dish is raised.

W. B. Bolton.

CONTINENTAL NOTES AND NEWS.

Avoiding Reflections on Polished Surfaces.—A foreign contemporary remarks that the photographer who wishes to photograph objects of polished metal, porcelain, glass, &c., is generally troubled with surface reflections, which solarise parts of the negative and also reproduce images of surrounding objects, including sometimes the camera and the photographer himself. The best remedy given to obviate these reflections is the old one of smearing the object with suet or fat, a little of which placed on a piece of linen should be applied to the surfaces.

Blue-stained Negatives for Winter Printing.—In a recent number of his journal, M. Liesegang points out that, owing to the yellow stain of some negatives, printing through them in winter is often a matter of great difficulty, and he recommends the conversion of the yellow stain into the more actinic one of a blue violet. This may be effected, he says, by immersing the plate for a few minutes in an old combined toning and fixing bath, as used for aristotype paper.

Some Properties of Metol.—In the *Wochenblatt* Herr Lavroff, of St. Petersburg, says that metol hardens the gelatine film to such an extent that it requires longer than with other developers for fixing and washing. Notwithstanding the clearness of the solution, plates therein may be exposed to a candle light at a distance of fifty centimetres without fear of fog when the image has appeared and before development is complete. He tried the experiment with hydroquinone, but the plate was badly fogged. With metol and sulphite (without alkali) he covered up half of a thin image which had taken ten minutes to appear, for twenty minutes, exposing the uncovered half the while to candle light, without fog supervening, the latter holding good although the plate was left in the developer all night.

Another Method of Preparing Platinotype Paper.—We have from time to time indicated several formulæ for this purpose as published by foreign experimentalists, the latest addition being that provided by Herr Watzeck in a recent number of the *Rundschau*. Paper is coated with a solution of

Arrowroot	1 gramme,
Cold saturated solution of sodium oxalate	50 c.c.,

the solution being boiled until the sediment dissolves, and, according to the degree of porosity of the paper, being applied to the latter two or three times. For black tones the dried paper is sensitised in

Saturated solution potassium chloroplatinite	5 c.c.
„ double oxalate of soda and iron	8 „
„ potassium chlorate	3 drops.

For sepia tones the following quantities of saturated solutions are taken:—

Potassium chloroplatinite	5 c.c.
Double oxalate of soda and iron	4 „
Neutral oxalate of soda	3 „
Mercuric chloride	1 „
Potash chlorate	3 drops.

More chlorate increases contrasts and a smaller quantity of mercury

gives darker tones. The solution of double oxalate of iron and soda being sensitive to light, it should be preserved accordingly. Both solutions given above suffice for coating a sheet of paper 40 × 56 centimetres. For the best results the paper should be dried at a temperature of 35° C.

A Neglected Property of Gelatino-bromide of Silver.—At the meeting of the Société Française de Photographie on January 6 last, the following letter from M. Balagny was read:—"In THE BRITISH JOURNAL OF PHOTOGRAPHY for November 18 there appears an article on 'A Neglected Property of Gelatino-bromide of silver.' At the previous meeting of the Photographic Society of Great Britain, the President, Captain Abney, remarked that, 'if the gelatine film was more experimented with, there were no end of possibilities which would open up in photographic printing. It was sufficient for them to consider the behaviour of a bichromatised gelatine film when submitted to the action of light.' This is a remark which I submitted to the Société Française de Photographie nearly three years ago, and it is on that idea that I based a method of collographic printing which I use daily. When a film of gelatine containing a silver haloid is bichromatised, two great advantages are obtained over the old process of collography—greater rapidity and better facilities for inking. Since the English journal (THE BRITISH JOURNAL OF PHOTOGRAPHY) speaks of the matter, permit me to state that I brought the matter before this Society in the year 1890.'

Austrian Copyright Laws.—The Austrian photographers are up in arms against a movement to limit the time of protection to pictures produced by means of photography to a period of five years, and in a recent number of the *Photographische Correspondenz* Dr. Eder states that, having at different times been approached by photographers as to his views on the subject, he regards five years an insufficient time. He is, and always has been, of opinion that not only photo-mechanical positives, but all other kinds of photographs, should enjoy a longer period of protection, and he denies that he has ever expressed a contrary opinion.

Photo-micrography and Industrial Hygiene.—The Imperial High School of Photography in Vienna has, it is said, completed some photo-micrographic work of great importance to the hygiene of industry. It has been sought to study and determine the influence of metallic dust, &c., on the health of workmen. Microscopic examination was made of the several kinds of dust to be found daily in factories and workshops, and the High School, at the request of the authorities, took photo-micrographs of all the samples examined. The pictures, with explanatory text, have been published by the authorities. The negatives were taken by Herr Valenta, and comprised forty-eight photo-micrographs, which were reproduced in phototypy and are said to be of great interest to those studying the diseases of workmen contracted in their labours.

Common Salt in Mercurial Intensification.—Before the Société Française, MM. Torres Frères, of Mexico, lately brought an intensification process which allows the plate to be bleached with mercury without having been submitted to perfect washing after fixing. It consists in the avoidance of the yellow stain, which would thereby be produced, by placing the fixed plate slightly washed in a solution of common salt 1 : 100 for about half a minute. Intensification then proceeds as usual.

STATUARY PORTRAITURE—HOW MR. C. W. MOTES OF ATLANTA, GEORGIA, WORKS.

I RECEIVED to-day your JOURNAL of the 6th inst., in which I find your leading article describing the illustration in *Wilson's Magazine*, "Sisters of Bethany." I desire to thank you for your excellent notice and for your high endorsement of my effort to produce something out of the "threadworn paths" of photography. I assure you I appreciate your opinions of my humble effort, and will place a higher estimate on the picture than heretofore, and it stimulates me to make stronger efforts to advance. I have mailed to you an unmounted print from the original negative, which I trust will reach you safely.

In regard to your criticisms you are right, but I desire to say we cannot always control our subjects as to styles. If bangs are in style, they cannot be induced to pose without *bangs*, as was the case in this picture. The style of the dress I had to leave with them, and they insisted on short sleeves, and the one standing, on plenty of underskirts. I tried to persuade her to remove her skirts so as to get rid of the bungling drapery behind, and show her form by having the drapery cling, but she would not, so I had to do the best that could be done under the circumstances. The one sitting obeyed my suggestions, and I think did her part well.

I do not claim the grouping to be entirely original. I had frequently seen and studied an engraving similarly posed, and had it in my mind when I made this. I mention this, fearing some one might accuse me of claiming originality in the composition.

Now, a word as to my methods in making this class of work. For background I prefer black velveteen; it is important to have the nap run upwards, so that the reflection of light is prevented. Incline the ground from the light, and the result (if not over-exposed) will be almost clear glass. I have three widths in my ground, seams running up, and am never troubled with seams showing if, as stated, the ground is inclined slightly from the light. In order to produce satisfactory results, it is absolutely necessary to use a black ground; and, if by unavoidable circumstances there is reflection on the ground, it can be removed by the method you describe without giving the cut-out appearance, which will invariably be the case if made on an ordinary background, especially around the head. Again, when made on black ground, I have frequently removed all the ground with a knife cutting around the figure. Frequently parts of the drapery that may be objectionable can be cut away, and made to conform to the taste of the operator. In this case I use a very sharp knife to bevel the edges of the film, to prevent it printing too *sharp*. For the pedestal I use wooden boxes covered with muslin. Coat with glue, and, while wet, sprinkle with sawdust; when set, knock off excess, and paint with colour to suit taste to represent granite. I then paint name or title on box, and *shade* so as to represent the letters cut out.

In my exposure I work for the shadows with a strong diffused light. Time with great accuracy—too much time will sure to produce flatness; too little black shadows are very objectionable in this style and lose the effect of marble. I have taken the liberty to be rather lengthy, as there seems to be some misunderstanding as to the methods I use; so, in the event you have occasion to refer to the matter, you can condense such as suit your purpose.

Atlanta, Ga., U.S.A., January 27, 1893. C. W. MOTES.

[We have received the unmounted print of the group, which is excellent. From the number of communications we are having, we are warranted in surmising that statuary portraiture is a subject of considerable interest to professional photographers—in England, at any rate—and doubtless the practical details of working, with which Mr. Motes supplements our article of January 6 last, will be highly appreciated by them.—ED.]

JOTTINGS.

ON January 27 I remarked that I had often wondered whether the phenomenon of shearing stress could be turned to practical account, and I added that the same thought had occurred to me on the recent publication of Mr. Carey Lea's experiment proving that great mechanical pressure alone was sufficient to darken the silver salt. A writer in a contemporary publication says that on October 12 last *he* said, "the experiments pointed to new possibilities in the way of printing. A slightly photo-engraved plate may give a developable image by simple pressure." Now, any one having the least photographic knowledge can see that these quotations are not at all parallel; but, as the writer appears, from the context of his remarks, to be deluding himself with the grotesque belief that his pages are the source of my inspiration, and, notwithstanding that I studied and wrote on the phenomena of shearing stress shortly after Captain Abney published his experiments some years ago, I hereby make over to the writer in question the full, absolute, irrefragable, undiminishable honour of antedating me by three months in the suggestion that shearing stress or darkening by pressure might be useful for reproduction purposes. At the same time I regret that, having no time to dispose of in the habitual perusal of the periodical upon which his

literary and scientific acumen confers a distinction that requires to be much more widely known to be appreciated at its proper value, I had no means of discovering that modern knowledge had received this epoch-marking addition on October 12, a date which henceforth should be printed in red letters in every scientific calendar and almanac.

"It signifies nothing," plaintively proceeds the gentle scribe, "this perhaps unconscious assimilation of our matter, unless one has regard to the fact that an affected ignorance of even the existence of other photographic (*sic*) journals is a flattering unction much indulged in by our aged contemporary," &c., &c., and so on. I am unacquainted with the peculiarities of the process by which a journal, youthful or aged, "indulges" in "a flattering unction;" but it is quite plain where the shoe pinches. You "affect" ignorance of "other photographic journals," his amongst them, and so, because like a sensible Editor you do not give free advertisements to all or any of the obscure hangers-on to the coat-tails of photographic journalism, the dictionary is ransacked for such laboriously manufactured epithets as "unconscious assimilation," and a whole column of the valuable space of this self-styled "vanguard of technical progress and invention" is taken up with a laughably hysterical denunciation of you and all your works. "Well, well," as the burly farmer said when his wife and mother-in-law, as was their custom sometimes, gave him a good drubbing, "what matters? It amuses them and doesn't hurt me." And so you may say! But, alas! that the world should "know nothing of its greatest" journals, and that the "vanguard of technical progress and invention" is condemned to make the welkin ring with lamentations, because its more aged contemporaries will not fold it to their manly bosoms!

It is fortunately a curiosity of journalism that mud should be cast at the forty years editorial reputation of a paper simply because the jottings of an occasional contributor do not gain the approval of the editor of another journal, and I should not have ventured upon this rejoinder had I not been the unwitting cause of the screaming and foaming at the mouth in which your contemporary has indulged at your expense. But, besides this, I have another object in view, and that is to discover the actual writer and the cause of his animus. He commences some twenty lines of unprovoked and clumsy Billingsgate with this remark: "But, *of our own knowledge*" (these are my italics), "we have not the slightest hesitation in comparing the accumulated tomes of the above quoted journal" (that is, THE BRITISH JOURNAL OF PHOTOGRAPHY) "to a waste-paper basket of antique and ample build—the repository of an unequalled weight of cameristic verbiage," &c. I wish to direct the attention of the reader to the italicised passage. Such a degree of knowledge, especially when it is read by the light of subsequent remarks by the writer, implies an acquaintance with the "accumulated tomes" of this JOURNAL such as cannot be possessed by anybody save its Editor, or somebody who has been compelled to make a close study of those volumes for, let us say, bibliographical purposes. Again, the writer dubs himself "an energetic inquirer into photographic facts." What kind of facts, I should like to know; scientific or historical? I can scarcely believe that the deplorably immoderate language I have quoted is the utterance of any self-respecting editor, or that he could have been aware of the nature of the copy he was passing. It could only be the work of somebody who nourishes some private resentment against this JOURNAL and its staff; some disappointed would-be contributor; some lurking bandit, like the "English" journalist who was recently exposed in these pages for a series of underhanded attacks in an American paper on English photographic men and things; some "Talbot Archer," in fact, of whom I wish your contemporary every possible joy.

I am glad to see that Mr. W. Thomas, in his able and practical paper on *The Hand Camera and its Use in Picture-making*, emphatically challenges the contention of many writers that a finder with a hand camera is unnecessary and useless. Some users of a hand camera are, I know, fond of airing their cleverness by saying that they can tell or guess when the object, moving or otherwise, they are pointing the camera at is in the field of view; but in the former case a great deal of skilful judgment is required to ensure anything like reasonable certainty that the picture has not "passed the plate." As Mr. Thomas says, "finders are necessary if you desire to ascertain that your main object of interest takes its proper position." In hand-camera work all uncertainties should, as far as possible, be eliminated, and therefore I endorse all that he says on the subject. As well do away with a focussing scale in a camera of variable focus as a finder.

Mr. Chapman Jones, at the conclusion of his paper on mercurial intensification, points out that the success of his process of intensification with mercury and ferrous oxalate depends upon the removal of the hypo that may remain in the plate after washing, which he says can be done by soaking in an acidified alum solution. On the assumption that hypo alone is present, has it been demonstrated by experiment that the solvent powers of water are insufficient to effect its removal, or is the acidified alum necessary for taking out the silver hyposulphite, which is possibly present wherever the hypo is? Would Mr. Jones recommend acid alum in preference to peroxide of hydrogen as a hypo eliminator? In connexion with the stain caused by intensifying a film from which the hypo had not been thoroughly removed, it would be interesting to know whether the hypo *per se*, or sodium hypo and silver hypo, are the cause of the stain. If the presence of the latter is essential to the production of the stain, then imperfect fixation is at the bottom of the trouble, and a fresh bath and hypo is necessary, unless silver hyposulphite is soluble in acidified alum. It seems to me that our information on these points is very meagre.

COSMOS.

NOTES UPON THE USE OF AMIDOL FOR BROMIDE WORK.

WHILST it may be said of the use of pyrogallic acid for negative work that not one of its competitors has ousted it from the foremost position, it is still more true of ferrous oxalate that up to the moment no other reagent produces finer results for bromide work, or produces them more easily. The use of an acid fixing bath in place of a simple solution of hyposulphite of soda does indeed enable good results to follow the development of bromide paper by hydroquinone or eikonogen, but it only substitutes one great difficulty—the use of an acid clearing bath previous to fixing—for another, viz., the doubt as to the stability of prints made by its aid.

The use of an ante-fixing acid clearing bath has always appeared to me the weakest point of bromide work. I have never been able to see my way to advocate its use, although I am quite ready to admit the excellent results attained by its aid, and even tempted by the fatal facility of the means to resort to its aid at times. But, notwithstanding this inconsistency on my part, I regard as a distinct evil the practical necessity of its use to prevent an iron deposit and stain on the paper when the oxalate developer is used, for it is indispensable that this acid solution should be entirely removed from the pores of the paper and film before the picture is placed in the fixing bath. This complete removal seldom obtains in practice. It is true that by careful working a considerable degree of purity of colour may be secured without the ante-fixing clearing bath, but the results are more difficult to obtain, and hence I assume that it is largely used. My point—a strong objection to the use of an acid clearing solution before fixing—is admirably enforced by the printed instructions issued with a popular make of bromide paper: "All the acid must be removed, or fading of prints will result."

It seems reasonable, then, to welcome the advent of any developer which offers a chance of escape from this inherent weakness of the process of development by ferrous oxalate, and I tried a sample of amidol with which the agents in this country had supplied me. I must say that doubt possessed me on the ground of the somewhat fulsome praise bestowed upon the last new thing, which for negative work I feared less useful than pyro. Besides this, a one-solution developer always raises one's prejudices. Following a custom more honoured in the breach than the observance, I made up a quantity of solution strictly in accordance with the maker's instructions, and using a sample of sulphite of soda which they supply for use with their developer. This is an excellent idea, as considerable variations occur in different samples of sulphites, and if a caution were added to the instructions to use the maker's own sulphite, it would be better still. I did not meet with success with the solutions so weak as the makers recommend. The pictures were flat, and always appeared to be over-exposed. Temporarily, therefore, I abandoned making pictures, and, instead, exposed several pieces of paper behind a Spurge's sensito-

meter, a useful little instrument, which enables one to save much time in experimental work when it is doubtful in which direction success or failure lies. It was now quickly apparent that the scale of gradation was not marked enough. Intensity of deposit was lacking in the long exposures, and there seemed some indications of the action of light right up the scale, as if the developer were extremely active to the least-exposed parts—as, indeed, I think it is—and insufficiently so to the others. My experiments were interrupted at this point, and, as the bottle of amidol developer was accidentally left without a cork, I was able to observe that the action of the air for twenty-four hours was to slightly colour the solution, a state of things which might be expected with a one-solution slightly alkaline developer. It did not appear, however, to have lessened its developing powers, or to have rendered it liable to stain the paper—points which I noted with surprise.

Taking up the experiment again, I now tried the maker's formula undiluted. This stands as follows:—

Sulphite of soda	800 grains.
Amidol	80 „
Water	8 ounces.

Allowing for the increase in bulk by the addition of the solid constituents to the water, this approximates to an eight-grain solution of amidol.

In my earlier attempts this had been diluted with three times its bulk of water, in accordance with the printed instruction. With the stronger solution I obtained much better results. The deep shadows were richer, the high lights purer. But development was too quick; in fact, the picture rushed up and was over-developed "in a hurry." Compared with pictures developed with ferrous oxalate, I found the gradations of the negative rather steeper, by which I mean the print was more brilliant with the amidol than with iron. This I considered a very satisfactory feature, as a flat (over-exposed) negative had purposely been chosen to test this point. By slightly diluting the amidol solution, the gradation could be lessened, but one soon gets to a greyness of colour (which is to be avoided) by adopting this expedient.

With a correct exposure, which I have not found to *vary from that for iron developer*, the results now compared favourably with others from a ferrous-oxalate developer working in conjunction with an acid clearing bath. But development was too hurried and under little control, which the addition of bromide hardly improved. The results were, however, exceedingly brilliant and very pure and white.

Encouraged by the promising nature of the results, I made a series of experiments with the idea of making the developer more permanent in character before use, of rendering its action more deliberate (whilst still speedy), and last, and not least, of giving some control over the development. The result is as follows:—Divided into two solutions, for convenience in preparation and for storage, the acid sulphite and amidol makes a bright and clear solution, without deposit, and which I find keeps well. The colour of the deposit (in the picture) is at least as good as when the solution is prepared with sulphite of soda, I think better, and compares favourably with iron. The bromide does not seem to increase the exposure, and only makes development slow enough to be under reasonable observation and control, whilst it is still quicker than it is with oxalate, which is itself a quick-acting developer. The carbonate of soda solution is to be added *quantum suff.*, and should be used with discretion, but the amount of bromide restrainer removes all tendency to fog or veil, to which defect this developer, however, seems little subject.

Amidol Solution.

Acid bisulphite of soda	8 grains.
Bromide potassium	1 grain.
Amidol	8 grains.
Water to make	1 ounce.

Accelerator.

Carbonate soda	48 grains.
Water to	1 ounce.

For use, add a few minims (four or five) of the carbonate to each ounce of the amidol solution. The completed developer may be used several times, especially if the bulk of the solution be maintained by additions of newly mixed, fresh solution. This is a noteworthy feature of amidol. The general experience with other developers, and for all purposes, is that, for successful and certain working, a developer can only be used once. This is not my present experience with amidol. To sum up, amidol, in my opinion, is the most dangerous competitor of the iron developer for bromide work, and is well worth a trial. It promises to remove the necessity, and even the advantages, of an ante-fixing acid clearing bath. By increasing the strength of solution, much greater contrast can be obtained upon occasion than has hitherto been possible, and *vice versâ*. Of the comparative cost, I cannot yet speak. It does not reduce the exposure and it is not a dirty developer.

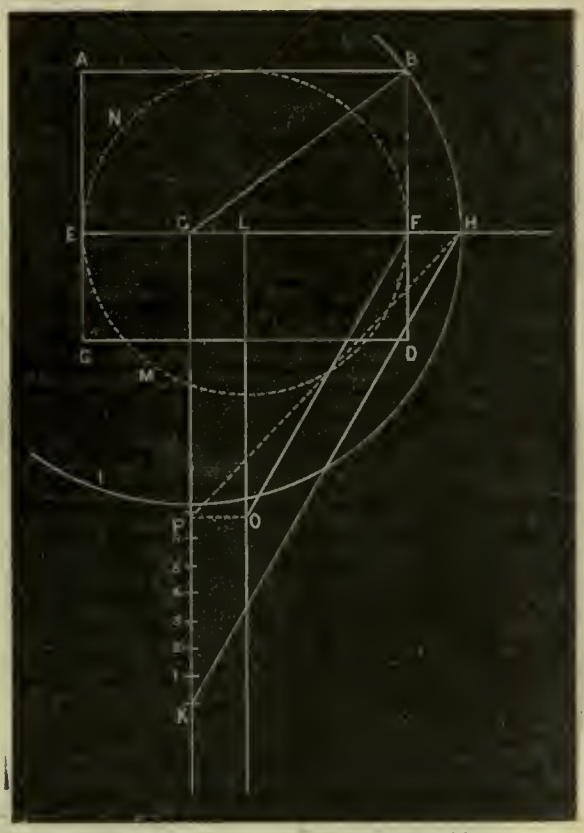
S. Herbert Fry.

CALCULATION OF THE ANGLE OF VIEW.

[London and Provincial Photographic Association.]

In the British Journal Photographic Almanac for this year there is to be found, for the first time, a table of natural tangents by Mr. A. Haddon, by which the photographer may calculate the angle of view included on a given plate by a given lens, or, conversely, the focus of a lens to include a given angle on a given plate. Unfortunately, the rules formulated by the author of the article accompanying the table are incorrect. As they may lead into error those who accept them without question, I offer this criticism and correction in the hope that the tables may thereby be made of value.

According to the first rule: for calculating the angle, half the length of the plate must be divided by the focus of the lens; the nearest natural tangent to the quotient should then be sought in the table, and the arc opposite it, multiplied by two, will give the angle.



A B C D. Picture plane.
E F. Horizontal line.
G. Centre of vision.
B H I. Base of cone of rays 60°.

By Mr. Haddon's rule:—
L. Centre of vision.
F M N. Base of cone of rays 60°.
H. Correct station point, or focus.
O. Incorrect station point, or focus.
P K. Difference, inches 6·93 about.

Angle G K H=30°.	30°×2=60°
„ G P H=44.	44×2=88
	Error 28

The error is, the direction to take half the length of the plate. To demonstrate this in a simple way, compare the procedure with that of a draughtsman, who wishes to make a drawing, in perspective, of a room twelve feet wide by ten feet high, to scale of one inch to the foot. In the diagram, E F is the horizontal line, which must be at the height of the spectator's eye—say, four feet above the floor. Suppose the centre of vision removed two feet to the left of the middle of the horizon. Next describe a circle to represent the base of a cone of rays including the picture plane A B C D, no more and no less. This

is done by taking the centre of vision G as centre, and the line to the farthest corner as radius. It is a rule in perspective that the line of direction shall be at right angles with the horizontal line, and terminate in the centre of vision. Assume the cone of rays to include 60°. The base of this cone is the circle B H I. The draughtsman could now determine the exact position of the spectator. From G, at right angles with the horizontal line, draw G K, the line of direction. By means of a protractor, connect H with K, so that the angle G K H includes 30°. G K is now the principal ray of a cone of 60°, and represents on the plan the distance of the spectator from the picture plane. This line is seventeen one-third inches long, very nearly. As the picture formed by a rectilinear lens is in true perspective, and conforms to the same conditions, it can be said that a 12 × 10 plate, with the centre of vision removed two inches to the left of the centre of the horizon, at a height of four inches, will include an angle of 60° at about seventeeen one-third inches focus.

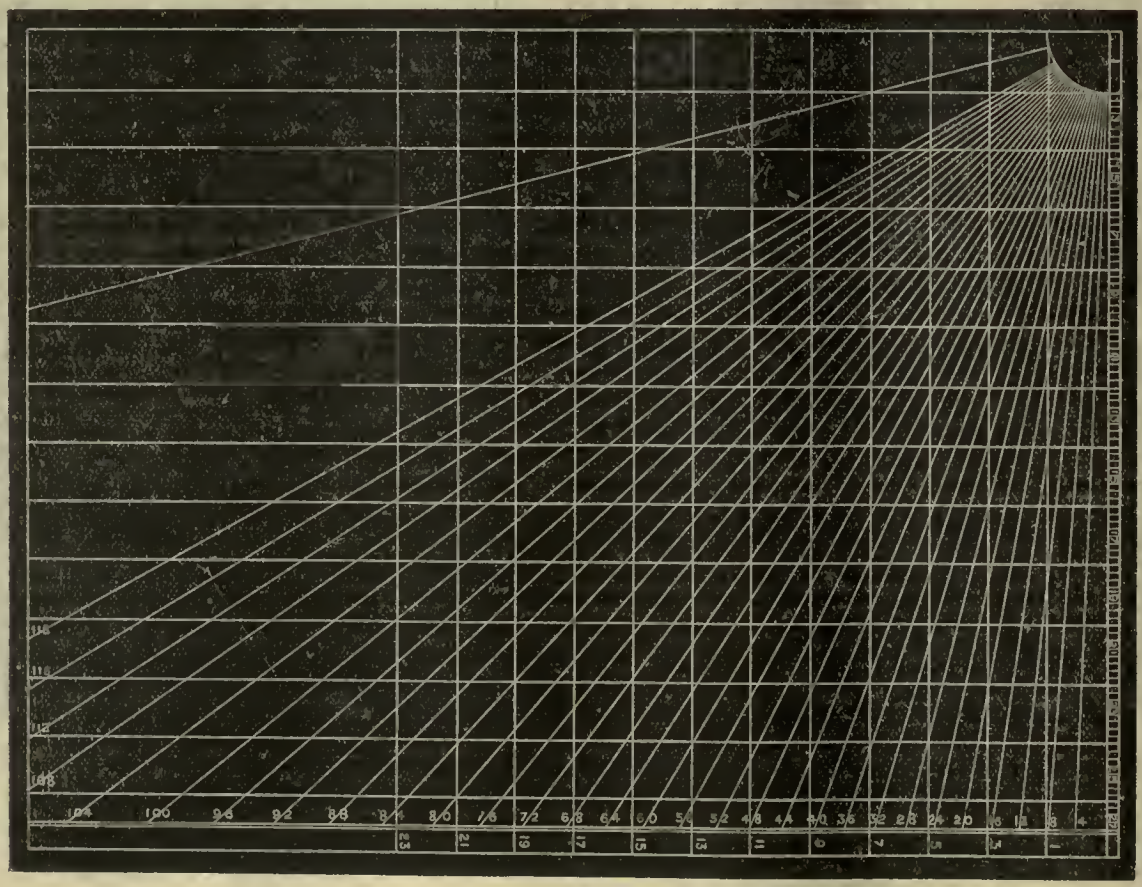
Next work the problem by the method of the article in the ALMANAC. Divide the horizontal line E F in half at L. With L as centre and L F as radius, describe the circle F M N. From L at right angles with F E, draw the line L O. With a protractor connect F with L O at an angle of 30°. The circle F M N is then the base of a cone of rays of 60°, and O is the station point. But the circle F M N does not include the whole picture, and the point O transferred to the line G K shows a minus distance of about 6·93 inches. The photographer consequently would have used a lens of about 10⅜ inches instead of 17⅓ inches focus. Connect P with H and measure the angle. It will be found that from this station point nearly 88° have been included instead of 60°.

book on *Pictorial Effect in Photography*, also warns the reader against the use of the centre of the picture as the centre of vision.

The worthlessness of the rule becomes more apparent when we apply it to pictures of equal length, but different height.

Take the series 12 × 4, 12 × 6, 12 × 8, 12 × 10. The rule would give all these different pictures as taken under the same angle, regardless also of the fact that the centre of vision might be different in each case, an assertion which is obviously incorrect. Take a twelve-inch line at ten inches focus. With the centre of vision midway, the angle included is 62°, but, removed four inches to the right or left, it is reduced to less than 57°. A line of given length may, therefore, include more or less angle, according to its position on the picture plane, as may be proved by the scale produced. This scale is divided longitudinally and latitudinally into spaces representing inches. From one corner, as centre, radii are drawn, representing the ninety degrees of a quadrant. The numbers from right to left represent inches focus, and those from top to bottom inches distance from centre of vision to extreme limit of picture, or farthest corner of plate. By means of this scale the angle of view, or focus of lens for a given angle, may be found without calculation for any picture, which method some photographers may prefer.

Having demonstrated the error in the rule, it will be seen the following correction must be made. The rule to find the angle of view should be:—Ascertain the position of the centre of vision; from this measure the distance to the farthest corner of the plate, and divide it by the focus. Seek the nearest natural tangent to this number in the table, and read off the corresponding arc. Twice this arc is the angle required.



The nature of the error will be found in the assumption of a fixed centre of vision, at the centre of the horizontal line, with the horizon as diameter of the base of the cone of rays. In the example given, the centre of vision was removed two inches to the left, therefore the radius L F was from the wrong centre and much too short. Artists rarely use the middle of the horizontal line as the centre of vision. They prefer to avoid it, because the centre of a picture is its weakest point. This may be proved by examining the pictures in our galleries, or, to come nearer home, consult the lecture before this Society by the late Mr. Norman Macbeth, printed in THE BRITISH JOURNAL OF PHOTOGRAPHY for January 6, 1888. Mr. H. P. Robinson, in his

To find the focus the rule should be:—Divide the angle we wish to include by two, which will give the arc. Find the natural tangent opposite this arc in the table; measure the distance between the centre of vision and the farthest corner of the plate, and divide it by the natural tangent found. The quotient is the focus.

One word of caution in conclusion. Should it be necessary to photograph on a plate of given dimensions under a given angle, first ascertain the length of the principal ray, and then select the lens which will give the image at that focus. In most cases this will be difficult, as the lens stock will rarely be found to include one which is suitable. It is preferable to photograph the subject approximately to

size, using a plate of somewhat larger size, and a lens of rather shorter focus, to allow for the necessary adjustment for objects in the foreground. Place the camera in position to include the correct angle for lens and subject, and trim the print. PHILIP EVERITT.

THE HAND CAMERA AND ITS USE IN PICTURE-MAKING.*

Experiences in Cattle Stalking.

Of the various kinds of work eminently suitable to the hand camera, I may mention pictures composed of animals—cows, horses, sheep, and so on.

If any here have had experience in trying to secure this class of picture, we shall be at one when I say, to obtain a well-composed picture, with the idea (if there is one) fully carried out, is a matter of difficulty when working in the ordinary manner with tripod; especially is it so if one is out alone. Cattle have, under such circumstances, a *beastly* desire to see the picture on your ground glass for themselves.

My first experience in cattle stalking was my last for some years. Being out on the prowl, seeking what I might devour, photographically, I came across a fine herd of young bullocks in a field, and in my innocence and usual good nature, undertook to immortalise them. Over the fence I went, quickly got into position, and, everything in readiness, focussing done, and dark slide ready for taking its place—but, what on earth had happened? Everything possessed of four legs was as fuzzy as fuzzy could be, and over it all had to be done again, this time being more troublesome; the vain things evidently each desiring to obtain a better position for showing themselves off, and were constantly on the move to the front, so much so, that I thought it desirable to go further away, and begin over again. They unanimously agreed to the former part of my programme, but disagreed *in toto* with the latter portion, and whether it was they shrewdly guessed I was only a new beginner, and not likely to do them justice or not I never knew, but one thing was certain, they had a preference for my room rather than to my company—and meant having it, for it was simply from that point a question of going out, or being put out, of the field. I fancied the former, and they the latter.

I went, and how camera first, and then myself, got on the opposite side of the iron fence I never knew. There was a shortness of time about the whole affair that was bewildering; but this is certain, on looking round I noticed several of these new-found friends offering their services through the fence in a very energetic fashion. Photography and art were at a sad discount for the rest of that day.

I was down in the same part of Yorkshire this last summer, and passing the same field, turned the tables on my old friends, and got one good cattle picture and another of a more amusing character, when one was trying to stimulate his memory with a good scratch, very likely having heard of my last visit from his great-grandfather; however, there was no difficulty this time, everything was changed, and the operations over in a very few minutes.

Then, again, with sheep, no bother after getting stand, &c., ready, and picture arranged and focussed, to find they have had enough of it and are off. Now the other method is to decide on position, quietly walk to within required distance, just be ready, and when they are kind enough to line up as you desire, off goes the shutter, and so do you; everybody pleased—they at your departure, and you at the medals already secured in imagination, that is if you go in for such wicked deeds as trying for medals.

The Pleasures of Hand-camera Work.

Then, again, it is undoubtedly capable of being used with satisfaction on the sea amongst the shipping, and along the shore for real picture-making. Hardly any subject, whether storm effects, cliff studies, or, in fact, anything you desire to deal with on the coast, comes amiss, when using a good rapid plate and a lens such as I described; these and all the odds-and-ends met with can just as well be done with the hand camera as with one used on a tripod, with a heavy balance in its favour on score of convenience in carriage and working. A goodly proportion of landscape work comes well within its scope, and, in fact, as I have said before, anything requiring an exposure of not more than one second can be got with certainty, and none of the trouble connected with the use of the ordinary camera and its numerous accessories.

It would be possible to continue the list of advantages it possesses, and the pleasures derived from its use, for a considerable time, but I do not propose doing so, except to say it is a real godsend when out *skying*, being ready at the instant, and be the changes ever so rapid none need be allowed to escape this friend; and this is, as I hope to show you, one of the strongest aids to picture-making. If it was of no other use than that of getting sky negatives, it would be deserving of our careful attention; as it is, you will find it a good friend and faithful servant if you first understand it and use it properly and with care, not expecting the impossible, or calling upon it to do that which in our present state of advancement is within the province of the camera and tripod and protracted exposure.

* Concluded from page 73.

Blue Spectacles a Useful Aid.

There is one small but useful aid in outdoor work.

You may often have found a scene that carried you away with its beauty, and a plate or more having been carefully exposed and developed, only to find the resulting negative bring disappointment and disgust.

Now this has been perhaps a scene full of variety and contrast, but variety and contrast of *colour*, and this, when reduced to monochrome by photography, has disappeared.

Here you will find a pair of blue spectacles of immense use by giving you a better idea of how the scene is apart from its colour, and so often save both your pocket and temper; they are also of use and comfort in watching a sky effect, with the sun glaring at you. Without them you are quickly blinded, but with them on you can stare away at the sun, moon, and stars without inconvenience, and so see just the effect you are waiting for at the precise moment most suitable for your purpose, and thus add one more good sky negative to your stock.

You will see a few slides kindly lent me by my friend Mr. Bright, of the Camera Club, and I use them to show some of the varied kinds of work to be done with a hand camera. After they have been shown I shall be glad to answer any questions as far as possible, and still more glad to hear the opinions and experiences of members who may have devoted themselves to this branch. We have not at our disposal to-night sufficient time to go into and deal fully with the matters more intimately connected with the making of pictures—composition, light and shade, and so forth, but I hope to take up this subject again on some future occasion, if you care to devote another night to it. W. THOMAS.

ELECTRIC LIGHTING AS APPLIED TO PHOTOGRAPHY.

An example of the way in which the electric light can be adapted to photographic purposes has recently been brought to our notice. The installation was fixed for Messrs. André & Co., of Bushey, by Mr. Henry J. Rogers, M.I.M.E., electrical engineer of Watford, and consists of an Elwell Parker dynamo of 105 volts and 28 ampères, driving 1–2000 c.p., and 1–4000 c.p. Brockie-Pell Arc Lamps. The peculiarity of the installation is, however, in the method in which the arc lamps are arranged for convenience in focussing the light on the "study." The lamps are hung on brass rollers running on copper rails fixed in grooves in wooden frames, the positive and negative cables being attached to the ends of the copper rails, and the circuit being closed from one rail to the other through the carrying wheels of the lamps. The lamps thus have a travel of about six feet longitudinally without any movement of the cables. The frames on which the lamps are suspended can also be raised and lowered by shifting counter balance weights hanging from cords passing over a series of pulleys, and, as the framework upon which the lamps hang is also suspended on pulleys running on transverse tee irons, the whole of the lighting apparatus can thus be moved on one side out of the way of the operator. It will be seen from the above description that the lamps can be moved vertically, longitudinally, or transversely; thus every requisite for successful photography has been attained in this installation.

The dynamo is driven by a four h.p. Otto gas engine, with two fly-wheels, and there are the usual resistance coils, switch board, cut-outs, and volt meter.

Mr. Rogers is about to fit up an incandescent installation on the same circuit as the arc lamp circuit for lighting Messrs. André's studios.

NOTES FROM SCOTLAND.

Photography and School Boards.

The Edinburgh School Board, which has spared nothing in its desire to render their new schools not only perfect so far as that can be done in the internal arrangements for teaching and matters connected therewith, but in external architectural effect, has erected several of the finest examples of building in that city. They have further commissioned Mr. Aytoun to photograph for exhibition at the Chicago World's Fair exterior views of several of the schools, among them Jorphicen-street and Sciennes (the latter name derived or corrupted from an old Catholic foundation near its site, St. Mary di Sienna, *circa* 1200 to to 1300 A.D.). There are also interior views in the latter of the workroom, with boys at their joinery work, and girls amusing themselves in their swimming dresses in and around the swimming bath attached to the

school. There are also pen-and-ink drawings of the school furniture which is of a superior type, by the pupils. The fine bit of architecture by Playfair, of the High School, has also, in spite of its difficult position, been beautifully rendered in several views. These will form a part of the Board's contribution to the Fair.

That rather conservative body, the Royal Scottish Academy of Arts, has not thought it beneath its dignity to borrow an idea, and from a photographic source. It will be remembered by those who were privileged to see it that the Exhibition of the Edinburgh Photographic Society, 1890–91, was held in the galleries which the Academy is also allowed to occupy, and that the hanging of the pictures and the draping of the walls gave a very fine effect to the general show as a whole. The more august body, the Royal Academy, has this year in its annual Exhibition departed from the usual maroon-coloured barn or auction-room style of hanging. As one of the dailies puts it, "We have changes in the mode of hanging, in the decorations, and in the arrangement of the galleries," and these are but a reflection of the good taste and example shown them by the organizers of the Edinburgh Photographic Exhibition.

A New Departure.

A proposal has been brought before the Edinburgh Photographic Society to change its annual time of appointing Council and office-bearers from the beginning of the session in November to its later meeting in June. This seems so valuable a suggestion that we think it well worthy of consideration by that wider body, that photographic public which associates into societies with various designations extends all over this country, we might say the world.

The Council and office-bearers are elected at present in November, and, as a third at least of these are ineligible for re-election, a continued and desirable change of officials occurs annually, and before these new members get into working order a large portion of the early part of each working year is wasted; they therefore propose that the appointments of those officials should be the last work of the last meeting of the session in June, thus leaving them the whole of the recess to arrange and mature plans for the following year, and also to begin that in October instead of November.

This seems to be one of the most sensible proposals we have seen for the business working of photographic societies, which always make of the summer and autumn months a holiday for outdoor work, rest, and recreation. The adoption of it need not disarrange the ordinary terms of the beginning of the session, and of payment of subscriptions and other matters of that nature, for, although it might be better were the two periods simultaneous, yet they are by no means a necessity. As the names of the officials of all such bodies are carefully registered in the various almanacs, annuals, and year-books, those published at the beginning of each year would be certain of being correctly posted up to date.

We commend the idea to the consideration of those engaged in the work of carrying on the business of such societies as one likely to be of considerable help to them in their sometimes arduous duties.

Determination of Measurements by Photographic Means.

In a contemporary an anecdote is related as to the origin of the mode of doing this, and as it seems newly imported, and "Made in Germany," it may be as well to scotch it at once. It is, shortly, that Dr. Stolze says, in a recent number of *Photographische Nachrichten*, Dr., or Mr. Meydenbauer, architect, conceived the idea in the summer of 1862, during the restoration of Wetzlar Cathedral, and told him of it at that date. All the world knows that this had been done long before that, and by nobody more exactly or perfectly than by Charles Piazzi Smith, then Professor and Astronomer Royal for Scotland, in his memorable work at, in, and on the Great Pyramid of Gizeh. Previous to that date, also, the present writer was employed by Mr. David Kinnear, architect, inventor of the Kinnear camera, and an accomplished photographer, to photograph to scale, and with measuring rods set in various parts, the Free Church (St. George's) of the late Rev. Dr. Candlish, preparatory to its removal and reconstruction, on an improved design, in Stockbridge, Edinburgh, a mile away from its then site, and where it now stands, an ornament to the locality. Nothing was thought of it more than an ordinary bit of work.

AN EXHIBITION OF NEGATIVES.

The Birmingham Photographic Society had a very instructive and interesting meeting on the evening of Tuesday, the 31st ult., when a non-competitive Exhibition of members' negatives was held. The object of the Exhibition was to place before the general members, and especially the beginners among them, a standard of good work, and it is gratifying to report that, so far as the quality of the work on view is concerned, the Exhibition was eminently a success. Upwards of 100 negatives were shown, the work of sixteen members, and these were displayed to the best advantage on racks running down each side of a long table, a row of lamps being placed down the centre, and the light diffused by the intervention of tissue paper. It would be no exaggeration to say that there was not a second-rate negative amongst them, but the exhibits of Messrs. E. C. Middleton, E. H. Jaques, J. T. Mousley, J. H. Pickard, William Rooke, and E. Underwood called forth unstinted admiration. Mr. W. S. Horton also had on view a very fine series of collodion negatives, copies of celebrated pictures, taken many years ago, which were much admired. Altogether the Society has just cause to congratulate itself upon the success of the Exhibition and the good to the general members which will undoubtedly accrue from it.

AMMONIUM PICRATE FOR PREVENTING HALATION.

Before the Photographic Society of Japan on December 2, Messrs. W. K. Burton and K. Arito showed the results of a set of experiments with plates stained with picric acid neutralised with ammonia (presumably really picrate of ammonium) to prevent halation. Mr. Burton had, some years ago, tried the effect of staining films with various dyes to prevent halation, but had not been very successful. As a rule, if halation were prevented, the plate was very much slowed, or there was great difficulty in getting density. With picric acid this was not so. The sensitiveness was somewhat reduced, but not much; whilst, so far as density was concerned, the difficulty had, up to the present, been that too great density had been got in every case. The picrate did not seem so much actually to slow the plate as to act as a retarder in development. This necessitated a developer strong in alkali, and, even with very small proportions of pyro, or of eikonogen, the density came up too great. Doubtless further experiments would lead to the discovery of a remedy. The next were to be made with plates coated with emulsion with which picric acid (or picrate of ammonium) had been mixed. Both halation and solarisation were completely prevented.

Several hundred lantern slides were shown on the screen, and it was decided to hold a lantern evening in Yokohama at an early date.

CLEVELAND CAMERA CLUB EXHIBITION.

The first *conversazione* and exhibition in connexion with this Club was held last week in the Co-operative Hall, Middlesbrough, when some very pretty sets of photographs were exhibited both by amateurs and professionals. The judging was in the hands of Mr. Frank M. Sutcliffe, and his awards were as follows:—Set of six pictures: 1st prize (silver medal), Dr. Stainthorpe, Saltburn; 2nd prize (bronze medal), Mr. Jobling, Yarm. Single picture: 1st prize (silver medal), Dr. Stainthorpe, Saltburn; 2nd prize (bronze medal), Philip Bulmer, Chester-le-Street. Lantern slides: 1st prize (silver medal), Mr. Taverner, London; 2nd prize (bronze medal), Mr. J. W. Huggins, Hexham. The Mayor (Mr. C. Lowthian Bell) opened the exhibition, and a very large and exceptionally fine collection of lantern slides were exhibited by means of the limelight under the management of Dr. Stainthorpe.

Our Editorial Table.

A Catalogue of Stereoscopic Views.

We have received the catalogue of stereoscopic views issued by Messrs. Underwood & Underwood, of Liverpool, Chicago, &c. It contains particulars, with numerous illustrations, of many thousands of stereoscopic views of the chief places of interest on the habitable globe, together with, in many cases, explanatory notes. To lovers of the stereoscope unable to obtain views of distant places this catalogue affords the means of gratifying the most variegated tastes in stereoscopic views, and is besides admirably got up and printed.

Political Calendar.

The Meisenbach Company have sent us a specimen of their improved process of photo-engraving in the form of a Calendar for 1893. The subject, entitled *Queen of Flowers*, has been engraved from the coloured supplement to the *Lady's Pictorial* Christmas number, a picture of twenty-one printings, and is a charming and delicate example of monochrome reproduction from paintings and colour work by their "special orthochromatic process." The border consists of over 600 portraits of the members of the present Parliament, and, notwithstanding the minute size of the portraits, each is distinct and clear, and can be at once recognised by those acquainted with the original. The fineness of detail is remarkable, and we agree with the Company that it is questionable whether it would be possible to produce a type printing block giving equal results by any other known method of engraving. We esteem the Calendar as a unique specimen of process engraving, and both as regards the quality of the reproductions, large and small, and of the successful preservation of the enormous number of likenesses included, we congratulate the Company on a most admirable piece of process work.

Aide-Mémoire Pratique de Photographie.

By Albert Londe. Paris: J. B. Baillière et Fils.

The excellence and variety of M. Londe's desultory photographic writings, as well as his official photographic position at the Paris Salpêtrière, is sufficient guarantee that any work on photography from his pen is sure to be distinguished by carefulness of execution. The handbook under notice treats both theoretically and practically of most branches of modern photography, and is profusely illustrated. A chapter devoted to colour-photography includes a detailed description of M. Lippmann's experiments.

„ 17	Leamington	Trinity Church Room, Morton-st.
„ 17	Maidstone	"The Palace," Maidstone.
„ 18	Hull	71, Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

February 2,—Mr. G. W. Atkins in the chair.

Messrs. Robert Debenham, G. D. Sargent, and L. N. Tyndall were elected members.

Printing-out Opals.

Mr. A. Haddon said he had tried the opals recently sent for distribution by the Paget Company, and had obtained most beautiful positives. There was one advantage in the use of the smooth surface over the matt-surface kind, in that with the former one would obtain a gradation in the shadows which most probably would be lost in the matt surface, on which, as compared with the glazed, the half-tones would suffer to a certain extent. He would most certainly select the smooth surface in preference to the matt.

"Haddon's Reducer."

Mr. F. A. Bridge said that, at the meeting of the Photographic Club on the previous evening, Mr. H. W. Sanford showed a print on gelatino-chloride paper which had been over-printed, toned, and fixed. Being found too deep, it was reduced by Mr. Haddon's reducer (potassium ferridcyanide and ammonium sulphocyanide), the image entirely disappearing. The paper was then washed and an amidol developer applied, with the result that a beautiful warm-toned print was obtained.

Mr. Haddon said it was well known that sulphocyanide would dissolve the silver salts, and that the ferridcyanide would attack the metallic silver.

Mr. J. S. Teape had once toned with uranium until the image had disappeared, but it redeveloped perfectly.

Mr. Haddon said that possibly the bromide in the developing solution converted the deposit into silver bromide, when development would be carried on, reduction most probably having taken place in the presence of light.

Mr. W. E. Debenham said that possibly such a proportion of the constituents of the reducing solution was used as not absolutely to dissolve the image, there being, perhaps, not quite enough sulphocyanide present.

The Late Mr. William Bedford.

Mr. W. F. Slater presented the Association with a portrait (handsomely framed) of the late Mr. Bedford, as presented with this Journal of January 27 last.

Albo-carbon in Paraffin.

Mr. J. E. Smith asked for information as regards albo-carbon in paraffin. Did it aid the illumination, or would it cause an explosion?

Mr. R. Child Bayley had tried albo-carbon, and could not get it to dissolve in paraffin.

Mr. Haddon said that camphor was often recommended and used. It required the use of a much longer chimney to consume the carbon, otherwise it would be smoky. There was no fear of an explosion.

Mr. Charles H. Oakden said that albo-carbon was slightly soluble in paraffin. It was formerly recommended for microscopic lamps, but its use had been abandoned. There were two or three qualities on the market.

Mr. T. Bolas said it was difficult to see any possible danger by the use of albo-carbon, but, as Mr. Haddon had observed, a somewhat better draught would be required.

In reply to Mr. Smith, Mr. Haddon, remarked that heating the oil was to court an explosion or conflagration. There was no danger, provided the reservoir of oil was properly filled. They only had explosions if the reservoir were partly filled and oxygen from the air entered to form an explosive mixture.

Calculation of the Angle of View.

Mr. P. Everitt read a paper on this subject (see page 87), at the conclusion of which

Mr. Haddon said he had been accused of having attempted to deceive the 20,000 readers of The British Journal Photographic Almanac for 1893, and for having given a rule which was utterly absurd. He had given that rule in order to remove the cumbrous methods adopted by some to obtain the angle of view on a given size plate with a lens of given focus. He had not invented the term "angle of view" as given by him in his Almanac article; it had a quarter of a century's authority. He was not an artist, and knew little or nothing of perspective, and he was perfectly sure that the first gentleman who used the term "angle of view" in the sense it had been used for twenty-five years was not an artist or teacher of perspective, but rather an optician or mathematician. In ninety-nine cases out of a hundred, pictures were taken with the axis of the lens very nearly opposite the centre of the plate, and the angle was calculated between two extreme rays drawn from the sides of the plate. It was absurd to give a picture a fictitious value on account of a few trees, or twigs, or rocks at a corner, and so dignify it with an angle of 52°, instead of, say, 42°. His article did not claim be to a method for calculating the maximum angle of view, but of that included on the base line of the plate. Mr. Everitt himself had to some extent adopted the same rule, as he had drawn his line from the extreme corner of the plate, but had calculated from a position at the side opposite to which the axis of the lens pointed. He did not see why the angle obliquely to that position should be taken. He would like to refer Mr. Everitt to some slides shown at a lantern evening, and ask him if their pictorial effect would have suffered by the corners being lopped off. He (Mr. Haddon) would answer, Not in the least. In a seascape there was a large amount of sky, but should that be dignified with an increased 5° or 10° because it had so much blank paper? When one admired a view, one did not look from corner to corner, but horizontally, and that gave the angle of view included. He had not used the term differently from what it had been used for twenty-five years. Having quoted Hardwich & Dawson, Monckhoven, Grubb, the Editor of The British Journal Photographic Almanac for 1888, Mr. J. Traill Taylor (the author of the *Optics of Photography and Photographic Lenses*), and Dr. Clarence E. Woodman as giving practically the same method of ascertaining the angle of view, Mr. Haddon asked, Was that rule, from a mathematical point of view, correct or incorrect, or had he given a rule which was, mathematically, nonsense? Was it true that one got the tangent of the angle by dividing the base line of the plate? He did not think he had gone wrong as regards that. The term angle of view had had a new meaning given to it that evening which, up to the present, in photography had never been accepted, or, if accepted by some, he (Mr. Haddon) had decidedly never seen it in print. It was a question for the meeting whether in the future they were to throw overboard the old method or adopt the mode suggested by Mr. Everitt.

Mr. DEBENHAM said the great use of tables was to know whether with a certain lens one could do certain work. As to the base line of the picture, they would get the angle only for the base; but, in so far as it was desirable to know what a lens would do, it was necessary to go to the corners, and if we wished to have our corners we must measure for them. With regard to the actual angle included, he supposed Mr. Everitt meant the angle necessary to have in the plate?

Mr. EVERITT replied that the angle which the lens of seventeen inches focus, as given in the diagram, should subtend, in order to take so much of the picture as indicated, should be 60°.

Mr. DEBENHAM said that was a mistake. It was desirable that the plane of the field should lie in the focus, but all that was necessary was that the angle should be the part of the circle covered. He thought Mr. Haddon's table required correction to the extent that "base" was understood where they must reckon half the disgonal of the plate. It was not necessary that the axis of the lens should be directed to the line of vision. In using a wide-angle lens, the axis should be at right angles to the plate, so that the plane of definition should be in the same plane as the plane of the plate.

Mr. EVERITT asked Mr. Debenham if he would take such a picture as he had drawn in the diagram with a shorter-focus lens than seventeen inches, and obtain an angle of 60°?

Mr. DEBENHAM said that a lens of 30° angle was not required. He would get the same perspective with a lens placed at the same place with less than 60°, angle included. An angle of 48° degrees would do.

After further discussion,

Mr. TEAPE remarked that Mr. Debenham had said that it was not necessary to have a lens that would cover more than the part of the circle included by the angle, but he (Mr. Teape) thought that, if the sliding front were used, it was necessary for a lens to cover more.

Mr. DEBENHAM agreed that one must have a lens which would cover from opposite the centre of the sliding front to the side of the plate. That was desirable for including the amount of picture, but not necessary.

Mr. TEAPE said that a mistake was made in saying angle of view when we wished to know the angle of view; the term should be "extreme" or "maximum angle of view." As a matter of fact, every portion of a picture was viewed under a different angle.

In replying to Mr. Haddon, Mr. EVERITT said that gentleman had quoted certain authorities on his side of the question, and triumphantly said that for twenty-five years his rule had stood, and now photographers were confronted with a new one. The art of perspective was considerably older than twenty-five years. If those gentlemen who devoted their attention exclusively to books wished to include the largest angle with a lens of a certain description and gave rules, he (Mr. Everitt) could quite understand that they would value the method of Mr. Haddon, and naturally would transfer that method to the calculation of an angle on a plate without noticing that the corners were not covered. Mr. Haddon had tried to minimise the difference in angle made by the sky, or trees, or twigs in the corners of a picture; but, if such were of no consequence, why not confine your angle to the object of interest, and trim the print down? By Mr. Haddon's rule there was an error of 28° in the angle and of about 33⅓ per cent. in the focus of the lens, according to the example he (Mr. Everitt) had shown. Photography had recently been putting forth claims to be recognised as one of the graphic arts, and they should therefore adopt the parlance of draughtsmen and artists.

Harringay Photographic Society.—February 2, The President, Mr. D. Towers, gave a demonstration of *Bromide Enlarging*, Mr. F. Bennett occupied the chair.—The demonstrator used a restrained ferrous-oxalate developer, with Morgan & Kidd's paper, the result being a perfect enlargement. Three new members were elected, and the Secretary read the request for affiliation from the Photographic Society of Great Britain.

Hackney Photographic Society.—January 31, Mr. G. J. Avent in the chair.—The Hon. Secretary passed round an arrangement for fixing on any ordinary gas jet for use with limelight. It prevented the tube buckling, and was readily applied. From the question box: 1: "Do the fumes of ammonia cause permanent irritation to the mucous membrane of the throat, eyes, and nose?" Mr. DEBENHAM said in olden days he had used strong, large quantities of it, not in connexion with photography, and he had had chronic pharyngitis through it, but with the small quantities and weak solutions used in photography he did not think there was much danger. Mr. NUNN said he had been troubled with a sore-throat, which his doctor attributed to the use of ammonia. Mr. GEAR said he had killed a mouse with it in two or three seconds. Question 2: "What is the effect of a sample of hypo on prints after toning?" It was said that a bad sample would probably be acid, and set free sulphur, which ammonia would correct. Question 3: "Which is the better light for reproducing a faded photograph—artificial or daylight?" Mr. DEBENHAM said if the half-tones had faded daylight would be the best; lamplight would add yellow all over and defeat its own end. He had used a violet-blue light to increase the non-orthochromatic effect where the faded half-tones were yellow. Mr. DEBENHAM then proceeded to give his demonstration on *Transparencies by the Carbon Process.* The first thing to do is to get the tissue, which is coated with gelatine mixed with a pigment, unsensitised; sensitise before using with one ounce of bichromate of potash to one quart of water, with or without ammonia, preferably without. The gelatine and bichromate acted on by light produce an insoluble substance, which does not swell in water. The pigmented film must be developed from the back, otherwise it would wash off the paper, unless for transferring; then apply a new support, cemented by indiarubber varnish to film, and wash away the first paper. The lecturer preferred red-chalk tissue. Colours were various, and by subsequent treatment different ones could be obtained. In drying, glass was perhaps better, at any rate would keep better, as there was less chance of bichromate remaining, and less chance of distortion. It was very slightly sensitive whilst wet, may be dried some distance from the fire, edges must be covered during printing, and a photometer was necessary to gauge it. He showed one he had had with about three dozen photographs on it. Red-chalk tissue may be toned and intensified by staining the gelatine with ordinary ink or other dyes. Mr. Debenham preferred permanganate of potash (ten grains to one ounce). Transparencies were then made and handed round. Mr. GEAR had used transparency tissue, and preferred it to the red chalk. He preferred ordinary bromide plates to carbon, and thought that with the latter there was a slight blurring. Mr. BECKETT said he thought this was hardly correct, as the Woodbury lantern plates were most admired of any. Mr. GEAR said he cleaned his glasses with nitric acid and washed them before talcing. Mr. DEBENHAM said the talc must be thoroughly rubbed in, and if they were properly talced over, the pores, so to speak, of the glass would fill up and remain so.

Leytonstone Camera Club.—February 2, Mr. A. E. Bailey in the chair.—Mr. L. E. Morgan, from Messrs. Fuerst Bros., gave a demonstration on the uses of the new developing agent amidol. Having previously exposed a plate, he developed same most successfully with amidol, giving every advantage with half-tone and density possessed with pyro, but without the stain. Bromide paper and lantern plates were next dealt with, and all with a one-solution developer, and with the same success; after which Mr. Morgan was deluged with inquiries, to all of which a most lucid explanation was given. It was the general opinion of the members present that amidol has a great future before it.

Leeds Photographic Society.—February 2, Mr. Warburton in the chair.—Mr. T. Illingworth, of Halifax, gave a demonstration on development. In the first place, he advised amateurs to fight shy of rapid plates, and stated that he found ordinary plates serve him for almost all purposes. He developed several "Barnet" ordinary plates with Mawson & Swan's pyro-ammonia formula; plates exposed in the studio—one five seconds and one fifteen seconds—he used 12 drachms pyro solution, 8 drachms ammonia solution; three minutes to develop. One twenty and another thirty seconds, 12 drachms pyro solution and 6 drachms ammonia solution; seven minutes to develop. One forty, another sixty seconds, 16 drachms pyro solution and 6 drachms ammonia solution; fifteen minutes to develop. He then made a transparency, same plate, forty seconds exposure, five feet from ordinary gas-burner, developed with 12 drachms pyro solution, 8 drachms ammonia solution, all of which proved complete successes.

Lewes Photographic Society.—Febrnary 2.—Dr. Collins gave a lecture on his visit to the north of Scotland, illustrating it with a number of lantern slides of the Island of Handen and neighbourhood, showing the rocks covered with innumerable sea-birds which come here to breed.

Liverpool Amateur Photographic Association.—February 2, a lecture and practical demonstration by Mr. E. M. Tunstall on *Lantern Slide-making.*—All points of a nature likely to lead to failure were fully explained, including suggestions as to the best negatives, exposure, and development. The lecturer strongly urged that the developer recommended by the maker should be used; he, however, preferred hydroquinone as the simplest, and as a good all-round worker. After several example plates had been treated, at the suggestion of Mr. Tunstall, Mr. G. A. Carruthers was asked to show the members his method of making slides by reduction by artificial light. This was done in a Pearson & Denham's reducing camera by an exposure of six inches of magnesium ribbon burnt behind the negative (a 5×4 film), with a sheet of ground glass between the negative and the light, and by moving the magnesium ribbon about while burning to ensure even lighting, the result being a perfect slide, with not the slightest sign of uneven lighting. A Mawson plate was used, this, in the opinion of the lecturer, being one of the fastest and most reliable plates for the experiment.

Dundee and East of Scotland Photographic Association.—February 2, Mr. J. D. Cox presiding.—A beautiful and interesting series of scientific experiments with the lantern were shown by Mr. Peter Feathers. Mr. Feathers demonstrated how the apparatus could be used for illustrating chemical and physical phenomena, such as the decomposition of water and of metallic solutions by electrolysis, the refraction of light in a soap bubble, the action of sound, waves, &c. Mr. Murray Feathers followed with a lecturette, entitled *A Holiday Trip to the Channel Islands.* A splendid series of photographic views of the Channel Islands were displayed on the screen. Mr. Feathers gave a racy account of life in the Islands, and described in glowing terms their picturesque towns, delightful rural scenery, and the magnificence of the coast scenery, with its towering cliffs and yawning chasms.

Glasgow Photographic Association.—February 2, Mr. Wm. Lang, jun., F.C.S., President, in the chair.—Mr. John Stuart gave a demonstration of printing in platinum and gelatino-chloride papers. Of both processes a large series of prints were developed or toned, and finished ready for mounting. At the close Mr. Stuart was thanked for his demonstration, which was much appreciated by those present.

Leith Amateur Photographic Association—January 31, Annual Meeting, Mr. Wm. M. Smith in the chair.—The Treasurer and Secretary read their respective reports, the one as to the financial state, which was pronounced satisfactory, the other gave a record of the work done during the past year, which was also approved of. The following gentlemen were then appointed for the ensuing year:—*President:* Mr. William Dougall.—*Vice-President:* Mr. William M. Smith.—*Council:* Messrs. Guthrie, Ewart, Hunter, Chapman, Dewar, Jas. Hislop, H. W. Hislop, Dr. M'Creadie, J. Lamb.—*Treasurer:* Mr. M. Campbell.—*Secretary:* Mr. Alexander Pitkeathly. The Secretary afterwards intimated that in the recent National Lantern Slide Competition two of their members had been successful exhibitors—Mr. Smith, who had been awarded the silver medal; and Mr. Guthrie, a former medallist, had received honourable mention.

Photographic Society of Philadelphia.—January 11.—The paper for the evening was read by Dr. John H. Janeway, U.S.A., his subject being *Some Thoughts on the Chemical Development of Dry Plates.* (See a future number.) Dr. JANEWAY remarked, in connexion with the reference in his paper to sound produced by the action of light, that he had noticed, while on duty on the western plains, sounds proceeding from telegraph wires—just after dawn and before sunrise—which he believed were due to the action of light rays. Mr. JAMES WILSON asked if most of the fog referred to by Dr. Janeway was not caused by decom-

position of the pyro or material used in development, and whether, if fresh developer had been used at repeated intervals, instead of adding more alkali, this fog would have been produced. Dr. JANEWAY said that where freshly prepared pyro developer had been added, instead of more alkali, fog had ensued. He did not think it was due to decomposition. Pyro might cause discolouration, but not fog, and discolouration could be removed. Mr. Earle exhibited the "Perfection Magazine Flash-lamp," for burning pure magnesium. The prominent feature of this lamp was its adaptability for either instantaneous or time exposures. The lamp was constructed on the principle of the Argand burner, with the purpose of ensuring complete combustion. Mr. ROSENGARTEN inquired whether any member, in experimenting with flashlight, had used powdered aluminium. He had been given a formula the other day—a mixture of aluminium, chlorate of potash, and some other highly oxidising substance. A party in one of the journals claimed that it was quite as valuable in its power as magnesium, and not explosive in any way. Professor SADTLER stated that he had used aluminium in the form of a very thin foil, and it burned with fully as vivid actinic light as magnesium, but was a little slow in ignition. Dr. JANEWAY suggested that the celluloid diffuser sometimes used in flashlight work could be protected from the danger of ignition by coating it on both sides with silicate of soda—liquid water glass. Professor SADTLER asked the Doctor whether he got the preparation to adhere uniformly. Dr. JANEWAY said the only requisite was to dilute it one-half and apply with a flat brush. It flowed very readily and dried in a few moments. Mr. EARLE thought the reason why the celluloid took fire in Dr. Janeway's case was because of the dampness of the magnesium powder, burning particles being blown against the screen, instead of being consumed. The powder should always be dried before using. Mr. LUDERS asked if the moist breath blown into the lamp would not account for the dampness of the magnesium. Mr. EARLE said that it might.

ADJUSTING LIMELIGHT JETS.

To the EDITOR.

SIR,—I have never seen the following simple method of adjusting limelight jets, in use or in print. Having found it effective, I send it for what it is worth.

The rod supporting the jet tubes has a screw cut on it and milled-edged nuts above and below the socket.

To adjust the jet, loosen the top nut and screw the lower one up or down as necessary, at the same time moving the jet to and fro till in right position, then clamp with the upper nut.

I see jets advertised with endless thumb nuts to adjust, but never one in which the lime can be set out of vertical, by which the light may often be improved.—I am, yours, &c., H. G. M. CONYDEARE.

Camera Club, Charing Cross-road, W.C., February 1, 1893.

FLEXIBLE STEEL TUBING.

To the EDITOR.

SIR,—My excuse for troubling you with this letter is that the above-mentioned tubing seems to be unknown to the majority of lanternists, yet I think if they knew it they would be glad to discard the troublesome, evil-smelling rubber tubing now in general use, especially those users who, exhibiting in large rooms with blow-through jets, have to carefully lead the rubber pipe from the gas jet to the lantern, and yet are always in fear that some careless person may step on the tube and extinguish the flame. The smaller bores (quite large enough for lanternists) can be coiled in a circle of eight-inch diameter, and require a pressure of twenty-seven hundredweight to crush them. They are perfectly gas-tight, and free from any smell; and, being galvanized internally and externally, will not rust. Lastly, and not least, the price is considerably lower than that of the best rubber. No serious objection can be raised as to the additional weight, five-sixteenths weighing only two and a half ounces, and three-eighths three ounces per foot. Connexions are made with pieces of rubber tubing two or three inches long, as usual. The comfort of working the lantern without any fear of kinks, or the doubling up of the piping, is great. I say, Try it, and I don't think any one doing so will give it up.—I am, yours, &c., FRANK HAES.

28, *Bassett-road, W., February* 3, 1893.

[Mr. Haes, some weeks since, showed us a sample of the tubing in question, which we should think an admirable substitute for rubber tubing.—ED.]

FINISHING GELATINO-CHLORIDE PAPERS.

To the EDITOR.

SIR,—There has been a diversity of advice given as to the finishing of P.O.P. and kindred papers. I have often wished to finish P.O.P. by burnishing as albumen would, but at first could not succeed at all. One writer says, "Have the burnisher" (I refer to a bar instrument) "very hot," but in this way I spoilt prints wholesale. After considerable experiment, and when I had almost decided to get a roller enameller, I discovered that if the burnisher was only heated to a degree that the hand could hardly bear, the prints went through easily and with a splendid finish. This may be useful to those who are still using bar burnishers.—I am, yours, &c., OTUELLO.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the EDITOR.

SIR,—I cannot but express regret that Mr. Robert E. M. Bain should have any reason to complain of the treatment of his photographs at our last exhibition. Immediately on reading Mr. Bain's statement that he received them roughly tied together with a piece of cord instead of in the wooden case in which they were sent, I inquired of our agent concerning the matter. He is emphatically *certain* that these exhibits were returned in the box in which they were received. I can only suppose, therefore, that the case was opened after leaving our agent and before arriving at its destination.—I am, yours, &c., CHAPMAN JONES, *Hon. Secretary.*

Photographic Society of Great Britain, 50, Great Russell-street, Bloomsbury, London, W.C., February 4, 1893.

A DEVELOPER QUESTION.

To the EDITOR.

SIR,—The formula for a snap-shot developer that I gave in the ALMANAC has, in my hands, proved a practical success, as the various makes of plates that I developed with it have stood the quantity of *anhydrous* sodium carbonate mentioned without fogging.—I am, yours, &c., F. MIALL.

13, *Shelgate-road, Clapham Junction, S.W., Feb.* 4, 1893.

THE DUBLIN EXHIBITION.

To the EDITOR.

SIR,—In the report of the Exhibition of the Photographic Society of Ireland, published in THE BRITISH JOURNAL OF PHOTOGRAPHY of 27th ult., I find an error has appeared, by which Mr. John Stuart, of Glasgow (who sent some admirable flashlight pictures), is also credited with the production of the very fine portraits of Bishop Dowden and Professor Blackie, while those works, as well as several other splendid photographs not mentioned in the report, were very kindly sent by the eminent portraitist, Mr. W. Crooke, of Edinburgh.

I trust you will kindly publish this communication, giving honour to whom honour is due.

Thanking you on behalf of the Exhibition Committee in anticipation of correction.—I am, yours, &c., ALFRED WERNER.

38 *and* 39, *Grafton-street, Dublin, Feb.* 4, 1893.

DETERMINATION OF PLATE SPEEDS.

To the EDITOR.

SIR,—Mr. Williams has favoured your readers with the results of some comparative trials he has made with plates marked in accordance with our system. As, however, his conclusions are arrived at by mere ocular inspection, we trust Mr. Williams will pardon our saying that we do not attach any importance to them, nor do we believe that he could possibly decide, by ocular inspection, that one plate had received ten per cent. more or less exposure than another.

The eye is quite incapable of estimating such differences, and even when the difference is sufficiently marked, the eye is altogether unable to assign to it any numerical value. Quite recently we showed prints from two negatives, one of which received twice the exposure of the other, to

two practical photographers, and they were quite unable to decide which print was from the more, and which from the less, exposed negative.

We, ourselves, advocate quantitative methods, and our object in writing is to ask Mr. Williams to be good enough to send us the negatives to which he has referred. We will then compare them by actual measurement and report upon them in due course.—Yours, &c.,

Appleton, Widnes, Feb. 6, 1893. F. HURTER & V. C. DRIFFIELD.

To the EDITOR.

SIR,—In your issues of January 27 and February 3 appear two articles by Mr. G. F. Williams on the determination of plate speeds by the method introduced by Messrs. Hurter & Driffield. It is clear that one of the makes experimented upon must be of our manufacture; we therefore wish to say a few words on the subject. We do not consider that it is our province to enter into any defence of the scientific aspects of Messrs. Hurter & Driffield's method of speed determination, or whether the law they lay down as to the action of light be correct or not—this we feel can be better handled by them. Our object is to defend and assert the practical reliability of the speed numbers which we affix on each box of plates of our manufacture.

We see by Mr. Williams's own statement that he has experimented with five batches of one make, and with only one of another. Of the two makes which he letters X and Z, the latter we take to be ours, for we have never issued any plates over actinograph number 130. In the experiments, our plate Z has never been tried against another plate of our make of a different speed, thus the whole argument based on these series of experiments falls to the ground as regards our speed numbering. Knowing the value of the system from more than twelve months' daily working we are most desirous of offering the utmost facility for its trial. We should be pleased if Mr. Williams or any committee of experts would take the matter up with us.

We invite Mr. Williams to favour us with a visit at Southgate and in conjunction with our Mr. Cowan practically test the speed numbers. We are inclined to believe that he may see good grounds for changing his present opinions.

We may add, five English plate-makers, besides ourselves, one American, and one Belgian, have purchased Messrs. Hurter & Driffield's photometer for determining the speed of plates.—I am, yours, &c.,

22, *Soho-square, London, February* 7, 1893. MARION & CO.

To the EDITOR.

SIR,—I make it a rule not to be personal, so I will do my best not to ruffle Mr. G. F. Williams's equanimity more than necessary.

I do not remember any particular flourish of trumpets with regard to the Warnerke sensitometer, and from the first I think that most of the dry-plate makers were aware of the difficulties attending its use; but its numbers were used simply for the want of something else; instance the fact that, to this very day, three of the most important dry-plate makers print the Warnerke numbers on their labels. Quite apart from the difficulty of getting two Warnerke screens exactly alike, sensitometers of all kinds have failed for the want of that very knowledge of the laws of photographic exposure which Messrs. Hurter & Driffield have tried so hard to bring within the understanding of photographers generally; and also, for the same reason, camera-testing also fails, excepting under favourable conditions, which are rarely understood.

Mr. Williams speaks of his love for instruments of precision, and mentions those used in the science of electricity. Doubtless he knows of the characteristic curves of dynamos. Will he say why photographic exposures should not have their characteristic curves also? Has he ever used a Hurter & Driffield photometer, and will he venture to deny that this beautiful instrument is one of precision? May I inform Mr. Williams that it would compare favourably with a great number of electrical measuring instruments in general use? I must not, however, wander from the true point of discussion in Mr. Williams's article.

I venture to think that Mr. Williams has been a little hasty in speaking of Messrs. Hurter & Driffield's classical labour of years as an utterly unreliable, new-fangled method. Abuse is no argument, and I also venture to think that Mr. Williams will be sorry some day that he did not give the Hurter & Driffield system a little *actual* investigation before writing about it in the way he has done. He may take my word when I say that this system is not going to be a *fiasco* in any sense of the word.

I ask Mr. Williams if he has any right to judge Messrs. Hurter & Driffield's system by the interpretation of any dry-plate manufacturer? Is this fair? Has he ever actually investigated the Hurter & Driffield system? Has he the right to presume that, on his bare assertion, he is going to sweep away the work of years of patient investigation? Really, Mr. Williams, I thought better of you!

Not once does Mr. Williams speak of the *relation of density to speed*. This point, the very essence—the soul—in fact, the *all* of the Hurter & Driffield system, is completely ignored, or not noticed by him. Has he really gone through the "investigations" he speaks so slightingly of? I can scarcely think so. It seems to me that Mr. Williams's notion of the Hurter & Driffield system consists in the use of a candle for testing. This does not constitute their system. In consists in reading sensitiveness through *all* the densities of the plate in the period of correct representation, and does Mr. Williams think that he can read sensitiveness, even in the camera, without the proper consideration of density? And if he does not think so, will he say how he values this consideration? Here we have the very pith of the matter, and yet there is not a word in the article about it. Has Mr. Williams considered the true meaning of sensitiveness? Mr. Williams will agree that it is by the opacities in a negative, caused by exposure and development, that every one must in some way give a value for sensitiveness. Will he tell us what precautions he took against reading a mere development factor for sensitiveness? Can he distinguish under-development from under-exposure? I question this *very much*. I have tried experienced men on this point, and they fail, but the Hurter & Driffield photometer would not fail to easily show the difference. If Mr. Williams is prepared to deny that there is a period of under-exposure, one of correct exposure, and one of over-exposure in any given plate, perhaps he will state what he considers the true law of the case. If, on the other hand, he is prepared to admit that these periods exist, he has, in defence of his testing, to say what provision he took to distinguish them and give their proper value in the estimation of speed.

I say without hesitation that no comparative camera tests are worth a straw, unless exposure and development be such as to produce identical negatives *in the correct period*, and as this correct period varies considerably in different makes and qualities of plates, camera-testing is really *very* difficult. Let me tell Mr. Williams that there are gentlemen who make plate-testing by the camera a profession. Some little time ago, I gave two of these gentlemen some plates of considerably different sensitiveness for comparative testing. What was the result? In one case, 500 per cent. error, and in the other 400 per cent. Further *camera* tests proved the error, when identical negatives were demanded. In the case of plates having a relative sensitiveness of two to one, an error of 50 to 75 per cent. is easily made by camera-testing, owing to a widely different developing factor under the same conditions being likely to exist.

In ordinary portraiture, the photographer is kept in check by the necessity of producing a negative of suitable printing quality and this is where a rapid plate is properly estimated; but let such a photographer take to mere plate-testing, he immediately proceeds to do the very thing he ought not to do, he does what Mr. Williams tells us he did in *getting the most out of every plate*. No regard is paid to comparative printing quality, and therefore, as the true relation of density to speed is not taken into account, camera-testing, under such conditions, is a mere farce. Before the second chapter of Mr. Williams's article appeared, I foretold what he would do, viz., that he would over-rate the slower plates and under-rate the quick ones, and this is just what he has done.

I now come to the candle question. It is manifest that, provided that all makes of plates obey the same constant in the relative sensitiveness to candle-light and daylight, it does not matter a fig what that constant may be. Do plates obey that constant, generally speaking? All that I can say is this: that, after hundreds of tests, neither Messrs. Hurter & Driffield, Mr. Alexander Cowan, nor myself are able to say that plates vary in this respect. Even orthochromatic plates for ordinary landscape work obey the same constant very well, though, of course, it is easy to see that, under certain conditions of screen and light, such plates would require a different constant.

There is, however, a grave charge against the standard candle. It is not to be relied on as a standard, for its light is variable to an unexpected degree. I confess that, until I knew better, it misled me on two occasions to the extent of twenty-five per cent.; and, as I wish to be perfectly honest in letting your readers know the truth, I may say that, to my sorrow, the plates marked 135 and 140 were marked higher than they should have been. This was well known to some of the dealers whom we informed of the mistake, and, in justice to Mr. Driffield, I wish to say that he was the first to call us to account. Such, however, was the latitude in working that several people told us that the plates worked very well to the marked speeds, so that the error was not serious.

I am actively engaged on a better light for standard purposes, meanwhile we are working now to the same carefully standardised check-batch as Messrs. Marion & Co., through the courtesy of their Mr. Cowan. Until we get a reliable standard light, the only way is for makers to combine in the use of a check-plate. I can assure your readers that for all practical purposes they can rely on the speed numbers. This matter has been thrashed out by *so many* camera tests, that the few trials made by Mr. Williams go for nothing in deciding the Hurter & Driffield. Men who, by pure calculation, can, as I have seen, produce a transparency which will entirely obliterate a negative into one even tint, know what they are talking about. I have no doubt but that Mr. Williams would be horrified if he knew the errors in his own readings. If, as I gather from his article, he has ignored *density in relation to speed*, his tests must be entirely unreliable.

It is waste of time to argue the length of one's foot, when it can be measured. Please, Mr. Williams, go and measure your negatives.—I am, yours, &c.,

JAMES CADETT.

Greville Works, Ashtead, Surrey, Feb. 8, 1893.

A CORRECTION.

To the EDITOR.

SIR,—In your report of the discussion which followed the reading by Mr. Debenham of his paper on *Photographing Paintings by Artificial Light*, before the London and Provincial Association, I am erroneously reported to have recommended for isochromatic work a screen of a *yellow-red* tint, whereas my remarks were directed to call attention to the necessity of choosing one of a *pure yellow colour*, because with a screen of an unsuitable tint the time of exposure was likely to be unduly prolonged with a minimum of isochromatic effect. I shall be much obliged by your insertion of this correction.—I am, yours, &c.,

February 8, 1893. W. H. BARNES.

PHOTOGRAPHING AT THE CHICAGO EXHIBITION.

To the EDITOR.

SIR,—Your always valuable and welcome JOURNAL came to hand, and as you are always trying to keep your readers well posted, you should add a P.S. to Mr. S. A. Crawford's letter (p. 78) to the effect that Mr. Official Photographer, C. D. Arnold by name (very glad to take pictures, &c., against pay, &c.), does not even answer my inquiry to effect. Personally I have written three times to him without being able to obtain an answer, my first letter dating November 12 last. The above may prove interesting to other parties who may be tempted to ask Mr. C. D. A. for any reference or negatives.

By the way, Mr. Editor, what do you say to the American generosity towards allowing photographers on the Exhibition grounds? You were at the time very hard against French meanness in 1889. Let me remind you of the rules that existed then. Twenty francs, or 16*s.*, for one day's work, and no restriction to sizes or cameras—permission renewed if weather unfavourable, or 300 francs (12*l.*) for the whole time the Exhibition was open.—I am, yours, &c., ALBERT LEVY.

4, *Avenue Pinet, Asnières, Seine.*

P.S.—Is there any practical and easy way to wash film negatives after hypo, say, one dozen at a time, same as glass plates?

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

SEIKS.—We shall probably be having such an article shortly.

F. E. G.—The most suitable colour for the curtain would be a dark grey.

LUKE HEALEY.—Possibly one of the rapid types of lens would be the better for "all-round work."

KINNOUL HILL.—Your local gasfitter we should think could obtain an albocarbon burner for you. We do not know the cost.

GORDON PATERSON.—The specimens are very good, and we should think by their aid you would not have much difficulty in securing a position as improver.

CARPATHIAN.—A seven-inch is, perhaps, abnormally long in the focus for hand-camera work, but could be used successfully if the near objects are not too prominent.

PROFESSOR STENNING.—Presses for the Woodbury process are, we fear, not obtainable second-hand, but we will inquire. Thanks for your greetings; we reciprocate.

HAROLD GLASIER.—Messrs. J. J. Atkinson, Liverpool; Messrs. Holmes, Sadler, & Holmes, of Manchester; and, we believe, other dealers can supply you with the Air-brush.

J. HIGHFIELD.—Instruction in all branches of photography is given at the Polytechnic School of Photography, 309, Regent-street, W., and the fees are moderate. Write for particulars to Mr. E. Howard Farmer at that address.

HADLEY.—The euryscope has a larger aperture than the rapid rectilinear lens, and consequently works quicker. But it will not with its full opening cover so large a field with the same definition, nor will it possess the same "depth of focus."

W. A. T.—At pp. 790-2 of the ALMANAC you will find formulæ for sensitising albumenised paper, and for a hard negative varnish. Opalines may be obtained of most photographic dealers. Use gelatine or starch as the mountant.

G. PHILLIPS.—For the purposes of enlarging and reducing, the focal length of the lens is less material than its power of covering the negative to be enlarged or reduced. Either a single or doublet lens may be used—the latter by preference—for both purposes.

R. A.—Asphalt, such as that used for roadways, is not the kind used in photography. The right kind can be obtained at most photographic warehouses, and, for certain, at Hopkin & Williams', Cross-street, Hatton Garden. It is generally sold under the name of bitumen, and not asphalt.

W. B. SHERK (Waterloo, Ontario).—The Photographic Convention of the United Kingdom for 1893 will be held at Plymouth in the week commencing July 3 next. Full information can be obtained of the Hon. Secretary, Mr. F. P. Cembrano, jun., 10, Cambridge-gardens, Richmond, London, S.W.

M. D.—For such subjects as your desire an objective of somewhat longer focus will be best, say an inch and a half or two-inch power. The ordinary stand will do quite well if used in the way shown in the sketch. Extra rapid plates will not be necessary, unless with unusually opaque subjects.

ALLEGRO.—A studio built as described will answer very well, though we much prefer, particularly for groups, one of the ridge roof or the "lean-to" form—that is, with the vertical side-light and sloping roof. We do not know the addresses of any professional photographers who are working studios of the form referred to.

W. E. BRIGHT.—We have never seen a case of injurious action of hydroquinone on the skin. It is true that we have heard that it has a pernicious effect, but that is all. However, in working, there is no reason why the solution should come in contact with the skin if a little neatness and care be exercised in the manipulations.

STUDIO asks: "Is a studio with only a side-light (eleven feet high and about thirteen feet long) as useful and as easily worked with a satisfactory result with even lighting as the ordinary studio with top and side light?"—Yes, for single figures or studies, or groups of two or three; but for general all-round work the ordinary studio, with top and side light, is preferable.

HENRY JONES writes: "Will you kindly inform me how I can obtain information as to the composition of the mucilage placed on the back of postage stamps?"—The majority of the English and Colonial stamps are produced by Messrs. De la Rue, Bunhill-row. They may possibly supply the desired information if written to. We believe dextrine is the adhesive employed, with, perhaps, some addition.

ALFRED JACKSON.—1. Probably the spots are due to imperfect washing, and the negatives not having been varnished with a sufficiently protective varnish. 2. A lens of two to four inches longer focus would be better for inch and a-half heads than one of eight inches. 3. We have had no experience with that particular brand of plates. We should advise you to try the experiment yourself with a couple of plates.

ENGINEER says: "Could you tell me if any large firms of engineers keep photographers? If so, must they understand engineering, and what branches of engineering would they be required to know?"—We believe many engineers employ their own photographers. Probably a thoroughly good knowledge of practical photography would be more useful than an acquaintance with engineering, although the latter would be no disadvantage.

F. MACKENZIE writes: "With a pair of lenses of portrait type, such as stereographic, is it necessary to retain the hood when they are being used, or can they be used without it successfully? If not, when using a Thornton-Pickard shutter, could it (the hood) be dispensed with?"—A Thornton-Pickard shutter could be used with the hood, and for non-shutter work they may or may not be dispensed with, according to the position of the sun.

R. E. T. says he has some sensitised opal plates that work very well up to the time of washing, then they commence to frill. He says the washing is nearly, if not quite, completed before the trouble commences.—The remedy we should suggest, as the trouble does not begin until the major portion of the "hypo" is removed, is that before the frilling point is reached the plates should be immersed in a solution of alum, and the washing then completed.

S. HARDY.—Eikonogen, hydroquinone, and ferrous oxalate are all good developing agents, but they do not suit some persons' working and their taste so well as pyrogallic acid. With regard to amidol, the same may be said. We produce good work with every one of them. Why not try them all for yourself instead of being confused with other people's ideas? A little experience is far more valuable than a great deal of "hear say" in practical matters.

J. HAMILTON asks: "Would you be so kind as to inform me the best method of making enlargements on artists' stretched canvas for painting in oil? I do not want to take canvas off stretcher, if possible."—The most satisfactory processes for producing photographs on canvas are the carbon and the dusting-on processes, as they yield permanent results. In either case it will be necessary for convenience in working to take the canvas off the stretcher and replace it when the photograph is finished.

R. GODDARD says: "Would it not be an advantage and an improvement if we had tinted glass covers for lantern transparencies, say, shades of green, blue, yellow, purple? The eyes would then aid the imagination. The public are tired of the monotony of the cold, unpainted slide; they want warmer tones, and the various solutions offered for this purpose are a very doubtful success."—Such tinted glasses have long been articles of commerce, although they are not used as cover glasses, but as supplementary glasses.

A. E. NODES.—It is impossible for us to give any opinion as to whether you have or not received full value for the residues you sent to the refiners. The weight of the residue is nothing to go by; it is the amount of silver that it contained that has to be considered. We have frequently described how residues should be treated for sending to the refiner, and also for estimating their value. Where these directions have been followed we have never heard of any dissatisfaction with the returns when the waste has been sent to a respectable refiner.

OTHELLO says: "I have a cabinet portrait lens, no name, but apparently of French manufacture, which, use how I will, will not give a clear negative. The camera used I have ascertained to be perfectly light-tight; in short, it works all right with other lenses; but when this portrait objective is put in, the image on the ground glass is misty and the negative slightly fogged, even if under-exposed. I have tried screening from studio light, but with no effect. Can you suggest the cause?"—No. Send us the lens, and we will endeavour to ascertain why it will not give a clear negative.

T. W.—I. The lens with the medium focus will be the most useful for general purposes. A wide-angle lens should never be employed except in cases of necessity, such as when the amount of subject required cannot be obtained with a longer-focus instrument. Wide-angle pictures are usually unpleasant on account of their violent perspective. 2. For copying purposes a camera focussing from the back will be far more convenient than one focussing from the front, as in the latter case the front conjugate focus is altered with every movement, which makes accurate focussing extremely inconvenient.

OMEGA complaints that, a few months ago, he engaged a canvasser for club work. He says: "He offered to come and work the thing entirely on commission. I agreed to this, and paid him a much higher percentage than would have been the case had he had a weekly salary. He left abruptly last week, and I do not know where he has gone. I now find that he has taken several subscriptions, and not accounted for them. The police say it is not a case for them. What can I do?"—The only thing is to find the man and sue him in the County Court—that is all. Had the man been paid a salary, however small, he would have been a servant, and could be prosecuted for embezzlement.

WATERPROOF says: "I have a quantity of *carte-de-visite* mounts which are waterproof, and I cannot get the prints to adhere to them with ordinary mountants, such as starch and gelatine. After the prints are dry they peel off quite clean. Can you recommend a good mountant—one that will not cause the prints to fade? I can manage all right with thin glue, but am afraid to use that."—If our correspondent can succeed with thin glue he will succeed equally well with thin gelatine, provided the gelatine be similar in physical characteristics to the glue. Such a gelatine is Nelson's "No. 2 soluble," or Cox's soup gelatine. Both these gelatines may be accepted as having no injurious action on the photograph. With common glue this is not the case.

QUÆRO says: "I have recently been much troubled from spots (see enclosed print), caused by dampness in the sensitised paper when in contact with the negative during the process of printing. I notice some brands of paper are much more given to this fault than others. Is there any known process whereby I can remove these spots from the negatives, or are they entirely spoilt for further use? Any information will be thankfully received."—Several methods have from time to time been suggested in the back JOURNAL and the ALMANAC, though in some cases they have not proved altogether successful. Some little time ago Mr. H. N. King, in our pages, announced that he would restore any negative sent to him, gratuitously, to illustrate a method he had devised. Better communicate with him.

STEREO writes: "Can you tell me what should be the appearance of an albumen transparency plate after sensitising? After reading Mr. Hodges' description of the process, I have been trying to produce them, and, after following out the instructions which he gives in his *Lantern Slide Annual* most minutely, I have not been able to get more than the merest ghost of an image, after considerable forcing and very prolonged development. The exposure I gave was ample, and I am certain the fault is not there. My plates, when ready for printing, are quite transparent, like clear glass. Should this be so? I notice the developer that Captain Abney gives for practically the same plates contains fifteen times the amount of pyro that Hodges' does."—The appearance of an albumen plate after sensitising is opalescent, but much less so than a wet-collodion one. With the albumen process there should be no difficulty in obtaining any degree of density. The albumen process is a slow one, and it therefore requires a long exposure. The development is also a slow operation. We now refer to the albumen process such as that which has been frequently described in our columns and in the ALMANACS.

MESSRS. FUERST BROS. inform us that they now sell metol as well as amidol.

PHOTOGRAPHIC CLUB.—February 15, *Home-made Apparatus.* 22, Monthly Lantern Meeting.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Annual General Meeting will be held at the Society's rooms, at eight o'clock, on Tuesday, the 14th inst.

WEST LONDON PHOTOGRAPHIC SOCIETY.—February 14, A Paper on *Art and Photography*, by Mr. A. Horsley Hinton, President of the Holborn Camera Club.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. — February 16, *Demonstration of the Air Brush*, Mr. W. H. Harrison. 23, Annual Musical and Lantern Entertainment, Mr. J. Traill Taylor in the chair.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—The meetings for February and March are:—February 21, Lantern Night. March 7, *Photo-lithography*, by Mr. A. E. Smith. 14, Special Lantern Night in Reading-room.

MESSRS. O. SICHEL & Co. write us to say that, although they have opened show-rooms at 47, Oxford-street, for the convenience of their customers, they have not removed from their old address, 52, Bunhill-row, to which all communications should, as hitherto, be addressed.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES WITH THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The first of the lectures and demonstrations by Mr. Denison on *Photogravure* will be held on Friday, the 17th inst., at Bloomsbury Hall, Hart-street, Bloomsbury, W.C., at eight o'clock.

WE have received from Messrs. Arthur Schwarz & Co. samples of Dr. Andresen's diamidophenol. We shall take an early opportunity of testing its developing power.

TOOTING CAMERA CLUB.—Next meeting, February 19, Lantern Night. It has been decided to change the headquarters to Upper Tooting, and the temporary place of meeting for this night will be at the Bell Coffee Tavern, Upper Tooting, when photographers residing in the district will be welcome.

ARRANGEMENTS are in active progress for the holding of an important local exhibition by the Croydon Camera Club, at the Braithwaite Hall during Easter week, to be open during five days and evenings. Prospectuses will be out during the current week. Applications for space for showing apparatus, &c., and for terms of advertisements in catalogues, should be made to the Hon. Sec., G. R. White, 55, Albert-road, Croydon.

THE Annual Exhibition of the Dunedin (N.Z.) Photographic Society took place in November last. The Society was joined this year, as last, by the Nelson Camera Club, who sent a nice collection of pictures, chiefly in bromides and platinotypes. The total number of exhibits was smaller than before, but the quality of the pictures shown was higher. The plan tried of two societies exhibiting together had been found to work well, not only in making a better display, but also in creating a fraternal feeling between societies in different parts of the colony.

ANNUAL DINNER OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, Captain W. de W. Abney, C.B., R.E., F.R.S., President, in the chair.—The Fifth Annual Dinner of the Above Society will take place at the Café Royal, Regent-street, on Monday, February 13, 1893, at half-past six. The whole of the Council, as far as possible, will attend, and ladies will be cordially welcome. After dinner there will be music, songs, and recitations. Tickets 6s. each, for which an early application is requested, may be obtained of Mr. W. England, 7, St. James's-square, Notting Hill, W.; Mr. Bayley, Assistant Secretary, 50, Great Russell-street, W.C.

WE learn from the "Foreign Notes" of a New York contemporary that the *Amateur Photographer* has started a Lantern Supplement, and that THE BRITISH JOURNAL OF PHOTOGRAPHY, "not to be too far behind the times," also publishes a similar supplement. This comes of our transatlantic contemporary drawing his inspiration from a tainted source. As a matter of fact, the Supplement idea originated with this JOURNAL three years since, although we suffered it to lie *perdu* until recently, and even then it was the first to carry it into effect. Our New York friends must select an "historian" possessing, at least, a reasonable amount of historical honesty.

WE are sorry to learn of the death of Mr. G. M. Whipple, Superintendent of the Kew Observatory. The deceased gentleman had a distinguished scientific career, and his connexion with the chief meteorological observatory in the country dated from 1858. He had made important contributions to the study of solar physics, the determination of wind force and velocity (a still only partially solved problem), assisted in a series of pendulum experiments to determine the force of the earth's gravity, and contributed to the Royal Meteorological Society a large number of valuable papers on rainfall, cloud photography, and kindred subjects. The magnetic part of the report of the Royal Society on the Krakatoa Eruption and subsequent phenomena was written by Mr. Whipple. He was only fifty years of age.

THE following are the Judges' awards at the exhibition of the Photographic Society of India, held in Calcutta a few weeks ago. It will be observed that many very well known pictures by English exhibitors secured recognition:—Class 1, Landscape, Architecture, Interiors: Amateurs—Gold medal, Mr. T. M. Brownrigg, *Evening, Derwentwater.* Silver medals, Captain Bullen, R.E., *Foot of Kedarnaeth Glacier, Gangutri;* Mr. J. E. Austin, *Winter;* Mr. Sub-Conductor O'Neill, *In the Timli Pass.* Bronze medals, Mr. M. V. Portman, *Interior of an Edible Birds' Nest Cave, Andamans;* Dr. F. Noetling, *Frescoes in a Pagoda at Pagan, Burma;* Mr. A. R. Dresser, *Meeting of Conway and Lledr Rivers;* Miss M. Watson, *Vallombrosa, Tuscany.* Professionals—Viceroy's medal, Messrs. Johnston & Hoffman, *Peaks N.E. of Simlolchu.* Silver medals, Mr. F. P. Cembrano, *A River Fog;* Mr. W. Bedford, *Salhouse Dike;* The Autotype Company, *Alpine View.* Bronze medal, Shrinivas Madadeo & Son, *Six Silver Prints.* Class 2, Portraits and Groups: Amateur—Silver Medal, Mr. C. B. Moore, *Groups of Three Little "Nips."* Professionals—Silver medal, Mr. R. Hotz, *Group of Children.* Bronze medals, Mr. W. W. Winter, *Blushing Sixteen;* Messrs. F. Kapp & Co., *Set of Window Transparencies.* Class 3, Genre Pictures and Studies: Amateurs—Silver medals, Surgeon-Captain A. G. E. Newland, *Life and Scenes on the Chin Hills;* Mrs. S. Francis Clarke, *"Aha!"* Bronze medal, Mr. S. Francis Clarke, *The Seven Ages of Man.* Professionals—Gold medal, Shapoor N. Bhedwar, *Consecration of a Parsee Priest.* Silver medal, Mr. E. Scamell, *Series of London Street Cries.* Bronze medal, Mr. S. C. Sen, *Noon-day.* Class 4, Photographs of Objects of Motion: No awards. Class 6, Photo-Mechanical Processes: Professionals—Gold medal, Mr. R. Panlussen, *Pferdemarkt.* Bronze medals, the Typographic Etching Company, *Specimens of Photogravure;* Mr. W. L. Colls, *Specimens of Photogravure.*

JOURNAL OF PHOTOGRAPHY.

No. 1711. Vol. XL.—FEBRUARY 17, 1893.

THE EYE AND THE CAMERA.

The ever-recurring analogy of the human eye and the photographic camera and lens is always of so much interest that no apology is needed before bringing to our readers' notice recent discoveries in optical science in which the resemblance between the two is shown to be still more close. In the eye we have four transparent optical media through which the rays pass to form an image on the retina; in the photographic analogue we have media which equal, exceed, or are less in number, according to the construction of the lenses. The eye has, first, the cornea; next the aqueous humour; after that the crystalline lens; and, finally, the vitreous humour, immediately behind which the image is thrown. In our apparatus, the work of man, we have crown glass or its equivalent; flint glass, the latter possibly of more kinds than one; and, finally, in the interior of the camera, atmospheric air, which corresponds to the vitreous humour. The sides of the camera itself correspond to the walls of the eyeball. Whether influenced by a knowledge of the construction of the eye or not we cannot say, but the makers of our early cameras gave them black walls, just as the eye has. Two most important differences, however, are to be seen in the two cases. In the camera the surface which receives the image is separated from the chief curved refracting media by air, the index of refraction of glass into air being very much greater than from the crystalline lens into the vitreous humour, an entirely different series of refractions taking place in consequence. There is no doubt that if there were practical means of carrying such a system out in photographic work, some remarkable results would be obtained. The second difference to which we would draw attention is one which, if earlier observed, as were the darkened walls, would have led to a better appreciation of a still much-neglected point. We are not aware that attention has been drawn to this remarkable and valuable provision as a still more extended analogue to the "backing" of the sensitive surface with black pigment (over all, except one spot). The retina, which receives the image, is transparent, as is our photographic plate, and reflections which would mar the delicacy of its perceptions are by this backing provided against. It is true that a minute area is not so provided; but, as the inner surfaces are curved, the effect of the circumjacent non-backed retina upon this central spot may be readily imagined. It is thus seen that a due study of the eye would have provided a skilled inventor with effective modes of treating our photographic instruments, one, at least, of which modes was not adopted for years after the advent of photography.

We are now come to a point which will enable us to more fully understand the most recent aspects from which we are taught to regard the eye. When flare spot was investigated, and its cause discovered, no one drew attention to the fact that the eye also had its difficulties to contend with from internal reflections; but, as a matter of fact, at the beginning of the present century, Purkinjie described four different kinds of these reflections that he had seen himself, though, of more modern investigators, Helmholtz and others were only able to discern three. These reflections are not the Purkinjie figures described in most works treating of the eye, and caused by shadows from overlying blood-vessels thrown upon the retina; but are distinct images of such an object as a lighted taper, exactly like what is seen in a photographic lens when held between the eye and a spot of light. These three reflections can be seen if two persons hold a lighted taper between their eyes, and, moving it to and fro, so that the reflections appear to come from the pupil, which, as we need scarcely explain, is not a black substance, but merely a hole—an exact diaphragm in fact—in the iris (hence our "iris diaphragms"). The brightest image is formed from the front surface of the eye, and the other two come from the "lens" and the hindermost medium (the vitreous) respectively. The fourth reflection requires the greatest skill in searching for. It arises at the back surface of the front medium, the cornea, and will be seen by observing the brightest image with a magnifying-glass. When this latter is caused to leave the centre of the pupil, there will be seen, between it and the centre of the pupil, another small, pale, clearly marked image, which makes four reflections.

It has always been pointed out that the fewer the reflecting surfaces in a lens the quicker it will be. In a single lens 92 per cent. of useful light is obtained; but the eye gives 97. The internal reflections into a camera, say, in the case of a single lens, amount to one-sixth per cent., but to the eye to not one-eightieth of that amount! But at last even this small amount of reflection has been observed in two distinct phases. This makes six reflected images now perceivable in the eye, and a seventh was expected to be visible. It was found in an artificial eye, but not in the living organ; the amount of available light in the eye swamps this image.

In conclusion, we may continue the analogue by pointing out that, as the lens-maker carefully examines in every instrument he makes the way the various images of a spot of light behave in different positions of the lens, and so knows whether the components are duly "central," so an examination of the images in the living eye enable the physican to discover when anything is wrong with its interior optical media or surfaces. It is thus seen in this brief survey how much that is valuable in

photographic practice is indicated by a study of the eye. Is it too much to anticipate that even yet it may be found to point out further improvements in optical construction or the application of optical principles in photographic technics?

PHOTOGRAPHING HORSES.

On more than one occasion of late, photographs of horses have been sent us by correspondents, for various purposes, which have seemed to us so unsuccessful in the rendering of the equine subjects, both as likenesses and as technical representations illustrating the principal points of the originals, that we have thought it opportune to devote a brief article to the subject, in which branch of their profession most photographers at some time or other will probably have found themselves engaged. Without pretending to the possession of any trace of "horsiness" ourselves, we can at least appreciate the circumstance that, as in the portrayal of the human species, something more than hap-hazard or chance is demanded at the hands of the photographer before a favourable result can be expected.

We cannot possibly do better than indicate at once in general terms the character of the equine photographs we have recently seen, and which we will take as displaying to a singular degree of perfection the very worst way in which the friend of man should be photographed. The animals have been taken against such backgrounds as stable doors and the sides of houses, and so that only the near fore and hind legs were visible in the photographs, while the animals' heads were drooping, the ears turned backwards, the positions betokening listlessness of demeanour, and vouching so little on behalf of the animals' spirit and character, that we can quite imagine to the eye of an horse expert the photographs conveyed far from a favourable idea. What we here say applies, we have observed, to racehorses, carriage horses, and even to the simple Dobbin of the tradesman's cart.

Captain Hayes, a distinguished authority on the horse, and whose photographs of that and other animals, which have been recently shown at the Polytechnic Institution and some of the photographic societies, attest the possession of a very high degree of photographic skill, which we can confirm from personal inspection of them, gives some simple directions for the photographing of horses which may be so useful to photographers that we make no apology for here alluding to them. That gentleman, if we take him aright, recommends that a horse should, where possible, be photographed away from his habitual surroundings, such as his stable, for the reason that when near home his condition is largely influenced by his environment, so that his bearing and attitude are of a *dégagé* character, and therefore not entirely favourable to the display of his best points. Captain Hayes says that when a horse is in a strange place he is all agog with curiosity and alertness and the excitement engendered by novel surroundings, a condition which is the most suitable for obtaining an animated portrait of him.

In this interested and excited condition the animal's ears are well placed forward, the curvature of his outlines is at its most natural rendering, and possibly the four legs are so placed on the ground as to impart a realistic air to the animal. The horse should be photographed, according to Captain Hayes, against the sky-line in profile—and broadside on. Other authorities, however, unite in recommending the picture to be taken slightly in perspective. Both methods, doubtless, are excellent for securing a likeness, but we should incline to favour that of Captain Hayes, where it is sought to secure an animated picture and to show the dominant points of the animal, although possibly the latter, from the standpoint of picturesqueness as understood by artists, has something to recommend it. In any case, however, it is seldom that a satisfactory picture of a horse taken "end on" can be obtained. We recommend this consideration to the attention of the numerous amateurs who are fond of including sheep and cows in their pictures. Such animals, taken end side on, often have a grotesquely squat appearance.

It is, we believe, at times difficult to get a horse to stand so that his four legs are placed in such positions as to show separately in the picture taken broadside on. Too many photographs of horses portray the animals, as it were, standing on two legs only, on account of the photographer having an insufficient conception of how the portrait of a horse should be taken, or possibly of a lack of the necessary patience to secure a suitable attitude. Hence, as short exposures as practicable are to be recommended, a condition of things which, with a stand camera, necessitates a very rapid lens and plate and a quick shutter. Captain Hayes, we believe, works with a twin-lens hand camera.

In the foregoing we are alluding less to horses in rapid motion than in the comparative repose of the paddock the field, or the stable-yard, our remarks not being intended to include horses racing or jumping, although there is a certain parallel throughout. Farm subjects including studies of the placid animals usually to be found therein, necessarily should engage special attention on the part of the photographer towards the horses, as well as to the two-legged figures in the picture.

Few photographers have the skill of getting a horse to stand as they would wish him to, and therefore the use of a hand camera is all the more to be recommended, having regard to the ease with which subsequent enlargements may be made. As regards the backgrounds, the sky is, of course, less suitable for grey horses than for those with dark coats, as the outlines might not appear so sharp as they really were, and in that case a mass of trees, or even the side of a house, offers no objections. Now and again a single horse may be found so tractable as to allow of an exposure by means of a cap being given, but where several horses are to be included quick shutter exposures are indispensable. The variety of movement in which they indulge can only be appreciated by the photographer who has to wait till they are still before removing the cap from the lens.

AMATEURS' BACKGROUNDS AND ACCESSORIES.

I.

There is probably no point in connexion with portraiture to which amateurs, as a rule, give less attention than to the background, although, as every observant individual must agree, nothing contributes in a greater degree to the final effect in the picture. It is a pet theory with many of the class that amateurs' portraits are "so much more natural," because they are usually taken under more home-like conditions, and without the conventional surroundings of the regular professional studio. But it is possible to take an exaggerated view of the supposed advantages referred to, and by carelessness allow what might otherwise be an artistic portrait to degenerate into the commonplace.

Reviewing the various styles of portraiture that have prevailed since the earliest days of photography, we shall find a vast difference in their general character at different periods. Take, for instance, the Daguerreotype of forty years ago or more, and we have to chronicle an almost entire absence of accessories of any kind, the style of picture at that time, and for some years later, consisting chiefly of busts, or at most half-length sitting figures, in which there was little room for the introduction of anything in the shape of furniture or ornament. But with the advent of the *carte-de-visite* there came an entire change, and with balustrades, pedestals, bookcases, pianos, and similar accessories, solid or sham, together with curtains and painted backgrounds in every possible style of subject, the actual portrait frequently had to take a very subsidiary position in the picture.

The next change was in the direction of more artistic lighting, and with cabinet and larger portraits came "Rembrandt" and "Salomonesque" effects, and a partial return to the simple style of earlier years. It would be difficult to say what is the "prevailing" fashion at the present day, for while accessories of various kinds, as well as scenic backgrounds, are just as much used as formerly in certain classes of portraiture, though perhaps with more artistic taste, we have also a wide choice between the plain vignette or bust and the home portraits and family groupings that have become so fashionable in recent years. It is in the latter direction, indeed, that modern photographic portraiture is surely tending, owing to the ease with which the exposures may now be made in ordinary rooms, or without the necessity that formerly existed for a specially glazed studio.

Home portraits, as we usually understand them, are such as are actually taken at the home of the sitter, though there are professional portraitists, both in this country and on the Continent, who make a feature of this style of picture in studios specially fitted for the purpose. Whichever plan may be adopted, however, it is certain that the professional will suit his background and accessories to the immediate requirements of the case, and not leave the portrait to take its chance amongst incongruous surroundings; the amateur, on the other hand, is too apt to take things as he finds them, and, for want of a little thought and management, to produce work that were better left undone, when it might almost as easily have been of a totally different character. How often, for instance, do we see home portraits, or those taken in an ordinary room, well lighted and posed, and possessing all the characteristics of naturalness, and yet entirely spoilt by the obtrusion of some article of furniture very much out of focus, filling up a portion of the background. Or it may be that the blurred pattern of an elaborate wall paper draws the attention away from the portrait, or the latter is perchance half lost in a mass of total darkness.

Again, in the case of outdoor pictures or groups, it is seldom that a due amount of care is taken in arranging the figure or figures so that the surroundings harmonise and form anything worthy of the name of picture. Beyond placing the sitter so that a fair amount of light may fall on him or her, no further care seems to be considered needful, and the backgrounds may be composed of shrubs, foliage, and brickwork in happy confusion. Such a rendering may be natural in one sense, but it lacks the *ars celare artem* necessary to make it artistic. It is not, of course, everywhere possible, even with the best efforts, to bend the surroundings to the artistic will, and where such is the case it is, in every sense, preferable to relinquish the attempt, and to substitute a plain and unobtrusive background which will, at least, leave the portrait to stand upon its own merits.

We by no means wish to decry the practice of utilising the natural surroundings, either indoors or out, where they can be artistically combined in the formation of a picture; but what we do counsel is the exercise of judgment. Thus, perfectly natural and, perhaps, artistic full-length portraits may be made by posing a standing figure in front of the fireplace, or a sitting one at a table, or *escritoire*, or even beside a window; but to take a mere head and shoulders under similar circumstances would be little less than ridiculous. In like manner, a natural and pleasing group may frequently be made with available outdoor surroundings if a little attention be given to common sense and perspective; but to see three or four figures cut off at the knees or waists, posed against a background of climbing foliage, is neither natural nor artistic.

The Free Portrait Case.—The Treasury appear to be sparing neither time or money in the prosecution of the man Gould in this case. Witnesses are being brought from all parts of the Kingdom to prove the extent of the fraud. The case was first brought before the Folkestone magistrates on December 30, and weekly ever since. A layman might have expected that such an expenditure of time was scarcely necessary in a matter of this kind, but the lawyers evidently have a different opinion.

Difference of Opinion.—It is curious, at times, to note the diverse opinions that different persons may have on the same subject. The scientific world has been pretty unanimous in opinion as to the utility of Herr Anschütz's clever invention, which is now on view in the neighbourhood of Charing Cross. But this idea is not shared by every one, as the following remark by one lady to another overheard outside the place in the Strand the other day. "It's a show of pictures of moving figures. It's awfully stupid." It is quite possible that if what the exhibition were intended to illustrate were made more prominent it would be the better understood by the general public.

"A Novelty?"—An evening contemporary informs its readers that, by an ingenious process of engraving, practised in Germany, a subject can be drawn on a plate of zinc, which is covered with a layer of bitumen, either by the artist or by photographic means, then plunged in a bath of diluted acid. The acid then attacks the metal, and in a few minutes sufficient depth is obtained. Our contemporary adds that the process is already seriously affecting working engravers. Apparently it is not aware that the majority of blocks used in illustrating the daily and weekly papers are produced in this way, and have been for years past. Possibly some few of its readers may think that some new invention is referred to.

Sale of Poisons.—Some little time ago we referred to a crusade the Pharmaceutical Society had made against grocers for selling patent medicines containing poison—Dr. Collis Browne's Chlorodyne to wit—under the Pharmacy Act. The decision of the County Court Judge, which was in favour of the Society, was appealed against, but the appeal was, last week, in the Court of Queen's Bench, dismissed with costs. Leave was, however, given to take the case still higher, namely, to the Court of Appeal. As we have said before, photographic dealers who are not pharmaceutical chemists should be careful whom their assistants supply with the prohibited articles, as the Society occasionally become very energetic in asserting its privileges.

Photographing at the Chicago Exhibition.—After all the murmuring about the two dollars a day and other restrictions as

to taking photographs at the Show, it now appears that these terms only hold good up to May 1, or while it is in a more or less chaotic state. After that date they will not obtain. It is announced that the "official photographer" will take pictures to order at stated prices. Those who have been protesting against the two-dollar impost when they imagined the Exhibition would be in "full swing" are now given to understand that the privilege of photographing on those terms will be withheld. Of course our American friends can make what conditions they choose, and others may think what they like about them.

Combustion of Magnesium Powder.—At a recent meeting of the Photographic Society of Philadelphia a condition in connexion with magnesium powder that is frequently overlooked here was alluded to—namely, its dryness. If the powder contains moisture, it is obvious that its ignition will be retarded, and many particles when projected through the flame will often escape combustion, with a corresponding loss of light. It was also pointed out that moist breath blown through the lamp would sometimes cause dampness of the powder. There is yet another cause which impedes the combustion of magnesium, namely, oxidation of the metal itself. When its surface is coated with a layer of oxide a greater heat is required for its ignition than when it is bright. For this reason the stock of powder should be, as much as possible, protected from the action of the atmosphere by being closely pressed into well-corked bottles.

Patent Law Reform.—Mr. Leng, M.P. for Dundee, has recently been in correspondence with the President of the Board of Trade on the subject of the granting of patents. In it Mr. Leng directed attention to the fact that, when a patent was applied for, no information or notice was given to the applicant, even if there were a score or more patents already in existence that would cover the supposed new invention. He suggested that this country should follow the system carried out in the United States, Germany, and some other countries, of making an official examination before the patent is issued. Mr. Mundella, in his reply, says that the proposal would involve a radical change in the principle and policy of the patent laws; but the suggestion should receive "careful consideration"—the usual stereotyped phrase. If the member for Dundee's idea were carried out, there is no question that the receipts of the Patent Office would be considerably reduced, and its profits lessened; still, when it is considered that in America a patent for seventeen years, with a certain kind of guarantee that the thing has not been patented before and therefore the patent is valid, for about 7*l.* 10*s.*, between 90*l.* and 100*l.* seems dear for a British one for only fourteen years, that may be absolutely worthless through the invention having been patented previously. We have no hesitation in saying that, if an examination of specifications were made, the number of patents now granted in connexion with photography would be materially curtailed. With an examination of specifications one abuse of patents would be checked. Patents are often now taken out which the patentees know quite well are not valid through the invention being old. They thereby obtain a fictitious monopoly, which others imagine is really genuine, while the invention is public property.

The Eight Hours a Day in Photographic Establishments.—Messrs. James Valentine & Sons, the well-known photographic publishers of Dundee, recently issued the subjoined notice to their *employés*:—"Notice. Alteration of working hours. We have been considering the hours of employment, and have decided to institute a forty-eight hours' week for all our *employés* at Perth-road, Dundee, and Baldovan, the week's work to be arranged as follows: Mondays, 8 a.m. till 5 p.m.; Tuesdays, 8 a.m. till 6 p.m.; Wednesdays, 8 a.m. till 5 p.m.; Thursdays, 8 a.m. till 6 p.m.; Fridays, 8 a.m. till 8 p.m.—dinner hour as usual on these days; Saturdays, 8 a.m. till 1 p.m. We do not intend to reduce wages, as, with the co-operation of our *employés*, we believe it possible to fully maintain the same production as under a fifty-two hours' week. We propose to give this scheme a fair trial for six months from this date (February 9), when, should our anticipations not be realised, it may be found necessary to reconsider the matter. We, however, hope that our *employés* will unanimously endeavour to make the movement a success by prompt commencement of work daily, and continued attention to it during the hours specified. As the success of the scheme depends entirely on the diligence of every *employé*, it must be distinctly understood that any idling or negligence may cause the instant dismissal, without warning, of any *employé*. Trusting that this proposal will meet with your hearty approval," &c. The local papers applaud the action of Messrs. Valentine, and a few nights ago, at a social gathering of the firm's *employés*, the introduction of the eight hours a day was acknowledged in terms of the highest thanks by representatives of the latter, one of whom stated that the establishment of Messrs. Valentine was steadily progressing year by year, and in regard to the latest movement—that of working a forty-eight hours' week—which was no small matter where about 230 persons were employed, he thought they ought to assure Mr. Valentine by a hearty round of applause that they meant to make it a success. We congratulate Messrs. Valentine on their enlightened enterprise, which we hope will prove as successful as they wish, and will be imitated by other large photographic firms throughout the country.

RAPID SOLUTION-MAKING.

In the pages of this Journal for February 3 will be found an illustration of an apparatus for the rapid making of solutions, which embodies a plan I have had in use in my laboratory for some years past, and which I can speak of in the highest terms. It is described in an article from my son's pen in The British Journal Photographic Almanac for this year, where full details of its usefulness and manner of use will be found. Those members of the Convention who did me the honour to call upon me during the Chester meeting will remember the apparatus, if such a name can be applied to so simple a contrivance. I do not remember when Mr. Ayres, as referred to by the Editor, described such an arrangement; in my own case the invention was spontaneous. We all know "great minds think alike!" doubtless in our cases the invention was original, whichever can claim priority of publication. The purpose of this brief memorandum, however, is not as a reclamation of priority, but to again draw attention to a plan of extreme usefulness for lightening and facilitating the monotonous routine work of making stock solutions. It may be stated that, apart from the special apparatus described a fortnight ago, there are already on the market the necessary utensils, in the shape of the perforated receptacle for the crystals, and the jug or jar for holding the liquid. The former, as used in my laboratory, is made at the Lambeth Potteries (and very probably at other manufactories where chemical utensils are made); it is known as a "perforated dipping basket." In Doulton's pattern the means of suspension is a handle, like that of an ordinary basket, made in one piece with the vessel itself, and the buckets can be had in all sizes, from a capacity of one pint to one gallon.

A very important matter in the jugs employed, when used for "hypo," is to obtain one the glaze of which will not give way to the action of that chemical. The ordinary jugs for domestic and culinary work are useless after a time, and I have found that the common salt-glazed red ware most commonly obtainable at the dealers in sizes of a gallon or upwards will begin to leak in a fortnight's time. At least, that has been my experience, and I had several of them before finally adopting the kind I now employ, each holding three gallons, and which have been in daily use for several years. These latter also are of Doulton ware, sold as "acid jugs." Of course porcelain could not be excelled for the purpose, but for large jugs its price would be prohibitive, and even for the dipping basket itself, unless of diminutive proportions, the cost of real porcelain would greatly exceed that of stoneware.

I need scarcely remind my readers that, without any intention of deceiving the public, many of the utensils for photographic use sold under the name of porcelain are not porcelain at all—dipping baths, dishes, &c.—and their glaze quickly gives way under the action of ordinary chemicals. G. Watmough Webster, F.C.S.

AMERICAN NOTES AND NEWS.

Positives Direct.—Mr. Charles W. Weatherwax writes to the American journals: "I have discovered a simple solvent for metallic silver, and beg space in your valuable journal to acquaint your many readers with a very simple and practical way of making positives direct in the camera. I will not enter into a discussion on the reversal of the image, but give my method as follows:—*First*, expose the plate in the usual manner. Develop with—

No. 1.

Sulphite of soda (crystals)	3 ounces.
Eikonogen	1 ounce.
Hot water	45 ounces.

No. 2.

Sal soda	4 ounces.
Water	15 „

To develop, take of—

No. 1	3 ounces.
No. 2	1 ounce.

When the negative is almost developed, expose it to daylight, keeping it well covered with developer. In about thirty seconds you will see the change from negative to positive. Wash and fix in the usual manner, and you will have a well-defined positive." We should like to see this experiment duplicated and confirmed, if only to establish the fact of an alkaline developer being a "solvent of metallic silver."

To Prevent Silver Stains.—Mr. J. Heygessy, in the *St. Louis and Canadian Photographer*, who had tried many remedies for preventing silver stains without success, says that one day, being in a hurry to get a few prints from a negative, he noticed silver stains spreading all over it save where the retouching medium had been applied. Ever since then he has rubbed the medium over the entire negative, and has tried every way to produce silver stains upon rejected negatives, purposely making the paper damp, but cannot do so Any medium having turpentine for its base answers the purpose.

Sunday Work in the States.—*Anthony's Bulletin* says: "Hereafter Boston photographers are forbidden to work on Sundays. This will be a serious loss to certain of them who do a larger business on this than on any other day. It seems that the law regarding Sunday work has long been in existence, but had practically become a dead letter. All this is to be changed, as the Chief of Police has expressed his intention of strictly forcing this regulation."

A Convertible Camera and Photograph Exhibitor. A recently patented invention in the United States is a convertible camera and photograph exhibitor, by means of which negatives may be taken and the pictures, after being printed on suitable material, such as sensitised film, to produce transparencies, reinserted into the camera and viewed under transmitted light, in the camera, through a lens in the camera case. The device is designed to afford not only a good camera, but also means for magnifying and inspecting the finished photographs, and is preferably made so small as to be conveniently carried in the pocket.

"As Others See Us."—The editor of the *Photo-Beacon* (erstwhile the Chicago *Beacon*), in the course of an appreciative article on "Prints on Rough Paper," remarks: "The so-called impressionistic photography was unfortunate in having for its godfather a man steeped in egotism, and whose language was as intemperate as is that of a temperance lecturer, and consequently both he and it were simply laughed at by all but a very few. As nothing kills so quickly as ridicule, the disciples of the then-called "fuzzy" school had a hard fight to make their way, and not indeed till their self-constituted leader, disgusted at not being appreciated according to his own idea of his merit, turned his back upon photography, did they get anything like a patient hearing." Dr. Emerson will chuckle at reading this, we are sure. We hope to find, when he reads his paper next month at the Great Britain Society, of the council of which he is now a member, that he has *not* turned his back on photography, as the *Photo-Beacon* has it.

American Photographic Societies.—A writer in an American journal claims that there are about 100 photographic societies in the United States, and the editor of *Wilson's Photographic Magazine* (the appearance of which in its new dress is exceedingly attractive and quite up to date) interjects, "More than that." Assuming that there are 120, we in Great Britain, with not much more than half the population of the States, have between 200 and 300 societies.

ON THE PRODUCTION OF BLACK AND WHITE NEGATIVES BY MEANS OF ARTIFICIAL LIGHT.

II.

In a former article I described a convenient method of using the Argand burners as a means of lighting the subject, and mentioned that a very effective set of reflectors were those made of plaster of Paris, in form almost similar to such as are in use on microscope lamps. These reflectors are not to be had in the market, so a worker must spend some little time and trouble in making them for himself; but such trouble will be amply repaid by the after pleasure of working with them.

Procure from some stucco shop about three pounds of pure white plaster of Paris (make sure it is pure white), for frequently samples having a distinctly pink or yellow tint are supplied as white; and having got this, next procure a large lump of common clay, work it up by the hand until it is nice and soft. Next procure two pieces of thin cardboard, or very stiff paper will do, and proceed to roll one of them into a tube, one inch larger in circumference than the glass funnel of the Argand burner; the length of the paper tube should be about as long as the funnel. With the other piece of cardboard make another tube about one inch larger in circumference than the other; these two tubes will serve the purpose of making a mould into which the plaster of Paris is to be afterwards poured. It is well to expend a little trouble in getting these cardboard tubes nicely rounded in shape. Sometimes a metal tube or a wooden roller may be picked up in any household that will come in very handy for rolling the paper round so as to get a good shape. If such can be got, it will make the labour of producing the tubes mere child's play.

When the glue is dry the tubes may be drawn off the roller; they are then ready for being placed end on, one inside the other, on the lump of clay which is conveniently used by being padded down on a common soup plate. Make sure the ends of the tubes are well pressed into the bed of clay—if you cannot get a supply of common clay, some fine sand or glaziers' putty will do as well—to hold the tubes upright, and so prevent the plaster from running out at the bottom. The two tubes at the top can be separated the proper distance, and held in such position by merely placing small splinters of wood, or a piece broken off a match will do nicely.

The mould is now all ready to receive the plaster of Paris.

To any of my readers having no experience in the working of plaster of Paris, a few words of explanation will be acceptable, for it is a peculiar material to work with. Shortly after plaster of Paris is mixed with water, and appears to a novice to have acquired the consistency of thick cream, it suddenly begins to set, and in a very few minutes becomes a hard block or mass of stucco. Therefore, when working with it, everything should be nicely arranged beforehand. See, therefore, before you begin to mix the plaster that the mould is right and in a convenient position to receive the fluid plaster.

There need, however, be no flurry, and a worker should not get excited; although it has to be expeditiously gone about, there is no difficulty in using it before it hardens in the mixing bowl. The best utensil to mix the plaster in is a large bowl having a pouring lip; it is advisable to get such, for without the lip very likely as much will be poured outside the mould as in it.

Having got a suitable bowl and a thick stick, flattened at the end, place four or five good handfuls of plaster of Paris on the bottom of the dry bowl, and with the stick make a hollow in the plaster, and having a jug of water at hand, in which a little common alum has been dissolved, pour steadily into the centre of the plaster of Paris. Stirring from the sides inwards by means of the flattened stick, go on adding water till all the plaster of Paris seems to have become dissolved and the mixture is about as thick as cream. There is no need to hurry, but there must be no undue delay when it is all mixed in

pouring it into the mould. After being poured into the mould, let it stand for about half an hour, when the whole can be lifted away from the clay, and the two paper moulds may be torn off the plaster. If these instructions have been carried out, the result is a perfect cylinder of plaster of Paris, which, on drying thoroughly in a warm room, say, in about two days, will be of a beautiful white colour. When dry, the cylinder has to be trimmed by means of a sharp knife, and with such proceed to cut an aperture out of the side and end, just like the shape of a microscope lamp. There is no difficulty in this, as the plaster will cut easily. With the aperture cut out the reflector is all ready for being placed over or to surround the glass funnel of the Argand burner. This is the best form of reflector I know, and serves at the same time to shield the worker's eyes when photographing by night, as well as preventing the rays of light entering the lens when the lamps are being worked at close quarters.

Somewhat recently I have been making experiments by using coloured reflectors of this pattern in conjunction with isochromatic plates when copying coloured subjects, and, at some future time, may give the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY particulars of the results obtained.

So much for what experience has shown me is the best and most practical method of lighting by means of common house gas, and once these reflectors are used they will never be discarded.

Next in importance to adopting a good method of illumination is the employment of a plate suitable for use with house gas. In isochromatic plates we have everything that can be desired. Such, however, should not be of the utmost rapidity—a slow or medium plate yields better results than the extra rapid quality.

In using these excellent plates, a word of caution is necessary. Before exposing a plate every camera and dark slide ought to be thoroughly overhauled and examined for any leakage, the interior of the bellows should be reblacked if in any way worn, every bright speck on the interior of the camera front should be obliterated with a good black stain, and no lens ought to be used that will tend to throw rays on the side of the bellows. The dark-room lamp must be suitable for these plates. I firmly believe one half the dark-room lamps supplied at the present time are quite unsuitable for use with isochromatic plates, and when developing see that the dish is provided with a cover to shield the plate even from the light of a deep ruby lamp. Attention to such points as these will go a long way in aiding the production of negatives free from fog, so detrimental in the class of work we are considering. A safe lamp will be found by shielding the light by means of one piece of orange and one of deep ruby glass.

Perhaps one of the best subjects a beginner can get to practise on is an ordinary page of printed matter, and practise on such until he can with certainty produce clear glass, or as clear as gelatine will give, and the blacks so opaque that no light is visible through same when held up before an ordinary gas jet at a distance of eight or twelve inches.

To use the Argand burners a good rigid table should be obtained, and a copying board about six feet long by fifteen inches wide. This copying board is a great acquisition, as it enables the object to be placed and held *in situ* in a true plane with the sensitive plate.

If somewhat large work has to be done, the top of a kitchen table may have wings screwed on to the sides. These arms will extend over and hold the lamps at any distance out. My operating table is provided with such, and I find it a great convenience.

In using two Argand burners the supply from one gas pipe may be insufficient; it is therefore advisable to feed each burner from a separate pipe. When this is done both burners are easily made to work at their best capacity, and, what is of equal importance, when one is being screwed down, the other is unaltered, as is likely to occur when both are fed from the one pipe by means of a T-piece.

A very little close examination will show when the surface of, say, a page of printed matter is evenly lighted all over. At first a few failures will likely to be met with; these will be observed on development of the plate, but after a few exposures it is easily apparent when an equal illumination is obtained. Such failures are more likely to occur when large surfaces are being copied; therefore a beginner had better commence with a small page of printed matter, as previously suggested.

Two good Argand burners are said to be equal to about thirty-five candles, but with the reflector described the light is beautifully concentrated. At the same time there is an absolute freedom of shadow or any dark lines so often met with, and troublesome in the using of very many of the common form of oil lamps, even including the Sciopticon form. If the Argand burners are carefully placed at equal distances apart from the centre of the picture, there will be a perfectly evenly lighted surface, and one of great brilliancy; in fact, I know of no other method of acquiring such an evenly lighted surface as by their means when used in conjunction with these plates and plaster of Paris reflectors.

T. N. ARMSTRONG.

ON THE COMPARATIVE ADVANTAGES OF THE WIDE-ANGLE AND TELE-PHOTOGRAPHIC LENSES.

[South London Photographic Society.]

IN your invitation to read a paper on some optical subject, you have been good enough to select a title for me. I shall approach the subject chiefly from the side of the "man of measurement," for adequate criticism of photographic representation by optical means requires the combination of an exhaustive study of the physiology of "vision" and the recommendations of a mature student in pictorial art.

As I understand, the two main branches of photography are mathematical exactness on the one hand, and on the other such artistic skill applied to the representation of the subject as the instruments and methods we have at our disposal will allow; the first a scientific record, and the second an attempt to make such objects and scenes in nature that we wish to reproduce "*look right*," to use an artist's phrase.

WHAT WIDE-ANGLE AND TELE-PHOTOGRAPHIC LENSES DEPICT.

Carried to extremes, neither photographs taken by wide-angle lenses nor by tele-photographic lenses depict actually what is *seen*. The wide-angle lens forces the perspective to such an extent that a "den" may be made to look palatial in its proportions, and tele-photographic images may be made, large and clearly defined, of objects situated at such distances that the details shown in them would be quite invisible to the naked eye.

On the subject of the first branch, viz., scientific photography, provided both types of lens are non-distorting, the drawing given by them is in exact accordance to the laws of monocular perspective, and being due solely to the fixed point of sight for the time being. The tele-photographic lens has a very pronounced advantage in being able to record that which could not be seen without recourse to the telescopic aid, and the wide-angle lens has its own scientific value in that it can record in one view a greater amount of subject, so much so that from one standpoint the whole horizon may be recorded in three views, in other words, taking in as much as 120° in each operation.

When we come to the consideration of instrumental aids to pictorial photography, or our endeavour to make a picture *look right*, our object lies in the direction of seeing how nearly we can approach to a parallelism to visual impressions. I have thought it might be of interest to you if we were to go through such laws in connexion with the subject of "sight" as might assist us in an analysis of the best instrumental means to adopt in order to keep our representations as much in touch with these laws as possible, for the subject before us is really one involving in a great measure the science of perspective.

THE LAW OF VISIBLE DIRECTION.

Knowing that the images on the retina of the eye are inverted, it is interesting to ask, first, how it is that we have erect vision. The question would appear to have puzzled metaphysicians; the scientific answer as explained by Le Conte, Helmholtz, and others (Le Conte is most familiar to me, and I have frequently drawn from him), is found in what is known as the "law of visible direction," and is stated thus:—"When the rays from any radiant strike the retina, the impression is referred back along the ray line (central ray of the pencil) into space, and therefore to its proper place." Points in the horizon are referred back in a straight line to the horizon, radiants above the horizon impress the lower half of the retina and are referred upward again, and points below the horizon on the ground impress the upper half of the retina, and are therefore referred downward. Thus every impression on the retina reaching it by a ray line through the nodal point is referred back along the same ray line to its true place in space, so that we may say that space in front of us is under all circumstances the outward projection of retinal states. If we compare the properties of other senses, we shall find a complete analogy; if we receive a blow in the front part of the body and were not even to perceive the impact of the blow, our senses would enable us to infer very very distinctly the direction from which the impact came. It thus appears difficult to comprehend that the retinal images should be other than inverted, as also that their projection could give us other than erect images. In the photographic camera

we have thus far a very close analogy; is is complete as regards the inverted image, and the possible transmission back again into space by "the law of direction," as also by the "law of conjugate foci," by which points in the image and object are always interchangeable. In the ordinary camera we can, of course, only compare its visual rendering with that of monocular perspective. Stereoscopic views seen through the stereoscope complete an *illusion* that is dependent on the fulfilment of another law, known as the "law of corresponding points." From this law proceed all the phenomena of *binocular* vision, with which, however, we are not concerned this evening. From the "law of direction" proceed all the phenomena of *monocular* vision, and we will proceed to examine the different forms of perspective included in monocular vision that enable us to judge of the relative sizes, distances, &c., of objects in the field of view.

Different Forms of Perspective.

There are three, viz., Aerial, Mathematical, and Monocular, or Focal Perspective. The fourth, and only other form, binocular perspective, is not capable of representation on a plane surface either by the painter-artist or photographer. Before dismissing this form of perspective, however, it may be worth while noticing its bearing on the "focus" question. By binocular vision we gather up all the distinct impressions in what is called the "deep" field, by running the point of optic convergence back and forth, and thus gather up all the distinct impressions into one mental image. From the fact that we can utilise this power in the same manner, with either monocular or binocular vision, in sweeping the point of sight laterally over a "wide" field, and collect a distinct impression of the scene, some writers on photography have contended for universal sharpness, or, at any rate, uniform treatment in respect of the quality of definition throughout photographic representations. Other writers, following on the lines first laid down by Dr. Emerson, have maintained that that portion of the photographic picture which in nature was of chief interest, and when looked at exercised a particular optical convergence of the eyes, should be emphasised by better definition than the remaining portion of the picture. As a matter of fact, outside the small area of distinct binocular vision, all objects in the "deep" field are duplicated, either homonously or heteronomously, and are therefore indistinct, but cannot be exactly represented on a plane surface. It seems to me that Dr. Emerson's plan contributes, in no small degree, to a more complete illusion optically.

To return to the first three forms of perspective:—

Aerial Perspective.

(1) *Aerial Perspective.*—"The atmosphere is neither perfectly transparent nor perfectly colourless. More and more distant objects being seen through greater and greater depths of this medium become, therefore, dimmer and dimmer, and bluer and bluer. We judge of distance in this way; and if the air be more than usually clear, or more than usually obscure, we may misjudge" (Le Conte). Most of us have probably observed for ourselves that in foggy and hazy weather objects look larger, and we are very apt to over-estimate distance. A train or vehicle coming towards one in a fog is very likely to be almost upon us before we are aware of its proximity, due to this illusion. On the other hand, the undoubted testimony of all mountain-climbers is, that they misjudge distance in the opposite direction in very clear atmosphere, as, for instance, a mountain top, that may appear to be only, say, two or three miles off, generally turns out to be ten or twelve. Aerial perspective is of little importance when employing wide-angle lenses of short foci, as experience has taught photographers the insignificant rendering they give to distance, and, in fact, such lenses are best dispensed with except in confined situations, when aerial perspective is not appreciable. In tele-photography, on the other hand, it is of great importance, not only in the judgment of distance, but also for the quality of definition attainable.

No matter what lens be employed to attain good definition of distance, the clearer the air the better the result; but, as before stated, in tele-photography, one can record on the photographic plate, no matter what the conditions of atmosphere may be, considerably more than the unaided eye can perceive. Furthermore, it is quite beyond dispute that small images produced by ordinary aplanatic lenses on the sensitive film, and subsequently enlarged to dimensions equal to those produced by direct photography, will bear no comparison whatever as regards definition. The comparative proofs I hand you were taken by Col. Colville on Wimbledon Common in hazy weather. He was working in conjunction with Capt. Simpson, of the Intelligence Department of the War Office, and the results will speak for themselves. You will note that the enlargement from the ordinary sharp-looking negative has not a vestige of definition at all. I am indebted to Capt. Simpson for the loan of the negatives from which Mr. Bridge has prepared the comparative lantern slides I show you. They exhibit the manner in which tele-photography can analyse an ordinary view. If a tele-photographic lens be used at a very short distance from the photographic plate producing an image of the same size as that of an ordinary lens of considerable length of focus, the definition is practically identical. It should favour the long-focus lens from the fact that this is easier to construct on optical grounds, but, with a finely finished and corrected positive element for the tele-photographic lens, I have failed to find a difference as against ordinary lenses, with equal intensities, up to forty-eight in. focus. An ordinary lens of *twenty-five feet* focus would be required to attain the dimensions of Boissonas's *Mont Blanc*, exhibited at Pall Mall. I cannot say whether an ordinary lens of such a focus would have given better definition. The experiment is hardly likely to be tried.

Mathematical Perspective.

(2) *Mathematical Perspective.*—Objects become smaller and smaller in appearance, and nearer and nearer together, the farther away they are. Thus streets appear narrower and narrower, and the houses lower and lower, the more distant they are. Parallel lines of all kinds, such as railway stringers, bridge timbers, etc., converge more and more to a vanishing point (Le Conte). Our judgment in the matters of size of objects, and degree of convergence of parallel lines, enables us to judge distance with great accuracy and almost without limit. Again, the size of an unknown object is judged by its angular diameter multiplied by its estimated distance. The retinal image of a given object, or the image of that object on a photographic plate, may have the same area covered by a larger object at a greater distance, or a smaller object at a less distance. In vision the estimated size of the object which produces the image will depend upon the distance we imagine the object to be from us. Thus estimates of size and distance are very closely related to each other, and an error in one would involve an error in the other.

It is important to note in this connexion that if we mistake the size of a known object, as, for example, a boy for a man, we shall to the same extent misjudge distance. It appears to me that this is the crux of the unsatisfactory images given by wide-angle lenses, or lenses of short focus when a near foreground is included. In viewing photographs taken by such lenses we never do, as a matter of fact, place our eye (or take our point of sight) at such a distance from the photograph that the angular dimensions of a foreground object and another object, distant, it may be, only a few yards further off, shall include the angles which mathematical perspective has rendered them in the photographic image.

Take the case of an ordinary interior. The figure of a boy in the foreground would be represented by a much larger image than that of a man at the further side of the room. To look at such a photograph from the ordinary distance of vision—say ten to twelve inches—it would convey the impression that this room must be immense as regards its length, that such proportions could possibly be brought about. Our knowledge of the comparative dimensions of the boy and the man is such as to make the treatment of the latter not only disproportionate, but ridiculous. The same argument applies to the unsatisfactory rendering of all architectural subjects in confined situation. Were it possible to remove the point of sight, or the camera, further away from the subject in the foreground, one would immediately bring about less disproportion between the sizes of objects in the foreground and more distant points of the subject. We value short-focus lenses on account of their adequate depth of definition through receding planes, but their perspective, when including near foreground, never *looks right!* The painter-artist fulfils in his drawing what no lens yet constructed can do; he takes his point of sight at an imaginary distance, anywhere further back from where he is forced to stand (if he finds it necessary)—at a distance, in fact, that his knowledge teaches him will practically put all his facts in the picture more nearly in the same place, so that the picture, as a whole, will look right; as, for instance, the daisy that he is painting in the foreground may really include an angle as large as the lady's foot some distance away, but he does not draw it as it actually is in mathematical perspective dimensions, but in his mind he makes that daisy go away and keep its relative size as a daisy to a human foot. This, from a near point of sight, the camera cannot do. If one were enabled to get far enough away to make such a subject more nearly on one plane, and so look right, it would, as a rule, be so small in size as to be useless. The advantage of "long-focus" lenses, or the more extravagant form, the tele-photographic lens, may now come in where a sufficiently uninterrupted and satisfactory view of any subject can be obtained. Distant groups of cattle, villages,

architectural structures, &c., can thus be well illustrated, for, although they are considerably distant, the size of the image is such that they do not become insignificant.

Example.—Take an interior 50 feet long, or a group 50 feet deep, say nearest figure 10 feet and furthest 50 feet, and take both figures as 6 feet in height. With a lens of 10-inch focus the dimensions of the near and distant figures are 6½ and 1¼ inches respectively, or a proportion of five to one. The same subject, with the lens removed 50 feet from the first figure (and, therefore, 90 feet from the furthest), would give the dimensions of the figures as 1¼ and ⅛ inches respectively, or a proportion of only five to three. A longer-focus lens, viz., 50 inches, at the greater distance would maintain these more reasonable proportions, and also give the same absolute size, viz., 6½ inches to the foreground figure, as in the first case, but a proportionately larger image to the distant figure, viz., 4 inches. Now, a tele-photographic lens, to give the equivalent of 50 inches, would only require an ordinary camera extension of from 12 to 15 inches.

Another interesting comparison between wide-angle and tele-photographic views arises from the fact that we almost invariably look at the former from a greater distance than that of the focus of the lens with which it was taken, and at the latter from a less distance than that of the corresponding focus of the lens. So that wide-angle views may be said to be seen through a magnifying-glass, and tele-photographic views through a magnifying-glass.

Outline Form and Solid Form.

The other aspects of mathematical perspective are those of *outline form* and *solid form*. As we have but little to do with the latter in photography, we had better dispense with this first. In sight we judge of it chiefly by binocular perspective, but we also judge of it by light and shade. Light and shade are admirably rendered by photography. Binocular perspective comes into play very much more for near objects than for distant ones, and hence the illusion of solidity produced by the painter is most perfect *at a distance*, where binocular perspective is very small. In all photographic work one main feature has been its paltry and insignificant rendering of distance, but I think it will be agreed that tele-photography has overcome this drawback, and placed the illusion that is most easily carried out by the artist within the reach of the photographer.

For reasons already stated, *outline form* is most unsatisfactory in photography when near objects are depicted at the sides of a picture taken by wide-angle lenses. We have seen that the drawing given to such objects is in strict accordance with monocular perspective, and this can easily be proved. No doubt many will remember this illustration of Mr. Debenham's vase (*British Journal of Photography*, October 30, 1891). Looked at in the ordinary way, it appears to be entirely out of drawing, although, viewed under the necessary fixed conditions described, the vase can be made to assume its proper shape. The unsatisfactoriness of such outline form in photography is so palpable as to make some subjects impossible in pictorial work. Take an ordinary interior with, say, an old couple one side of the room and a young couple at the further side. The necessary distortion brought about by a wide-angle lens could pay but a poor compliment to the features of those it depicted.

Focal Perspective.

(3) *Focal Perspective.*—Monocular focal perspective again will have but a very small bearing on the subject. We are aware that, if one eye be concentrated on some particular near object, that object is distinct, but all other objects nearer or further away become dim. This is perceptible within much narrower limits than that of binocular vision, and can only in a minor degree contribute to the question of the insistence of better definition for some part of the picture as compared to the remainder.

The fact that the exercise of focal perspective is comparatively imperceptible has an interesting bearing on photographs, in that it accounts for the more perfect illusion of depth and solidity effected when they are looked at with only one eye, as the perspective comes out a great deal more distinctly; and here we note the great contrast that there is in viewing natural scenes with one or both eyes. With one eye the reverse takes place to viewing the photograph, and we require both to fully appreciate distance and solidity.

In concluding, gentlemen, I fear I must admit that I have hardly adhered to the title of my paper, and also I am afraid I have had but little to say that is new, but I hope the subjects touched upon and the suggestions I have ventured to make may not be without interest to you, and may encourage photographers to include among their other studies that of "vision," for I am sure they will find it not only a most interesting one, but also one that I may say is absolutely essential to the production of the best work.

T. R. Dallmeyer.

THE OPTICAL LANTERN: ITS CONSTRUCTION AND USE.

[Before the Brixton and Clapham Camera Club.]

Mr. B. E. Pinder, one of the members, read a paper on the *Optical Lantern: its Construction and Use.* With regard to the lantern itself, he advised his hearers to purchase none but those of English manufacture, as being more solidly constructed and longer lived than foreign lanterns. It is, however, absolutely necessary that the lantern itself should be fitted with the best made English condensers and objectives. With regard to the latter, the most useful focus was eight-inch, the lens being two inches in diameter when four-inch condensers are used. Reliable templates should always be used in order to make the disc exactly concentric, without which it is impossible to show registering pictures accurately. He advised that the springs in the spring plates should be weakened, and found that washleather pads prevented the clicking of the plates whenever a slide was withdrawn from the stage. He recommended the use of grips to hold the jets firmly when properly centred, and advised purchasers to obtain the best jets they could afford. In using mixed jets, the chamber should be well packed. He himself found that the closely woven gauze, such as is used for cheap tea-strainers, compressed into a conical plug and inserted in the mixing chamber, answered admirably, especially when using the ether light. Having described the use of cylinders, regulators, and dissolvers, he proceeded to give a practical demonstration of the use of the lantern, for which purpose he had brought to the meeting a fine biunial recently constructed for him by Norton, of Russell-square. The lights described and used were the oxy-calcium, the oxy-hydrogen, and the ether lights. He found that the ethoxo light required too much attention to use very often, but advised the passing of the hydrogen, instead of the oxygen, through the saturator. The light produced burned as steadily as the oxy-hydrogen light, but was more brilliant. He pointed out the necessity for keeping the ether in a safe place, preferably a hole in the ground, where accidents could not happen. Having shown how to adjust the lantern with templates, adjustable runners, and stops, he proceeded to give an exhibition of elaborate effects and statuary, the use of the roller curtain being also clearly explained.

The President, in thanking Mr. Pinder, said that the paper was made the more interesting by the practical demonstration. The members were surprised to find what a good light could be obtained from common billiard chalk, asbestos, fireclay, or even the bowl of the homely clay pipe, the two latter slightly vitrifying under the intense heat of the ether light.

During the evening the following resolution was passed:—"That the members of the Brixton and Clapham Camera Club having heard with regret of the death of Mr. William Bedford, one of the judges at their recent Exhibitions, hereby tender to his bereaved family their most sincere sympathy."

PHOTOGRAPHY IN ITS RELATION TO THE ART OF PRINTING.

[Richmond Camera Club.]

In dealing with our subject I do not think it will be out of place to sketch, if only in outline, the history of the sister arts mentioned in our title.

I call printing and photography sisters because, in their highest adaptation, both are applied in expressing all that is most beautiful in nature, in science, or in art. A photograph will present to us a delightful representation, and by the help of printing we can not only look upon a pleasing picture, but the words we read can speak to us almost with the force of a living agent. Printing may be described as the art of taking impressions from characters, or figures, on any kind of fabric.

What is Printing?

As we understand the term "printing" in the present day, it may roughly be divided into letterpress printing, lithography, copper or steel-plate printing, and photographic printing, such as Woodburytype, collotype, &c.

The first of these is from movable letters, metal casts, or blocks either of wood or metal; the second from drawings on stone; the third, as the description explains, from subjects engraved on steel or copper; and the fourth from sensitive gelatinous surfaces acted upon by light, and forming reliefs for printing typographically in specially constructed presses.

This is, perhaps, a somewhat technical definition of printing, and a much wider meaning may be given to the term which brings the history of the art back to the very earliest times.

It has been said by one writer that printing is the production of a copy by pressure. That is perfectly true with regard to the processes I have already named; but, to quote from a history of printing published some years ago,

"It may also be applied to a seal impressed upon wax to close a letter, or to attest a document; to coining, *i.e.*, to print upon gold, or silver, or copper, or whatever substance used. If we give this comprehensive meaning to the word 'printing,' we must recognise the ancient Egyptians as the earliest printers, for they printed inscriptions on bricks, and some of the stamps which they used for the purpose now form part of the antiquarian treasures of the British Museum.

"The Babylonians also practised the art in this rude form more than 2000 years ago, and bricks have been found bearing the name of Nebuchadnezzar. This may be called clay printing, and probably was the first step in the art.

"The next was the use of the seal for making impressions. The Romans used seals at a very early period of their history, and the principle of letter-press printing, though crude, was known to them. They seem certainly to have practised the branding of cattle with red hot irons, which, after all, is printing in hair, wool, and hide. That they narrowly missed the invention of printing by wooden blocks, which must have led to movable types, is evident from the inscriptions on some of the Roman pottery unearthed from time to time. Many of these inscriptions are in raised letters, stamped upon the clay when soft by means of dyes cut in intaglio.

"An accident might have suggested the whole art of printing to an inventive Roman, if one of these inscribed pots had become smoked by a lamp, and in that state had come in contact with a piece of linen or damp vellum; the fortuitous impression thus produced might have given birth to the art.

"The invention of money was another step in the art of printing As I have already stated, to stamp on a piece of money was nothing else than printing on metal. The method used has not been materially altered in the present day. An engraving of the device to be stamped, or die, as it is called, is cut in a punch, and the punch is forcibly drived against the metal, which is thereby stamped with the device.

"As seals were formed with a graver, and money with a die, it is obvious that engraving preceded the primitive method of printing.

"The first appearance of printing in a practical shape was when the seal, or other stamp, instead of being forced against a softer substance than itself, was wetted with some liquid of the nature of ink, and pressed upon another body, so that an image or picture of the stamp was transferred to that other body."

It is remarkable that, as the Chinese are generally credited with the first knowledge of the compass, and with the discovery of less useful but delectable things withal, as fireworks and roast pork, so printing was first accomplished in China, by a minister of the State named Foong-taon, in the tenth century.

"His plan was to place a page of writing, while it was wet, upon the face of a smooth piece of wood. The writing made a mark on the wood, just as a letter does when it is turned down upon a piece of blotting-paper; in a word, the writing was impressed or transferred to the wood. Then all that part of the surface of the wood not touched by the writing was cut away, leaving the letters standing out. These were wetted with some kind of ink, paper was then pressed upon them, and an inked copy of the letters was thereby transferred to the paper. This was really and truly the art of printing."

The Chinese are remarkable for their stationary character, and I believe it is a fact that they print in much the same way to-day as they did 1000 years ago. That movable types are not used may be owing to the nature of the Chinese language, consisting as it does—so, at least, I understand—of separate characters for every separate word, being, in fact, signs of words formed without the use of letters.

Printing with wood engravings was effected in 1285, and playing cards, invented to amuse the mad king, Charles VI., were also printed from blocks about 1350; so that we may presume that the art was transplanted from China to Europe most probably through Marco Polo's description of it on his return from his travels.

Movable Types.

The introduction of movable types forms a great stride in the progress of the art of printing. This improvement naturally grew out of block-printing; yet it was effected somewhat circuitously, and may have been as much the result of accident as of design. John Gutenberg was the first person who ever printed with movable types, though his right to the honour of the invention is disputed by the city of Haarlem, which claims the discovery of the art for one of its own citizens, Lawrence Koster.

The pretensions of the Dutch, however, in his favour have been extinguished, and Gutenberg is recognised as the inventor of printing in the methods mentioned.

In 1449 Gutenberg connected himself with a fellow-townsman, named Faust, in the prosecution of his invention, a connexion which terminated six years later by a law-suit commenced by Faust for the recovery of money advanced.

Previous to his quarrel with Faust, Gutenberg had made types of cut metal. The first book ever printed from these was the *Mazarine Bible*, so called because, after the existence of the edition had been forgotten, a copy of it was discovered in Cardinal Mazarine's library in Paris. The leaves are printed on one side only, and seven years were spent in producing it. The first letter in each chapter is painted in by hand.

Peter Schœffer holds the honourable position of being the inventor of cast metal types, without which the art of printing could scarcely have become generally practised.

The casting of types at once reduced the cost of their production to less than a hundredth part of what it must have cost to cut them, and thus ensured the eventual spread of the printer's art as an ordinary profession.

It is curious to note that it was the practice of the early printers to pretend that their books were manuscript, their object being not simply to conceal the art, but also to obtain the high prices which were given for manuscript books.

Books were curiosities because they were few and costly in production. They were deemed as valuable as houses and lands, and were conveyed from seller to buyer in the same manner as estates. The inducement held out by the value set on manuscripts was so great, that the early printers never sold their books as printed books if they could avoid it.

With one or two exceptions, all the books printed by Gutenberg, Faust, and Schœffer are in the British Museum.

Introduction of Printing into England.

The introduction of the art of printing into England has generally been assigned to William Caxton. He commenced printing in the year 1474, and found a patron in Mulling, Abbot of Westminster, afterwards Bishop of Hereford, who gave him an old chapel in the Abbey for a printing-office. The spot now forms part of the site of Henry VII.'s Chapel. The first book printed by Caxton was a *Book of Chess*, a title which sufficiently describes the nature of the work.

In 1483 there were only four presses in England—Caxton's, at Westminster; Rood & Hunt's, at Oxford; De Machlinia's, in London; and a fourth (name of the printer unknown), at the Benedictine Monastery at St. Albans. Caxton, however, seems to have been the greatest printer of his time.

Caxton died about the year 1491, and was succeeded in his business by Wynkyn de Worde and Richard Pynsent. The first, a most accomplished man, accompanied Caxton from the Continent. He introduced the Roman letter into England, and the shape of his types was used for two centuries afterwards. The punches and matrices he used in casting his types were in existence as late as 1758. The art of printing spread throughout Britain as the years rolled on. It seems pretty certain that it was not before 1480, at the earliest, that Oxford had its own printers; while the first printer in Cambridge was John Sibert, whose productions in Latin, Greek, and English bear no earlier date than 1521.

It is not necessary to follow the art as it spread gradually throughout the kingdom during the next and following centuries.

The Art of Photography.

If time permitted us to follow closely the various discoveries connected with the art of photography, I suppose we might go back to the period when the knowledge of the action of light was known to the Egyptians.

The discovery of the "camera obscura" (darkened chamber) may, however, serve very well for a starting point.

Giambattista della Porta, a Neapolitan, had noticed that external objects were reflected on the wall of a darkened room when the light was admitted through a small aperture. Following up the inquiry thus opened to him, he contrived the fitting of a lens in a movable box, and in this way produced the instrument which has suggested greater things, and which to the draughtsman and photographer is invaluable.

The action of light on chloride of silver was known as early as the sixteenth century, and the phenomenon was studied by early experimentalists, whose names will occur to you—Scheele (1777), Genebier (1790), Ritter and Wallaston (1801).

From the results of these investigations experiments were made by Thomas Wedgwood and Humphrey Davy in the Royal Institution, London, which were published in its Journal, 1802. Wedgwood, who was the fourth son of the great potter, may be regarded as the first photographer. He discovered a method of copying paintings on glass by placing beneath a white paper covered with a solution of silver nitrate, and exposing to the action of solar light. He could not, however, fix the images. But in 1814, M. Niépce discovered a method of producing, by means of the camera obscura, pictures on metal plates (coated with bitumen), at the same time rendering them permanent.

Another name will suggest itself to many—M. Daguerre. He commenced experiments in 1824, and two years later joined Niépce, and worked with him till the death of the latter in 1833.

In 1839, Henry Fox Talbot first published his mode of multiplying photographic impressions by producing a negative photograph (*i.e.*, with the light and shades reversed), and from which any number of positive copies may be obtained.

Photo-Zincography and Photography on Wood.

I think the earliest application of the art of photography to that of printing is the discovery of photo-zincography in the year 1860.

This is a process by which photographs are transferred to zinc plates, which may be printed from.

It was invented by M. Toowey, and perfected by Sir Henry James, Chief of the Ordnance Survey, and made known at the date already mentioned. Charts, maps, and engravings can be printed in this way at small cost. The adoption of the process by the Ordnance Survey Office has resulted in the saving of expense to the Government.

It was not till 1861 that photography was successfully applied to the transfer of works of art to wood blocks. This was accomplished by Mr. John Leighton in his illustrated edition of the *Lyra Germanica*. I have here wood blocks of two subjects showing the image photographed on the wood. The process is of much importance, as the original drawing is preserved, not only for comparison into the finished engraving, but it may be for its artistic value. The drawing also may be of any convenient size, and reduced on wood; a great consideration when minute objects are to be represented.

After the photographing on to the wood is done, the picture is "lined up," if necessary, and more clearly defined by the aid of the pencil and

Chinese white. This is not always done to aid the engraver, as a skilled engraver prefers to interpret the drawing in his own way without aid, even though the photo on wood be indistinct; but it is very often important that the subject should be clearly defined, so that the person to whom it is submitted for approval may judge of the correctness and suitability of the block for his purpose.

Photo Blocks.

Photography itself, as a science, has advanced very rapidly, even within the last few years. Discoveries are constantly being made of more or less merit, and makers of apparatus are ever ready with something new. But, apart, from this, during the last decade photography has entered very largely into the ordinary commercial undertakings where printing is employed. The art of making blocks with the aid of photography, for the purposes of illustrating forms at the present day, is a flourishing industry. Whilst admitting the beauty of a really good wood engraving, it must be granted that for truthfulness and delicacy nothing can excel a good zinco block for use with letterpress; and it has this further merit, that the cost is considerably below that of wood engraving.

Of course, artistic taste and great skill and care in manipulation are required to produce a beautiful illustration, though it is often the case that the choice of picture is with some one who is unacquainted with the requirements of the half-tone process, as it is termed. The beauty of execution in the block is due to the zincographer; but photographers also have a great deal to learn as to the requirements of the half-tone process, in order to ensure a really good block. This will account for the great differences in the appearances of some blocks in illustrated magazines and papers.

It is impossible to produce a good block from a negative or a print which does not lend itself to the process; and it is eqnally impossible for the printer "to make anything," as the phrase goes, from some blocks that are produced, owing to want of depth and other circumstances. Sometimes, however, by force of circumstances, it is really impossible to obtain a good negative or photograph to illustrate a given subject—a fact which will serve to explain, in a degree, the great variety in the quality of the block produced and printed.

There are, as you know, various methods of illustrating the text of any given work, more or less elaborate and more or less expensive in execution. For example, there are lithographs, where many colours are used; or many coloured prints from a series of wood blocks or zincos carefully registered, *i.e.*, so made that each colour will fall exactly where required. Photography is largely employed for the production of these pictures, or in lithography to ensure accuracy of outline, or for the sake of exactly reproducing stains of age, or usage, or imperfections in old documents, or parchments, or other subjects of antiquity.

Direct Photo Processes.

Then, again, there are the various and beautiful photographic processes and prints, printed direct on the paper which is to form the leaf of the book; or a photograph may itself be mounted on to the leaf of the book, to form an "inset" or frontispiece.

Of the methods I have already mentioned, I suppose that Collotype, Autotype, or Woodburytype, would be the best forms of illustration for certain subjects for commercial purposes, as they most closely represent actual photographs. Collotype is described to me as bichromatised gelatine spread upon glass and printed beneath a negative, then washed out and used as a printing block in specially constructed presses or machines. The gelatine, I believe, is affected a great deal by the weather, and I am told that there is difficulty in obtaining two impressions alike; but I have no doubt, in the hands of the experienced collotype printers of the present day, these difficulties will soon be overcome, and it certainly is to their great credit that such good work is turned out in spite of the drawbacks mentioned. Collotype, too, has one distinctive and attractive merit besides beauty, and that is economy in cost of production. But I must not, even if I could do so, dilate further upon this subject, as by the kindness of one of our members, I believe, we are to be favoured shortly by a demonstration at his works.

It was rather my wish to bring before you this evening examples of the employment of photography in helping the printer to produce an illustration at once effective and economical. For our purposes, then, we can divide the term printing into two main divisions, viz., lithographic and letterpress printing.

Photo-Lithography.

In the first of those, then, photography can be employed to produce a subject or design upon a lithographic stone, ready for printing purposes, in much less time and with greater faithfulness than can be secured at the hands of an average lithographic draughtsman.

Take, for example, a white lace curtain or piece of lace. It is required to show effectively the design of the curtain. This must at least incorporate a corner—most generally half a curtain is preferred. Now, it is quite obvious that to secure the print which you see (*specimens shown*), it would take a draughtsman a long while to complete his work, and it would of neeessity be very costly; so the end is achieved by means of what is called the photo-transfer process. An ordinary wet-plate negative is taken, and a print obtained on paper coated with bichromatised gelatine. This receives a coating of lithographic transfer ink specially prepared for the purpose. It is next floated in warm water till the lines are seen as depressions. With the aid of a sponge and water, the soluble portion (or white) is removed, leaving the picture in insoluble gelatine with its coating of transfer ink. It now only requires to be dried and transferred to the stone for printing in the usual way.

In printing the illustrations for a catalogue or book, the letterpress, or type portion, can, if necessary, be transferred to stone in much the same way by "transfers" being pulled on transfer paper, and the whole "laid down" and printed at one and the same time.

Photo relief etching is a term applied to a picture in relief on metal, which can be used like a woodcut in the ordinary printing press.

Reproductions of Line Drawings.

Photography is very generally employed in the production of line drawings. To produce blocks of these for the purpose of letterpress printing the image must be produced on zinc from a reversed wet-plate negative, giving, of course, a positive upon the zinc, but the reverse way to the drawing. The mechanical tint, or stipple, is added afterwards if required. The plate is now rolled up, and slightly warmed before placing in the acid bath or etching solution. It is then well rinsed under the tap, and dried with gentle heat upon a hot plate, and gummed in. After it has been allowed to cool, the gum is removed with a sponge. The plate is again "rolled up," and the surface coated with powdered resin and again subjected to the etching solution. The operation of "rolling up," warming down, dusting with resin to protect the sides of the lines, is repeated until the plate attains sufficient depth. The whole of the resin is then washed off, and the removal of the "steps,' or shoulder, is effected by a series of acid baths in much the same way as the depth is attained, with the exception that the resin is omitted.

Collodion for wet-plate photography, which I understand still maintains its stand for copying, was, as most of you are doubtless aware, introduced by Archer in 1850.

It is desirable, in order to procure the best results, that the subject be drawn larger than is actually required, and bolder in proportion.

I have also the pleasure to snbmit a specimen of another system, interesting on account of its producing somewhat similar results without the aid of photography. Here is a copper plate from which a "transfer" has been taken and transferred to zinc direct. The zinc plate is ready for etching in a similar way to the method just described. I also can show the finished block and impression from it. I have mentioned the production of lace for lithographic printing, but lace may also be illustrated by the aid of zinc blocks such as I have described. In the case of white lace the piece to be photographed is fastened to black material which does not "give off" any light; consequently the result is a beautiful reproduction, with sufficient detail to show the pattern. Black lace is made to adhere to ground glass and photographed against the light, that is, the ground glass is suspended in the line of light between, say, the window and the camera, the lace towards the lens.

So much for line drawings, but by far the more artistic blocks are designed by the term "half-tone blocks." These are specially suitable for portraits, landscapes, and architecture. The processes by which they are produced may be very simple when you know them, but they are not publicly known, and I am sorry I cannot do more than show you a specimen, the start and the finish, as I may call them.

Engraving Processes.

I read, however, that some modifications of the methods patented by Mr. Fox Talbot in 1852 and 1858 are understood to be in use. He called his process photoglyphic engraving. Talbot got the image with bichromatised gelatine. The necessary reticular grain was given to the plate in two ways. By one of these he covered it after development with a fine deposit of resin. It is then ready for the etching solution. By the other method he took fine muslin or netting, and applied it by mechanical pressure to the plate, which covered it with fine cross lines. Goupil, of Paris, has a process which is believed to be worked upon the plan of forming a gelatine image, and then electrotyping it; but, as I have said already, the patentees of the various processes do not allow information to leak out if they can help it, and most producers have chemical secrets known only to themselves, though general principles may apply to all the methods.

Most of you are familiar with the lettering, as it is called, on the covers of bound books. The designs for these are usually cut in brass, from drawings on paper; but, since the application of photography, zinc blocks are now being made which bid fair to supersede the older and more expensive brass blocks. The metal for these is rendered extra hard to resist the heat necessary in the process of gold blocking.

All process blocks can be duplicated to any extent by electrotyping or stereotyping at a low cost, so that one may readily perceive the advantage to be derived by advertisers wishing the same illustration to appear simultaneously in, say, fifty periodicals or newspapers. The cost of fifty original blocks would, of course, be practically prohibitive.

Zincography.

The public, then, reap a benefit by the production of the kind of blocks that I have attempted to describe, because attractive books, newspapers,

and periodicals are produced at a figure which would be well-nigh impossible if the old system of wood-engraving were resorted to. Zincography, in its development, has naturally told unfavourably upon many wood engravers; but these, again, in many instances, have linked this department with their original profession, and really, for first-class work, steel engravings and wood blocks of high quality hold their own, though for commercial purposes people will not pay the high prices demanded for them. But then, again, it is quite impossible to employ photography on some subjects, and a choice has to be made of some other method of illustration.

One reason of the popularity of "zincos" is that they can be worked with the type, ensuring, of course, a saving in the printing, the whole being done in one operation, instead of two or more, provided, of course, the type and block are to be printed in the same colour.

In the illustration of books and newspapers it is, of course, most desirable that the reproduction of the photographs should be made as perfect as possible, and in this connexion, before concluding, I must acknowledge my obligation to Messrs. Swain & Son, of Farringdon-street, not only for valuable aid in the technical parts of my paper, but for the skill and care exercised in producing, at my request, the excellent specimens I have been privileged to submit.

I cannot pretend to have exhausted the subject before us, but I trust I have said enough to show you the utility, if I may be allowed the term, of the Photographic art to commercial purposes. The application of the art in the way I have attempted to demonstrate has done very much to raise the tone of publications generally, and to educate the taste of the people who read them. It has also contributed largely to replace the crude and occasionally vulgar illustrations of bygone days, and it enables authors and publishers to put into the hands of readers of even the cheapest literature artistic and truthful representations of persons, current events, and matters of interest generally. J. H. ALABASTER.

LANTERN SLIDES BY PRINTING OUT.

BEFORE the Putney Photographic Society, on February 6th, Mr. W. E. Woodbury, of the Paget Company, gave a demonstration of making lantern slides by printing out.

Mr. Woodbury said he understood that making lantern slides by contact had already been demonstrated before the members earlier in the season; he would therefore confine his remarks to the manipulation of the new printing-out plates, and to making slides by reduction in the camera, with such apparatus as every photographer already had in his possession, or could readily make for himself. He would also show the method of working the printing-out opals, recently introduced by the Paget Company, which was very similar to that required for their printing-out lantern plates. He said that the treatment of the plates and opals was essentially a daylight process, in many respects similar to that in use for gelatino-chloride or albumenised papers. The first point to which he called attention was that the difference between the coated and uncoated sides was not great; it should therefore be remembered that the plates and opals were placed in the boxes face to face with a piece of chemically pure tissue paper between. If by chance they should become disarranged, the glass side could generally be distinguished by small streaks or patches of the emulsion accidentally left on, and, if these should not be sufficiently obvious, the surfaces might be breathed upon slightly, when the glass side would immediately show by the condensation of the breath, the coated side remaining unaltered.

The printing was generally done by daylight, the plates and opals being placed in the frames, and afterwards examined in a subdued light. In this connexion he said it would be obvious that the examination of the rigid glass would necessarily differ from that of paper, which could be bent back and replaced without difficulty. As regards the lantern plates there was no difficulty, as the emulsion was so transparent that density could readily be judged from the back. When one half of the frame was opened in the usual manner, the opals being too opaque for the image to show through, it was necessary to lift them off the negatives so as to be able to look at their front surfaces, and special means for replacing them in correct register with ease and certainty had to be resorted to. Mr. Woodbury said this could be done in three ways. First, the negative was placed in an ordinary printing frame and wedged firmly in position, the opal was put in contact on the top, and care taken that it was firmly placed against one side and one end of the frame, of which a note should be made; with ordinary care the opal could be taken up and replaced correctly without difficulty. Secondly, a piece of cardboard twice the width and of a length equal to a plate one size larger than the negative to be printed from, is folded across the middle, and apertures of the proper size for the negative and opal cut out opposite each other; the negative is gummed in one of these openings, the opal in the other, and then folded together face to face, and placed in a suitable printing frame with a plain glass in front. For a half-plate negative the cardboard should be $13 \times 8\frac{1}{2}$ inches, which, when folded, would measure $6\frac{1}{2} \times 8\frac{1}{2}$, allowing about an inch margin all round the negative, and would fit in a whole-plate printing frame. The description looks somewhat formidable on paper, but the whole operation was very easily performed, and answered its purpose admirably. It should, of course, be remembered that the same cardboard frame may be used repeatedly. Lantern-slide binding slips are conveniently used for holding the negative and opal in place. The third method consisted in the use of a special printing frame designed by Messrs. Paget, and which they will shortly place on the market at a very moderate cost. Each frame is arranged to take two sizes of negatives; for instance, half and whole, or quarter and half plates, &c. The negative is securely clamped in the lower portion by turning a cam, which is locked in any position by means of a screw; the opal is similarly held in the upper portion or lid of the frame. The lower portion carries four brass studs fitting accurately into corresponding sockets in the lid; on being lowered on to the frame the studs enter the sockets, and the two parts are thus always held in proper register with each other. By the use of this frame the last trace of difficulty disappears, and the opals and plates may be examined as readily as paper prints.

The opals and plates are printed somewhat more deeply than will ultimately be required. A little practical experience will soon enable the operator to judge the correct density. The same rules apply as to silver prints generally. Thin negatives should be printed in a weak light, hard ones in sunlight. Mr. Woodbury stated that good results could be obtained on these plates from negatives with a lack of pluck, which would place them out of court with most of the ordinary rapid brands. It is almost unnecessary to add that this is a great desideratum for those who have developed their negatives with a view to obtaining soft and delicate prints, or who may have failed to get the necessary density when using some of the many new developers. Such weak negatives have generally been disappointing for lantern work, and a plate producing slides which will compare favourably with the prints taken from the same negative will be hailed with delight by many good workers, perhaps more particularly among the growing ranks of those who devote themselves to stereoscopic photography. The size of stereoscopic negatives is convenient for making slides by contact. Each negative also gives two chances against spots, scratches, and other defects, as a slide may be made either from the right or left half. The prints composing the stereogram should, however, be soft, and of as delicate a gradation as possible. This requirement has hitherto to some extent militated against the successful use of stereoscopic negatives for lantern work, as lantern plates generally give the best results with rather plucky negatives inclined to be hard when printed in silver. When printed out, the opals and plates are ready for toning. Mr. Woodbury said that any of the usual baths will be found to answer. The Company issue the following formulæ:—

Combined Toning and Fixing Bath.

No. 1 Stock.

Hyposulphite of soda	20 ounces.
Alum	5 ,,
Sulphate of soda (not sulphite)	14 ,,
Water to	1 gallon.

Dissolve the hypo and alum each in about one quart of hot water, mix and then, add sodium sulphite which has already been dissolved, making up to one gallon with remainder of water. The mixture should be left for some hours to allow precipitate to settle, when the clear solution may be poured off or filtered, and is then ready for use. It will keep indefinitely.

No. 2 Stock.

Chloride of gold	15 grains.
Acetate of lead	64 ,,
Distilled water	8 ounces.

Dissolve the acetate of lead in the water and add the gold. A heavy precipitate will form, which should be shaken up when any is to be poured out. It redissolves when added to No. 1 Stock. For use mix eight ounces of No. 1 with one ounce of No. 2. When this bath is used the plates and opals should *not* be washed *before* toning.

Separate Toning Bath.

Sulphocyanide of ammonium	30 grains.
Chloride of gold	2½ grammes.
Water	16 ounces.

The plates and opals must be very thoroughly washed for at least fifteen minutes in running water to ensure even toning. For deeply printed images Mr. Woodbury recommended the combined, and for correctly or slightly under-printed pictures the separate bath. He also pointed out that in the combined bath toning proceeded very evenly, and could be stopped at any stage, care being taken, if the plate had not been in the bath at least fifteen minutes, that fixation should be completed in a separate plain hypo bath. Unless very carefully washed, prints would tone unevenly in the separate bath up to a certain point, and it might be found necessary to carry the toning somewhat further than intended. For warm tones, therefore, the combined bath would be preferable, and the separate for the colder shades.

He then proceeded to print some lantern plates and opals by means of the Platinotype Company's oxy-magnesium lamp, the operation being fully performed in a few seconds; he then toned some of each in the combined and separate baths, the manipulation throughout being of a simple

nature, and such as every photographer is accustomed to when toning silver prints. The results were highly successful, and they, as well as a number of finished lantern plates and opals, with glossy and matt surfaces, were handed round and greatly admired by the members. Mr. Woodbury then proceeded to make a lantern slide by reduction on the Paget Company's rapid lantern plate; the negative was half-plate size, and of average density, and of a good colour without yellow tinge. It was placed in a suitable frame, placed at right angles to an ordinary camera, which could be moved longitudinally on a board fitted with guides; the image was focussed by means of a couple of candles placed behind the negative. The lantern plate was put into the dark slide, and a ground glass placed about two inches behind the negative in order to diffuse the light; the lens worked at *f*-10, and twelve inches of magnesium ribbon was burned at a distance of about six inches from the ground glass, being moved about as evenly as possible during burning. The exposure proved to have been correct, and the slide was in every way successful; elaborate apparatus was therefore unnecessary, the chief point being that the light from the burning ribbon should be screened so as not to enter directly into the lens.

MR. H. M. SMITH ON "ENLARGING."

Before forty-three members of the North Middlesex Photographic Society and several visitors, on the 13th inst., Mr. H. M. Smith, of the Eastman Company, gave a demonstration of "Enlarging."

He commenced with the subject of large cameras and direct prints *versus* small cameras and enlargements, and, after discussing the various *pros* and *cons* of weight, portability, expense, and excellence of results, said he had come to the conclusion that he would use nothing but small-sized cameras and enlarge. He, in fact, went farther, and said he now used nothing but a hand camera for outdoor work. It was the greatest mistake possible to suppose that a hand camera was only suitable for snap-shots; when it could be used on a tripod, as most of those now on the market could, he maintained that work could be done with it in every way equal to that done with the ordinary camera, and he had made many enlargements from such negatives which had raised considerable discussion among able photographers as to whether they were enlargements or direct prints, most people taking them for the latter.

He then dealt with the manufacture of bromide paper, explaining the old method of coating by hand, and that now generally practised of coating a roll of paper about a mile long by forty-two inches wide by passing it through a trough containing emulsion, then over iced rollers to cool, whence it was carried to the roof of the building, where it hung in festoons of about thirty feet each to dry. The paper was thus prepared much more perfectly and cheaper than by the old method, as nine miles of such paper could be turned out in twenty-four hours. The paper was packed in dozens, eleven sheets facing one way, and the twelfth the reverse, thus enabling the user at once to see which was the film side. He also referred to the absence of glaze on the surface, making it very suitable for working on with colours.

Passing, then, to the actual enlarging he described the various methods of daylight and artificial light enlarging, but recommended amateurs to stick to daylight, as giving the best and most even results. The best way to find the proper exposure was to make a trial on a small piece of paper immediately before exposing on the large sheet, and modifying that according to the result shown by the trial. He was of opinion that the ferrous oxalate developer was still the best for bromide paper, and the formula given with their paper could be relied upon. He then developed in succession three prints of the interior of Salisbury Cathedral, one correctly exposed, the second under-exposed, and the third over-exposed, using the normal developer for each, and showing what the result of under and over-exposure was, at the same time explaining how these errors of exposure could be corrected by strengthening the developer by adding more iron for the under-exposed paper, and weakening it for the over-exposed.

Replying to questions, Mr. Smith said he did not recommend magnesium ribbon as an illuminant, because one could never tell exactly what condition the ribbon was in, and this would cause considerable irregularity in the illumination. The household gas, too, was not suitable, on account of the prolonged exposure required, which would be found somewhat troublesome. The relative speed of the Eastman paper was that the "extra-rapid" paper was three times faster than the "permanent." Starch paste or a gelatine mountant was the medium used by the Company for mounting their enlargements, but the latter was not so suitable as the former, on account of the quickness with which the spirit evaporated, causing it to dry before the print was in proper contact with the mount. Paper had been kept as long as four or five years after manufacturing before exposing, and yet was found in perfect condition. He did not recommend toning with uranium for sepia tones, because the deep shadows were liable to bronze, giving anything but a pleasing effect.

ROTHERHAM PHOTOGRAPHIC SOCIETY'S EXHIBITION.

On Tuesday and Wednesday, February 7 and 8, the Rotherham Photographic Society held its fourth annual Exhibition in the St. George's Hall. Compared with previous efforts, a marked improvement was noticeable in the quality of the members' work displayed, and in the general arrangements; while in the matter of public support accorded the promoters must have reason to feel encouraged. Lady Albreda Fitzwilliam performed the opening ceremony, in the presence of an influential assembly of townspeople, an appropriate introductory speech being delivered by Dr. Baldwin, the president. Mr. G. W. Chambers, J.P., D.L., moved the vote of thanks to her Ladyship, and the Rev. W. Blazeby, B.A., in seconding the proposition, observed that the present exhibition was even finer than the one held twelve months ago. He was glad the Rotherham Society, in one department, was pursuing a very good course, namely, preserving records of old buildings and old streets which were gradually passing away. He was glad, too, the members were paying some attention to the churches of the district.

The Exhibition has many attractive features. Lady Albreda Fitzwilliam, the Hon. Mabel Fitzwilliam, Miss Crossley (Maltby), and Rev. J. Whitehead, Congo Missionary, and formerly of Rotherham, each sent photographs. The members contributing were Dr. Baldwin (President), Mr. E. Isle Hubbard, Mr. G. T. M. Rackstraw, Mr. W. H. Haywood (Vice-President), Mr. J. Leadbetter, (Hon. Treasurer), Mr. H. C. Hemmingway (Hon. Secretary); Messrs. W. Firth, W. Mason, W. H. Shephard, A. T. Cocking, J. W. Whittington, J. W. Baker, J. Caseldine, J. Clarke, J. W. Clements, A. Feirns, and J. Sykes. There had been some attempt at "selection," and the result was appreciated. As to processes, it was apparent that the old style of silver printing had been replaced by the gelatino-chloride papers, and various tones, whether intentional or otherwise, were illustrated. Platinotypes were very few in number, and there was not a single specimen of carbon printing. Numerous gelatino-bromides of good quality found places. The loan collection of prints was extensive and interesting. Mr. R. Keene, of Derby, sent a number of choice platinotypes; Messrs. Elliott & Son, of Barnet, exhibited the "Wave" picture; the Autotype Company lent a number of reproductions, and the Great Eastern Railway placed at the disposal of the Society the very beautiful series of *Norfolk Broads* views. Other friends who rendered help were the Eastman Photographic Materials Company, Limited, Messrs. J. Martin & Company, and Mr. J. Leadbetter. Each evening there was a lantern display, the "Peak and Dale scenery" slides of a contemporary being followed by slides prepared by the members. Musical selections were also introduced with much appropriateness.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

The third annual meeting of the National Association of Professional Photographers was held in Manchester on Thursday, February 9, Mr. Thomas Fall (London) in the chair.

Mr. Fall briefly reviewed the progress of the N.A.P.P. since its commencement, and strongly emphasised the necessity of having one representative of purely professional society. The early experiences of the N.A.P.P. had resembled those of all new associations, and had included great difficulties, but the worst were now past. The Council proposed to push the social element, and strongly recommended an effort to affiliate with some existing or projected body, preferably in London, by means of which, while holding their own purely professional meetings on a special meeting night, they could also arrange to meet one or more provincial members whenever they might be in London. The proposed New Central Club seemed likely to offer exactly the advantages they wished for; and they, as a body of 150 representative professionals, could form a very strong and helpful section of any photographic society they joined.

The Council's report and suggestions were as follows:—

"In presenting this the second annual report, the Council congratulate the members on the increase of the subscribers from 84 at the first annual meeting to a total of 145.

"The Council suggest that a certificate of membership be issued to the members of the N.A.P.P.; that the members generally be invited to send to the Secretary designs in competition for such certificates, the same to be reproduced in one of the permanent processes; and that, after present date, all persons desiring to become members must be duly proposed and elected at the ensuing Council meeting.

"Propose that Mr. Fall be requested to act as President for the ensuing year.

"The Council have accepted the resignation of Mr. Richards as Hon. Secretary with regret, and desire the members to express their hearty thanks for Mr. Richards' invaluable assistance to the N.A.P.P.

"That Mr. Warwick Brooks, Manchester, be requested to accept the office of Hon. Secretary.

"The Council view with satisfaction the proceedings taken to inform the public of the facts of the free portrait swindle, and express their thanks to the Editors of *Truth*, of the *Practical Photographer*, and the press generally for their assistance in exposing these frauds.

"The thanks of the Council are conveyed to the Editor of the *Spy*, Manchester, for his fearless exposure of practices discreditable to photography in Manchester.

"Subscribers to Guarantee Funds have been called on for a first half of the amount kindly promised by them. Thirty-three pounds has been paid over for the working funds of the N. A. P. P. by these gentlemen, chiefly members of the Council.

"Up to present time, the expenses of the Council attending meetings in London, Edinburgh, Manchester, and Birmingham have been borne by the members of the Council.

"A number of members have not yet paid 1893 subscriptions, and the Council request that the same may be paid as soon as possible.

"The Secretary has visited Newcastle, Glasgow, Edinburgh, Hastings, Dover, Eastbourne, and other towns, to advance the interests of the N. A. P. P., without any cost to the funds.

"Council record their indebtedness to President (Mr. Fall), Mr. Whitlock, and to the press."

Several members supported the Council's suggestions, which were all carried.

It was decided to hold the next annual meeting in Birmingham.

Our Editorial Table.

The Professional Retouching Knife.

It is the belief of Messrs. Percy Lund & Co., who are the publishers of this implement, that it will ultimately become as indispensable to the retoucher as the retouching pencil. As to this we cannot offer an opinion, but we shall endeavour to give such a description of the "knife" as to enable those readers interested in retouching to arrive

at a conclusion each for himself. Imagine, then, one of those handy pencils so much in use by retouchers, in which the lead moves loosely in the wooden barrel, subject to being projected at the point, and pinched there by a turn of the nozzle; but in place of the lead a piece of hardened steel wire is substituted, one end of this being ground to a triangular point, and the other made flat with a bevelled point, as shown in the cut.

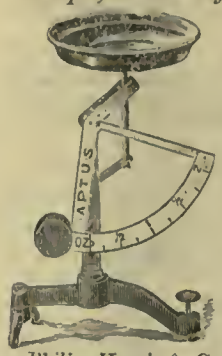
We have also on our table the *Idler* (Chatto & Windus), in which we find a well-written sketch of George Grossmith, with numerous illustrations, mainly characteristic portraits by that clever entertainer; the continuation of "Novel Notes," by Jerome K. Jerome; "My First Novel," by Miss Braddon, and many other articles more or less copiously illustrated by process blocks. *Great Thoughts* (A. W. Hall) maintains its high position in cheap serial literature. When a portrait of Dr. Phillips Brooks, with a sketch of his life and selections from his writings, were given, who would have imagined that, ere the February issue could have been in the hands of its readers, the talented Bishop should have retired from his terrestial labours? This renders the number doubly interesting. Other portraits are those of Commander Lovett Cameron, R.N., Rev. Hugh Stowell Brown, and W. L. Thomas, art director of the *Daily Graphic*, with T. Heath Joyce, its senior editor. These latter accompany an interesting account of the paper just named, including that of its photographic department, where the drawings are converted into the blocks used in its pages. The *Picture Magazine* (George Newnes, Limited) presents a collection of humorous and other pictures, many of them portraits of well-known writers, and others of scientific interest, collated from native and foreign illustrated journals.

We have also received the "Results of Meteorological and Magnetical Observations for 1892, at Stoneyhurst College Observatory, and St. Ignatius' College, Malta," compiled by the Rev. W. Sidgreaves, S.J., and Rev. J. Scoles, S.J., from which we learn that the new fifteen-inch refractor telescope to the memory of the late Father Perry is expected to be ready before the end of February.

Catalogues.

Ross & Co., 111, *New Bond-street, London, W.*—This forms a comprehensive catalogue of sixty-four pages, and particularises lenses, chemicals, apparatus, and photographic appliances of various kinds. It also treats of enlarging apparatus, microscopes, with their multifarious requisites, including object-glasses, for all of which this firm has long borne a high reputation. Telescopes, binoculars for field and theatre, meteorological, surveying, drawing, and nautical instruments, with other like things, form a compendium fitted to prove extremely attractive to the photographer and man of science.

Sharp & Hitchmough, 101, *Dale-street, Liverpool.*—In this closely compressed catalogue of sixty-four pages we find everything that can conduce to the most exigent requirements of the professional or amateur photographer, many of the articles being the special productions of the firm, although those of numerous other makers are included. The "Aptus" chemical balance seems a very handy instrument to have standing on one's table. We give a cut of it, from which it will be seen to possess weighing capabilities up to two ounces. Right certain we are that no one could make such a balance for himself for two shillings, the exceedingly low price at which we find it entered in this catalogue.



Philip Harris & Co., 144, *Edmund-street, Birmingham.*—A varied and comprehensive stock of cameras, shutters, lenses, plates, lanterns, and other things are here set forth. *Inter alia*, we find a bichromate battery of five cells intended for the dark room, the lamp of five candle power being fitted with a removable chimney of ruby glass. Included in this catalogue are directions for working the platinotype process by both hot and cold developing.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 2566.—"Improvements in or relating to Apparatus for the Exposure, Separation, and Storing of a Pack or Series of Photographic Films." Complete specification. J. T. Clarke.—*Dated February 6*, 1893.

No. 2663.—"Improvements in Cabinets for the Reception of Photographs or other articles." A. Jepson.—*Dated February 7*, 1893.

No. 2707.—"Improvements in and relating to Photographic Retouching Devices." Complete specification. A. S. Harry.—*Dated February 7*, 1893.

No. 2747.—"A Chambered Roller with the Chambering carried parallel right through, and as a Through-draft Roller applied to Photographic Burnishing Machines." L. Marion, H. Guibout, G. Bishop, F. Bishop, and J. P. Kirk.—*Dated February 8*, 1893.

No. 2926.—"Improvements in Photographic Apparatus." J. E. W. Erdesley.—*Dated February 10*, 1893.

SPECIFICATIONS PUBLISHED.

1892.

No. 5056.—"Photographic Camera Stands." Martin.
No. 18,230.—"Photographic Camera." Wright.
No. 23,315.—"Photographic Films." Clarke.
No. 23,487.—"Photographic Cameras." Communicated by Kemper. Boult.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
February 20.....	Camera Club	Charing Cross-road, W.C.
,, 20.....	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 20.....	Fillebrook Athenæum	Fillebrook Lecture Hall.
,, 20.....	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.
,, 20.....	Hastings and St. Leonards	
,, 20.....	Leeds Photo. Society	Mechanics' Institute, Leeds.
,, 20.....	Richmond	Greyhound Hotel, Richmond.
,, 20.....	South London	Hanover Hall, Hanover-park, S.E.
,, 21.....	Birmingham Photo. Society ...	Club Room, Colonnade Hotel.
,, 21.....	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 21.....	Exeter	City Chambers, Gandy-st., Exeter.
,, 21.....	Hackney	206, Mare-street, Hackney.
,, 21.....	Keighley and District	Mechanics' Institute, North-street.
,, 21.....	North London	Canonbury Tower, Islington, N.
,, 21.....	Paisley	9, Ganze-street, Paisley.
,, 22.....	Bath (Annual)	Roy. Lit. & Sc. Inst., Terrace-walks.
,, 22.....	Burnley	Bank Chambers, Hargreaves-street.
,, 22.....	Leytonstone	The Assembly Rooms, High-road.
,, 22.....	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 22.....	Southport	The Studio, 15, Cambridge-arcade.

,, 24.....	Holborn	
,, 24.....	Maidstone	"The Palace," Maidstone.
,, 24.....	Swansea	Tenby Hotel, Swansea.
,, 24.....	West London.....	Chiswick School of Art, Chiswick.
,, 25.....	Hull.....	71, Prospect-street, Hull.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

FEBRUARY 14,—Annual General Meeting,—The President (Captain W. de W. Abney, C.B., F.R.S.) in the chair.

THE AFFILIATION SCHEME.

The Hon. Secretary announced that the following societies had that day been admitted to affiliation by the Council:—The Leytonstone, Greenwich, Southport Social, West Kent Amateur, Brechin, Midland Camera, Hampstead, Birkenhead, Rotherham, and Woolwich.

THE ANNUAL REPORT.

The Annual Report was then read by the Hon. Secretary, of which the following are extracts:—

"During the year ending December 31 last, thirty new members have been elected into the Society, and we have lost sixteen by death, resignation, and other causes. The following table shows the changes in the number of members that have taken place:—

	Honorary Members.	Life Members.	Ordinary Members.	Non-resident Members.	Totals.
On January 1, 1892 ...	5	64	356	14	439
During 1892, elected	0	2	28	0	30
" " died.....	0	1	2	0	3
" " resigned or lost sight of ...	0	0	13	0	13
On January 1, 1893 ...	5	65	370	13	453

"The Exhibition at the Gallery in Pall Mall was conducted in a rather different manner from those held before, in that the exhibits were classified by the Judges before the Hanging Committee entered upon their duties, and the process of selection was much more rigorous. In round numbers, only about two-thirds of the photographs sent in were accepted for hanging.

"The number of exhibitors whose works were accepted was 202, that is more than we have had since the year 1887. The gradual decrease in the total of members exhibiting is compensated for by the non-members. There were twenty-eight foreign exhibitors, namely, sixteen sending from America, four from Germany and Austria, two from Switzerland, and one each from Australia, the Cape of Good Hope, India, France, China, and Japan.

"There were 166 lantern slides and forty-five apparatus exhibits.

"The Exhibition was open three evenings in each week, and through the courtesy of affiliated and other societies, and of friends, as well as of some of our own members, there was no lack of slides for the lantern shows. An extra evening was as usual devoted to the benefit of the Photographers' Benevolent Association.

"The admissions to the Exhibition show an increase of 20*l.* 1*s.* 3*d.* over last year, but there is a slight decrease on wall space and catalogues. The expenditure shows a decrease of 39*l.* 11*s.* 5*d.*, and allowing for some advertisements outstanding the loss on the Exhibition will be about 45*l.*, as compared with 90*l.* last. The Council have arranged with the Council of the Royal Water Colour Society for the next Exhibition.

"With regard to general finances, the entrance fees and subscriptions are less this year than last, as only two new members have paid the life subscription as against six last year. The sum of 22*l.* 19*s.* 10*d.* has been expended on the library, and 3*l.* 2*s.* on purchase of photographs. 141*l.* 11*s.* 6*d.* has been received from the guarantee fund on account of 1891, and as this scarcely balances the account for 1892, it will be necessary to again call upon the fund for the same amount.

"Several Committees have been at work during the year, and, as the result of their recommendations, the Council have effected economies in the management of the Society, and a revised series of 'laws' have been prepared, which are about to be submitted to the members. Nearly 3000 circulars have been issued to members of various scientific societies and others, setting forth the aim and work of our Society, and inviting them to join us. The immediate pecuniary result of this has not been large, but it has been considerably more than sufficient to defray the cost of the undertaking. The introduction of mineralised methylated spirit has been duly considered.

"A specification of the Society's lens standards, as added to and completed during the previous year, has been published, and copies of it can be had by any one who applies for them.

"The Council have begun to gather together a permanent collection of representative photographs, &c., by endeavouring to secure some of the exhibits that have been medalled or possess especial interest. In this they have met with a most hearty and generous response from those upon whom we must depend for success in the matter.

"The library has been largely increased during the year. Sixty-six volumes have been presented to the Society, about 108 have been added by purchase under advantageous circumstances, the serials for the year add fifty-two volumes, and besides these a considerable number of unbound pamphlets, &c., have been received. The number of serial publications arranged for by exchange with our own *Journal* has been increased from twenty-four to fifty-three, and it is hoped that in the near future this number will be still further augmented by important additions.

"The museum has been enriched by a copy of Fox Talbot's *Sun Pictures in Scotland*, a set of Daguerreotype apparatus, some calotype negatives, and sundry smaller but valuable items.

"The affiliation scheme which was brought forward in 1891 has been developed, and during the year fourteen societies have been received into affiliation, so that the present total is thirty. Numerous meetings of delegates have been held, and although much time has been occupied in arranging the procedure, and in discussing the most promising and useful fields for activity, the progress has been satisfactory, taking into consideration the novel character of the movement, its wide scope of action, and the absence of any precedent for guidance. A number of sets of lantern slides are already in circulation, including most of those sent for competition to the Exhibition, and several lectures or papers, with explanatory illustrations or examples, are also available. The programme decided upon for the present session includes a series of lectures on *Photogravure*, with a demonstration of the practical working of the process. Although the direct advantages arising from the movement have as yet hardly had time to become apparent, there is a hopeful prospect that it will not only benefit photography, but will strengthen the Society."

The adoption of the report was moved by Mr. T. Sebastian Davis, who took occasion to dwell upon the increased usefulness the Society was likely to have on account of the institution of a library and the appointment of an Hon. Librarian, and expressed a favourable opinion of the affiliation scheme. The motion having been seconded by Mr. W. England, the report was adopted.

The Scrutineers announced that the following gentlemen had been elected Members of the Council for the following year:—*President* Captain W. de W. Abney, C.B., F.R.S., D.C.L.—*Vice-Presidents:* Messrs. James Glaisher, F.R.S., Andrew Pringle, J. Spiller, and Sir H. Trueman Wood.—*Ordinary Members of Council:* Messrs. W. Ackland, G. L. Addenbrooke, T. Bolas, F. P. Cembrano, jun., E. Clifton, A. Cowan, T. R. Dallmeyer, T. Sebastian Davis, W. E. Debenham, P. H. Emerson, W. England, T. E. Freshwater, Colonel J. Gale, Mr. F. Hollyer, Dr. G. Lindsay Johnson, Messrs. H. Chapman Jones, Alex. Mackie, J. W. Swan, J. Traill Taylor, Leon Warnerke.—*Treasurer:* George Scamell.

Votes of thanks were passed to the Auditors, Scrutineers, the Hon. Treasurer, the Hon. Secretary, the Assistant Secretary, and duly acknowledged by those gentlemen.

In acknowledging a vote of thanks for his services during the past year, passed by acclamation, on the motion of Mr. J. Spiller, seconded by Mr. Sebastian Davis,

The PRESIDENT said he was much gratified at the vote. It was a pleasure to him to have presided over the meetings of the Council and the Society. He had felt it almost a duty to accept nomination on account of certain matters that transpired during the late Exhibition, and because he wanted it seen that the insinuations of a certain publication were unfounded. He had always met with the greatest cordiality from the Council and members, and for that reason he was induced to accept the nomination for the Presidency, as well as to show that the insinuations he had referred to were absolutely unfounded, so far as he was personally concerned.

The meeting, which next proceeded with the discussion of the revised rules, was adjourned when only about half the rules had been considered.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 9,—Mr. A. Haddon in the chair.

THE ASSOCIATION'S TECHNICAL LECTURES: NO. 1, "THE LENS."

The CHAIRMAN, in calling upon Mr. J. Traill Taylor to deliver his promised lecture on the photographic lens, said that it would form part of a series to be subsequently published in book form. Several promises for other lectures had been received, and it was hoped that the book, when published, would form a better work of reference on photography than they had at present. When a man undertook to write on photography, it was impossible for him to be thoroughly conversant with every branch of the subject; and, generally speaking, what he gave was simply a *résumé* boiled down from other works. Here they would have masters in different subjects, who would give the results of their experiences, so that in that way they would obtain a far better knowledge of the subject when they came to study the book than would otherwise be the case.

Mr. TAYLOR, in opening his address (which he frequently illustrated by referring to and exhibiting a considerable number of ancient and modern lenses that he had brought with him), said that the early opticians had great difficulties to contend with in the colour, &c., of the glass, the crown element being sometimes formed of deep green bull's-eye, and the flint of the bottom of a tumbler. He showed a large aperture portrait lens of this nature by Thomas Davison (who had by some been termed the inventor of the compound portrait lens), which, though it stopped a large amount of light, produced most charming pictures. Having noted the important parts which Guinand and Bontemps had played in the production of glass free from striæ, he said that in pre-photographic times the uses of lenses in combination for observatory purposes was well known, as well as their property of forming images over a moderately flat field, and he exhibited a specimen of an achromatic lens in use previous to the introduction of Petzval's combination. Alluding to its large size, he said in the olden times they used sensitised sheets of paper of large dimensions, and the lenses were of large diameter and long focus. Lenses of that class necessarily distorted, according to their diameter—the larger the area of the lens the greater the distortion. The orthoscopic lens was introduced to cure the distortion of the single lens, but was soon found to have a distortion of the opposite character. Having indicated the property of this lens of giving a larger image than any other lens of similar focus and discussed its other properties, Mr. Taylor said he regarded that lens as the lens of the future, and described how he had obviated the pincushion distortion which it gave by placing a thick piece of plate glass near to the ground glass of the camera. In 1869 he extended the application of the orthoscopic principle by employing as an objective an ordinary opera glass, which was strictly analogous to the orthoscopic lens, a system which had since been adopted by two eminent opticians in the modern tele-photo lens. *Apropos* of this, he showed two lenses respectively magnifying and diminishing when examined individually, and which when placed in contact formed plain glass incapable of giving an image; but when separated, and in proportion to the degree of separation, they became in effect a combination of long or short focus. Passing on to the next branch of his subject, "Simple Glasses as Image-formers," he said that numerous fine sharp photographs were taken with the despised plain spectacle glass, which should be of a meniscus form. He passed round some stereoscopic pictures taken in a hand camera by the aid of such lenses by Mr. Henry Sutton, the sharpness of which he characterised as remarkable. The first combination by which distortion was prevented was that of Cundell, which was introduced for a totally different purpose. It consisted of a pair

of meniscus lenses mounted apart, with a stop between them. He had compared the lens with lenses of the rapid rectilinear type of the present period, and found them nearly, although not quite, the same as regards the elimination of colour. Mr. Taylor concluded his discourse (which was largely of an introductory nature) by reference to the globe lens of Harrison & Schnitzer, Goddard's single lens (the precursor of a modern single lens which gave freedom from distortion), and a plea for the use of supplementary lenses for altering the foci of existing objectives, the chief point being always to have the back lens the shorter focus of the two. Something was wanted in photography analogous to Wray's microscopic lens, in which an adjustment of focus from four to six inches was obtained by rotating a collar in the jacket.

At the conclusion of the lecture, which dealt with many other phases of the subject, the CHAIRMAN said Mr. Taylor had given a great number of hints as to how amateurs might work in an experimental direction, and moved a vote of thanks to him, which was carried. The subject is to be resumed on a future occasion.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE SPEED-TESTING CONTROVERSY.

To the EDITOR.

SIR,—

"Those who in others' quarrels interpose
Oft will wipe a sanguinary nose."

Anxious to avoid this unpleasantness, I am, nevertheless, desirous (with, I doubt, not many others) that some one, either the illustrious scientists themselves or a capable exponent, should enlighten us outsiders about their method, and that they should do it in simple language.

I do not think, Sir, that this is an unreasonable request. The time has gone by when photographers will consent to use a set of arbitrary numbers as exposure factors, nor are they willing to accept any system which does not permit of examination and verification in their own studios. This, unfortunately, appears to be the present position of the Hurter & Driffield system of estimating speed in dry plates, and it cannot be the final one.

To be assured that we cannot detect an error of twenty-five per cent. in exposure, or to have a series of negative interrogations jerked at us (*vide* last week's correspondence), is not the assistance we seek.

Information is our cry. A clear and explicit account in plain words of the system, the theories that underlie it, and the method of working it and testing the plates, is what is asked for on behalf of us all by—Yours, &c., IGNOTUS.

February 13, 1893.

To the EDITOR.

SIR,—In reply to Mr. Cadett's letter in your last, I can fully bear out (from experimental tests) Mr. Williams' comments *re* speed of plates.

Mr. Cadett's communication consists principally of condemning that gentleman's methods of procedure, and informing him that his tests are no good, and that it is utterly impossible to arrive at a decision by comparative camera tests, after which sweeping condemnation he is compelled to admit the very thing which Mr. Williams had already proved, viz., that the numbers were fictitious, and consequently misleading. Mr. Cadett admits to two of the numbers being twenty-five per cent. wrong, yet goes on to say, "Several people told us the plates worked well to the *marked speeds*." Did these several people know what they were speaking about? Because, if so—*and evidently Mr. Cadett has faith in their assertion, or he would not have quoted it*—then I maintain that Mr. Williams scores again; for is it not further proof that either the Hurter & Driffield system is a fallacy, or that those using it do not understand it? Hence it follows that the numbers as at present used are a delusion and a snare.

I will conclude by saying that I do not know, even by sight, either of the gentlemen named; I therefore have not any party feeling in the matter.—I am, yours, &c., ARCANUM.

February 14, 1893.

To the EDITOR.

SIR,—Permit me to reply to the letters in your issue of 10th inst. To Messrs. Hurter & Driffield I beg to say that I have checked my estimates of percentage differences by giving augmented exposures to the sluggish plates, so as to get identical negatives, thus proving, generally, the accuracy of my estimates. My estimates are upon the finished negatives, not upon prints.

To the writers who have taken exception to my remarks, I desire to recommend a reperusal of the last paragraph of my article on page 70. Except incidentally, I have merely expressed my opinion of the Hurter & Driffield system without going into details, and I have endeavoured to keep two distinct subjects separate; the experiments were directed solely to ascertaining whether the various speed numbers were borne out in actual practice.

My conclusions having now been made public, I am prepared to abide by my experiments, and I will stand or fall on the question of their accuracy. Further, I will submit the whole of the results, together with a number not published, to any properly appointed juror or jury to be agreed upon—disinterested photographic experts—and to them I will describe, in fuller detail than is permissible in these columns, the whole series of experiments, and I will repeat in their presence, under proper conditions, any of the experiments submitted.

In conclusion, allow me to thank Messrs. Hurter & Driffield, and Messrs. Marion & Co. for the temperate and courteous tone of their letters.—I am, yours, &c., G. F. WILLIAMS.

February 14, 1893.

MESSRS. ELLIOTT & SONS' EXPOSURE TABLE.

To the EDITOR.

SIR,—In Table 2 of our exposure table a slight printer's error has occurred, and which we regret we overlooked. The three first columns, headed respectively *f*-6, *f*-8, and *f*-11, should have been headed *f*-8, *f*-11, and *f*-16.

Thanking you in anticipation for inserting this correction.—We are, yours, &c., ELLIOTT & SON.

Park-road, Barnet, Herts, February 10, 1893.

ELIMINATION OF HYPO.

To the EDITOR.

SIR,—In reply to the question that Mr. Cosmos puts to me in the last number, I would say that I think it is better to recommend acid alum rather than peroxide of hydrogen for the use of photographers when treating gelatine plates for the elimination of the traces of hypo remaining after the usual washing. Peroxide of hydrogen is not only an extra reagent for the photographer, and a somewhat expensive one, but it is of very uncertain strength as commercially supplied, and loses strength by keeping. I have found freshly opened bottles to contain only about a third the nominal amount, and bottles that have stood by a few months only about one-tenth. This diminution in strength is not obvious, and therefore I hesitate to recommend the reagent for general use.

My remarks concerning the need for eliminating hypo from gelatine plates to fit them for intensification apply to plates that have been well fixed in plenty of fresh hypo, and have been washed as usual for two or three hours. I doubt whether prolonged washing would *wash away* the remaining hypo. The combined action of air and water would perhaps destroy it, but its destruction in this way would be not only tedious, but uncertain, whereas by the use of acidified alum its decomposition is fairly rapid and certain. The stains that I have referred to in this connexion are not colour stains, but deposits of mercury salt where they should not be.—I am, yours &c., CHAPMAN JONES.

Royal College of Science, London, South Kensington, S.W., February 13, 1893.

FILLEBROOK ATHENÆUM EXHIBITION.

To the EDITOR.

SIR,—I shall be much obliged if you will allow me to communicate, through your columns, to the numerous readers interested the answer to a question of some importance which has arisen in connexion with the rules of the above Exhibition.

The point was, "Can one exhibitor take more than one medal?" and the decision of the Committee is that one medal only may be awarded to an individual exhibitor, but it may be either for a single exhibit or for a series, according as the Judges may determine.

May I take this opportunity of asking intending competitors to send in entries as soon as convenient, to save a rush of work at the last moment?—I am, yours, &c., JOSEPH W. SPURGEON.

Leytonstone, Essex, February 14, 1893.

STUDIO HEATING.

To the EDITOR.

SIR,—In your JOURNAL of January 20th, 1893, you have from the pen of Mr. G. Watmough Webster, on "Studio Heating," an able and, what is more valuable, a most practical article. If Mr. Webster would give us a little of his experience on studio building in your pages, he would confer upon me just now, and doubtless upon many others, one of the greatest boons ever offered to puzzled photographers. When about to build a new studio, what is the best kind of glass to use, and, above all, how to glaze so as to make it proof against leakage? What is the best principle to construct the side light and glass roof, north light, say size of studio thirty feet by fifteen feet.—I am, yours, &c., H. L.

February 4, 1893.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

F. G. HILL.—Your eyes are alright.

W. WENBORN.—Probably the bath you are using is not suitable for the paper.

HENRY HOLMAN.—Received. We presume the examples of your poetical skill are not intended for publication.

F. STEWARD.—A lens of about nine inches equivalent focus will enable you to take three-quarter-length cabinets in a room fourteen feet long.

O. B.—1. The darkened silver nitrate would be unsuitable for emulsion work. 2. To recrystallise silver it is not imperative that it be dissolved by the aid of heat.

GEORGE BLAKE.—There are firms, we believe, trading under the names of Mezzotype and Mezzotint companies. Try and select some less hackneyed term as a distinguishing trade designation.

JET.—1. Mr. W. I. Chadwick, of St. Mary's-street, Manchester, will supply you with a book on the magic lantern. 2. Many authorities hold that better illumination can be obtained with the mixed jet.

W. KERSHAW—1. If some gum be added to the water colour, it will dry as glossy as the print. Spotting colours are advertised that can be burnished if required. 2. Add the sediment to the residues, then any precious metal there may be in it will be recovered.

W. A. T.—1. Caramel mixed with dextrine is, perhaps, the most suitable backing you could employ. 2. Castile soap is the best lubricant. Dissolve two grains to one ounce of alcohol. 3. Either white or blue blinds may be the better, according to the aspect of the light. 4. The lens should point rather below the head.

E. H. D. says, *apropos* of his experience with Solio paper: "After toning, the prints are placed separately in a dish of salt and water as they tone, but they go on toning in this state, so that the first prints of a batch are more toned than the last. The prints are covered more or less with a white deposit before toning; those last toned show it most. This generally, but not always, fixes out."—He asks how this can be avoided. Will some experienced reader reply?

D. JACOB says: "I am much troubled with the sun in my studio, which faces nearly south. In the summer I can stop it out by drawing down thin white blinds, but at this time of year the blinds make the light too slow. Can you tell me of anything that would stop out sunshine, but yet admit a good light? Ground glass would, I know, be best, but it would cost more than I can afford these hard times."—Make up some thin starch paste and mix some whiting with it. Then stipple the glass over with that. It will stop out the rays of the sun, and can easily be cleaned off at any time.

K. K. writes: "It is a great nuisance at this time of year to get negatives dry when they are wanted to be printed from quickly. If heat be applied, there is the danger of the film running, and if they are put away to dry of themselves it sometimes takes twenty-four hours. Surely there ought to be a remedy for this?"—There is. If the negatives be placed in strong alcohol—methylated will do—for ten minutes or so, they may be dried before the fire. The spirit abstracts the major portion of the water, hence sufficient is not left to cause the gelatine to run when only a moderate heat is applied.

DISTEMPER says: "1. Would you kindly inform me of the best formula for intensification with corrosive sublimate. 2. I should also feel extremely grateful if you would favour me with information as to how to mix colour for painting backgrounds in distemper, and where to obtain same."—1. See p. 788 of the ALMANAC. 2. Mix whiting and lampblack together to the tint desired in water, to about the consistence of thick cream. Then add double size (melted), and well mix. The quantity of size should be about one-third of the bulk. A little Venetian red may be added to warm the tint if desired. The colour should be applied cold. The materials can be had at any oil-shop.

BROMIDE writes as follows: "I have a series of local views on sale in this town. One of the tradesmen, a dealer in fancy goods, has bought a collection of them, and I now understand that he intends having them, with others, reproduced by some cheap process, and to sell them in book form at 1*s.* per dozen views. Can he legally have the views reproduced which were taken by myself? I still have the negatives in daily use. Is it necessary to copyright them? If so, what would be the cost per negative, and how could I get them done? It seems rather hard, after taking the views, to have some one else reap the benefit of their production."—If the pictures are not copyright, any one can copy them. The cost of making a photograph copyright is one shilling, but it must be done personally at Stationers' Hall. Our publishers will do the needful for one and sixpence in stamps with a copy of the photograph. In future, we recommend you to make the pictures copyright before copies are issued. You will then have a remedy against pirates.

PHOTOGRAPHIC CLUB.—February 22, Monthly Lantern Meeting.

WEST LONDON PHOTOGRAPHIC SOCIETY.—February 21, Technical Social Meeting.

BLACKHEATH CAMERA CLUB EXHIBITION, March 3 and 4.—Intending exhibitors are informed that entry forms should be sent in by the 22nd inst.

PHOTOGRAPHY is represented on the newly elected Council of the Royal Microscopical Society by Mr. E. M. Nelson, Mr. T. Charters White, and Mr. James Glaisher.

MR. FRANK HOWARD, of Wallingford, Berks, has accepted the post of Hon. Critic to the Lantern Slide Exchange Club (Hon. Sec. A. J. Richardson Summerville Dore, Sheffield), in place of Mr. A. R. Dresser.

WE regret to learn of the death from consumption, on February 5, of Mr. A. W. Scott, of Weston-super-Mare. Mr. Scott was the inventor of the "Verak," the patented Saturator which bears his name, and devoted much attention to lantern matters, and he was besides a frequent contributor to this JOURNAL and its ALMANAC.

GRATING PHOTOGRAPHS.—Mr. John Robertson, Dundee, has sent us specimens of a class of work which he finds to take well with his customers. These are bromide proofs printed with the interposition of a line grating between negative and paper, which imparts precisely the effect of a Meisenbach picture. The same effect can, as Mr. Robertson observes, be produced in platinum, carbon, or silver.

DEVELOPING PRINTS.—By this term we do not mean bromide prints, but those intended to be printed out in the frame. Mr. J. H. Smith, Bowbridge, has sent us some excellent specimens, which were produced within half an hour on "P. O. P." He prints until the details are just visible, completes the printing by a developing agent (not communicated), tones in a sulpho-cyanide bath, and conducts the other operations as usual. The specimens, as we have said, are excellent.

MR. P. EVERITT writes in reference to his paper on *The Calculation of the Angle of View* in our last issue: "In the foot-note to the first diagram you have substituted H for K as designating the correct station point or focus. The second diagram is printed with top to right side, consequently the scale of focus runs from top to bottom. The scale of inches distance, between centre of vision and extreme corner of plate, must be read from left to right. The engraver has also incorrectly numbered the latter scale, which should start with two inches and be increased by two for each space to the left. It would also have been better had the engraver numbered the lines running from right to left instead of the half distances between them. Each line represents two inches addition to the focus, starting from O at the top right-hand corner."

CAMERA CLUB.—The 1893 Conference will be held in the theatre of the Society of Arts, by kind permission of the Council, on Wednesday and Thursday, April 12 and 13, under the presidency of Captain W. de W. Abney, C.B., D.C.L., R.E., F.R.S. The following is a preliminary outline of the programme:—Wednesday, April 12, Conference at the Society of Arts, 18, John-street, Adelphi, to be opened by the President, at three o'clock. Papers to be read from three o'clock to six o'clock in the theatre. Seven o'clock, Annual Club Dinner for members and friends. Thursday, April 13, three o'clock, renewal of Conference in the theatre, Society of Arts; papers to be read from three o'clock to six o'clock. Renewal of Conference at eight o'clock; papers and discussion from eight o'clock to ten o'clock. Friday, April 14, eight o'clock, exhibition of lantern slides in the theatre. Special tickets for this Exhibition. All photographers are cordially invited to take part in the Conference. The meetings at the Society of Arts are open to ladies.

THE CRYSTAL PALACE NATIONAL PHOTOGRAPHIC EXHIBITION, 1893.—The directors announce that the National Photographic Exhibition will be held in the nave, commencing Monday, April 10, and closing Saturday, April 29. Alcoves and screens will be placed in the nave as usual, thus ensuring an equally prominent position for each exhibitor. A gold medal will be awarded for the best alcove, and a silver medal for the best complete screen. All classes for photographs will be open to professional and non-professional photographers. A special class will be devoted to the work of lady photographers. A silver medal will be awarded to the best exhibit in this class. The National Challenge Cup for the best collective exhibit by a recognised photographic society will be offered for competition; and in addition diplomas will be awarded by the Judges if, in their opinion, any society or societies show work of sufficient merit. It has been arranged to have a section entirely devoted to photographs having received first and second awards at any recognised photographic exhibition. Carriage will be paid both ways on all exhibits in this section. The Opera Theatre will be set apart each evening for the exhibition of lantern slides, competing and on loan; these will be projected on the large screen. The south nave will be reserved for photographic apparatus, materials, demonstrations in practical photography, photo-mechanical processes, &c. All correspondence and inquiries must be addressed to Henshaw Russell, Manager, Crystal Palace, London, S.E.

*** Owing to extreme pressure on our space, several Reports of Societies, Letters, Answers to Correspondents, and other communications, are unavoidably held over. All these, if possible, in our next.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1712. Vol. XL.—FEBRUARY 24, 1893.

PHOTOGRAPHING STAGE SCENERY.

Whenever a new piece is to be produced at the principal London theatres it is a matter of importance with the conductors of the illustrated journals—which have recently increased to a large extent—as well as the numerous daily and weekly newspapers that occasionally illustrate their articles with sketches, that arrangements be made for obtaining illustrations of the principal scenes, characters, and situations in the piece, so that they may appear almost, if not quite, simultaneously with the notices of the critics. These illustrations are sometimes derived from sketches made by artists during the rehearsals, and now and then on the occasion of the *première;* but modern theatrical managers do not take kindly to the presence, during the rehearsal of a piece, of outsiders, particularly if they are connected with the newspapers, and thus as a rule other means must be found for supplying them with sketches. We believe that in this respect photography is called into service.

The appearance of highly finished drawings of the scenes and characters of a play in a newspaper within very few hours of the fall of the curtain has possibly often excited admiration for the remarkable readiness and skill of the artists and engravers; but all cause for wonderment vanishes if, as is sometimes the case, the rough sketches, from which those finished drawings were made, are in the hands of the newspaper artists some days before the production of the play. It is here that photography steps in. Photographs of the scenes are taken, and prints from the negatives supplied to the artists, who thus obtain the most reliable form of sketch from which to work. Photographs of this sort need not, of course, be exposed with any degree of nicety. All that is required is a negative that will give a print with sufficient vigour to yield the necessary outlines, and some discrimination in the lights and shades.

As regards the figures in the scenes, the fact that the character dresses may not arrive until a late moment, or that it is left to the final rehearsals to arrange the exact situations and groupings, combined with the circumstance that the dresses to be worn in the play are not worn during the rehearsals, would seem to occasionally interpose difficulties in obtaining completed photographs of the scenes in ordinary cases; but we believe that at the principal theatres provision is made for the photographers to have an opportunity of taking the entire scene, as it will appear in the public performance, with a view to the convenience and assistance of the artists, at a dress or final rehearsal.

Photographs of this description must necessarily be taken under disadvantageous circumstances and with the shortest possible exposure. We believe that a special magnesium flash-lamp is used, as to the powers of which some idea may be formed from a remark of Mr. Milner (a gentleman who, we believe, has had much experience in this class of work), made at a meeting of the London and Provincial Photographic Association a few months back. He stated that, using a lamp of this kind, he had exposed a plate on a scene at the Adelphi Theatre with the lens at *f*-32, and had obtained a fairly well-exposed picture in three seconds, the lamp consuming three or four drachms of magnesium in that time, and the flame being very large. No doubt the ordinary illumination of the auditorium assists in such cases in materially diminishing hard results.

We remember, some years ago, being in company with a friend who was taking a crowded scene on the stage of a London theatre, the only illumination employed being that of the house at its full. Working under the most favourable circumstances of rapidity as regards lens and plate, and with, if we remember aright, an exposure of about a minute and a half, tolerably well-exposed negatives were secured. The actors and actresses, of whom there were forty or fifty on the stage, kept remarkably still, and the results were such as to allow of reproduction, although they were not, of course, by any means well exposed. Ordinary plates were used.

The lighting of stage scenes and characters for effects to be appreciated simply from the auditorium is not always desirable from the photographer's point of view, the relative actinic power of the more or less yellow light from footlights, auditorium, stage, and of the limelight, especially if the latter be concentrated, being such as to operate against a harmoniousness of lighting in the photographs. In photographs of stage scenes that are intended for reproduction we are informed that this difficulty is overcome by the collaboration of the photographer with those whose duty it is to attend to the stage lighting, the photographer being then able to obtain his own effects. But in such cases the exposure of the plate must necessarily be approximated to correctness, and, as without the characters time is immaterial, by the absence of the latter the necessary length of exposure can be given.

With a photograph of a scene minus the figures, the actors, we believe, give the photographer special sittings in character, either singly or in groups. These portraits are taken accurately to scale, so as to harmonise with the dimensions of the scene itself, and combination negatives are then made of the background and figures. It is in this way, we believe, that some of the most widely circulated photo-mechanical reproductions of scenes from recently produced plays have been prepared.

AMATEURS' BACKGROUNDS AND ACCESSORIES.*

II.

That fairly experienced landscape-workers fall into serious errors when called upon to execute a portrait was impressed upon us a short time ago when we picked up the portrait of a lady executed by an amateur of several years' standing. The portrait was *carte-de-visite* size, and the head and portion of bust occupied the lower inch or so of the picture—an interior. The face was admirably lighted, and the exposure had been just right, and, so far as that part of the business was concerned, we should say it was an excellent portrait. But the background was formed by an ordinary sideboard, of course much out of focus, but just sufficiently sharp to show that the handles of the drawers appeared to be about a foot above the lady's head, showing that the operator—who, by the way, is a fairly tall man—had used the camera stand at the same height he would have done for a landscape, which, of course, necessitated the camera being pointed down on to the sitter in such a manner that objects on the same level as her face, but further away, appeared much higher. The general effect was grotesque in the extreme, but the artist was unable to see where the fault lay.

In order to avoid such mistakes, we strongly urge the employment of a plain background wherever there is any difficulty with the natural surroundings, either indoors or out. In fact, we should say for indoor work make it a regular practice, for it is so seldom the arrangements of an ordinary room admit of a full-length figure being properly lighted for a short exposure. We are alluding now, of course, to all cases where the source of light is a single window of ordinary size, and which is utilised in conjunction with a reflector. Of course, when there is more than the one window, or one of more than ordinary size, the circumstances may be very greatly altered, and full-length figures, or even groups, may be successfully attempted; but in the majority of instances it will be preferable not to attempt more than the bust or half-length, and to use a plain background.

Even then the average amateur will often persist in his tendency to do what is not right. There are backgrounds and backgrounds, and we have used ourselves, and seen used by others, a great variety of makeshifts, such as blankets, sheets, table-cloths, and even newspapers. The last, in the hands of a clever and resourceful operator, we once saw do duty in a case of emergency, and it was difficult in the negative to detect any signs of it, so skilfully was it worked. But many an amateur would have succeeded in rendering every letter it contained tolerably legible by bringing it as nearly as possible into the same plane as the sitter; we have actually seen under such circumstances the pattern of a damask table-cloth almost as perfectly rendered as if that had been the intention, instead of a portrait. In the same way the texture of the blanket, once a favourite makeshift background, can be made painfully prominent in a photograph, especially when used indoors with a strong side light falling upon it.

There is little real necessity nowadays for such expedients, unless it really be in a case of emergency, as proper backgrounds are to be obtained from almost any of the dealers at so low a price that no amateur who does anything at all in portraiture need be without one. If, however, there be any so placed as not to be able to procure a proper background, we should recommend, in preference to any other substitute, a sheet of unbleached calico in its natural condition. This can be obtained almost anywhere in widths up to seven or eight feet, which will be quite large enough for any requirements. For indoor work especially, the light colour will be a great advantage, as the amount of light that falls upon the background when placed a foot or two from the window and at right angles to it is small as compared with that that reaches the sitter, and consequently its colour is apt to be rendered much darker than is desirable.

After having secured a satisfactory background, there still remains the necessity for keeping it in proper condition. It is scarcely needful to say that it must be kept perfectly clean and free from stains, but perhaps it may be well to remind some that it is equally necessary to avoid creasing the material, as perhaps nothing so completely betrays a background. In the strong side light of an ordinary room, and to a less extent even in the open air, every smallest wrinkle or crease will be distinctly rendered in the photograph, so that every effort should be made to prevent them.

The best way of effecting this is, of course, to have the calico or other material stretched permanently on a frame; but this plan is liable to objection on the ground of the inconvenience of storing so bulky an article when not in use. Another method, however, almost equally effective, so far, at least, as preventing the creases making themselves visible, consists in having a light framework made to take to pieces like the portable lantern screens, and, in fact, to stretch the background on this when required in precisely the same manner. It will occupy but little space when not in use, and is easily and rapidly put up when wanted. The only other plan is to keep the background upon a roller like a map, and to suspend it when in use from suitable supports, with a sufficient weight attached to strain out any creases.

Few, we imagine, who have once experienced the difference that a good background makes in a portrait would willingly revert to the slipshod system that prevails in too many quarters, and to those who have not yet made the discovery we offer the advice, to try it.

* Concluded from page 99.

Studio Building.—In response to our querist, "H. L.", in last week's Journal, Mr. Watmough Webster has promised to give us, shortly a paper describing his experience of studio building, though he doubts his being able to put the matter "in a nutshell," as "H. L.," in a second communication to us, suggested he might be able to do.

The Proposed New Central Photographic Club.—We give elsewhere some official details of the proposed new central photographic club, the provisional committee of which contains the names of several gentlemen whose adhesion to the scheme augurs well for its success. That a club of the kind is needed in London may be gathered from the remarks in the report of the Council of the National Association of Professional Photographers, which we printed last week, in which it is stated that such a club would be a *desideratum* to many of its members. We wish the projected club every success.

The Photographic Society's Affiliation Scheme and Lectures.—We congratulate the Photographic Society of Great Britain, and the forty or more societies affiliated to it, on the large and interested audience at the first of the two lectures on "Photogravure" by Mr. Denison, of Leeds, last Friday at Bloomsbury Hall. Mr. Denison's paper and demonstration, if not new in substance, was a model of lucidity, and what a paper intended for photographers inexperienced in the process should be. We hope this movement will prove to be the nucleus of a technical photographic institute, as suggested last year by Professor Meldola.

Test for Tartaric and Citric Acids.—As these two substances, the latter especially, are of considerable importance in photographic technics, a delicate means of discovering their presence when suspected will naturally be of value. M. L. Crismer, in the *Bulletin Société Chimique*, has recently given a new mode of doing this. If powdered citric acid is mixed with an equal weight of twenty per cent. solution of molybdic acid, and a few drops (ten or fifteen per cent. in bulk) of pure dilute peroxide of hydrogen, and heated for three minutes in a water bath, shaking frequently meanwhile, a pure yellow colour is produced if no tartaric acid be present. But if there be any of the latter substance, even so small a quantity as ·2 per cent., a very distinct blue colour is perceptible.

Pure Glycerine.—According to Dr. J. Lewkowitsch, in a paper read at the Leeds Pharmaceutical Congress, pure glycerine is a far rarer substance than is usually supposed. As a matter of fact, a large proportion contains arsenic. This impurity cannot, as usually supposed, be removed by distillation; and indeed, once a sample contains this substance, the learned doctor is unable to point out any practical process for freeing it from the objectionable contamination. Then, again, so-called chemically pure glycerines contain notable quantities of "organic impurities, either fatty acids, &c., or so-called polyglycerols, under which name I may summarise all those substances having a higher boiling point than glycerine itself." He gives a table containing results of his examination of eight samples of so-called pure glycerine. They contain from about one-fiftieth to one-tenth per cent. of objectionable matter.

"A New Hypo."—According to the Vienna correspondent of the *Paris Photographe*, the days of sodium hypo as a fixing agent are numbered, ammonium hyposulphite being about to be introduced for that purpose. The new "hypo" obviates long washing, is a white substance, dissolves rapidly and well in water, forming a colourless solution. At the same degree of concentration as sodium hypo, ammonium hypo, he says, fixes more rapidly than the former, while the time of washing is reduced by one-half. The new bath, however, throws down a deposit after a few hours, but only needs filtration to restore it to its pristine power. To these vague details of the new hypo the same gentleman adds the information that, so far, it is only a laboratory product, and costs from eight to ten francs a kilogramme. Six years ago, however, hydroquinone cost 400 francs the kilogramme, now it is only 40. Manufacturers hope soon to supply ammonium hypo at the same price as sodium hypo.

A Living Negative.—The recently issued *Proceedings of the Royal Society* contain an article by Mr. H. Marshall Ward, F.R.S., on the action of light on a particular form of microscopic life, the *Anthrax bacillus*, in which the luminous rays are shown to possess a most powerful fermicide property. A series of remarkable experiments are shown, the one possessing most interest, being a veritable living negative. Our readers are aware of the methods employed by microscopic experts in the examination of microbes. A plate of gelatine is prepared in a special manner and impregnated with matter known or suspected to contain certain organisms. After a time, the spores or germs multiply and form colonies, which give rise to a change in the gelatine medium, and so render their presence readily observable. Mr. Marshall Ward prepared one of these cultured plates with *anthrax* spores, and taking certain precautions, indicated by previous experiments, against liquefaction of the entire surface, exposed it to sunlight with a mark over it. In this opaque mask or screen he cut out the letter E, and exposed it to sunlight on Cooper's Hill from 9.30 a.m. on Wednesday, November 30, till 3.30 p.m. the same day, when the plate was removed and kept in a gentle heat till the following Friday, on which day it was examined. The sunlight had killed every trace of *anthrax* where it had access to, and the result was, in Mr. Marshall Ward's words, "The letter E stood out sharp and transparent from the faint grey of the rest of the gelatine." It is not in our province to point out the remarkable results this discovery may lead to, but it is well worth placing on record the first example of a gelatine negative composed of living organic beings.

Latent Images.—At the end of last year we gave our readers a short abstract of a paper by Mr. W. B. Croft on latent non-photographic images, or, as he termed them, Breath Figures. We again refer to the subject, indicating as it does a direct bearing on photographic theory and practice, as it has become a topic of interest, and has led to a special correspondence in the pages of our contemporary, *Nature*. One of Mr. Croft's references was to the image often seen on the inner side of the covering glass of a picture that has been framed and glazed for some years. His explanation is that possibly heat and light have loosened fine paint particles, and these have been drawn up to the glass by the electricity made in rubbing the glass. His final impression is that most of the phenomena cannot be drawn out from the unknown region of molecular agency. One of his inferences is to a blind with embossed letters having left an image on the window near which they lay, though not in contact with the glass. In a further communication a similar effect is described as having been seen by him, as also by another observer, of the words, "coffee-room," set off in the same remarkable manner. Mr. W. T. Thiselton Dyer writes (to *Nature* only) describing an effect similar yet different, that seems to suggest explanations for some hitherto unexplained photographic abnormal appearances. At Victoria Station is a shallow box with glass sides, into which boards are let down with station names painted in white letters on a blue ground, "INNER CIRCLE" being the most frequently used board. One night he observed the box empty, but to his astonishment the words "INNER CIRCLE" were to be seen in quite clear letters on a dark ground. The only explanation he could think of is one which, in a modified form, might account for the imprinting of the subject of an exposed plate on another adjacent unexposed one. It is "(i.) that the light of the lamp had produced some molecular change in the paint coating of the notice-board; (ii.) that this had affected differently the blue and the white paint; (iii.) that the same cause had set up some different electrical condition of the board or the glass; (iv.) that a bombardment of particles of the blue paint had taken place on to the glass, to which they had adhered; and that (v.) the particles so adhering by dispersing the light produced the effect of the pale illuminated ground, while the dark spaces occupied by the letters, being relatively clean, stood out dark."

ON THINGS IN GENERAL.

ONE of the most amusing discussions that have been reported in these pages for some time past is that upon Mr. Haddon's most useful table on angles of view in this year's ALMANAC. Mr. Everitt's comment, taken alone as a sort of elementary disquisition on trigonometrical functions, would be interesting of itself, but, taken as an attack on Mr. Haddon's rule, entirely fails, for a very simple reason. To prove the latter gentleman to be in the wrong, Mr. Everitt takes his general and gives a false particular instance, and on these premisses complacently shows the absurdity of the quoted table. If any one will take the trouble to refer to Mr. Haddon's paper, he will find its title to be *Angle of View Included in a given Plate by a Particular Lens* It is to be observed that a plate, and not a negative or view, is referred to, and the concrete example of the abstract principle is a false one. Any unprejudiced reader will take it to be meant, or any one who wishes to know what angle will be covered when using plates of a certain size. Mr. Haddon was not called upon to state that the axis of the lens was assumed to be coincident with a normal from the centre of the plate, any more than that the lens was supposed to be used with its own proper hood and with its anterior surfaces opposite to the view. Something has to be assumed always in a paper for non-mathematical readers, just as Mr. Everitt himself, in his diagrams, assumes that in the supposititious lens of his hypothesis, the hood was large enough not to interfere with the possible field of view. I recommend every reader of the ALMANAC to take no notice of the objections passed to the paper, but to act on the plain common-sense indications he will obtain from reading it. There is one precaution he must take, he must take the cap off the lens or the angle included will be a negative one; and, further, he must not stand on his head when treating it, or the figures will be transposed.

While upon optical topics, it may be pointed out that, in the discussions on tele-photographic lenses, one point seems to have been

entirely lost sight of, though affecting the apparent effect of architectural views to an important degree. It is that, when a large view of a very distant building is taken by a lens of this type, all ordinary linear perspective effects are lost. A wide-angle lens is often accused of giving exaggerated perspective. One of these necessarily narrow-angle instruments gives no perspective at all, at least none that can be perceived with the unaided eye. If we are to take Mr. Dallmeyer's paper with no assumptions or postulates at all, *à la* Everitt, we shall find that we can pick holes in his paper read at the South London Society. He says, quoting Le Conte, "Parallel lines of all kinds, such as railway sleepers, bridge timbers, &c., converge more and more to a vanishing point." Of course, it is assumed here that the parallel lines are in a plane at an angle to the picture plane. I can most heartily endorse all that the writer says about the extremely interesting nature of the study of vision, and Le Conte's work is sufficiently popular to be understanded of the people. Helmholtz also writes most delightful and popular articles on the subject. His great work on physiological optics, to be had in German or French, is "caviare to the general;" but in the first volume of his series of popular lectures will be found an article on the eye, so full of information and non-technical language, that the book would be cheap if bought for that lecture alone. There is an English translation of the set published some years ago by Longmans.

Mr. Alexander Watts suggestion of the earthenware ground utensils for development is very good so far as it goes. "Cosmos" has shown one disadvantage it possesses, but another still more important is the large amount of solution they require. I have tried them for fixing, where, of course, the amount of solution is of little consequence. Those in my possession, capable of holding a dozen and a half plates, measure $9\frac{1}{2} \times 5 \times 7$ inches, that is, about 332 cubic inches, just under one-fifth of a foot: and, as a foot is about six and a quarter gallons, it will be seen that decidedly more than a gallon of solution is required for eighteen plates.

Such articles, and the correspondence involved, as those upon valuation of businesses, are of great practical value. Many an amateur decides to take up photography professionally, and, with no data such as those I refer to available, might easily lend himself or get led astray in the estimate of the value of a young business. There is no doubt that the question of goodwill is a very thorny one; often there is no real goodwill, and as often it is non-transferrable. But one aspect of the question should be borne in mind when forming a judgment. It is that, although there may be no goodwill, the fact that there is a stand obtainable, and a studio ready to enter, constitute a valuable consideration. Many a man who would like to start a business in a particular neighbourhood finds himself unable to find suitable premises perhaps for years; cases are not infrequent where goodwill of a particular shop has been bought simply to obtain premises and the purchaser starts a business of an entirely opposite character. I cannot but call attention to the letter by operator on this topic, for his data are very misleading. Fifteen shillings a week a piece for printer and reception-room attendant could not obtain nor be expected to obtain efficient workers—it is less than labourer's pay. Then, again, in his figures he estimates 375*l.* for cabinets at fifteen shillings a dozen; that amounts to five hundred dozen, for which he provides five thousand mounts! Finally, in a business of the size assumed, one would think the principal himself could do all the "operator's" work to save that salary. However, from whichever point of view it is looked at, such discussions are of decided benefit.

FREE LANCE.

A NEGLECTED DEVELOPER.

IT is now about twenty years since, soon after its discovery by Schützenberger, that hyposulphurous, or hydrosulphurous acid, as it was called by its discoverer, was first suggested as a possible developing agent; but it was not until early in 1877 that, under the name of the "hydrosulphite developer," it was put forward in a practical form by the late M. Samman, a civil engineer, of Paris.

The hyposulphurous acid of Schützenberger must not be confounded with the compound previously known under the same name, and which, in combination with sodium, forms the familiar "hypo" of the photographer. Up to the time of Schützenberger's discovery, chemists had been in some doubt as to the precise composition of hyposulphurous acid, then so called; its formula was generally written down as $H_2S_2O_3$, but for various reasons, which need not here be specified, many chemists regarded it as having the formula $H_2S_2O_3H_2O$, which, simplified, may be written as $2(H_2SO_2)$. The German chemist referred to showed, however, that his new acid had the formula H_2SO_2, and this set the matter at rest, and it was then recognised that the newer compound was more consistently to be designated "hyposulphurous" acid, while to the older, and hitherto known under that name, the title "thiosulphuric" acid was given.

Schützenberger's acid is formed by the deoxidation, by means of metallic zinc, of liquid sulphurous acid, while the older compound is formed by its sulphuration. The following formulæ show the precise relations of the three acids to one another:—

Hyposulphurous acid	=	$H_2S\ O_2$
Sulphurous acid	=	$H_2S\ O_3$
Thiosulphuric acid	=	$H_2S_2O_3$

The first-named is formed by acting on liquid, or rather aqueous, sulphuric acid with metallic zinc, which, in dissolving, abstracts one atom of oxygen, forming a yellow liquid possessing much greater decolourising and reducing power than sulphurous acid itself. It is, however, a very unstable preparation, and a preferable way to utilise its reducing action is in the form of its sodium salt. This, in conjunction with pyro, was, in fact, the hydrosulphite developer of M. Samman. A concentrated solution of sodium bisulphite is poured into a flask or bottle containing granulated zinc or zinc clippings, and allowed to stand for half an hour. The zinc dissolves, giving rise to the new acid, and the solution then contains, in addition to sodium hyposulphite (not thiosulphate), zinc-sodium sulphite, the former of which is really the active agent. This compound solution, mixed in equal proportions with a four-grain solution of pyro, constituted the developing solution which was remarkable for the regularity, beauty, and cleanness of its action.

At the time of its introduction gelatine plates were practically unknown, and the early experiments were made with collodion dry plates. With these it was found that a better though less energetic action was attained if, instead of the bisulphite, neutral sodium sulphite was employed, or the former salt neutralised, or partly so, with sodium carbonate. Later on M. Samman modified his formula, and in the ALMANAC for 1878 gives one in which the sulphite and bisulphite are combined, and instructions given to neutralise the free acid of the latter—in other words, to convert it into sulphite. It may be added that a solution of ordinary hypo, treated in the same manner with zinc, exhibits developing power, but, as might be expected, its fixing action is both more energetic and more rapid.

It should be noted here that, although the solution formed by the action of zinc upon the neutral sulphite possesses devoloping powers when mixed with pyro which the plain sulphite does not, it contains no zinc in solution, as may be proved by testing it with sulphide of ammonium. Its developing action is, however, much less energetic than when the bisulphite of soda is used, and was at first supposed to be due to alkalinity of the sulphite; but such is not the case, as it may be slightly acidified after decanting from the zinc without losing its power. To acidify the sulphite before pouring on to the metal would be equivalent to using a small proportion of bisulphite.

The solution, as has been already stated, attains its full energy after half an hour's contact with the zinc, when, if decanted, it commences at once to lose its newly derived power, reverting to the state of sodium bisulphite, the zinc being thrown down as a white powder. This change occurs with less rapidity after the pyro has been added, owing, no doubt, to the absorption of oxygen by the pyro instead of by the hyposulphite. In fact, the pyro and hyposulphite solution remains clear, and without deposit, for many hours. This peculiarity was noted in these pages at the time, but it remained for the late Mr. Herbert Berkeley, some years later, to apply the alkaline sulphites for the purpose of keeping the developing solution clear and preventing discolouration of the gelatine film.

As has been said, the early application of this developer was in connexion with dry-collodion plates, for which it proved most

suitable. The character of the image was entirely different from that produced with the ordinary alkaline pyro, partaking more of the pure metallic appearance of the wet plate. This characteristic rendered it especially suitable for transparency work, and even now without any modification it can be heartily recommended to the users of collodion emulsion. It is extremely easy of preparation, all that is required being a wide-mouthed bottle three parts filled with scraps of zinc, preferably in the form known as "granulated," granulated zinc being obtainable for a few pence a pound at any chemist's. Into this bottle a strong solution of bisulphite of soda—200 grains to the ounce of boiling water, allowed to cool after solution—is poured, and simply allowed to stand for half an hour or so, when it is ready to mix with the pyro solution. When done with, the solution should be poured off the zinc into a separate bottle and well corked, and in a few hours the zinc it contains will be precipitated, and the solution will have returned to much its original state, and may be used again. The zinc bottle should be rinsed out with clean water, ready for use when wanted again.

Metabisulphite of potash may also be used, and if found too energetic, that is to say, if it causes fog, a little carbonate of soda may be added until the smell of free sulphurous acid is greatly reduced. It may be noted that this developer does not owe its power to alkalinity, as it is more energetic when the sulphurous acid is used in the free state.

But, turning to gelatine plates, unfortunately the hydrosulphite developer does not specially recommend itself, at least in its original form. It is with the intention of making the cause of this clear that I have dwelt at such length on the chemistry of this curious compound, which, as I have shown, in the course of oxidation, deposits an insoluble basic salt of zinc. In conjunction with collodion plates this mattered little if it occurred at all, as the deposit formed only on the surface of the film, and was easily removed by washing or by other means. Not so with gelatine, however, for apparently by some special attraction exerted by the gelatine not only does this precipitation occur to a much greater degree, but the precipitate is formed in the pores of the gelatine as well as on the surface. From the latter it is easily removed by washing and friction if necessary, but from the body of the film it is not so easy to dislodge it, and the consequence is an unpleasant veil of a pinkish white shade that especially unfits the solution for transparency work, if not indeed for negatives.

W. B. Bolton.

(To be concluded.)

RETOUCHING AND VARNISHES.

As a retoucher of many years' experience, and having—no doubt as many others have done—occasionally had *failures*, which I invariably find teach us far more than our successes, and, having overcome them, I think that I may venture to point out to less experienced "knights of the pencil" how they may succeed in varnishing a retouched negative without losing so much as a single stroke of their carefully placed wok.

Pardon the digression, but I venture to think that, if the *whole* of the work of some of the "retouchers" of the present day came off with the varnish, the negatives would yield much more satisfactory prints, both as regards likeness and artistic effect.

To begin at the beginning, let us take the *medium*. I have tried many makes, and have been successful with them all. Of course I have my favourites, but only so far as regards the *tooth*, not because I find one comes off with the varnish more than another. I do not recommend retouchers to make their own medium, as it is not worth bothering with. A shilling or eighteenpenny bottle will do some hundreds of negatives if it is not wished for it to come off again with the varnish.

For those who may like to make their own, as I know there are many who will not buy anything they can possibly make, I have found nothing better than common resin dissolved in common turpentine. I have used such a mixture for years, and found it work splendidly. I should simply get a lump of resin, about the size of a walnut, put it in an ordinary one-pound jam pot, about half-filled with turpentine, and stand it on the hob, not too near the fire. When dissolved it should look something like strong ale, and when carefully *decanted* into a bottle it is ready for use. Personally, for some time past I have used the Autotype Company's medium. Do not leave the cork out of your medium bottle for long, as, if you do, you will soon have only a nasty sticky mess left. I do not like cotton wool for placing it on the negative, as it so often leaves it messy, with little pieces of the wool sticking to it. You are also apt to leave on too much, which, if you do, you may reckon upon a good part coming off again, and the retouching with it when varnishing. I find the best plan is to keep an old pocket handkerchief for the purpose, stretch it tightly over the end of your forefinger, then tip up your bottle of medium so that it moistens the cork, and with the cork moisten the handkerchief on the end of your finger, then rub it *well* on the part of the negative to be retouched. If it is a large head, you may require to give two dabs on the finger with the cork, but one is generally sufficient; but be sure you do not leave on too much. Then you may commence retouching almost at once, or you may leave it for a few hours, as convenient.

Now, as to the varnish and varnishing. I may also say that I have worked with many different varnishes, as a retoucher must necessarily do in going from berth to berth, and some employers are very obstinate and think the varnish (or anything else) that was used by an old assistant must do for the new, especially if it happens to be a little cheaper than what the new man recommends.

The varnish I generally use when I have my own way is the ordinary "white hard," to be obtained at any oil and colour shop, thinned down with methylated spirit and filtered. In a future article I may describe a very useful varnishing pot that I have in use.

Do not use the varnish thick, as it takes longer to set hard, and is likely to become "tackey" in hot weather, when the prints would leave marks upon its surface, and dust be more likely to adhere to it.

Although I prefer the "whitehard" varnish, most of the photographic varnishes in the market are good, and I have not yet come across one that would shift the pencilling if properly treated. Some few years ago I had just commenced work in a new berth, and had varnished about half a dozen negatives before leaving in the evening; my surprise may be imagined, on looking through them the next morning before sending them down to the printers, to find that the retouching was scattered all over the plates instead of on the face, &c., where I had placed it. I showed them to a lady retoucher sitting at a desk next to mine, and asked her if she could account for it in any way; of course, she laughed at the "new man," and told me that the emulsion had been thoroughly "cooked" long before it came into our hands, and, if I would be satisfied with only *slightly* warming it up, I should find matters all right.

I think that girl had got to the bottom of moved retouching. I tried her plan, viz., only *slightly* warm the plate, then varnish, being careful *not* to pour the varnish on the retouched parts, stand the plate in a rack to set for a few minutes while some more are being varnished, then commence with the first and dry them off by thoroughly warming them. I was never troubled any more; that was the worst case I ever met with, and I think that the varnish had a good deal to do with it; it was a home-made varnish entirely. The principal thought it perfection, made it himself, and kept the ingredients a secret, which I think was a blessing to photographers generally.

I have met at various times with slight cases of moving, but have always traced it to the medium being too thick on the plate, or else the plate being made too hot before varnishing, generally the latter.

In some firms all the retouching is done upon the varnish, and in quick trades of the middle class it is perhaps best to do so, as I have found that more work can be got through in that way, the medium upon the varnish giving a better tooth for the pencil, and the negatives can be varnished as soon as they are dry by a lad, and so be ready for the printer almost as soon as retouched. Now I have found that it is the *medium* upon the varnish which rubs off (and, of course, the retouching with it) with the constant dusting, &c., so that if the negative is retouched *before* varnishing, and one wishes to do only a *little* more after, it is best to dispense with the medium altogether, the varnish itself generally giving enough tooth; but, if the whole, or a great part of the work, is done upon the varnish, medium is necessary; to protect which in the quickest way is to *thoroughly* warm the plate, when it will be found that the medium and retouching have sunk into the varnish and is quite safe.

A word as to collodion. If you value your negatives, never allow even a single silver print to be taken from them in this damp climate of ours without giving them first a coat of something damp-proof. If you don't like varnish, give them a coat of enamel collodion: or, what is better, both, as, if you coat first with collodion, and, when that is dry, give a coat of varnish, you will have the best waterproof coating known.

If you don't like coating the plate with anything, then have a sheet of talc between the plate and print. But collodion has another

use. There is sometimes a dark piece of drapery you would like removed, a lady's waist may be too thick and require some off on the shadow side, or some other dark object you would like taken away, and yet you cannot get on enough pencil to do so, even by working under and over the varnish. Now, if you will use both collodion and varnish, and work on each with a little medium, you may go on indefinitely, using each alternately until the desired effect is produced, and, if both are used thin, the thickness of half a dozen coats is inappreciable. Should the collodion at any time take a slightly opalescent appearance, it will entirely disappear with the succeeding coat of varnish.

HAYNES WELCH.

DETERMINATION OF PLATE SPEEDS.

MR. WILLIAMS has not seen fit to avail himself of Messrs. Marion & Co.'s invitation to acquaint himself practically with our method of speed determination, nor to accept our offer to submit his negatives to us for measurement; and, as we have neither time nor inclination to enter into a prolonged discussion with him, we must leave him to discover for himself the fallacy of deciding percentage differences in speed by the ocular comparison of negatives. We should, however, like to say a few words more before, as far as we are concerned, the matter drops.

The system of speed determination which we have freely given to the world is, we believe, destined eventually to be generally adopted; in the meantime we can well afford to look on with unconcern while people, who either cannot or will not study the principles and theoretical considerations upon which the system is based, set themselves ruthlessly to destroy what we have taken years to build up.

We should be the last to claim that the working details of the system are incapable of improvement; but, while we warmly acknowledge the efforts of Mr. Cowan and Mr. Cadett to work the system with accuracy and efficiency, we cannot take any responsibility upon ourselves should errors occasionally arise. The adoption of the check plate, on the initiative of Mr. Cowan, is a proof of the anxiety of those gentlemen to take every possible precaution to prevent error.

Mr. Williams' repeated assertion, that he can detect by ocular inspection a difference of ten per cent. in two exposures, convinces us that he can never have devoted any attention to the law which is the foundation of our system, and which is graphically expressed by what we term the "characteristic curve." If he were to plot the characteristic curve of a plate, and then consider the effect upon it of a difference of ten per cent. in the exposure, he would easily convince himself of the utter futility of expecting to find any ocular evidence of such differences in two negatives.

Apart from this, Mr. Williams has probably never realised that, in the case of two plates of identical speed but having different characteristic curves, it is absolutely impossible to produce two identical negatives; and this fact, unrecognised by Mr. Williams, has led him to conclusions which any one acquainted with the characteristic curve would at once have seen to be fallacious. Nor has it probably, on the other hand, occurred to Mr. Williams that two negatives, on two similar plates, may have identical printing values, and yet be enormously different when examined either by the eye or by measurement. This is only another way of saying that, in a thickly coated plate, having an extended period of correct representation, there is considerable latitude of exposure. These are facts which may appear to be paradoxical to Mr. Williams, but for the explanation of which we can only refer him to our papers.

We have recently felt that we, perhaps, made a mistake in adopting, for our speed scale the numbers which we did, and that speeds now expressed as 10, 20, 30, for example, would have been better expressed as 1, 2, 3. The public seem to estimate these numbers far more by their differences than by their ratios, and have so acquired an exaggerated idea of their influence upon the exposure. Whether the speed of a plate is, in practice, ninety or one hundred, matters absolutely nothing.

It is somewhat amusing to find how photographers, who have existed for so many years without any system of speed determination whatever, all at once demand such hairbreadth distinctions. We suppose it will be some time before they learn to appreciate the degree of exactitude which it is either possible or necessary to reach. We are glad to say, however, that it is possible, by our method, to estimate the speed of a plate with considerably greater precision than is actually required in practice; but this fact will not be brought home to Mr. Williams and photographers generally till they turn their attention to the law which governs the action of light upon the sensitive plate.

If, when Mr. Williams has studied our theory of the action of light, he succeeds in disproving it, we shall feel compelled to pay more serious attention to him than we do at present; but, till then, we prefer to accept as true a theory which is in such complete accord with photographic phenomena generally, and in opposition to which he has not advanced one particle of evidence. We hope we may have said enough to lead Mr. Williams to consider whether, after all, our method of speed determination may not stand upon firmer ground than he at present wots of.

F. HURTER,
V. C. DRIFFIELD.

IMITATION PHOTO-ENGRAVINGS.

I WAS glad to notice in the last issue of the JOURNAL that you make mention of some "grating photographs" produced by Mr. John Robertson, of Dundee, as this is a style of picture that I have myself done a good deal with during the last two years or more since I first got the idea from your pages. The results, when properly executed, are exceedingly attractive—far more so, I think, than actual screen pictures, as the gradation is far softer and more natural than that produced from an inked plate, and I am sure more photographers would adopt the novelty if it were not for the difficulties involved.

It was a long time before I could produce anything that was at all presentable, although I followed as closely as possible the instructions given for preparing the grained screen, as well as its combination with the photograph. To any one taking up the thing for the first time, the production of the grained surface would appear, from the directions, to be the simplest operation in the world, the chief difficulty being, apparently, to select the kind of grain that will look best. But, when he comes to try it, it will be found anything but the easy job imagined. It is not only that the task of obtaining an even grain, of whatever kind it may be, is far more difficult than it seems, but, having obtained the necessary degree of uniformity, the size and density of the grain are most difficult for a novice to hit, and, moreover, have to be varied with the dimensions of the picture, and very often with the character of the negative.

Although I have never practically worked any of the photo-engraving methods, I can well conceive that the question of grain is an even more difficult one than is the sort of hybrid process I am now referring to, because, in addition to other troubles, there is that of getting a grain that will not too readily fill up in inking; in fact, the grain must not be finer than the absolute exigencies of gradation require. In our present method, however, as we have no inked plate to deal with, the grain may be as fine as we please; indeed, the finer it is the softer and better will be the gradation. Here was the first trouble I encountered. I could not persuade myself to make the grain fine enough in the first place, and I then rendered its coarseness more obtrusive by making the negative too dense.

It is impossible to convey in a mere written description either the size of grain necessary or the density of the grain negative, because these, as I have said, vary so much with circumstances; in fact, I am convinced that nothing but actual experience with a variety of different "gratings," as well as portrait negatives of different kinds and densities, will enable the operator to secure exactly what he wants; but, if he will bear in mind one or two simple points, I think he may save himself much trouble. Let only rather thin negatives, but full of detail, be selected for the purpose, let the grain be as fine as may be without being too fine to deprive the picture of the character it is sought to give it, and let it not be made too obtrusive by giving too great density to the grating negative. It has to be borne in mind that, like retouching, the effect produced on the print is far greater than appears in the negative.

As regards the production of the grained plates, that naturally constitutes the chief difficulty; I believe they are to be obtained commercially, though I have as yet been unable to secure anything satisfactory at a reasonable price, so have had to make my own; and perhaps my experience may be of some assistance to others, as I think I have tried every method I have seen suggested or that I could suggest myself. Ruled screens are, of course, completely out of the question unless you have a ruling machine, and even then I question whether the mechanical difficulties involved are not greater than the result justifies.

I have tried photographing various kinds of gauze, metallic and otherwise, perforated zinc, perforated card, *et hoc genus omne*, but am always met with the same difficulty, namely, a perfectly even division of the original. In any of the woven fabrics it will always be found that there are here and there single threads or strands of different thickness to the rest, or that are badly spaced, and in such materials as perforated zinc there seem to be at regular distances wider spaces between the lines of perforation, as if these were made by means of

rollers which at each revolution imparted their own irregularities to the sheet of metal. Every one of these departures from strict uniformity produces its effect upon the resulting grain; indeed, when this is so fine as to be scarcely distinguishable to the eye except with the aid of a magnifier, the irregularities seem to be even more prominent than on the larger scale.

A method of ruling, described about two years ago, in which a perforated strip of paper or tinfoil is drawn across the surface of a sensitive plate, so as to form a series of fine lines when exposed to light, seemed to promise a way out of the ruling difficulty, and on a small scale I found it answer very well. But I was not fortunate in being able to procure the necessary tools for making the perforations fine enough to work directly, and, when the dimensions were increased to a sufficient extent to admit of reduction, the mechanical difficulties seemed to be increased out of all proportion, and I had to relinquish that method.

Eventually I gave up attempting to get a mechanical grain of any kind, and turned to what may be called, in contradistinction, a natural grain—one obtained by spreading a granular substance evenly over a suitable surface. This at first offered no great promise of giving a better result, though after some perseverance I at last managed to arrive at something that seemed to be nearer the mark. The process I eventually adopted consisted in spreading the grain evenly over a flat surface, and then photographing this under proper conditions of lighting, when a beautiful grain of the greatest uniformity can be obtained, and that is more than I can say in favour of any of the methods of pressing the grained surface into tinfoil or soft metal, so as to form a matrix from which to take impressions in gelatinous or other ink.

I tried first of all spreading the granular material on glass, with the intervention of an adhesive, and, when dry, using this as a negative by transmitted light, from which to reproduce others in film form. But the result was unsatisfactory, as I could not find any grit that was translucent enough and yet gave a good grain. Such screens were, in fact, too opaque, whereas the beauty of the reproductions by *reflected* light from a granular surface is, that you get what may fairly be called a selective grain, that prints more forcibly in the shadows than in the high lights.

The plan I have used with most success consists in, first of all, stretching a sheet of paper smoothly and lightly over a plate-glass surface, and coating this in turn with a thin solution of gelatine, spread very evenly by pouring it on and off again, rather than with a brush. When this is perfectly smooth, I sift over it, by means of a perforated zinc tray, powdered emery, mixed in three different grades of coarseness—40, 50, and 60, as the numbers go—and, when the gelatine has set, I shake off the superfluous powder by gently tapping one corner of the plate on the table. Then another sheet of smooth paper, and a second piece of plate glass are laid on the dusted surface, and as much pressure applied as I dare without danger of breaking the glass, in order to render the surface as smooth as possible, when it is allowed to dry.

The dark tint of the emery prevents any harshness, or rather hardness, in the subsequent photographing, and if a good diffused light, coming principally from the front, be used, a grain may be produced by reduction that will rival in softness, evenness, and minuteness, anything in the way of photogravure, and give printing results upon albumen or gelatino-chloride paper that are far preferable, I think, to the mechanical "Meisenbach" grain. In effect, the prints, if toned dead black, look just like photogravures, and are no more difficult to make, when the suitable grain negative has been selected, than plain ones.

The film negatives are made on collodion emulsion, the glass being first rubbed with talc to make the collodion "strip," and, of course, the grain may be reduced to any degree of fineness. I have been unable to get the clearest and best "gratings" by using the process of reversal by means of nitric acid or ferric sulphate, but by the direct method no difficulty will be experienced if too strong a light be not used, and no attempt made to get density. The grain negative should be as delicate as possible.

The trouble of spreading the emery may be saved by using ordinary emery cloth, if it can be got free from cracks and creases, and is strained evenly on a flat surface; but I prefer to spread the powder myself.

W. LINDSAY.

PROPOSED NEW CENTRAL PHOTOGRAPHIC CLUB AND INSTITUTE.

WE have received the following official communication on the subject:—

A PROPOSAL has recently been discussed and adopted by a provisional committee, having for object the establishment of a photographic club and institute, occupying a central position in London, easily accessible from the principal railway termini and by the chief omnibus routes, &c., and therefore convenient both for town and country members. The provisional committee discussed the following leading points of the scheme:—

1. That the club be called the Central Photographic Club.
2. That the club premises be open during recognised club hours, refreshments being obtainable, and the premises to comprise meeting room, smoking room, library, dark room, and other photographic and ordinary club conveniences.
3. That membership be at the disposal of ALL INTERESTED IN PHOTOGRAPHY, both in town and country.
4. That the subscription for town members be 1*l.* 1*s.*, and for country members 10*s.* 6*d.* per annum.
5. That it is desirable to make the social element a strong feature of the proposed club, while at the same time technical photographic meetings, lantern entertainments, exhibitions of pictures, apparatus, &c., should also be held.

The idea of the proposed club as outlined above is strongly supported by a great many gentlemen who have expressed their intention of joining. For this and other reasons a very large membership may be anticipated. A meeting (to which all interested in the proposed club are hereby invited) will be held on Monday, March 6, at eight o'clock, at the Memorial Hall, Farringdon-street, E.C., to appoint a permanent working committee for organizing the club, to discuss details and suggestions, &c., and generally to arrange preliminaries.

Provisional committee:

BIRT ACRES, A. COWAN, T. E. FRESHWATER, F.R.M.S., F. W. HINDLEY, J. HOWSON.

REDMOND BARRETT, R. BECKETT, F. W. EDWARDS, T. FALL, E. HOWARD, FARMER.

R. P. DRAGE, WM. FENTON JONES, A. HADDON, A. HORSLEY HINTON, JOHN A. HODGES, CHARLES H. OAKDEN.

J. TRAILL TAYLOR, T. BOLAS, T. C. HEPWORTH, H. STURMEY, E. J. WALL, THOMAS BEDDING.

WOOLWICH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THIS young Society is fortunate in having for President such a prolific producer of photographs as Mr. A. R. Dresser, inasmuch as at its first annual Exhibition, which was held last week, it was able to make up for a comparatively small display of competitive work, by showing a large selection of that gentleman's well-known pictures, and thus the Exhibition as a whole, which also included non-competitive exhibits from Mr. Pringle, Mr. Davison, and Mr. Seyton Scott, was not shorn of any of the elements of attractiveness to the outside public. The Exhibition, which was held in the large room of the Woolwich Polytechnic, was decidedly creditable, as a first attempt, to all concerned in it.

In the class for Members' work we liked Mr. A. Godfrey's portrait studies, and the Rev. E. J. Doherty's large yacht pictures, as indicating promise of better things in the future. Mr. G. C. King showed, in *Sunset after Storm*, a capital study, in which the heavy shadows of the subject were well rendered; Mr. W. Davies, a charming view of Shanklin, with the peculiar uranium tone which Mr. Dresser affects, and in which he finds many imitators in this and other exhibitions. In the class open to all amateurs, Mr. C. F. Archer's large bromide study of a female head, *Interested;* Mr. J. A. Young's portraits; Mr. C. Court Colea' Oxford interiors and Iffley views; and several of Mr. T. M. Brownrigg's Pall Mall exhibits were noticeable. Mrs. S. Frances Clarke showed some soft, delicate, and well-lighted outdoor studies, the lady's figure in them being charmingly posed, which to our thinking, were unfortunate in not securing an award. In the class open to amateurs who had never received an award in open exhibitions, we had seen and criticised most of the pictures before. Viscount Maitland, Mr. Edward Hawkins, Mr. C. H. Oakden, Mr. W. Howell, Mr. J. O. Grant, Mr. H. E. Farmer, and others showed good and familiar work therein. The class for hand-camera work was a small one, but Mr. W. Thomas, Mr. A. Brooker and Mr. Charles Job made up for the paucity of the exhibits by the good quality of their work.

The Judges were Messrs. A. R. Dresser and Andrew Pringle, and the following were their awards:—Class 1. Prints (Members only).—Bronze medal, C. G. King; bronze medal, Geo. J. Gill; diploma, W. Dawes. Class 2. Lantern Slides (Members only).—Silver medal, W. Dawes; bronze medal, C. G. King. Class 3. Prints, open to any amateur photographer.—Silver medal, C. Court Cole; bronze medal, T. M. Brownrigg. Class 4. Prints, open to any amateur photographer who has never received an award in an open competition.—Silver medal, Chas. Moss; bronze medal, Viscount

Maitland; bronze medal, Ed. Hawkins; diploma, Ernest R. Ashton Class 5. Lantern Slides (best set of six), open to any amateur photographer.—Silver medal, W. Taverner; bronze medal, H. E. Farmer; diploma, E. Hawkins. Class 6. Set of four prints taken with camera held in the hand, open to any amateur photographer.—Silver medal, E. Hawkins; bronze medal, Chas. Job; diploma, A. Brooker. Gold medal for best picture in Exhibition, Chas. Moss.

THE PHOTOGRAPHIC SOCIETY'S LECTURES ON "PHOTOGRAVURE."

No. I.—Preparation of the "Resist."

In connexion with the affiliation of photographic societies to the Photographic Society of Great Britain, Mr. Herbert Denison, of Leeds, gave on Friday last, February 17, the first of two lectures on *Photogravure*, when Mr. J. Traill Taylor presided. The attendance at Bloomsbury Hall was an extremely large and influential one, including, besides many members of the Photographic Society of Great Britain, several well-known engravers and process workers, and members of the following Societies:—Photographic Club, London and Provincial Photographic Association, South London Photographic Society, Photographic Section of the Croydon Microscopical Society, North Middlesex Photographic Society, North London Photographic Society, Greenwich Photographic Society, Brixton and Clapham Camera Club, Leeds Photographic Society, and many others. Several ladies were also present.

The lecturer, having said that he had accepted the invitation to give the lectures because he was glad to see the Society taking its proper place in the education of photographers, alluded to the difficulties of obtaining assistance or advice in the practical working of photogravure, and expressed his indebtedness to Mr. A. W. Turner, of the Survey of India Office, Mr. Bolas, and Mr. W. T. Wilkinson, for much useful information He commenced his subject proper by indicating the kind of plate one aims to produce in photogravure. The plate, he said, is of copper, with the image in intaglio, that is, the portions of the plate bearing the darks of the picture are sunk, having been eaten out by an etching fluid, and the whites are represented by the original bright surface of the plate which has been protected from the action of the solution. The plate is printed from by having a specially prepared stiff ink, composed of lamp-black or other pigment, ground in linseed oil, rubbed into the depressions by means of an ink dabber, *i.e.*, a roll of woollen material, the fibres at the end of which have been frayed out. A small quantity of the ink is taken up on the frayed end, and with a rocking motion and some pressure the whole surface of the plate is inked. The plate is then wiped entirely clear, the ink remaining in the etched portions. To print, a sheet of damp paper, with a few thicknesses of "blanket" behind it, is placed on the plate, and the whole passed through the rollers of a copper-plate press, the shadows, half-tones, and high lights of the resulting print being proportioned to the depth to which the image on the plate had been etched.

Having pointed out that if the etched spaces were not broken up into a number of minute depressions instead of a few large ones, the ink would be wiped out from the hollows as well as from the surface, the lecturer indicated how the copper surface could receive the necessary protection by the application of a solution of bitumen in benzole, the effect being upon the evaporation of the solvent, to cover the plate with little dots which resist the action of the etching fluid, and to impart a grain to the picture. A carbon negative, called the "resist," is next placed on the copper plate, the thinnest parts of the gelatine offering the least resistance to the action of etching solution, and so on through the half-tones to the high lights. Upon the resist being cleaned off, small bright points, which have been protected by the bitumen dust, stand up to the original surface level, and form the grain.

From the principles of the process, which is known as the Talbot-Klic, and is extensively employed commercially, Mr. Denison passed to its practical side, enumerating the following list of materials which are required; A printing frame, Autotype special transparency tissue for the transparency, a tin box with a weighted lid to keep the tissue in, an actinometer, a porcelain dish, and a solution of bichromate of potash (six drachms to the pint) for exciting the tissue, ferrotype plates to dry the latter on, two developing trays of tin, a squeegeeing board covered with zinc, a small gas stove, five per cent. solution of alum, methylated spirit, glass plates coated with bichromated gelatine. The foregoing are necessary for the transparency. For the plate the following are required: Copper plates (obtainable from Messrs. Hughes & Kimber, West Harding-street, E.C., or Mr. A. Nicolls, Cyrus-street, E.C.); some pure cotton wool (to be obtained from chemists) and washed whiting for cleaning and polishing the plates; a dusting box about a foot square at base, and eighteen inches high, arranged to revolve upon pivots placed in the middle of each side, with a door at the front through which a plate may be passed after shaking up the dust by causing the box to revolve; about a pint of powdered bitumen or asphaltum to place in the box; a sheet of iron about a quarter of an inch thick, and larger than the copper plate; this is to place over the gas stove, and is used for fixing the bitumen dust to the copper by heat; a flat ruler; a draughtsman's pen; a camel's-hair brush for varnish; five solutions of perchloride of iron of different strengths, and five dishes for them.

The negative required should be of the class to give a good print in platinotype or plain silver and free from defects. Having described the sensitising of the Autotype Company's Special Transparency Tissue by its immersion in a bichromate bath of the above given strength, pigment side downwards, until it curls outwards, this being, he said, a better guide than stating a definite time, although the latter is usually from two to four minutes, he said it is squeegeed, tissue side down, to a clean ferrotype plate, and dried at a temperature of 65° in the dark and stripped, when it will have a fine bright surface. The printing of the transparency from the negative was next dealt with, and its development upon glass coated with bichromated gelatine exposed to light, so as to form an insoluble substratum for the transparency. One of these plates being placed in a dish of cold water, the exposed tissue is also placed in it, face upwards. As soon as it has uncurled, the exposed tissue is squeegeed in contact with the substratum on the glass plate, and developed in water at 95°. When the pigment commences to ooze out at the edges, the paper backing can be removed with the finger, and the warm water is dashed over the plate until the soluble gelatine has been washed away.

Mr. Denison said that, as the transparency was to be printed from, it should be judged from the same standpoint as one would a negative, being vigorous and full of detail in the high lights, showing very little clear glass when placed on white paper. Both in regard to the transparency and the carbon negative to be made from it, the lecturer fully entered into details, and at the conclusion of the paper demonstrated sensitising the tissue, development, &c., in accordance with the details laid down.

To-night (Friday), the second lecture takes place at the same hall at eight o'clock, the following being the syllabus:—*Résumé* of first lecture; preparation of the copper plate; laying the ground; fixing the ground; transfer of the resist to the copper; development of the resist; drying off; protecting the margin; the etching; finishing and retouching the plate; pulling a proof. A practical demonstration will be given of each step in the process after the verbal description.

THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The Annual General Meeting was held on Monday, February 20, in the rooms of the Photographic Society of Great Britain, Mr. J. Traill Taylor (President) in the chair.

The President said that he regretted that he had been unable to attend the Committee meetings, but that his attendance had really been unnecessary owing to the fact that the late Mr. William Bedford, as Chairman of Committee, had been such an efficient head. He had intended to refuse re-election as President in favour of the late Mr. Bedford, and had already intimated his intention before Mr. Bedford's death. That gentleman's loss to the Association was such a blow as could hardly be expressed, but he (Mr. Taylor) was still obliged to retire from the presidency owing to the fact that his medical adviser had ordered him to withdraw as far as possible from all evening engagements.

The report of the Committee was taken as read.

Mr. J. Spiller (the Treasurer), in presenting his report, said that the Association was to be congratulated on an unusually good balance-sheet for two reasons—firstly, because the disbursements had been unusually small; and secondly, because a windfall of fifty guineas had come to the Association through Dr. Lindsay Johnson. The list of subscribers of 1*l.* and upwards was better than for many years past, and the only unsatisfactory thing about the balance-sheet was that the small subscriptions of under 1*l.* still reached but a very small total. In moving that the balance-sheet be adopted, he wished to include special thanks to the Photographic Society of Great Britain and to Mr. Frederick Hollyer for their substantial contributions to the funds.

Mr. F. W. Hindley inquired whether the total of small items had been diminished owing to the fact that the subscribers had increased their subscriptions and come into the list of 1*l.* and upwards.

The Secretary replied that this had only occurred in one instance.

The balance-sheet was unanimously adopted.

Mr. T. E. Freshwater expressed deep regret at the retirement of Mr. J. Traill Taylor, who had been for many years a most valuable President. The Association was greatly indebted to him, not only for his presiding at the annual meetings, but also for very considerable help

that he had given in other ways. He begged to nominate Mr. George Mason, of Glasgow, for the position of President. Mr. Mason was unanimously elected.

The following were elected members of the Committee:—Messrs. R. Child Bayley, F. H. Berry, Robert Beckett, R. P. Drage, T. E. Freshwater, F. W. Hindley, H. R. Hume, P. G. Hunt, T. C. Hepworth, Alexander Mackie, E. W. Parfitt, and W. J. Tabrum. As no new nominations had been received for Treasurer or Trustees, these remain as before, namely, Trustees, Captain W. de W. Abney, C.B., R.E., and Mr. W. S. Bird; Treasurer, Mr. John Spiller, F.I.C. Messrs. Thomas Bedding, H. G. Rapson, J. Guardia, and Burnett were elected Auditors.

Votes of thanks to the Treasurer, Secretary, Auditors, and the photographic press and the retiring President concluded the meeting.

The following is the balance-sheet for the year ending December 31, 1892:—

RECEIPTS.

Audited, compared with Vouchers, and found correct { THOMAS BEDDING. J. GUARDIA.

January 30, 1893.

DURHAM CITY CAMERA CLUB EXHIBITION.

AN Exhibition of members' work was held in the Shakespeare Hall, North-road, Durham, on February 14. There were five classes restricted to members, and a sixth class for lantern slides, open to amateurs and professionals alike. In both departments there was a large number of exhibits. In Class 1, for the best set of six prints of general out-door work, Mr. J. Morson, jun., secured the premier honours. The set for which he obtained the bronze medal included photographs of prize sheep and poultry. They secured general admiration. In the same class Mr. F. Cluff was awarded a certificate. Mr. Cluff's work included three landscapes—a view of *Elvet Bridge*, another of *The Count's House*, and a study in hoar frost—and three snap-shots of golf-players. Mr. R. H. Blythe, in the first class, was awarded "honourable mention." Class 2 attracted a large entry. It was devoted to general out-door work, and exhibitors presented three direct prints—half-plate and above. Miss C. Fawcett was awarded a bronze medal. The prize-winning set included views of *Lake Lowerie*, *The Matterhorn*, and *The Castle of Heidelburg*. Mr. Edgar Meynell also secured a bronze medal in this class. His set was made up of lake-district views—*Rydal Water* and *On Windermere*—and a tree study, entitled *Birches*. Councillor Ernest White entered five sets, and was awarded a certificate for a set containing a print of *High Force*, *The North Door of the Cathedral*, and *The Cathedral from the Banks*. Mr. J. N. Hunter, whose work was adjudged to be equal to that presented by Mr. White, was also given a certificate. His set included views of *The Cathedral*, *Prebend's Bridge*, and *Count's House*. Class 3 was devoted to portraiture; Mr. T. Harker carried off premier honours. A certificate was awarded to Mr. J. Hunter, and Miss C. Fawcett obtained "honourable mention." In Class 4, for enlargements, Mr. E. White secured a bronze medal, and Mr. J. Morson a certificate. The class restricted to members' lantern slides attracted a large entry, and altogether the collection of slides was a remarkably fine one. Premier honours were carried off by the Rev. R. J. Pearce. He sent views of *Millyill Force*, *Askrigg*; *The College*, *Durham*; and *Patinscale*, *Keswick*. Mr. J. Morson was also successful in this class, he securing a certificate. His work included Continental views and a picture of a fortune-teller taken on *The Racecourse at the Last Miners' Demonstration*. In this class the Rev. H. E. Fox, Mr. G. W. Bater (of Old Elvet), and Mr. J. E. Green (of Gilesgate), also sent some very creditable work. As might be expected, the open class had a large entry. There were thirty sets of six in competition. The Mayor of Durham (Councillor W. Sanderson) gave a silver and bronze medal for distribution in this class. Mr. J. H. Gear secured the silver medal with *Fishing in Preserved Waters*, *Study of Cattle*, *Helping Mother*, *Handel's Organ*, "*Come here, you rascal!*" and *Going to Sea*. The bronze medal was taken by Mr. George E. Thompson (Liverpool), and the certificate went to Mr. E. Cowan (Newcastle). A special bronze medal for flower studies was won by Mr. William Travener (of London). The Judges were Mr. Lyd Sawyer and Mr. M. Laws, photographers, of Newcastle, and Mr. Edgar G. Lees (of Cullercoates, Secretary of the Photographic Society, Newcastle). An idea of the quality of the work sent in to the Exhibition may be gathered from the following report of the Judges:—"The exhibits sent in to this Exhibition show a high order of merit, and in Class 2 the Judges gave an extra bronze medal and certificate owing to the excellence of the work shown."

RECENT PATENTS.

PATENTS COMPLETED.

MAGNESIUM LIGHT CARTRIDGE FOR PHOTOGRAPHIC PURPOSES AND PROCESS OF PRODUCING SAME.

No. 20,119. EUGEN HACKH, Stuttgart, Wurttemberg, 31, Königstrasse. *December* 10, 1892.

THIS invention relates to the mixing and producing process of magnesium light, which, on account of its exceptional steadiness, and as it burns an absolute white light, is very suitable and specially advantageous for photographic purposes.

The method of manufacture is so far essential for the invention, that an oxidation of the magnesium powder during the mixture of the constituents of the light, as also during storage, is thereby impossible. For the practical requirements of the photographic art, the invention has a farther and a very far-reaching import, in that the magnesium light is made in cartridge form, which enables the steady concentration of the light in any direction or on any object desired, whereas by the use of magnesium powder as a so-called flashlight, which has hitherto been the case, this fixed concentration is impossible.

For manufacturing the magnesium light I use a mixture of metallic magnesium powder and so-called mealing powder, as used for fireworks, &c., but which, in combination with magnesium powder for rapid magnesium light production, has not hitherto been applied to photographic purposes.

The proportion of ingredients of the mixture varies according to the constituents of the mealing powder from fifty to sixty, and magnesium powder fifty to forty. These substances are thoroughly agitated and equally mixed in a revolving drum, and the disadvantages of oxidation of the magnesium powder during the mixing are prevented by the introduction of a current of carbonic acid, nitrogen, or any other inert gas in the otherwise hermetically closed drum, and which current not only purges the oxygen out of the drum itself, but also out of the pores of each particle of powder, so that the mixture of the powder takes place in an atmosphere which excludes any possible oxidation of the magnesium powder.

The extracting from the drum of the mixture of powder thus produced takes place without its coming in contact with outside air by small quantities of the powder mixture being put in cartridge form.

Such cartridges consist of a flat disc made of cardboard or any other suitable material adapted for holding the light powder, and which, by being folded, prevents the oxidation of the contents by contact with the oxygen of the outside air; or this cartridge disc is covered with paper or other suitable easily and completely combustible.

The use of sheet metal is not recommended for these cartridge plates, not only on account of the heavy costs of same, but also because they absorb a

great amount of heat, and thus the burning of the light powder is less perfect. Cardboard or other non-conducting paper material is, on the other hand, specially suitable.

The plate can be of asbestos board, which offers still more advantages for the purpose in question. The plate has a kind of wooden supporting peg in the middle, which serves for receiving the igniting contrivance, for which electric sparks are used, since, by this, an instantaneous ignition is obtained at any moment desired without any difficulty.

In order to make these light cartridges burn more rapidly, fibres of asbestos can be mixed with the constituents of the powder, being there distributed in a very fine and equal degree during the process of mixing the powders. This addition of asbestos fibres varies, according to the effect required, between five and ten.

Fibres of asbestos are specially suitable for this purpose on account of them being unburnable, and they therefore do not absorb the oxygen of the mealing powder, which is thus of more profitable effect in the perfect combustion of the magnesium powder. Again, owing to the asbestos being a non-conductor of heat, no heat is drawn from the light powder during its combustion, and hence the latter gives a whiter and stronger light.

As mentioned in the introduction, the closed disc-like cartridge form of magnesium light offers the exceedingly practical advantage of enabling the object to be illuminated with the most diverse effects, since this light cartridge can be moved to all directions and the light concentrated on a certain part of the object, which cannot be done with magnesium light in the form of a loose powder burnt off on a plane surface as hitherto practised.

Having now particularly described and ascertained the nature of this invention, and the manner in which the same is to be performed, I declare that what I claim is:—1. A magnesium light cartridge substantially consisting of a mixture is held by a disc-like casing consisting of paper, cardboard, or other suitable material, and is closed by folding such casing or covering same with a sheet of paper easily and completely combustible, substantially as described. 2. The process of producing magnesium light consisting therein that the ingredients of such light are mixed in an hermetically closed drum, from which air is exhausted or substituted by carbonic acid gas, nitrogen, or another inert gas, so that no oxidation of magnesium can take place, substantially as described. 3. The combination with the mixture producing the magnesium light cartridge, the employment of asbestos fibres finely distributed in such powder substantially as described.

A Machine for Pasting, Mounting, and Performing the Various Processes in Finishing Photographs.

No. 525. Joseph Wilkinson, Blue Hall, Ingleton, York.—*January* 7, 1893.

The various processes in pasting, mounting, dabbing, or squeegeeing a picture to the card, drying, lubricating or soaping, and rolling or burnishing are now performed separately by hand labour.

I propose to substitute an automatic machine that will perform all the processes above named much more advantageously than what is now done.

To commence with, the pictures, after being printed and washed, I propose to put in a box, case, or other receptacle, made according to various sizes as required. At the bottom of this box I fix a spiral spring which works against a false bottom, upon which the pictures are placed, and at the top are pegs or wires, against which the pictures are pressed. The same end may be attained by elastic bands or similar means which will press the pictures upwards against the pegs. This box containing the pictures is placed in position on a stand. A number of boxes can be arranged to be fixed and worked by the same machine. I fix a brush, roller brushes, or rollers, as may be preferred for the pasting process, to a table attached to a pivot, resting upon a substantial pedestal. With the pivot is connected a rack, which is worked by a handle on the endless-screw principle, and the action of this is to regulate the position of the brush so as to adjust it to the picture. A crank connected with the other part of the machine works the table horizontally, the brush making the segment of a circle in its action; but I can so arrange it as to work vertically or obliquely. The brush is supplied with paste by passing over corrugated wood or metals horizontally or on an inclined plane. I arrange at this part an apparatus similar to the ordinary printing press, which contains the cards, and in its action brings one down upon the picture in the box, according to register. The other part of my machine consists of a number of rollers and burnishers combined, fixed in two lateral portions or sides constituting the framework, to work as will appear in the manner following:—To perform the process of dabbing and pressing the picture firmly to the card, I supply a roller or rollers covered with some kind of absorbent material, such as cotton, felt, &c., which will lay the picture flat. These rollers may be made of any weight and dimensions, according to requirements. A revolving sheet, which may be in one or more lengths, runs under the rollers. This sheet is continued past the last roller for a certain length to act the part of drying apparatus. This is done by means of heat from gas, steam, or other heating processes applied to this portion. From the drying apparatus the sheet passes on to the part of the machine which is to lubricate or soap the picture. This consists of one or more rollers, which are made of steel or other metal, and with guides to carry the picture over, and are supplied with soap from a box, which works by a spring or springs, pressing the soap in block against the roller or rollers. The soaping rollers are made to revolve at a much quicker rate than any of the other rollers, and in a contrary direction to which the picture has to travel. This is effected by means of a reverse-acting wheel or strap, and in order that every part of the picture may be thoroughly lubricated, this being a preparation for the burnishing process. Following the soap-rollers are fixed a number of burnishers. These are made in a similar manner to those now worked by hand, consisting of a steel bar and roller over the same, and are heated in the usual way by gas or spirit jets. The first burnisher after the soaping roller is a cold one, this being done to prepare the picture for the heated ones which afterwards follow. These burnishers can be multiplied to any extent to give the photograph the required polished or enamelled surface, and can be placed any distance from each other according to the size of the card, or by placing carrier rollers between, any size of picture can be thereby worked through the same machine. I arrange for these burnishing rollers to work either by strap, chain, or endless-screw movement. The burnishers are locked by a bar, which runs along the side of the frame and fits in a groove of each, and this is fastened by a screw. By loosing the screw the bar can be slided along, and all the burnishers are then free.

The machine is made in its various portions of wood, metal, and other materials which appear most suitable, and is fitted with the necessary wheels and cogs to work it by power—gas, steam, or any other motive power—or it can be divided into parts and worked by hand, either treadle, crank, or handle.

When the machine is set in motion the box is placed in position for the brush to come properly over it for pasting the picture to attach it to the card, the latter being brought down upon it by an apparatus arranged similar to the ordinary printing press, as previously stated. The picture being fixed on the card, the pegs are released by a catch, spring, or other similar automatic device, and passes on to the revolving sheet, which is between the two sides of the framework, and in passing under the first set of rollers before described the processes known as dabbing and squeegeeing the picture to the card are performed, it passes along to the drying part, and then over the lubricating or soaping rollers, and finally between the rollers and burnishers, and is then delivered into a box, finished in every respect,

If it is desired to have a picture not lubricated, I arrange to divert it after leaving the drying apparatus part to a set of rollers, worked on the same principle as the rollers of the burnishers, and it is then finished as a rolled picture only, and delivered into a box the same as the above.

It will thus be seen, from the above description, that a picture is never handled after being put into the box from the washing process until finished, which is a great advantage, causing it to come out cleaner and better finished.

My machine will enable the various processes of photographic work here described to be performed by power, and in consequence there will be a great saving of labour, fewer assistants being required, and the process will be more perfect in its action than the present methods of hand labour.

Improvements in Shutters for Photographic Cameras.

No. 4122. Edward Howard Percy Humphreys, 8, Hyde-park-gate, London.—*January* 7, 1893.

My invention has reference to shutters for photographic cameras, and it consists in forming such shutters of a tube having two openings or apertures diametrically opposite each other, or of a solid rod or bar having an opening or aperture formed through the same at right angles to the axis. The tube or rod is free to be turned on its axis, and is provided with a spring which, when set, tends to give it a partial rotation. A catch retains it in the set position. The tube or rod is so placed with respect to the lenses, that when the opening or openings above described are in line with or face the lenses, the beams or pencils of light pass through them.

The focus of the object to be photographed is taken when the opening or openings are in line with the lenses. The tube is then turned partly round until it engages with the catch, and in this turning movement the spring is set, and the openings in the tube are moved out of line with the lenses, a dark or full portion being presented to them. When it is required to make an exposure, the catch is released; the spring then causes the tube to partially rotate, and in this movement the openings come temporarily in line with the lenses, so that the photograph is taken.

Instead of a single tube or rod, I can, and preferably do, employ an inner tube or rod, and an outer tube having openings corresponding with those in the inner tube or rod, and in this case either the outer or the inner tube, or both the outer and the inner tubes, can be arranged to rotate. Or, instead of, or in addition to, a rotary motion, either of the tubes may be free to be moved longitudinally.

In some cases I fit one or both of the lenses in the opening or openings of one or other of the tubes.

My shutters can be employed as either instantaneous or time shutters. When they are used as time shutters I provide for retarding the movement of the shutter under the action of the spring, so as to produce more or less retardation, as may be required. This may be effected by more or less winding up the spring, an indicator or scale being used to show the various degrees of retardation, or the desired object can be obtained by means of a brake or similar device; or I employ two catches, one of which holds the shutter in the dark position and the other in the light position. Then, when a time exposure is required, the shutter would be moved to the catch that holds it in the light position, and would be released by the operator when the necessary time had elapsed.

Improvements in Photographic Cameras.

No. 4138. Henry Grant Madan Conybeare, The Hut, Ingatestone, Essex. *January* 7, 1893.

It is frequently desirable, more especially when photographing architectural objects, that the sensitive film should occupy a vertical position whilst the body of the camera is inclined in an upward direction. The parallelism of those lines of the picture which represent vertical portions of the object is thereby better maintained.

Also, when the film is carried upon a flexible material, which whilst in the camera is wound from roller to roller, it is necessary that the material should be tightly strained between the rollers in order that the film during exposure may present a plane surface to receive the image.

The purpose of my invention is to attain these objects more efficiently and conveniently than heretofore.

I suspend the box or slide which carries the sensitive film upon pivots so that it may be free to automatically assume and maintain by the action of gravity a vertical position whilst the body of the camera is inclined.

Also to admit of a like adjustment of the position of the film when it becomes necessary so to place the camera that the automatic regulation by the aid of gravity is unattainable, I arrange one of the pivots above mentioned, so that it can be moved a suitable distance along the body of the camera to compensate for the inclination to be given to the camera at the moment of exposure.

To ensure a suitable tension upon the material carrying the film I mount the roller from which it is drawn upon a rocking frame provided with a spring which yields whilst the material is being drawn off from the roller, and afterwards by its reaction strains the material tight. To prevent the unwinding taking place too freely I provide a bar which presses against the film roller; the bar is carried by two springs which are attached to the rocking frame.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
February 27.....	Camera Club.....	Charing Cross-road, W.C.
,, 27.....	Dundee Amateur.....	Asso. Studio, Nethergate, Dundee.
,, 27.....	Lantern Society	20, Hanover-square.

,, 4.....	Hull	71, Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 16,—Mr. E. Clifton in the chair.

Messrs. Woodbury and Jamieson were elected members.

Examples of collotype by Messrs. Morgan & Kidd were passed round for inspection.

THE AIR BRUSH.

Mr. W. H. HARRISON, of the Polytechnic, prefaced a practical demonstration of the Air Brush in working up bromide enlargements by saying that it was remarkable for its mechanical properties and artistic results. The apparatus is worked by air being pumped by means of a treadle into a container; the air is then led up a pipe to the hand piece containing two tubes. By depressing a thumb piece a valve is opened and the air rushes through the two tubes which divides the current of air into two portions; one blows a small wheel round, and this sends the needle point backwards and forwards and passes through the liquid. The other current of air passes downwards to the needle point carrying a minute portion of liquid which is then carried to whatever direction it is pointed at. The closer the machine is held to the paper the finer the line that is drawn, while the further away it is the cone spreads and a larger result is obtained. But, inasmuch as the quantity of colour that is needed to make a fine line would take an enormous time to cover a large surface, some means is needed to increase the flow of colour, which is obtained by pulling the thumb piece back, which sends more of the needle into the current of air, thus taking more liquid and increasing the flow of the ink. Lamp-black dissolved in water is used for the colour. As a means of putting in backgrounds and working up drapery, a knowledge of how to use the air brush is soon obtained. For putting in high lights Chinese white looks too blue, and would not do for the purpose on that account. A short needle would not throw off such a large cloud of colour as a fine one.

Mr. L. S. TEAPE suggested that a tint might be removed by means of clean water in the handpiece and the application of blotting-paper to the surface.

The CHAIRMAN, in reply to Mr. Harrison's question why the brush was not more used, indicated the price, 9*l.* 9*s.*, as being high, and said that if a body of men were trained up to its use photographers, seeing the advantage in the saving of time, might be disposed to employ them.

Mr. P. EVERITT thought the brush would be useful for making vignettes in negatives.

Mr. HARRISON said that in his class at the Polytechnic a photographer after only three lessons had found the results he obtained with the air brush much appreciated by his customers.

Mr. JAMIESON suggested that the electrification of the needle point might answer, as the quantity of colour would not be increased in volume but only the facility with which it was thrown from the point and in a finer line. That principle was employed by Thompson in his galvanometers. An electric turning device would also relieve the foot.

During the evening Mr. Harrison practically demonstrated the air brush by working up a bromide enlargement with it, the finished result placed alongside of an unworked picture eliciting great praise from the meeting. He also showed colour work and a large head worked up in four hours from a faint pencil outline.

At the conclusion of the demonstration Mr. Harrison received a vote of thanks, in acknowledging which he took occasion to say, humorously, that he hoped to see many of the members present among his class at the Polytechnic.

North London Photographic Society.—February 7, the Rev. E. Healy in the chair.—Mr. J. F. Nisbett was elected a member. Messrs. W. T. Coventon and J. Oakley were elected delegates to represent the Society on the affiliation committee for the current year. Mr. Parfitt wished not to be re-elected, as he considered the delegates should be chosen from those who were not members of the Photographic Society of Great Britain. Mr. A. E. Smith showed a collection of photographs of views taken in Kew Gardens, and Mr. Parfitt some very pleasing portraits taken, in order to obtain softness of outline, with the front combination only of a cabinet portrait lens. They were taken out of doors, and Mr. Parfitt said he used no background to screen objects behind the sitters, as, owing to the depth of definition of the lens being so slight, such objects were not rendered on the plate. In the course of a discussion about amidol, a letter from Messrs. Fuerst was read, in which they stated that, so far as they knew, amidol is not poisonous, and the reason they said in the instructions issued that the amidol substance is not to be touched with the fingers is that, if this is done, it will stain them very badly. They further stated that amidol in solution will not stain the fingers. Several members thought this last statement required modification. Mr. Healy had used the developer for lantern slides, and had obtained a nice warm tone, but at present had failed to get sufficient density. It was resolved that in future the meetings of the Society should commence at eight o'clock sharp. The next meeting, on the 21st inst., is a Lantern Night, when the convention slides of the Devon and Cornwall Society will be shown.

Hackney Photographic Society.—February 7, Mr. R. Beckett in the chair.—Mr. L. E. Morgan gave a demonstration on amidol. The Hon. Secretary asked whether the cartridges were any special preparation, but was informed they only contained sulphite of soda and amidol; any alkali could be used, and, in answer to a question, the lecturer said carbonate of ammonium could successfully be used with it for lantern slides. Mr. Sodeau liked citrate of soda for over-exposed plates. Amidol could be used dry like pyro, owing to its easy solubility. A number of plates could be developed in the one solution. The HON. SECRETARY said he had recently developed twelve bromide papers and one lantern plate, and the solution seemed to be good enough for more. He preferred the formula given by Mr. Dresser. Mr. RODER asked whether amidol would develop Morgan & Kidd's papers. Mr. MORGAN said he had not tried himself, but felt satisfied they would. Two plates of street scenes having received one-twentieth of a second at *f*-8, and taken this month, were then developed and bromide papers exposed. The HON. SECRETARY, in proposing a vote of thanks, said he used amidol some long time since, but had a difficulty of getting density; he had, however, again tried, and was very favourably inclined to it. Mr. MORGAN said he used pyro before, but now gave it up in favour of amidol. The attendance was very large, and being a ladies' night, the fair sex were well represented.

FEBRUARY 14, Mr. R. Beckett presiding.—Some discussion ensued on a print developer with amidol, two and a half minutes, by the Chairman. Mr. Barker asked, Was there any tendency to destroy the transparency in the shadows? The CHAIRMAN said, Not so much as iron, which was too energetic when fresh. Mr. NUNN asked, Was there any advantage in stopping down when making lantern slides? Mr. S. J. BECKETT said no advantage would be gained, if lens was good, in stopping down beyond what would cover the lantern plate. Mr. SODEAU knew of a lens which was defective in centre. From the question box: "Can an ordinary magic lantern lens be used for enlarging purposes?" The answer given was that it could for three and a quarter inches square or parts of a quarter-plate. The front tube would have to be drawn right out or an addition made. The projecting lens should be good or slightly stopped down. Mr. W. H. SODEAU then read a paper on *Photographic Chemicals*. The principal subject he dealt with was their keeping qualities. He attributed the power of keeping according to the atmosphere. A list of deliquescent chemicals was given. He advocated the use use of glass stoppers which if stuck at any time could be tapped or put in warm water. The Hon. Secretary had seen vaseline recommended. Mr. GOSLING said he generally found warming in the hand sufficient. Mr. Sodeau proceeded to say, caustic corrodes the glass and sometimes joins the stopper to the neck. Indiarubber corks were useful, but should not be used for benzine or like compounds. Developing agents were best kept in an acid condition or filled up to the stopper of the bottle, or ordinary wash bottles can be used if paraffin is kept on the surface of the liquid. He recommended the use of vaseline inside the neck of the bottle for substances which creep up the side. Magnesium should be kept in well-corked bottles, metabisulphite potassium would keep fairly well in paper, if in large lumps, though not advisable. The strength of anhydrous soda was about twice the strength of the ordinary carbonate of soda. Sulphurous acid would only turn to sulphuric by oxygen.

West London Photographic Society.—February 14.—Mr. A. Horsley Hinton read a paper entitled, *Specialisation in Art Work* (see next week's No.). In the discussion which followed, Mr. Tripplin, whilst paying full deference to the views of Mr. Hinton, pointed out that photography was elevating in itself

and that too high a standard of refinement in photographic work should not be universally insisted upon. The majority of members were business men with limited time, and could derive great pleasure from their photographic work if they secured a picture of a view that pleased them, even though it might not possess all the qualities of a work of art. He admitted, however, that by working to a high standard degeneration was prevented. Mr. WHITING insisted on the importance of education in picture-making, and suggested that great good would result from the forming of a class of instruction in art—the rules of art and composition should be well instilled. Mr. HINTON, replying to the previous speakers, pointed out the difficulty of ascertaining what it is in a picture which pleases, and of securing it. He stated that the photographer's aim should be to catch the sentiment of the subject as far as possible. He would not be bound by rules of composition, which were scientific, and thus opposed to the artistic. He suggested that good would be derived from competitions in the illustration by photography of a given subject. Mr. SELBY disagreed with Mr. Hinton on the importance of rules of art, stating that it was necessary, particularly at first, to have a grammar to work upon. Mr. Winter agreed with the objections of Mr. Hinton to rules of art, and deprecated the copying of the methods of the painter. He would take what was pleasing to the eye, and he strongly urged the advisability of cultivating the technical side of photography as an aid to the pictorial side. Mr. Winter concluded with a candid criticism on some of the photographs exhibited by Mr. Hinton, and the discussion closed with a vote of thanks to the lecturer.

Greenwich Photographic Society.—February 1, Mr. H. H. Turner, M.A., F.R.A.S., in the chair.—Mr. W. E. Debenham gave an exhaustive demonstration of transparency-making by the carbon process. At the conclusion of the practical portion a few lantern slides produced by this process were projected, and it is worthy of note that there was an entire absence of any evidence of relief in the slides thus submitted. Mr. Debenham was thanked for his interesting lecture. The following were elected members of the Society:—Professor Lambert, M.A., Messrs. Parrett, Duckham, Parsons, and Holliss. The Committee announced that in view of the Society's youth they had decided to postpone date of closing entries for Lantern Slide Competition, (originally January 31), till April 30, and to admit slides made from negatives taken at any time provided no awards had been previously gained. On the proposition of Mr. Haddon it was unanimously resolved that the Greenwich Photographic Society affiliate to the Photographic Society of Great Britain.

Woolwich Photographic Society.—February 9, Mr. W. H. Dawson in the chair.—Correspondence between the Hon. Secretary and Mr. R. Child Bayley respecting affiliation with the Photographic Society of Great Britain was read to the members. The proposal was warmly received, and it was unanimously resolved that the Hon. Secretary take steps to apply for affiliation. Mr. L. E. Morgan then proceeded with a demonstration on "Amidol," the leading features of which have been reported in this JOURNAL. It should be said that the meeting was highly pleased with the results obtained.

Croydon Camera Club.—February 13, Annual Meeting.—The report and balance-sheet being presented and adopted, the officers and Council for the current year were chosen as follows:—*President:* Mr. Hector Maclean, F.G.S.—*Vice-President:* The Mayor of Croydon (Mr. F. Fass, J.P.), the Hon. Sydney Herbert, M.P., Messrs. F. T. Eldridge, J.P., and B. Gay Wilkinson.—*Council:* Messrs. Frost, Hirst, Holland, Isaac, Neeves, Oakley, Packham, and Wratten.—*Treasurer:* Mr. A. G. Sargeant.—*Hon. Secretary:* Mr. G. R. White, 55, Albert-road.—*Hon. Assistant Secretary:* Mr. S. E. Burrows. The meeting was well attended by the members, and a large collection of prints, lent by Mr. E. J. Wall, was displayed upon the walls. On the proposition of the President, and supported by several influential members, it was, *nem. con.*, decided that the Club be forthwith affiliated to the Photographic Society of Great Britain. It was also resolved that, after the present month, the ordinary meetings be held upon Wednesday in each week instead of as now, Monday. The annual dinner of members and friends is fixed for March 8, at the Greyhound Hotel. Tickets, price 4*s.* each, to be obtained of the Secretary. The particulars and regulations of the local Exhibition, which will be open for four days and evenings, on April 5, were read and approved, and ordered to be printed and circulated. The Exhibition will be held in the Braithwaite Hall, and will be inaugurated by the Mayor.

Aston Natural History Society (Photographic Section).—February 9.—Mr. Walter Tyler gave a paper entitled *How to Develop on Tour.* The lecturer practically demonstrated how exposures could be tested by a few plates being developed while on the trip. With such simple means as a few pieces of Willesden paper folded for dishes, an ordinary window-blind lath on a knife edge for an extempore balance, and some ruby fabric round a candlestick on a penny for his lamp, he showed how practical, if not orthodox, development could be performed while away from home. A piece of card, $4\frac{1}{4} \times 3\frac{1}{4}$, cut in the middle, and hinged by stamp paper, on which was laid the sensitive paper and then the negative) served as his printing frame, the whole being secured by two elastic bands. Table, dessert, and teaspoons acted respectively as his one ounce, half-ounce, and drachm measure, while threepenny pieces were used to weigh his one ounce of hypo, and a sixpenny piece five grains of pyro.

Birmingham Photographic Soc ety.—A large and appreciative audience assembled in the large lecture-room of the Y.M.C.A., Needless-alley, on the evening of Tuesday, the 7th inst., when a paper was read by Mr. C. J. Fowler on *The River Severn, from its Source to the Sea.* The lecture was illustrated by a series of 300 excellent slides, the outcome of a survey of the river undertaken in 1891 by Messrs. Middleton & Fowler, when upwards of 400 pictures were secured. The course of the river from the point where it rises in a swampy hollow on Plinlimmon to its reception by the Bristol Channel is replete with interest, and some of the more famous places, such as the cathedrals of Worcester and Gloucester, Berkeley Castle, Buildwas Abbey, Much Wenlock Priory, Tewkesbury, Bridgenorth, &c., of which very fine pictures were shown, elicited hearty applause. In addition to this, the completeness of the subject added very much to its interest.

Bristol and West of England Photographic Association.—February 10.—It was decided the hold the meetings fortnightly instead of monthly, and that a question box should be started.

Burnley Photographic Society.—The Annual Meeting of this Society was held on the 1st inst., when the balance-sheet, which was fairly satisfactory, was adopted. Mr. Jno. Butterworth, J.P., was re-elected President, and Mr. J. Altham Secretary, and Mr. A. H. Kellet Treasurer, in place of Messrs. Sutcliffe and Lee resigned. The following were elected to the Council:—The Rev. T. Layland, and Messrs. T. Ormerod, V. Dunkerley, J. Holgate, J. L. Lee, J. J. H. Bell, A. Howarth, and W. H. Hoghton.

Derby Photographic Society.—February 14, Mr. Keene presided.—The Hon. Secretary brought forward a circular which had been received from the Photographic Society of Great Britain, in connexion with the affiliation scheme, and after a short discussion it was decided to join with the Photographic Society of Great Britain. Mr. Porritt (President of the Leicester Society) gave a paper on *Isochromatic Photography.* Mr. Porritt had to illustrate his paper a set of negatives of stained-glass windows, also a hand-painted set of designs for same, to show what an amount of gradation could be obtained by means of isochromatic plates with the use of a yellow screen. He also had a large number of lantern slides, one set being from negatives taken on ordinary plates, and the others of same subjects taken on isochromatic plates. Mr. Porritt passed round a few yellow screens of different tints, and explained which, in his opinion, was the better way to make them.

Leicester Photographic Society.—February 10, Mr. J. Porritt in the chair.—It was decided to hold the meetings on Thursdays instead of Wednesdays after the summer recess. The President then read a paper by Mr. A. B. Webber, of Bromley, on *Isochromatic Photography*, who sent a large number of paintings, transparencies, and fifty lantern slides to illustrate his subject, and proved a most useful stimulant to the members who work in that direction. The results of isochromatised plates were still more definitely shown by the useful method of showing two prints or lantern slides of the same subject with iso and plain plates, and which were exceedingly useful in showing the value of the prepared plates. The church windows shown by Mr. Webber were admirable examples of the process, as also several differently coloured chrysanthemums in variously coloured vases, also several other tests of colouring, as wools, cloth, &c., which amply illustrated the utility of the process in colour photography, and in maintaining the value of the visual colour scale.

Liverpool Amateur Photographic Association.—February 9.—Dr. Charles A. Kohn, of the University College, delivered to the members a lecture on *Chemistry of Photography.* He illustrated his remarks with interesting experiments in a very clear and lucid manner, demonstrating the mystery of the action of light and formation of the latent image on the photographic plate. Other similar practical lectures follow every Thursday until the end of April.

Sheffield Photographic Society.—February 7, Mr. B. J. Taylor in the chair.—Mr. J. W. Charlesworth opened the discussion, "Was amidol a good developer for lantern transparencies?" which was taken part in by most of the members present, and eventually decided that, given a good negative, warm tones could be produced.

South Manchester Photographic Society.—Mr. R. B. Barningham in the chair.—Mr. C. Lord described a ramble through Switzerland with a camera. The tour was taken in the summer of 1891, the party consisting of two parsons, a merchant, a doctor, and a lawyer. This was the fifth time, said Mr. Lord, that he had visited Switzerland, but the first time with a camera. The party went to Antwerp by way of Harwich, and train was taken for Schaffhausen and the falls of the Rhine. The first impression of the falls was disappointing. The height of them is only about sixty feet, but the breadth is nearly 400, and they have the appearance of supendous rapids rather than a cataract. It is only by drawing close to the falls that their vast magnitude can be realised, and the immense volume and force of the water estimated. One of the great attractions of Switzerland is Cloudland. Clouds are always brighter and more varied in mountainous than in flat regions. It is beautiful to watch clouds from below sailing quietly along or scudding before the wind, and mark the transfiguration wrought by the glow of the setting sun. But to his mind it was more wonderful to look down upon the clouds from some peak high above the cloud line.

Amateur Photographic Society of Madras.—January 12, Annual Meeting.—After the transaction of other business, a grant of 2*l.* 2*s.* was made to the Photographers' Benevolent Association of London. The Honorary Secretary again drew the attention of members to the proposed collection of lantern slides illustrating the Madras Presidency for the Society of Great Britain, and said he had received not a single offer from any member to co-operate with him in the collection! The following were elected as the committee for the ensuing year:—*President:* Mr. C. Michie Smith, B. Sc.—*Vice-Presidents:* Messrs. C. Slater and E. W. Stoney, M.I.C.E.—*Committee:* Messrs. Surgeon Lieut.-Col. S. L. Dobie, Mr. W. M. Gerrard, Mr. A. E. Lawson, Mr. V. G. Lynn, Mr. A. L. H. Palmer, Surgeon Major J. L. VanGeyzel.—*Hon. Secretary and Treasurer:* Mr. F. Dunsterville. The President, having delivered an address, asked the members to pass a very hearty vote of thanks to Mr. Dunsterville, the Honorary Secretary, to whose labours they were chiefly indebted for the revived interest in the Society. The proposition was put to the meeting and carried unanimously.

Singapore Amateur Photographic Society.—The election of officers at the annual general meeting resulted as follows:—*President:* Mr. H. M. Simons.—*Committee:* Messrs. H. M. Simons, E. J. Robertson, T. F. S. Quin, Hon. A. L. Donaldson and W. Gutcher.—*Hon. Treasurer:* Mr. T. F. S. Quin.—*Hon. Secretary:* Mr. E. J. Robertson.

FORTHCOMING EXHIBITIONS.

March 1, 2 ..... *Fillebrook Athenæum Photographic Society. Hon. Secretary, Joseph W. Spurgeon, 1 Drayton Villas Leytonstone, Essex.

March 3, 4	.....	*Blackheath Camera Club. Hon. Secretary, C. W. Piper, 46, Shooter's Hill-road, Blackheath, S.E.
,, 22, 23	.....	Leicester and Leicestershire Photographic Society, Co-operative Hall, High-street, Leicester. Hon. Secretary, H. M. Porritt, 66, London-road, Leicester.
April 5–8	.....	*Croydon Camera Club, Braithwaite Hall, Wellesley-road, Croydon. Hon. Secretary, G. R. White, 55, Albert-road, Croydon.
,, 17–29	.....	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.
May 4–6	.....	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.

* Signifies that there are open classes.

Correspondence.

THE CONVENTION SLIDES, 1893.

To the EDITOR.

SIR,—The Devon and Cornwall Camera Club have prepared a set of 118 slides, illustrative of the neighbourhood of Plymouth. This set, which has been entitled *Places to be Visited by the* 1893 *Convention*, is now in circulation, and I should be pleased to have applications from the secretaries of any societies who desire to show them at their meetings.

Immediate application would be desirable, to enable me to arrange the route to be followed by the slides.

I may say that March 7 is the first date on which the slides are now available; any London society making application might probably have them on that date.

I venture to ask your insertion of this note, as I feel sure that you are interested in anything that may help forward the next meeting of the Convention.—I am, yours, &c., R. HANSFORD WORTH,

Hon. Secretary Devon and Cornwall Camera Club,
Hon. Local Secretary Photographic Convention of the United Kingdom.

12, *George-street, Plymouth, February* 18, 1893.

HOW TO USE A BUNSEN.

To the EDITOR.

SIR,—You will see by the enclosed that I invented and patented a self-adjusting Bunsen burner, and which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY over fifteen years ago. You will perceive that the one end of lever reduces the inflow of the gas, while the other end reduces the quantity of air by lowering the sliding tube over the air holes. Can you, or any one of your readers, say who was the first person who used regulators (or governors) in connexion with the oxygen and hydrogen gases?—I am, yours, &c., WILLIAM BIRRELL.

109, *Graham-street, Airdrie, February* 13, 1893.

RAPID SOLUTION MAKING.

To the EDITOR.

SIR,—We consider those photographers to whom instruction in the elementary operations of their business is necessary and useful should feel sincerely indebted to Messrs. Baird, Ayres, & Webster (*père et fils*) for directing attention to the simple but efficient means by which they prepare their solutions.

We trust we may, however, be pardoned for feeling somewhat amused at the claim to novelty implied, if not distinctly made, in the announcements, when we state that we have had the Doulton perforated dipping basket in use for many years in our laboratories, and find it to be all that those gentlemen describe it to be *in our own hands*.

They, however, omit reference to the "dreadful facility" with which the semicircular handle is broken off by careless and thoughtless assistants, thus making the method, in the long run, an expensive one, and obliging us to adopt a simpler and even more efficient course. The method for the daily preparation of our hypo-bath solution will illustrate all the others.

A jar of suitable capacity, specially reserved for the purpose, is loosely covered with strong unglazed calico, which is firmly tied round the turned-over rim. The hypo soda, being weighed or measured, is poured into the calico bag thus formed, and droops down to a convenient depth inside the jar. Water is then added until it attains such a height as to be in contact with the crystals. The whole is then set aside until the afternoon. When the hour for fixing the first batch of prints arrives, the calico (now void of crystals) is removed, and the jar is found to contain a *filtered* solution of hypo ready for use.

We have not failed to notice that Mr. Baird's "Lothian" jar dispenses with the easily broken handle, but we dispense with the jar also, and with the additional advantage of producing a *filtered* solution, and if this description prove useful to your readers, we shall be glad.—We are, yours, &c., J. MARTIN & Co.

General Photographic Works, New Southgate, N., February 20, 1893.

VALUE OF GOODWILL IN PHOTOGRAPHIC BUSINESS.

To the EDITOR.

SIR,—Your article in No. 1710 was really good, and should be appreciated by those recruits in photography who feel themselves capable of taking to mastership. The tendency of your article is more in favour of the second valuation than the first. Being one of those operators who would like to do something in one way or another, but having counted the sands on the seashore for several months and having nothing else to do, with the exception of applying for a situation or looking into other people's businesses, with a view to taking one over, I will spare a few minutes to give you a peep behind the scenes.

About situations; there are plenty open. If you like to pay out of your own pocket, you may even gain a few shillings, just enough to keep a bachelor from starving; but, as for a responsible post that would suit an educated married man, I almost fancy they are out of fashion.

The other line—I hope you won't get cross—is even more illustrative, and I fancy is not coming up to your 1710 form. For how many ideals and instructive suggestions did you and your predecessors go in, in all those numbers, from 1 to 1710, and how many of them have gone to the wind? As I have looked at nearly fifty businesses for sale, I will give you a small jotting on the point. What do you say to this—that I did not come across one business where proper books were kept, and that is the bare fact. Further, about half a dozen had only something like a studio as it should be. Dark rooms, well, I saw six, not more; the rest pleased themselves with cupboards, boxes, and drapery. The places for the printing are dwelling-places for sun, moon, and rain, but in general the higher the rent the smaller the printing place. I cannot help mentioning one business—about five years ago you could not buy it for several thousand pounds, last year you could have it for one year's rent (nearly 400*l.*) including everything belonging to the business. That London place had no accommodation for printing whatever, not even a printing frame, but it had—and mark that—proper heating accommodation, the only business where I saw it.—Another half a dozen had chimneys; the rest nothing whatever.

About the accessories I won't say much, only that in general photographers seem to have the knowledge of one or two. I always found a chair and something like a balustrade all through. Toilet room, as well as a decent w.c., is generally not found necessary. The only thing that I could not grumble about is the shop or reception room; that seems to be the place which is cleaned once every week. The studios are generally nothing more nor less than greenhouses, the known type, a lot of wood, filled out between with glass, light from all sides. One construction I must mention; I found it five or six times and believe you never advised it. The end of the studio is covered all round for about one yard, next also all round about one yard of glass, and the adjoining part is again covered in dark.

Some of the pictures taken in those studios have full faces, dark fronts of the noses, and both ears in the light. Artistic productions!

Some of these lords wanted just to sell these things, just as they stand; they had no time to attend to them, having another business, and, naturally you believe it, it was the workman's fault that business did not go as well as formerly.

One thing I wish, and that is to be able to use my pen like "Cosmos." I could then occupy my time in writing a book on valuation of photographic premises, or Robinson Crusoe in London and fifty miles round. You will say that is black paint, you who are used to writing on photographic ideals. A year ago I could not understand how some photographers could produce a dozen 15 × 12 cabinets for 12*s.*, and why this trade is in disrepute with the public. No wonder!

This is only lifting the veil a bit, and I hope that you and your friends will investigate the subject before sending a flashlight on the audacious

February 13, 1893. OPERATOR.

To the EDITOR.

SIR,—Upon reading "Operator's" letter *re* the above, I was a bit surprised; but your leader of the 11th is a startler! Yet Jupiter nodded, and I suppose we (that is, those that still think photographic goodwills a marketable commodity) may differ from you. I am one that thinks so, especially now that the building laws are so strict: you cannot alter houses and run up studios just as you please, as in the old times, therefore a studio, in a good position, with a fair return, is worth its price, and any business is worth the last year's returns (*not profits bulk*), large or small.

The things for consideration by one wishing to enter into the business are, as to whether the premises are in a good neighbourhood, of good

approach and repute—and its not only a matter of what has been done, but if, by better work, management, push, &c., he could increase the returns—then to consider if it would pay better to have all the trouble of alteration and incidental expenses, and waiting for business by opening new premises. If I have 300*l.* capital, and buy Mr. Camera's business for, say, 250*l.*, I begin to get returns same day; and should I spend the other 50*l.* in redecorating, new specimens, and advertising, I should increase the returns immediately; whereas a new studio may be altogether a failure. Therefore I am still of opinion that photographic goodwills are worth a price, and, like the devil, the business is not so black as painted.—I am, yours, &c., STARTLED.

February 18, 1893.

To the EDITOR.

SIR,—As one who has had some experience as a professional photographer at the seaside, I certainly think—and am sure I am not alone in thinking—that three years' purchase is too much to give for the goodwill of a photographic business, especially when, as you said in your leading article for February 10, so much depends upon the energy of the person who is working the business.

Your correspondent, "Operator," in your issue for February 3, in giving what you consider a not over-liberal estimate of wages, is, I assure you, not very far wide of the mark—at least, so far as my experience goes. There are plenty of operators, and capable men, too, who will work gladly, and work hard, during the summer months at a seaside town for 30*s.* a week, and will take considerably less than this during the winter.

There are plenty of girls, too, who will willingly officiate in the reception-room, burnish, help in the printing and mounting, and a hundred and one other little odds-and-ends, all for fifteen shillings a week. With regard to the employment of boys for printing operations, I consider that five shillings a week is quite sufficient, as they are, as a rule, too young to be self-supporting, and by this means manage to learn the mysteries of the business, and very often finally blossom into photographers on their own account.

There are not many photographic businesses in this country which make a clear profit of £220 in the course of a year. I have the strongest possible reasons for believing that if a census were taken of the returns of all the professional photographers in England, the average profits would be very much less than this.—I am, yours, &c., PRIMUS.

February 14, 1893.

To the EDITOR.

SIR,—Write me down an ass! Although it hath not been set down write it now. Here have I been working and worritting at this photography for thirty odd years, pluming myself upon belonging to an honourable and lucrative profession. About twenty years since I started to make a business and home for myself, deluded myself that with the bit I saved and the bit I might get for my goodwill when I wished to retire would enable me to take mine ease. And now I am told, on your authority, that it is not worth a rap, and that I had better have been a grocer. Well, certainly the grocer at the street corner cuts a bigger dash than I.

As there is no goodwill in photographic businesses, and negatives are not worth storage, I am going to give mine to the public. In future I shall give all my sitters their negatives. As soon as the lease is up, I shall retire and take a public-house or grocery.

Photography spells Poverty.—I am, yours, &c., OLD UN.

EFFECTS OF HEAT ON AMIDOL-DEVELOPED NEGATIVES.

To the EDITOR.

SIR,—A few days ago I had what was to me a new experience, and, as I do not recollect of seeing it mentioned before, I wonder if it is well known. I had developed two plates with amidol, and, as they appeared to be over-exposed, I stopped the development perhaps too soon; but that, I presume, has nothing to do with what I wish to mention. After the plates were fixed and washed, they were set up on end to dry, and had become quite dry for some breadth all round the edges when I wished to put them away in a safe place, and finished the drying by heating them gently at a fire; but, when the drying was finished, I was surprised to find that in both plates the portions dried at the fire were very sensibly darker than the edges which had dried spontaneously.

I enclose prints, which show the heat-dried parts distinctly by the lighter colour of the ground. Can it be that this is peculiar to amidol? I have before used a little heat to finish the drying of a plate, but never observed any darkening from that cause.—I am, yours, &c.,

February 11, 1893. GEORGE H. SLIGHT.

WASHING CUT FILMS.

To the EDITOR.

SIR,—May I suggest, in reply to your correspondent A. Levy's query *re* washing cut films, that, if he lays them whilst wet on spoilt negative glasses, they will adhere firmly by suction, and can then be stood up in the washing rack and treated just as though they were ordinary glass negatives.

Although there is probably nothing at all original about this method of washing films, I cannot remember to have ever seen it in print.—I am, yours, &c., J. E. HODD.

4, *Goldsmith's-gardens, Acton, February* 11, 1893.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

To the EDITOR.

SIR,—As I presume you will have some mention of the meeting of above at Manchester, on Thursday last, I cannot refrain from a word or two, urging the attention of my brother professionals and this Society, and I venture to hope that you will kindly add your own opinion as to the importance of the Society to our trade, *as a trade* generally.

My excuse, if one be needed, for this letter, is that I am probably one of the latest members, and I feel sure that photographers, as a body, are neglecting their own interests by holding aloof. For many sound and solid reasons it is high time we united, for argue and talk as we may, it is a solid fact that the bulk of photographers are not making fortunes; the big men are, of course, all right, but the owner of the small provincial business, no matter how good and clever a man he may be, is not by a long way so well to do as those in a similar position of twenty or twenty-five years ago, and one of the reasons is to be found in *the amateur*. I don't say this with the slightest ill feeling, but the truth remains, all the same, that many of the dealers and stock houses cater distinctly for amateur customers to the decided detriment of the working photographer. I send you herewith circular just received, and better proof I could not give. Now, one of the dealers here is a top shop and fancy goods dépôt, two others are chemists, and it is obviously an attempt to get these people to cater for amateurs. It is time all this were put a stop to, and it can only be done by the combination of all *business photographers*. It is impossible in space of a letter to go into all the reasons for a genuine trade society, all I would urge is, that every photographer in the kingdom should look into this for himself; almost every trade or profession of any merit or standing has its society, and the want of such an one in our trade has been the cause of endless abuse and loss to the *workers*.—I am, yours, &c., "UNITAS."

February 14, 1893.

INTENSIFICATION.

To the EDITOR.

SIR,—Not understanding chemistry, I generally pass over articles containing chemical symbols, but as most operators are interested in mercurial intensification, I thought I would make this an exception and try to get some meaning out of Mr. Chapman Jones's paper in last week's BRITISH JOURNAL OF PHOTOGRAPHY, entitled, "A Chemical Study of Mercurial Intensification." Not being a chemist, I cannot be said to be an experimentalist, but have worked on the principle of sticking to one plate, one developer, one intensifier, and one reducer, and carefully watch the results and thoroughly understand their power by observation.

Now there is one remark I note in Mr. Jones's paper, under the head of "Practical Conclusions," where he says, "It is impossible, *without falsifying the gradation*, to develop too dense, and afterwards reduce to the desired condition."

I will now give my method of intensifying and how I use it for reducing an over-developed negative *without*, I think, *falsifying* the *gradations*.

INTENSIFIER.

Sat. sol. bichloride of mercury	2 ounces,
Iodide of potassium, about	2 drachms,

added to the mercury until the scarlet colour is almost vanished, then add 8 or 16 ounces of water.

To intensify, I flow the plate with the above until the correct density is obtained; afterwards fix *without washing* in hypo, not too strong, and wash well, of course, afterwards. Now to reduce a negative, no matter how dense it may be, I flow with intensifier until the iodide of mercury has uniformly changed the plate or, rather, film. I then, *without washing*, take the plate from intensifier and dip in an upright bath of recrystallised cyanide of potassium—you will then note a negative that would perhaps take a week, in good light, to print—rapidly and uniformly reduce with the most delicate gradation of light and shade. I only intensify on rare occasions, and the same thing applies to reduction, because I like to regulate my developing in such a way that the correct rendering of the lighting is obtained; but I think a sure intensifier and certain reducer is a most pleasing power in the operator's hands. I also find the above reducer very useful in removing silver stains from gelatine negatives.—I am, yours, &c., ALFRED E. DIGHTON.

22, *Mount Ash-road, Sydenham Hill, London, February* 5, 1893.

BLISTERS.

To the EDITOR.

SIR,—Your correspondent, Mr. A. Levy, seems troubled with the use of the new methylated spirit as a prophylactic in the case of blisters.

Before I gave up the use of albumenised paper I was now and again troubled with them, until the cure—so far as the brand of paper I was then using was concerned—came to me by chance. Whilst toning I found I had no hypo prepared. I hastily got some ready by suspending a muslin bagful in some very hot water, and by the time I required to put my prints in it was still quite warm. No blisters rose. I tried repeatedly afterwards, warming my hypo, and never had another blister. I should be glad if this method may bring Mr. Levy and others relief.—I am, yours, &c., J. CARTER BROWNE, D.D.

Thurning Rectory, Oundle, Feb. 6, 1893.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

PHOTOGRAPH REGISTERED:

S. V. White, Reading.—*Photograph of William Isaac Palmer, taken on March* 14, 1885, *but not published until January* 28, 1893.

PUZZLED.—Such an article will appear shortly.

LANTERNIST.—There is practically no loss of light when using the long instead of the short-focus lens.

W. H.—Either A or B will answer your purpose. Not having seen C or D, we cannot speak of them from personal knowledge.

IGNORAMUS.—Try the effect of warming the solution. Are you sure you are employing the solution at a uniform temperature?

WILLIAM WEBB.—We believe the article is the subject of a patent, but we must decline to express an opinion as to its validity.

W. D.—Apply to Messrs. Eyre & Spottiswoode, New Street-square, who are the proprietors of the Woodbury Company's business.

M. POWELL.—We cannot supply the details of the processes you allude to, not having cognisance of them. Had you not better employ a patent agent?

J. HIGHFIELD.—1. *The Studio and What to Do in It*, by H. P. Robinson (Piper & Carter), will probably give you the desired information. 2. Yes.

W. FREEMAN.—As both lenses are negative, no matter how they are placed in relation to each other, their sum will be negative, and they will not form an image.

ENGRAVER.—In the JOURNAL for April 8, 1892, you will find two articles describing how subjects may be photographed on wood for engraving purposes.

T. J.—There are several firms of photographic dealers at Cape Town. The prices of photographic goods are somewhat higher we believe, freight, &c., having to be taken into account.

R. A. SYMES.—The stains are caused by the negatives not being sufficiently washed between the different operations. Unless this is perfectly carried out, staining is very prone to arise with mercurial intensification.

RODNEL.—You have so good an idea of the apparatus that we should think you would be able to construct it for yourself. The arrangement works perfectly, any lantern-maker would be able to construct it from your description.

A. MUIRHEAD.—You would be infringing the patentee's rights by making the camera for your own use or to dispose of; and even though you were not, we cannot reconcile it with proper conduct to copy other people's manufactures.

B. C. CURTICE.—You can cure the distortion in the photograph when copying it by either tilting the photograph or swinging the back of the camera. See that the vertical lines of the temple are parallel with the frame of the ground glass or focussing screen.

NERO.—To engage in photography on the sands at the seaside we believe it is necessary to procure a permit from the town authorities, most of whom now (happily for the visitors) regulate the number of photographers by licence. Apply to the Town Clerk.

COLONEL GUBBINS, M. D., and other correspondents.—Mr. Frank Haes informs us that the flexible steel tubing to which he referred in his recent letter may be obtained from the United Flexible Metallic Tubing Company, 96, High Holborn, W.C. We do not know its price.

W. LLOYD.—The picture is not distorted, but the perspective is very violent. This is caused by the interior being taken with a very short-focus or what is known as a wide-angle lens. When such wide angles are included the pictures always have an unpleasant appearance.

J. BROWN.—Spots, such as those on the print sent, may proceed from several causes, such as want of care in the manipulations, impurities in the cement with which it is mounted, deleterious matters in the mount, &c. By merely looking at a print, it is obviously impossible to say from what source such spots proceed.

EXPERIMENTALIST.—We could give you a formula for photo-transfer ink, but it would be very troublesome to make in small quantity, and probably in inexperienced hands would not turn out satisfactory. Better buy it; you will then get a reliable article. It may be had from any dealer in lithographic materials.

J. HAWKES SMITH (Bowbridge, near Stroud, Gloucestershire.)—Messrs. Kilner Bros., King's Cross, supply such bottles.

E. WILTON.—No tax, we believe, is payable for a horse and trap, provided they are used solely for trade purposes, and photography would be classed as a trade. But if the horse or vehicle be used at any time for other than business purposes, it would at once become liable for the tax. The name and address must be legibly written on the right-hand side of the trap.

LENS.—If a lens of the rectilinear type of eighteen inches focus will not cover sharply, a 12×10 plate with a stop equal to *f*-32, it must be a very faulty instrument. As the lens was supplied subject to approval, it should be returned without delay. A lens is not necessarily bad because it bears no maker's name, though a name is generally some guarantee of quality.

G. W. C.—1. The Euryscope named will serve your purpose quite well. We speak from personal experience. 2. The query as regards plates you must ascertain for yourself. It involves our making comparative trials of the twenty-three brands you tabulate, which you, as a reasonable man, could not expect us to make. 3. From Piper & Carter, publishers, Furnival-street, London, E.C.

R. O. S. complains of "an opalescent coating on his lantern slides when he developes with the ferrous oxalate. He says that with pyro or amidol he does not get it."—The coating complained of is oxalate of lime from lime in the washing water. It can, however, be easily removed by immersing the slides in a very dilute solution of hydrochloric acid. A few drops of the acid to each ounce of water.

T. WALLACE.—The best information that has been published on retouching is that given in the two series of articles by Mr. Redmond Barrett that appeared in our pages. Study them well. A few practical lessons from a good artist will then be all you require. The services of retouchers are not so well paid for now as they were some years ago, except in cases of exceptional ability, by first-class houses.

LANCASHIRE LAD.—There are two sides to most questions; but, according to your own statement, you were entirely in the wrong. What you were asked to do was the legitimate work of an assistant, and your positive refusal to do it, coupled with the strong language you say you used, though you may now be sorry for it, we should say would, in the County Court, be considered a justification for summary dismissal.

INDIA says: "I should be glad if you or any of your readers can give me any information *re* starting a business in India. In what part is one most likely to succeed? Is there much opposition? and any other particulars which might be of interest to one going to India to start a business, or whether you know of any firm there requiring a partner?"—Perhaps some of our correspondents can supply the desired information.

WISEACRE.—We have had no experience of the lens referred to, but if it is of the spectacle-glass form: 1. No doubt. 2. No. 3. The same law applies as in the case of other uncorrected lenses. 4, 5, 6. We do not know. 7. We have had no experience of the shutter. 8. If you have arrived at the size you wish the object on the plate to be, the table will give you the remainder of the information. 9. Roughly, the equivalent focus of the lens.

S. W. says: "I am much troubled with my prints sticking to the negative while printing, particularly in the summer, and also just lately, when the printing room was unusually warm. I use a varnish sold specially for gelatine plates. Can you suggest any remedy?"—The only thing that we can suggest is that another kind of varnish be tried. The varnish may, however, not be at fault, for we found, some years ago, that if the film contained hyposulphite of soda, although a reliable varnish was used, after a time, especially if subjected to heat, the varnish became more or less tacky.

HORTON (Cardiff).—Flare cannot be avoided in a Petzval portrait lens when used with a stop for taking an outdoor subject, such as a view, no matter where the stop is placed. In the studio no flare spot is usually produced. The best marginal definition by such a lens is obtained when the stop is nearer to the front than the back combination. It is in the case either of a cemented doublet of the "rapid" type, or of a single achromatic landscape lens, that flare, when present, vanishes by a slight alteration of the distance between the back element and the stop. When enlarging direct with a portrait combination, the back lens must be directed towards the negative, the front to the sensitive sheet or plate. If the foregoing does not quite meet the difficulty write, again.

G. & W. MORGAN write:—"In enamelling we are a good deal bothered with air-bells. Our plan of procedure is about the usual way, cleaning the plate, dusting with French chalk, coating with collodion, and warming the plate before putting on the print. We use Coignet's gelatine, and make up about one gallon of solution; if acid, add ammonia, put the prints in the solution, then take them one by one and lay them on the warm plate till we get eight on; lay a thin piece of paper on top and squeegee well down. After about one hour lay on backing paper, keep them in a warm room from twelve to sixteen hours before stripping. We shall be obliged if you can assist us to get over the difficulty."—If the gelatine solution is free from air-bubbles, and care be taken that none are formed in placing the prints, no trouble will be met with. In placing the prints on the glass, lower one corner first, and then, gently, the whole of the picture.

RECEIVED.—Communications from James Cadett and several others. Thanks; in our next.

PHOTOGRAPHIC CLUB.—March 1, *Combined Toning and Fixing Baths*, by Mr. J. B. Wellington. 8, Optical lantern lecture on *Winchelsea and Rye*, by Mr. Brooker, of Hastings.

THE Bolton Photographic Society have decided to hold an Exhibition (four days) during the second week in April. Six silver and six bronze medals will be offered for competition.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 2, Technical Lecture, *Cameras, Dark Slides, and Tripods*, by Mr. Edgar Clifton. 9, *The Lens*, by Mr. J. Traill Taylor (second evening). 16, Monthly Lantern Night.

SEVERAL correspondents who this week write for information, but without enclosing their names and addresses, are informed that their questions remain unanswered in consequence of their contravention of our rules as printed in the JOURNAL every week.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical Meeting, February 28, at 50, Great Russell-street. *Panoramic Photography.* Colonel Stewart will open the discussion and show his "Panoram." Other panoramic apparatus will be on view. To be followed by the adjourned General Meeting.

BLACKHEATH CAMERA CLUB EXHIBITION.—Mr. George Davison, being unable to attend as one of the judges at this Exhibition, to be held on March 3 and 4, the Rev. F. C. Lambert has kindly consented to take his place, working in conjunction with Messrs. Cembrano and Pringle. Entries will close on 28th inst.

THE proprietors of Cresco-Fylma are offering two prizes for the best enlargements by their process, viz., three guineas for the best negative, two guineas for the best transparency floated on to opal. Mr. E. J. Wall has consented to act as Judge. Entry forms and conditions, together with full particulars, may be obtained of the Cresco-Fylma Company, Brighton-road, Surbiton.

MR. PHILIP THOMAS, Hon. Secretary of the Cheltenham Photographic Society, writes from the College Pharmacy, Cheltenham: "The Cheltenham Amateur Photographic Society has made up a set of 100 lantern slides for loaning to other societies, and I shall be obliged if you will make it known that the set is at the service of any secretary on application, the only condition being that carriage shall be paid one way."

THE Leicester and Leicestershire Photographic Society's exhibition of photographs will be held in the Co-operative Hall, High-street, on Wednesday and Thursday, March 22 and 23, 1893, under the patronage of Sir James Whitehead, Bart., M.P., ex-Lord Mayor of London, J. A. Picton, Esq., M.P., J. W. Logan, Esq., M.P., and others. All communications respecting the Exhibition should be sent to the Hon. Exhibition Secretary, H. M. Porritt, 66, London-road, Leicester.

THE Fourth Annual Exhibition of the Holborn Camera Club was held on Saturday last at Anderton's Hotel. The Exhibition, although a small one, proved in every way successful. The exhibits were divided into four classes: 1, Over half-plate; 2, Half-plate and under; 3, The best interpretation of "twilight;" and 4, The best set of lantern slides. Mr. A. J. Golding was successful in every class, coming out at the top each time. Two lantern show swere given during the evening. The annual Cinderella dance was held on Monday last in the same rooms.

WE are informed that the biggest photographic enlargement ever made on one piece of paper has just been produced by Messrs. Morgan & Kidd. It is 8 ft. 4 ins. long, by 4 ft. 5¼ ins. wide. The work has been done for a well-known London photographer, who, it is stated, intends showing it at the Chicago Exhibition. For some time Messrs. Morgan & Kidd have been erecting extensive plant and machinery, and enlarging their various departments to enable them to carry on their business more expeditiously, and amongst other things, the plant necessary for producing these large pictures has received their attention.

THE North Middlesex Photographic Society have arranged a series of elementary lessons for beginners as follows:—1. A talk on the management of cameras, lens, stops, &c., in the field. 2. Outing to put theories into practice. 3. Development of plates exposed at outing. 4. Toning gelatino-chloride prints. 5. Improvement of negative by reduction, intensification, &c. There will be no charge whatever for attending this meeting, which will be held at Jubilee House, Hornsey-road, N. The Society has room for a limited number of gentlemen, not members of the Society, who would like to attend, and full information as to dates, &c., can be obtained by applying to Mr. George Gosling, Hon. Secretary, 13, Lausanne-road, Hornsey, N.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A Meeting of Committee was held in the rooms of the Photographic Society of Great Britain, February 20, before and after the Annual General Meeting, Mr. Alexander Mackie in the chair. A letter from Mrs. William Bedford acknowledging the Committee's expression of regret at the death of the late Mr. William Bedford was read. Messrs. Robert Beckett, C. J. Emeny, and P. H. Hunt were accepted as subscribers to the Association. Messrs. J. Traill Taylor, J. S. Rolph, and G. T. Harris were added to the Committee. Mr. A. Mackie was elected Chairman of the Committee in place of the late Mr. William Bedford, deceased. Seven applications for assistance were considered in full detail. It was decided that in three cases the applications could not be granted, but in the other four cases assistance in the forms of grants and loans, to the extent of 24*l.* 16*s.* 6*d.*, was given.

POLYTECHNIC CO-OPERATIVE EXCURSIONS TO THE WORLD'S FAIR, CHICAGO, starting each week during May, June, and July.—The Committee of the Polytechnic have been fortunate in obtaining, at greatly reduced rates, a number of berths upon the express steamers, which leave Southampton, of the Inman and International and H.A. Steamship Companies. Parties will leave every week during May, June, and July, and the tour will include a visit to New York, Philadelphia, Washington, Chicago and the Exhibition, and the Niagara Falls, and will cover a distance of over 8000 miles, returning to Southampton after an absence of one month. The special fare for the round trip from London is twenty-seven guineas, and includes rail fare to Southampton, second saloon accommodation on steamer, railroad journey from New York to Chicago and return (visiting above-named places of interest *en route*), accommodation in New York, Philadelphia, Washington, and Chicago, and return journey to London. The number of each party is limited. Further particulars may be obtained on application to the Secretary, Polytechnic, 309, Regent Street, London, W.

SOCIAL EVENING.—On Saturday, February 11, the *employés* and friends of Messrs. Percy Lund & Co. held their third annual "Social" in the Teetotal Hall, Bower-street, Bradford. Over a hundred persons sat down to tea, and a number of others joined them later in the evening for the entertainment which followed. The London branch of the business was represented by Messrs. H. Snowden Ward and W. C. Hay, and the firm's provincial travellers, Mr. F. Parkin from the north ground, and Mr. Spencer Warren from the south, were also present. Mr. Percy Lund presided over the entertainment, which was entirely sustained by the *employés*. The programme included songs and recitations; a mock trial arranged by those taking part in it, several tableaux, and a vocal waltz, which was received with enthusiasm and vigorously encored. Between the stated items of the programme a few games were interpolated for the younger folk, and the proceedings finished with a couple of verses of "Auld Lang Syne."

AUSTRALIAN PHOTOGRAPHS FOR CHICAGO.—Among the New South Wales exhibits at the Chicago Exhibition will be an extensive collection of photographic enlargements, executed by Messrs. Kerry & Co., of Sydney, for the Commissioners appointed by the Government of New South Wales, and representative of country life and scenery in that colony. Before being sent to Chicago they were publicly exhibited for a few days in the National Art Gallery of New South Wales, in the same room with Poynter's *Queen of Sheba*, where they attracted the largest attendance on record at that place. The pictures include representations of ox teams hauling cedar on the Richmond River, the various operations of handling wool from the time it is ready at the shearing sheds to its being placed upon the railway tracks, the magnificent scenery of the Snowy River with Mount Kosciusko in the distance, ocean views from the romantic heights of the Illawarra Range, scenes in the Jenolan and Garrangobilly Caves, Katoomba Falls, Govett's Leap, &c. The shearing and lamb-marking scenes are excellent, but the view which will probably excite most interest will be that of Randwick Racecourse, near Sydney. It measures fourteen feet six inches by three feet six inches, and furnishes an excellent idea of a race meeting in one of the Australian capitals. It is probable that on the termination of the Chicago show the collection will be sent on to London.

CROYDON CAMERA CLUB.—1893 Exhibition, April 5 to 8. The following are the particulars of prizes and classes:—A. Hand-camera Work: Four prints on one mount. Open to all members. Prize, bronze medal. B. Lantern Slides: Sets of four. Open to all members. Prize, bronze medal. C. Outdoor Views (not portraiture, groups, or *genre*): Size, half-plate and over. Open to all amateur members. Prize, silver medal. D. *Genre* or Figure Subjects, direct or enlarged: Open to all members. Prize, large framed etching of painting (by Mr. H. Maurice Page). E. Any Subject: Open to lady amateurs throughout England who have never won a prize in open competition. No size limits; but if hand-camera work, then not less than four prints on one mount. Prize, bronze medal. Entrance fee, 2*s.* each. F. Any Subject: Open to all Surrey photographers who have never won a prize in open competition. No restriction, except that hand-camera work must be entered not less than four prints oneach mount. The winning print or set in Class F. will be reproduced in Woodburygravure, and the prize consist of forty copies thereof presented to the winner, besides which a copy will be sent to each competitor and to each member of the Club. Entrance fee, 1*s.* 6*d.*; members free. G. Exhibits by Members: Not for competition. H. Works of Distinguished Photographers: By invitation only. Not for competition. Further particulars may be obtained of Mr. G. R. White, 56, Albert-road, Croydon.

FORFARSHIRE INTERNATIONAL PHOTOGRAPHIC EXHIBITION.—The first Exhibition will be held in the Reid Hall, Forfar, on Thursday, May 4, 1893, and following two days. The following are the officials:—*Hon. President:* Alexander Robertson, of Burnside, Sheriff-Substitute of Forfarshire.—*Hon. Vice-President:* Robert Whyte, Procurator-Fiscal of Forfarshire.—*Chairman of Committee:* Gilbert W. Don, Clocksbriggs House.—*Vice-Chairman:* J. Watson Craik, Forfar.—*General Secretary:* W. J. Anckorn, Arbroath, N.B.—*Treasurer:* R. Bruce, Banker, Forfar.—*Local Secretaries:* A. H. Simpson, Chemist, Forfar; James D. Ross, 6, High-street, Brechin; and A. Davidson, Chemist, Montrose. The Classes for Competition are as follows:—Class 1, Amateurs confined to Forfarshire, any subject, any printing process, irrespective of size. Class 2, Amateurs, Open Class, Landscape and Marine, irrespective of size or process. Class 3, Amateur, *Genre* and Portrait. Class 4, Professional, Portraits, irrespective of size. Class 5, Professional, *Genre*. Class 6, Open Class, Enlargements, untouched. Class 7, Professional, Landscape, with or without Figures. Class 8, for Ladies only, any subject. Class 9, Open Class, Lantern Slides, set of six. Class 10, Medalled Class (Champion), no restriction in number of pictures. One gold medal will be awarded to the best picture in the Exhibition; also a silver and a bronze medal will be at the disposal of the Judges for any special photographic work, any subject or process.

*** In type, but unavoidably held over, articles by Hector Maclean, T. Nr Armstrong, J. Pike, W. H. Davies, a paper by Mr. Horsley Hinton, and othe. interesting communications. These we will endeavour to overtake next week.

JOURNAL OF PHOTOGRAPHY.

No. 1713. Vol. XL.—MARCH 3, 1893.

PANORAMS, WIDE ANGLES, AND PERSPECTIVE.

While it may be difficult to indicate a sharp line of division between a narrow and a wide angle of included subject in a photograph, a like difficulty does not prevail as to the nature of the perspective in which such a picture is presented. The Panoram, as given in the title to these notes, differs from the ordinary camera in this, that whether a wide or a narrow angle of view be included in the picture, the perspective is not plane, but cylindrical or panoramic.

The Panoram—as described by its inventor, Colonel Stewart, R.E., at the meeting of the Photographic Society of Great Britain on Tuesday evening—is a camera containing several ingenious devices. A fair idea of its nature may be had if we describe it as a Johnson & Harrison pantascopic camera fitted with an Eastman roll-holder instead of the dark slide for glass plates which characterised the elder invention. The principle of the camera mentioned permits of its taking in a view that includes the whole circle of 360 degrees, but as it was introduced anterior to the days of films and when glass plates formed the sensitive support, it was evidently impossible to utilise plates so abnormal in length compared with height as to give practical effect to its possibilities, hence 120 degrees was selected as an angle sufficiently large.

By the application of the Eastman roll-holder the original great bulk of the instrument is minimised to such an extent as to reduce it to that of an ordinary portable camera. As the image falls upon the sensitive surface through a narrow vertical slot immediately in front of the film the roll-holder does not necessarily exceed a very few inches in width.

The camera rotates upon its stand, the axis of rotation being the focal centre of the lens; and the slot through which the light passes to the film is of unequal width so as to allow of a greater practical exposure being given the foreground than the sky. The motive or driving force is clockwork, as in the pantascopic camera, and this likewise causes the revolution of the roll-holder by which the film is carried across the plane of delineation at the focus of the lens. A complete rotation of the camera (the one exhibited had a lens of ten inches focus) ensures the covering of a band of film a little exceeding six times the focus, which in this case would form a continuous picture over five feet in length.

But while the camera possesses this giant's power it is not necessary that advantage be taken of it. On the contrary, the clockwork after being started may be stopped at any stage by the mere manipulating of the pneumatic ball, and the exposure may be such as only to include an angle of the smallest conceivable dimensions, if the subject be one that does not warrant more being included. The termination of the rotation ensures the marking off of the portion of film exposed by the action of a pricker, after which the clockwork is wound up and everything is in readiness for the next exposure, which may include either a wide or a narrow angle of view as before.

An ingenious method of developing these long pellicular negatives has been devised by Colonel Stewart. He fastens the exposed band to the periphery of a wheel of suitable width, and then rotates it slowly in a vessel of developer, which need not be any larger or deeper than just to submerge the film. Several negatives of this class which were exhibited attested the success which attends this novel and ingenious system. A similar method may be adopted with the printing from films of great length.

A camera of the nature here indicated, while useful for such pictorial purposes as involve the depicting of any subject in which there is continuity, such as a range of hills, a chain of lakes, or a coast scene, must prove of special value in military reconnaissance, and it will form a useful addition to our appliances.

But it may be said, as the perspective of such pictures will be cylindrical they will necessarily be distorted. To meet this, we may say, speaking hypercritically, that photographs of every kind are distorted if they are not looked at from the correct point of view. When this is attended to there is no distortion in pictures in either plane or cylindrical perspective; otherwise there is.

Let a number of spheres be placed squarely in a row in front of a camera containing a wide-angle lens and then be photographed. A careful examination will reveal the fact that, while the central one is of the same height as that nearest the margin, yet the latter is not circular but elliptical, the width exceeding the height in dimensions.

The central one is quite circular; but, in proportion as the others recede from the centre, so does the horizontal width increase. This arises from a circular beam of light being made to impinge obliquely on a flat surface. No picture whatever can be seen with absolute accuracy unless the eye or point of observation be opposite the centre of the picture, and at no greater distance from it than the focus of the lens by which it was taken. Only in this way will the elongated marginal spheres adduced as an example be seen *as* spheres. A similar principle applies to the examination of a panoramic view. To see this with accuracy, the picture must be bent in a curve, the radius of which equals the focus of the lens, and the eye must be in the centre of the curve, so as to be directed squarely to each part. No distortion will now be apparent.

WASHING PHOTOGRAPHS.

We make our title as wide in its scope as possible, as we propose to include in our purview not only negatives, but prints of various kinds. We are led to consideration of the subject owing to inquiries, familiar enough to any one known to have experience, as to the cause of this, that, or the other kind of spot which, in even a brief practice of photography, exercise the mind of the tyro, and not only him, but, not infrequently, the expert. It is not our purpose to write a disquisition on spots in general; we have in view a particular aspect of the subject—those spots attributable to the water employed. First, let us say that we consider efficient washing of prints may be done with an extreme maximum of twelve hours, if properly carried out; with negatives, a maximum of four hours may be considered sufficient. We refer to this point as, from personal knowledge, we can say that some workers considerably exceed these limits. One amateur who came to us with a tale of unavoidable "frilling," was astonished when we informed him that the twenty-four hours' washing he gave his plates was the cause of his frilling, and was almost incredulous when he learnt that he might consider from two to four hours ample time to leave his negatives in a running stream of water. Then, again, the universal consensus of opinion from printers with extensive experience is, that prolonged soaking injures the quality of the print.

The condition of the washing water is a prime factor in the production of spots and stains of an extensive and varied character. It will only be necessary to briefly allude to hard waters, in which a large quantity of carbonate of lime is held in solution by carbonic acid. Such waters are fruitful in producing negatives with a closely adherent scum. Again, waters of a ferruginous character deposit iron under some conditions, and so stain the prints. This cause, when the iron is not very largely present, might possibly escape attention.

But the foremost cause of all, whether running streams or water from a public main is made use of, is the presence of suspended matter. Good samples of water, fit for use as a beverage, may, in average conditions of purity, contain so much suspended matter as to cause a deposit of more or less fineness over every print or negative placed under its influence, even though the impressed surface may be placed face down in the trough or other receptacle. The suspended matter may be fine particles of inorganic matter, or, what is more probable, low forms of vegetable life that have either escaped through the interstices of the filter bed or have germinated in the water in its progress through the mains. If any one supplied with what he deems the purest of water will merely attach round one of his water taps a piece of clean flannel, and allow the water to run gently through, he will, in the large majority of cases, be surprised at the amount of "dirt" he will in an hour or two find arrested by even so open a woven fabric. Such matter will largely attach itself to photographs in washing, and produce a faint, though decided, scum or discolouration, which occasionally forms in clots, and gives rise to distinct centres.

But it must be remembered that, as the water mains themselves become coated internally with a deposit from the water passing through them, this is liable to be disturbed when alterations are being made. A neighbour, for example, is having his water supply altered. What is the result? For some hours, perhaps, the water is decidedly muddy, and if negatives or prints be washing it is quite possible that all this muddy water is being used, and its presence never observed. Especially is this so with prints which are being washed through the night, as is so generally the case. If a cistern is used and the water not taken direct from the main—an excellent plan in one direction, as it ensures constant pressure—a portion of this mud is intercepted, but not all, and the further evil remains of a portion of this accumulation of mud some day or other surely being disturbed and despatched to its innocent victim, a batch of photographs under washing operations. Again, many stone cisterns are not kept air-tight, some not even covered: atmospheric dust is bound to accumulate and be deposited upon the pictures being washed.

Instances could be multiplied, if need be, to give point to the obvious moral. All water for washing purposes should, before entering the washing trough, be passed through a filter of some kind. We look upon this matter as one of prime importance, but one which is neglected in by far the largest proportion of cases. How the water is to be filtered we need not indicate. A home-made filter of two thicknesses of flannel is used in some studios we are acquainted with, and very frequently, we are informed, have they to be cleaned or renewed. There are numberless filters upon the market to suit the most fastidious taste. We have one suggestion to offer. Whether the filter be one to discharge filtered water into the store reservoir, to filter it after storage, or to attach direct with the main and supply filtered water as the tap is turned on, in any of these cases let the filter chosen be one that is readily cleansed and its contents removed, or, better still, one that is self-cleansing. Many excellent filters of the latter pattern can be obtained; the matter is rather one of embarrassment of choice. In conclusion, let us say to all photographers, Filter every drop of water you use, and use a self-cleansing filter for the purpose, and so avoid a fertile source of spots and stains.

WARM TONES WITH IRON DEVELOPMENT.

Although the class of tones usually associated with iron development—by which, of course, we mean ferrous oxalate—ranges only between grey and black, yet it is by no means impossible, under certain circumstances, to obtain warm tones, as all workers of Alpha and similar papers are aware. But the conditions requisite are such as to practically bar the application of this method in a great many instances where protracted exposures are objectionable, as the effect is gained by using a very weak developer after an exposure of abnormal length. For contact printing, or for enlarging in a good light, and from suitable negatives, no objection need, perhaps, be raised, but in the dull light of the winter months this system of working is almost impossible.

A correspondent, however, in another column this week, calls attention to another means by which the same end may possibly be equally well attained without the same necessity for increasing the exposure; indeed, speaking from recollection of the behaviour of the developer referred to by him, we believe the general tendency is to give the warm tones with a normal exposure, though, as in other forms of development, the effect increases proportionately with its extension. The means referred to consist in substituting ferrous sulphite for ferrous oxalate, either partially or wholly, but preferably by making a mixed solution of the two salts.

Mr. M. Carey Lea was the first, soon after his introduction of the ferrous-oxalate developer, to call attention to the developing power of several of the other ferrous salts, and amongst those of which he spoke most favourably is the one in question, the sulphite, which, however, has not, up to the present time, been recognised as an established developing agent. It has

been put forward, as our correspondent points out, as a means of restoring the energy of a spent ferrous, oxalate solution, and it was in employing it in that connexion that we some years ago noticed its remarkable tendency in the direction of warm tones.

This is more particularly the case with collodion emulsion plates, with which we have obtained images that could not be distinguished from the red chalk or "Bartolozzi" effects that have become popular for some classes of portraiture. With gelatine films the colour is not, as a rule, so decidedly red, unless a considerably augmented exposure be given, but it is sufficiently removed from the ordinary ferrous-oxalate tone to deserve the title of "warm." The colour so produced is, moreover, particularly well suited to toning either with gold or platinum, passing from the original red stage through the same range of purple shades as in the case of an albumen print. In fact, in this respect the toning is far more certain, and the final result far more like an ordinary silver print, than when a chloride film is in question, and satisfactory tones can be obtained either by transmitted or reflected light, that is, either for transparencies or paper prints.

Ferrous sulphite is not itself soluble in water, though it is freely soluble in excess of sulphurous acid. It is also soluble—though probably by conversion first into oxalate—in oxalate of potash. It may be made by dissolving iron wire or filings in aqueous sulphurous acid, the result being a mixture of ferrous sulphite and hyposulphite, the former of which slowly crystallises from the solution or may be precipitated by adding alcohol. A better plan, however, is to prepare it from freshly precipitated carbonate of iron, in which case it is obtained free from the hypo sulphite.

The process is conducted as follows:—A concentrated solution of ferrous sulphate is mixed with an equivalent proportion of carbonate of soda, also in solution, and the bulky, gelatinous precipitate—white at first, changing rapidly to dark green and eventually foxy red—is thrown on to a calico filter and left to drain with as little exposure to the atmosphere as possible The carbonate is extremely unstable, passing quickly, if exposed to the air, into the state of ferric hydrate, when it assumes the characteristic brownish-red colour; it is impossible to altogether avoid this change, but every effort should be made to prevent it as far as possible by protecting the mass from the atmosphere It is hopeless to attempt to hasten the separation of the excess of water, or to get the mass into a more condensed form; all that can be done is to let as much water drain from it as will in a reasonable time.

The next operation is to convert the carbonate into sulphite. For this purpose, if a very dilute solution is all that is required, let a given quantity of the aqueous sulphurous acid of commerce be shaken up with a quantity of the dirty green carbonate—rejecting, as far as possible, that which has changed to the red colour—until it will take up no more; then let it settle, and decant the clear portion, or filter it. This, however, constitutes at best a solution of very low and indefinite strength, and the preferable, though more troublesome, plan is the best.

Arrange an apparatus for the generation of sulphurous acid gas by fitting a cork to a wide-mouthed bottle or jar. Bore two holes in the cork, and into one fit a bent tube to lead off the gas, and into the other a funnel with a long stem to reach nearly to the bottom of the jar. What is known as a "thistle-head" funnel will answer, but it is better to use one with a stop-cock, obtainable in all sizes at the philosophical apparatus dealers.

Let the jar be three parts filled with saturated solution of sulphite, or, better, bisulphite of soda, insert the cork, and see that all the joints are tight. Place the precipitated carbonate in a wide-mouthed bottle, into which the bent tube from the generating jar is inserted, so as to reach nearly to the bottom. When this is all arranged, pour gradually into the generator, by means of the funnel, strong hydrochloric acid to decompose the sulphite. The acid must be added only a few drops at a time, as each addition will cause violent ebullition; and here is where the utility of the stop-cock is found, as the funnel may be filled with acid, and a few drops allowed to trickle into the jar as the effervescence subsides, and without allowing the gas to escape except by way of the bent tube.

The sulphurous acid, as it escapes, is taken up by the iron, and carbonic acid in turn is given off. Gradually the green colour of the carbonate changes to a dull brown, and eventually the liquid becomes clear, and then consists of a solution of ferrous sulphite in excess of sulphurous acid. Obviously it is of uncertain strength so far as regards the excess of acid, even though, with a definite quantity of iron to start with, the volume be made up to a certain quantity. But, if the passage of gas be arrested just before the solution becomes clear, a tolerable approximation can be made to uniformity in successive batches.

The solution thus formed itself possesses developing power, but it is better used in conjunction with ferrous oxalate. By the addition of potassic oxalate alone, a developer of ferrous oxalate is formed, but the solution is not rich enough in iron to be advantageously employed in this manner. Far better is it to mix it in definite proportions with ferrous oxalate developer, made in the ordinary way, by which means a better idea can be formed of the actual constituents.

Lantern Slides as Window Decorations.—The lantern season will soon be drawing to a close, but there is no reason why the slides should not still be objects of enjoyment by utilising them for decorative purposes. We were recently shown a frame of about a score of lantern transparencies, backed with ground glass. The frame was of lead, such as that used for church windows of stained glass, and the slides were surrounded by a narrow margin of various coloured glass. Strips of tinted glass, of quiet tones, were also interspersed between the photographs, which gave an exceedingly pleasing effect. With each transparency two nicks were cut in the lead, sometimes at the top, sometimes at the bottom, and at others at the sides so as not to weaken the frame generally. This enabled the lead, which is soft and ductile, to be turned back, so that any slide could be readily taken out and replaced by another as required.

Exclusive Rights.—Another exhibition in connexion with photography is projected at the Crystal Palace. The prospectus contains the following:—"Notice is hereby given, that the right of taking photographs in the Palace and grounds has been let by the Company under an agreement for a term of years, and all exhibitors are expressly prohibited from taking photographs of any kind whatever. Any one invading these rights renders himself liable to a claim for damages." It is tolerably well known that Messrs. Negretti & Zambra have held this sole right for very many years—if we mistake not, from the first opening of the Palace. The Company have, like the authorities at the Chicago Exhibition, often been censured for letting exclusive rights; but it has no doubt been with them a consideration, as at Chicago, whether permitting the unlimited use of the camera would increase the returns to the same extent as letting the sole rights to a commercial firm.

Improved Blood Albumen.—When an unusually malodorous sample of albumenised paper is met with, it is frequently

assumed that it is necessarily prepared with blood albumen. This is a fallacy, because blood albumen need have no more odour than that from eggs, while the latter may be, and often is, used in a most offensive condition. The application for a patent for the manufacture of a light-coloured albumen from blood has been made by a Dr. Carl Cosinera, of Berlin, the specification of which has just been issued. The inventor says, when defibrinised blood is mixed with slightly acidified ethyl, or methyl, alcohol, or acetone, the albumen and the globuline contained in the blood are precipitated, while the colouring matter of the blood, hæmatine, remains in solution. The method is briefly this: One part of defibrinised blood is introduced in a thin jet into four or five parts of ethyl alcohol of ninety-five per cent., previously acidified with one per cent. of sulphuric acid, the mixture being well stirred during the addition of the blood. Albumen separates in the form of almost colourless flakes, and the red-brown coloured mother liquors are separated by filtration. The albumen is then to be washed with alcohol, and afterwards with water. It can afterwards, if desired, be bleached with any oxidising agents, such as hydrogen dioxide, &c. Considering the small proportion of albumen contained in blood and the price of alcohol, even methylated, we fear that photographers will not reap much advantage in their albumenised paper from the new process of obtaining albumen, however excellent it may be.

Photogravure.—We have often in the past directed attention to the little interest taken by professional photographers in the various mechanical methods, photogravure in particular, also that work which could very profitably be done here was being sent abroad in large quantities for execution. Whatever the profession may have been doing, it is certain that of late many amateurs have been taking a great interest in photogravure, as evidenced by the large number who attended the two lectures by Mr. Denison. The process described by Mr. Denison is an exceedingly simple one, and will yield excellent results, requiring no expensive plant for its working. A copper-plate press, such as that used at the demonstration, costs but about 12*l.*, while a second-hand one may be had for much less. A couple of pounds will cover the cost of the dusting-box, heater, "jigger," &c. The same heater that is used in the printing will also serve in laying the ground on the copper plate. It will be better for the experimentalist, at first, to send his plates to a regular copper-plate printer to print, as skill is required in copper-plate printing as in all other work. Copper plates are not expensive; the half-plate size cost from about two shillings to three shillings each, according to quality and finish, other sizes in proportion. Beginners in the work who are *au fait* with carbon printing will have far less to learn than those who are not, because the whole thing is dependent upon that process—the production of a carbon transparency, and from that a suitable carbon negative on the copper plate. The other portion of the work is very simple; therefore experimentalists will, as a matter of economy, do well to master the details of carbon printing, and they are very easy, before essaying etching on the copper. If that be done, no difficulty will be experienced in getting the most suitable carbon image for the purpose on the plate.

THE WEAKNESS OF "STRONG POINTS."

Although to some it may at first sight seem that discussion respecting those so-called laws which have been formulated for the guidance of all who yearn to become art-perfect is outside the scope of a photographic periodical, nevertheless, as I shall presently show, the particular one I wish to direct attention to is of unusual importance to all photographers, and I think my criticism of it will be welcome to a considerable number of the fraternity.

The object of this paper is to remove from its high pedestal a certain graven image which a large proportion of us have hitherto with confiding superstition worshipped, not merely to the exclusion of quite a host of other equally potent little idols, but also to the grievous neglect of the great mother goddess—Art. And the name of the graven image aforesaid is "Strong Points.'

Who first set up this minor deity, so that it has come to be received as a major one, I wot not. Anyhow, Mr. Howard draws particular attention to it in his *Sketcher's Manual*, where, as far as photographers are concerned, it might have lain dormant until this very moment and longer, had not Mr. H. P. Robinson given it prominence and his own *cachet* by devoting a whole chapter of *Picture-making by Photography* to its consideration. Ever since then the camera crowd has adopted and cherished this wonderful one rule as a *sine-quâ-non* in all pictorial designs. This has been much helped forward by the various handbooks of photography which, big and little, have taken up the above now omnipotent law and enlarged upon it with unflagging satisfaction.

It is so easy to demonstrate, so simple to master, so substantial to handle.

Take a T-square, divide your paper into nine equal rectangles, then where the vertical and horizontal lines intersect you have your "strong points;" upon one of these place your chief object. The recipe is more readily practicable than are the directions for boiling a potato. It is but a rhetorical exaggeration to say that from Abney's text-book, published ever so many years ago, down to Bothamley's shilling manual, which every one was last year reading, the advice upon line composition is mainly "strong points," leavened by a holy horror of that damnable heresy "symmetry."

All this widely disseminated literature, which is, as regards art matters, necessarily founded upon opinions borrowed one from another, and all from one, has, in due course, borne fruit, which has nourished a race of judges and critics, who apply, as a kind of touch-stone, this magic principle of "strong points" to every luckless print, picture, or view coming under their ken.

Is the main subject—say, the village church, or the toiling reaper—in or near the magic spot, then is the *pons asinorum* safely got over; but, should the leading motive be palpably distant from one of the "strong points," then *anathema!* In vain may the landscape be brimful of sweetness, fancy, and delight, if it has sinned against this awful little law, it is only worthy of perdition—that is, perdition of medals. And so it must needs happen that "full many a time and oft," not the best, but the second best, of two works is placed first.

Far be it for me to deny that some one of the aforesaid points is the strongest region in the rectangle of a picture, nor dispute that it is a good place to group the salient objects, because it is impossible to demonstrate the negative of a contention which only rests upon a fanciful impression—and, besides, I do not doubt but that in many instances some such a position is best for the purpose, for the sake of convenience, if for no other reason; but what I most earnestly protest against is the growing habit of making this comparatively insignificant rule a chief test of artistic merit.

To illustrate the immateriality of observing the law of "strong points," let me briefly refer readers to one or two paintings which they may with ease inspect for themselves from the hands of artists whom even photographers will not care to declare untrustworthy.

First, an example of David Cox, whom we all know. In the South Kensington Museum is one of his master works, called a *Water Mill in Wales*. A most cursory glance at this (which is also reproduced in Redgrave's short memoir of the painter, and can be seen at most free libraries) will enable the student to note that it is composed in absolute defiance of the "strong points" dogma. The most vivid juxtaposition of light and dark, the chief incident, the dominant forms, are arranged upon a vertical line, which, with almost mathematical precision, divides the picture into two equal parts!

Next witness P. De Wint, whose *Lincoln Minster* (which can be seen in the same gallery and the same book) is placed exactly central upon the paper, so that the bisection of diagonal straight lines occurs at the very acme of pictorial interest, which is therefore both vertically and horizontally equidistant from the sides.

Turning to figure paintings, it is less necessary to advert to the examples in which the model is placed on or by an upright central line, because the fault—if fault it be—is too common to need emphasising, but the localising of the centre of interest halfway between the top and bottom is less often done for the very sufficient reason that, inasmuch as the head forms the key, it is, as a rule, almost a physical impossibility to get the aforesaid centre of interest very far from the upper boundary of the canvas. Of course it can, by the exercise of some ingenuity, be done, especially where the figures are small in comparison with the dimensions of the composition. Now, in spite of all inherent difficulty and improbability, it cannot be gainsaid that quite a number of figure subjects might be cited having their leading and dominating emphasis, alike human and artistic, in the very middle of the picture. Indeed, in several instances the artist seems to purposely and contemptuously flout that upstart idol "Strong Points."

I have made no diligent search for examples of the above, but find plenty of them ready to hand; of these I append one or two.

Firstly, there is *The King's Daughter*, by Herbert Schmalz, shown at the New Gallery in 1889, and reproduced in *Pictures of the Year*, published at the *Pall Mall Gazette* office. In this, although there does not seem any reason why such should be the case, the chief figure

is not only midway between each side of the canvas, but her face, which is the essence of the painting, is over a point equidistant from each corner.

Again, who is there that, having seen, can forget Henrietta Ray's entrancing *Zephyrus Wooing Flora*, which was in the Royal Academy of 1888? Well, here we find that the two heads are arranged upon a central perpendicular line, and, moreover, a circle of relatively small radius described about the centre of the picture will include the faces of Flora and her swain.

No useful purpose is served, or I would continue the list of works by eminent artists showing a complete disregard of the tenet of "strong points;" but enough has been done to prove that the rule, "Put your chief object in the corner," as if it were a naughty boy, is not by any means an essential one, but is one of those unimportant regulations which, good in its way—as is, say, sea-bathing or smoking—may be practised or not, at the pleasure of the artist, without detriment to his production.

In conclusion, I hope my remarks will induce those who take upon themselves, or have thrust upon them, the duty of passing judgment upon photographs to be in the future less prone to condemn a study simply because it does not conform to the greatly overrated doctrine of "strong points."

HECTOR MACLEAN, F.G.S.

SPECIALISATION IN FINE-ART WORK.

[West London Photographic Society.]

THE photographic world is a comparatively small one, and it needs only that a man should make a few pictures and contribute an article to the photographic press to ensure his being known to the average photographer; hence I may not be taking too much for granted if I presume that I and my misdeeds are not altogether unknown to at least some few of those who have courteously come here to receive me this evening. And, this being so, I am wondering what you expect of me. Your syllabus makes me responsible for a paper on "Art and Photography." How delightfully vague; how good of your Secretary to give me such elbow-room! I have been presumptuous enough to suppose that my works or my doings are not wholly unknown to you, and from this, and from the title which is put down for me, I imagine that you may perhaps share the general though somewhat erroneous notion that I am pledged to uphold the possibilities of photography in the field of fine art, and may possibly be expecting me to speak of such matters to-night—expecting me to once again enter the lists, to fling down the glove to you, and demand the homage of every artist to this fair sun-goddess, and compel your acknowledgment of her purely art claims, admitting her in all respects equal to those queens of the tournament, the pictorial arts, whose claims are already established and whose sovereignty is acknowledged.

"FIDDLING ON THE SAME STRING."

Now, ladies and gentlemen, I propose to do no such thing. I am by no means in fighting condition, and have grown wary of late how I enter into any such conflicts as the championing of photography as an art might lead to.

It is a considerable time ago that I accepted, with great pleasure, your President's invitation to come here to-night, and my memory may be at fault; but I believe I gave as the title for a brief discourse "Specialisation in Art Work," and I did so with a deliberate intention.

I was at that time smarting under a newspaper critique which described some of my own picture attempts as "fiddling upon the same string," which I considered as uncalled for as it was foolish (I hope the reviewer is here to-night). In the heat of the hour I felt eloquent, and partly for the sake of self-defence, and also because I felt that I might thereby drop some remark, some slight suggestion, which should be of use and of interest to others, I elected to read a paper on "Specialisation," which is, perhaps, a prettier expression for "fiddling on the same string."

WHAT A PICTURE SHOULD BE.

But, whilst I foreswear any intention of urging upon you the high artistic position which I may or may not believe photography should hold, my remarks must apply essentially to that side of photography which, in order to avoid the debatable term artistic, we will call the pictorial aspect of photography, meaning by that photography employed for the production of a complete and æsthetically pleasing result—a picture, not a diagram, or a mere reflection of objects or circumstances—a picture, not a mere memorandum to be employed by the painter, artist, or draughtsman, in his subsequent work—a thing of beauty, not a pictorial anecdote, nor an exhibition of execution, or a cleverness which may come of much careful training, but a picture which corresponds to the impression which any arrangement in nature left upon the artist's mind, and may be depended upon to awaken a response and a similar impression in the spectator to whom it may appeal. I trust I am making my meaning understood. I want so particularly to clearly express my own notion of what a picture should be, it would clear the way very much for those who claim that photography may be art. I don't say it is, at least not here! Truth, to tell, I am trying to find out, it may be I shall be following an *ignis fatuus* all my days, but it is a fascinating pursuit and a pleasant one, and, any way, it will keep me from meddling with my brother photographer who makes topographical views and curiosities of manipulated skill his special care.

NATURE RARELY RIGHT ARTISTICALLY.

In the endeavour to produce by means of the camera *pictures* properly so called, we must disregard every other consideration; it is by no means sufficient that a photographic picture should be an exact copy of nature, it must aim at something more than that; remember that, artistically, nature is very rarely right. You may remember who it is that has said, "To say to the painter that nature is to be taken as she is is to say to the player that he may sit on the key-board;" and, again, "Nature contains the elements, in colour and form, of all pictures, as the key-board contains the notes of all music," and it is for the artist to select, to emphasise, to suppress the notes according to his fancy, and to group, to combine, and weave the whole into an harmonious chord.

How is this to be done by photography? Well, well, I am not here to say it can be done, I will not now say it ever will be fully done, but I may privately think sometimes that we are perhaps nearer the goal than we were.

Please observe the "sometimes" and "perhaps." Am I not very cautious?—too guarded, too doubting, I know, for many who, having secured with their camera a little impressive bit of landscape, very pleasant to look at, often full of suggestion, in feeling, in taste, in treatment so far above the typical photograph that, in a proud moment, they fancy the doors of the Temple of Art standing wide open to receive them.

EXAMINING AND STUDYING NATURE.

So, now, if we are devoting our photography to the production of pictures, in the best sense of the word, it will be necessary for us to examine that nature which, like a keyboard, contains all those notes which we shall need to make our harmonious composition, and study them all the more closely because we find that the composition ready to hand is usually far from perfect; and, having acquired an intimate knowledge of things around, we become more fastidious and less easy to please. I know of no more hopeful a sign in the photographer than the over-exacting and dissatisfied mood of the man who has been there before, and will visit that spot again and again, patient until this and that feature are in proper unison, waiting and watching so that the objectionable shall be removed and the wished-for come to pass—perhaps, after all, to go empty away, because he found nature not wholly right. Dutifully and reverentially he hoped nature would come right—come as he wanted her—because he, lacking the painter's skill, could only photograph a little less than nature chose to show him. Herein is the barrier. Who will break it down?

NOT ENOUGH SERIOUS STUDY.

This waiting, and watching, and patient study implies a seriousness of purpose which is all too rare amongst our photographers. With those who find in photography a pleasant pastime, an occupation for leisure hours, much that I have said must appear very unnecessary and making much ado about little. With such a one I have nothing to do for the present, and I can only presume to interest those who, like myself, care for photography, not for its own sake but merely as possible means to picture-making, and hence I make complaint that much photographic energy is misapplied. There is too much of the *hobby* and not enough of the serious study: too often a holiday-making air about the excursion with the camera, a triviality of purpose and insignificance of aim. This cannot fail to make itself felt in the resulting works, and it is not fair to judge of what can possibly be done with photography by such examples. Let me tell you that the man who goes out with his photographic appliances with the serious purpose of getting a picture which shall express some of the poetry and sentiment of nature, but returns home without having used a single plate, has done a better day's work than many who may have exposed the entire half-dozen here and there at each prompting of fancy and inclination.

Still, there is hope—nature is not always so coy; and, on the other hand, sometimes the photographer may do well to be a little less exacting, or at least be content with a compromise.

If the photographer cannot gather and choose the elements of his composition as he wishes, still, if he accept, after diligent search, what is given him, the greater truthfulness with which he can portray this little may be some compensation for his limitations in another direction.

Waiting for Nature in the Mood we Desire.

But let me attempt to come more precisely to the matter in hand. I have pointed to the necessity of finding nature in her best mood. I don't mean necessarily in her most sunshiny and smiling mood, because, for my own part, I find nature weeping, or wild and stormy, more charming than in radiant sunshine. You know what Mr. Whistler says about "the sun blazing, the wind blowing from the east, the sky bereft of cloud, and without all is of iron. The windows of the Crystal Palace are seen from all points of London. The holiday-maker rejoices in the glorious day, but *the painter turns aside to shut his eyes.*" But it is necessary to wait until we find nature in the mood we desire, and this means many visits to the same spot, perhaps many plates exposed. If I could but drive home to each landscape-worker the desirability of often visiting the same spot, I should be well repaid for speaking.

The facility with which a plate may be exposed, and something like a satisfactory picture obtained, is probably photography's greatest stumbling-block. If only we could sufficiently restrain our impetuosity, and never expose the plate until we have become acquainted with every feature, every form in the scene, we should be surer of success, and we should probably be surprised to find that the effect which pleased us at first is far surpassed by the effect which we subsequently discovered. But our habit is to wander over yonder green hills to-day, and, not finding a subject to please us, to-morrow we traverse the woodlands, and next day the meadows, securing something perhaps from each.

Ringing the Changes on a Single Landscape.

But surely it is hardly reasonable to suppose that, if we secured a fairly pleasing effect on the day we visited a certain favourable point, by returning and going again we may be able to improve. We can hardly suppose that nature was forewarned of our first coming, and prepared herself in her best guise for that particular moment. A lucky chance may favour us in that way sometimes, but I say that, if we bring away a charming picture of a given spot on our first or second visit, continued visiting and further observation will more probably result in something even past our highest conceptions.

And, if this is true of a definite spot, so is it still more so of a certain class of scenery. I will say that within the limits of one small valley, on the slopes of a single mountain, by the banks of a river, between one lock and another, there is subject-matter for a life-time. Changing seasons, changing skies, and not until you have studied it all shall you know how much there is in it worth noting, or what effects are possible. I think it is a fair comparison to ask that, suppose a scene to contain twenty matters of detail, twenty notes of form, light, shade, &c., will you tell me how many changes you can ring on twenty notes in music? And why not in our landscape?

And in the course of all this prolonged study we shall have exposed a great number of plates, and every picture will be of much the same character, and we shall hear it said, "How long this fiddling on the same string?" What matters if at last our melody is more perfect—as it is sure to be—than when for the first time we struck it?

Something to be made out of the most Unattractive Subject.

I do not know whether any of you have known what it is to have acquired a taste for a scene or for a certain description of landscape which before you had felt no particular liking for. Have you ever known what it is to pass through a district and be quite unmoved to admiration, but upon a subsequent visit to express surprise that you had not before noticed this or that picturesque possibility? I have, and felt it very keenly, and then, yielding to inclination, have found that what I had previously regarded as a very unpromising district to be crammed full of beauties wholly unsuspected.

I am convinced that most spots, carefully studied, will, after a while, have a very different aspect viewed pictorially; and many of us might do worse than to sternly resolve to make something out of the most unattractive and unlikely material, making, in spite of first impressions, a picture where such seemed impossible. It would probably be a more profitable occupation than running to and fro upon the earth and touring in far-off places. I am speaking artistically and pictorially, and make no reference to the pleasure of the thing.

A Little Bit of Practice.

Following all this theorising with a little bit of practice, I remember that, within a period of seven days last spring, I exposed six plates on the same spot, each time believing that I had found the view in the best possible light and circumstances.

At the side of a broad space of water was a little promontory of green grass and moss, perhaps some twenty feet in area, fringed around with tall reeds, at that time newly springing into greenest life, but which in summer would have shut out my view, marsh-marigold, and butter-burr sprinkled the ground with their glorious yellow flowers and jewelled the rugged grass—grass so soft and yielding that the feet sunk in the spongelike turf and made one wary of walking. On this little region of turf I spent whole days, and watched the particular scene in front of me from fifty different positions, and, as I have said, exposed some six or seven plates, and, though none are bad, certainly the latter ones are better.

Study a Particular Class of Subject thoroughly.

I cannot too strongly advocate confining attention, for a considerable time at least, to a particular class of subject, and learning thoroughly. Is it not what the painter does? He will study in one particular district for a long period, not because he wishes to practise mere skill in copying, but because we cannot know the conditions under which various objects appear best until we have seen them under all.

And, but that time will hardly admit, and I have not the present inclination to claim your patient hearing longer, I might advance as a reason why it is only by long watching that we may know what is best, that ultimate impressions are usually more lasting, and therefore in better taste than immediate impressions. Things which improve upon acquaintance are generally more worthy our attachment, and, in these sensuous appeals, are more satisfying. The subtle and obscure, veiled, hidden away, hard to find, be it form or colour, possess a more enduring charm than the gay and glittering thing which quickly attracts but as quickly palls upon the senses.

A. Horsley Hinton.

THEORIES OF DEVELOPMENT.

[Photographic Society of Philadelphia.]

I listened with much pleasure and great interest to the lecture of Dr. Mitchell, delivered at the last meeting of this Society, and was especially gratified to find that some opinions of mine, held for some time, regarding development were supported by such an able and eloquent advocate. I refer principally to the building down or etching of the film of the dry plate in contradistinction to the building up in the wet plate by the application of the alkaline developer, which, to my mind, accounts partly for some of the mishaps that frequently occur to all of us. But I think it hardly fair that the Doctor should so summarily have dismissed the photo-physical part of development, especially so in view of the lately very striking discoveries made in regard to light. I refer to its production of sound. It was found, so the report states, that when a beam of sunlight was thrown through a lens on a glass vessel containing lampblack, coloured silks, worsteds, and other substances, this beam of light being cut up by a revolving disc, so arranged with slits as to make alternate flashes of light and shadow, sound was heard, the ear being placed close to the glass vessel, as long as the flashing beam was falling on the vessel. By continued experiments a more wonderful result was obtained. A prism being interposed between the disc and the lens, it was found that sounds were given with different intensity by different parts of the spectrum, and at times no sound was heard in other parts of the same. The report goes on to say that when the red played on the green, or green upon the red, the sounds were the most intense of all, but when blue was used there was little or no sound given off. The published account of these experiments in the *Art Journal* are not as full or well arranged as one would wish, and we will anxiously await further developments. But from these experiments, if correct, it will be necessary to give to light other powers than have been conceded to it, and will considerably modify, if not change entirely, the theories of the formation of the latent image as now held.

Three Theories of Development.

It is well known that, in regard to the formation of the latent image and its subsequent development, there have been three classes of investigators and defenders, two of these classes holding very widely different views on the subject:—The photo-physical, who claim that the action of light by its dynamic force so arranges or disarranges, as the case may be, and so makes less stable, the molecules of silver held in the gelatine film as to enable the developer to bring forth and render visible the image unseen until action has taken place.

The photo-chemical, who claim that it is a tolerably certain fact that under the action of light the haloid of silver, the bromides, chlorides, and iodides have a tendency more or less powerful to return to the metallic state, which tendency is promoted and made permanent by the action of developers which are always reducing agents; that is, they are substances which are able to reduce the soluble salts of silver to the metal state. But will either of these two theories account satisfactorily for all the changes that take place from the time of exposure to the fully developed plate?

The third class are in favour of a combination of the two classes, or claim a mechanical and chemical combination, and set forth thus: The dynamic action of the wave of light, setting free the invisible particles of silver in the granules which form the emulsion on the plate, and these nuclei of metal acting as centres upon which the chemical action may take effect and proceed to the end. We know that some agents have the power of starting an action, and that others, though not able to start the act, have the power of continuing it and completing it. Another theory is that the development of a negative may be effected in one or two ways. First, the new compound may possess an attractive force. The action of light on sensitive compounds of silver tends to cause the formation of a substance capable of attracting the metal of which it is a salt when slowly deposited from a solution. This first deposit is capable of attracting more of the metal, and in this way an image is gradually built up. This is the theory of the physical development of the wet-collodion plate. If the theory of the dynamic power of light can be proved, it can also be used as a theory for the development of the dry plate. Secondly, the image may be the result of the reduction, more or less complete, to a more elementary state of the altered compound when treated with certain solutions, in which state it may have the same attractive power as before. This is the *rationale* of all alkaline development.

"Actinic Force" and "Dynamical" and "Mechanical" Powers of Light.

But to return to the discoveries previously mentioned, and subsequent ones following rapidly, as they will. If correct they will of necessity displace to a great extent, if not entirely, the vagueness that now surrounds the words "actinic force," "dynamical," and "mechanical" powers of light—words that are too frequently used to conceal our ignorance or to impress upon the minds of others an erroneous estimate of our own wonderful knowledge. If a wave of light is capable of producing sound, it must have ponderance, a power to disturb an equilibrium, to disrupt and to separate, in fact, a dynamic power in many ways. By dynamic power we mean the power inherent in light to strike, to move, arrange, separate, congregate, disrupt, build up, or destroy any of the elementary substances, and in many cases their compounds upon which it acts.

The very disturbances which these waves of light are subject to in passing from and through different media must of necessity cause the generation of an immense amount of energy, and when we call to mind the immense velocity of these waves of light, and their uncountable number, we cannot as yet estimate the force contained in a single ray, or the power it exercises upon any sensitive substance it impinges on. It has been repeatedly denied that light produces any separation of the elements in the formation of the invisible image, such as occurs when a visible image is formed by its action. But where is the proof for this assertion? I have as yet been unable to find it, though I have sought for it diligently, and am forced to believe it to be the *dictum* of one, repeated by others as true. The fact is, that, surrounded by light, we have all the time been wandering in darkness. Cannot the occurrence of halation or solarisation be explained if we give due credit to the dynamic power of light, as defined? By halation we mean not only the havoc it plays on a window in an interior, but also with a landscape, the foliage becoming blurred, losing its true tone value, and thus becoming both inartistic and unscientific. We have been taught that the reflection of light from the outside or back of the glass or transparent support is the cause, and to prevent it we must back the plate with some opaque substance in optical contact. This explanation and teaching is true, as far as it goes, with our rapid plates and films. But why do these returning rays exercise this power, and produce this effect, if they have not hammering force, so to speak, upon the already disturbed molecules of silver in the film?

Wuestner's "Improvements" on the Sandell Plate.

A plate has recently been introduced in England, called the Sandell plate, that is said to be entirely free from a chance of this mishap. It is coated by two or three emulsions of different sensitiveness, and to my mind this tells the story. The first coat is decidedly less sensitive than the others; in other words, the light power is used up by the time it reaches the glass, and there is no reflection.

The objections raised against those plates, in the main, consisted of the extreme length of exposure said to be necessary; but even here "the doctors disagreed." Wuestner, of Jersey City, has very much improved the Sandell plate. His first substratum was a slow orthochromatic, and upon that spread one or two emulsions of high and highest sensitiveness, working upon the premises that halation occurred less with dyed than plain plates. Since then he has also prepared another brand, simply with plain bromide of silver emulsions of different degrees of sensitiveness. It is said that either of these plates works rapidly, and can be safely used for instantaneous exposures, and that halation has been reduced to *nil*. The reversal of the image is evidently caused by the same action of light as in halation, but that action has ceased before halation is produced.

Fog.

The veiling and the ultimate production of fog can be accounted for if we agree that the dynamic action of light causes the molecules of silver to be so arranged and freed from their environment in the gelatine film, so that the latent image is formed, and, by development, made visible. All goes well if there are plenty of molecules of silver for the developer to act on. But let the film be weak in especially the iodide of silver, we find at a certain point the developer stops its work. An additional quantity of the alkali is added, the work begins again, then stops. More alkali is added to force the developer. Suddenly a veil appears, followed quickly by a fog that destroys our work. You may ask me for my explanation of this destruction. The plates most subject to fog are those koown as "rapid." The film is thin and very delicate. Bromide of silver is in excess, the iodide much less than normal. Whilst the light was so arranging the molecules of silver to form the latent image, it doubtless disarranged and partly separated some adjacent molecules, not needed for the image, from their weak support. The development ceased because all the silver of the image was used up, or nearly so. More alkali, the accelerator, caused the using up of the remaining molecules. An additional dose of the alkali started the pyro or reducing agent in search for more material to work upon against the adjacent only partly protected molecules, and then—well—you all know what happens when a lighted match touches a pile of gun cotton.

John H. Janeway, M.D., U.S. Army.

THE PHOTOGRAPHIC SOCIETY'S LECTURES ON "PHOTOGRAVURE."

No. II.—Etching the Plate.

On Friday evening last Mr. Herbert Denison, of Leeds, delivered the second of two lectures on *Photogravure*, in connexion with the affiliation scheme of the Photographic Society of Great Britain. There was again a very large attendance. Mr. J. Traill Taylor presided.

Cleaning the Plate.

After giving a brief *résumé* of the previous lecture, which dealt with the preparation of the carbon negative or resist, Mr. Denison next treated of the copper plate for its reception. The plate, he said, should have a perfect surface, and be free from scratches. It should have bevelled edges, which avoid the risk of the plate being scratched in after bevelling. To clean it from grease, &c., which might cause irregular etching, lay the plate on a piece of clean paper larger than the plate, and rub the face with cotton wool moistened with a solution of American potash, strength immaterial. When the greasiness has disappeared, rinse the plate under the tap, and rub with another pledget of cotton wool moistened with nitric acid solution—1:3; rinse again, and rub over with washed whiting moistened with a five per cent. solution of ammonia. Whiting for the purpose can be prepared by mixing ordinary whiting with water, decanting the solution after the coarser particles have settled, and allowing the finer particles to settle when the whiting is dried for use. The plate should have a final rinse in hot water, and be dried with a clean cloth.

Laying the Ground.

The bitumen ground is laid in a box, the size of which depends on the size of the plate. Through the bottom of the box wire nails are driven from the outside so that the points stick up inside and serve as a rest for the plate out of the way of the dust, which will lie at the bottom of the box. A piece of wire netting fixed at a convenient height answers the same purpose, or a little stand of two pieces of wood in the form of a cross. The inside of the box should be lined with glazed paper to prevent the adhesion of coarse particles. The plate is admitted through a door in the box, and the latter is suspended on pivots so as to be easily revolved. About half a pint of finely powdered bitumen is placed in the box, which is revolved about twenty times, when the plate is placed in

position, and after from three to five minutes the plate is taken out. It will have a layer of bitumen in small particles.

The more delicate the subject the finer the grain required; a dark subject requires a coarse one. The quality of the grain can be varied by allowing the dust in the box to settle for a longer or shorter time, or by leaving the plate in the box a longer time, or by inserting it again. If the dust is allowed to settle for about two minutes, all the coarser particles will have subsided, and only the finest will remain in suspension; so that, if the deposited dust is found to be insufficient, the operation can be repeated. For ordinary subjects Mr. Denison finds that the most suitable grain is obtained by allowing the dust to settle for from half to one minute, and leaving the plate in the box for ten minutes.

Fixing the Ground.

This is done on a copper-plate heater—that is, a plate of iron about a quarter of an inch thick, and larger than the plate to be heated, placed on a suitable gas-stove. In a makeshift arrangement, a sheet of paper is placed under the copper plate, which is set on the heater and watched till the ground is seen to become transparent and afterwards to darken. The plate is allowed to cool spontaneously. If the plate has not been heated sufficiently, the ground will not be attached to it; if too much, the particles of bitumen will run together. To find whether the ground is properly attached to the plate, a camel's-hair brush should be applied to a corner of it when cooled, and the plate examined with a glass.

The exposed tissue, having been brought into contact with the plate under water and squeegeed down, is allowed to remain so for about ten minutes; then immersed in water at 100°, the paper backing stripped and development carried on as previously described. The resist is dried with methylated spirit and water, the former being added until all the water has been removed from the film. When dry the margin of the copper is protected with black varnish, a line being first of all drawn round it with a draughtsman's ruling pen charged with black varnish; the back of the plate and the edges are also varnished. The plate before etching should be kept in a cool room to avoid stripping or cracking of the film.

Etching the Plate.

The iron perchloride etching solutions to be employed are:—

No. 1.	45°	Beaumé's Scale,	47	per cent.	of iron	in the solution.
,, 2.	40°	,,	41	,,	,,	,,
,, 3.	38°	,,	38	,,	,,	,,
,, 4.	35°	,,	35	,,	,,	,,
,, 5.	27°	,,	27	,,	,,	,,

The stronger the solution the less penetrating power it has; a solution at 45° will only penetrate the thinnest part of the film, one at 27° will penetrate any thickness. No. 1, therefore, will etch the deepest shadows, No. 2 the next thinnest portion of the film, and so on to No. 5, which penetrates the thickest or high lights of the picture. It requires some experience to decide for how long each solution should be allowed to work before the plate is transferred to the next weaker, but a good guide is to allow each solution to operate until the darkening of the copper ceases to spread to a thicker part of the film; when this occurs, the plate should be transferred to the next solution. The action of each solution after the first is cumulative. The etching of the plate as a rule takes from eight to twelve minutes; No. 1 solution taking one minute, No. 2 two, No. 3 about three, No. 4 two or three minutes, and No. 5 until the highest lights are discoloured, and from half to a minute longer. It is advisable to use the solutions at, say, 70° Fahr. The iron solution is made by putting about 7 lbs. of solid perchloride into a large wide-mouth bottle and pouring boiling water on it sufficient to cover it; the liquid is drawn off with a syphon, and will register between about 43 and 45 on Beaumé's scale, a portion of it can be evaporated down to form No. 1 solution, and water added to obtain the other four strengths. If the resist has been printed on standard brown tissue to a depth only just sufficient to give detail in the shadows, no difficulty should be experienced in watching the darkening of the copper beneath.

Cleaning the Plate.

When etched, the plate is washed under the tap, and rubbed with the fingers until the film is removed. After drying, the varnish is removed from the margin and back with a pad of cotton wool moistened in benzole, which also takes away the ground. The plate is next rubbed with another pad of cotton wool, a small quantity of spirits of turpentine having been poured on the plate; after drying, it is further cleaned with cotton wool moistened in methylated spirits and dried, the final polishing being given with the washed whiting and five per cent. solution of ammonia already spoken of. The whiting being removed with dry cotton wool, the plate is ready for printing.

Making Corrections.

A proof is next pulled to see what corrections are necessary. Portions of the high lights which have been edged too deeply may be reduced by burnishing with a steel burnisher, faults caused by spotting and pinholes filled in with an etching needle, and the light portions strengthened with a roulette. If the plate has not been etched sufficiently, it may be re-etched, which is done by rolling up the plate with a gelatine roller using a special ink composed of

Spermaceti	14	ounces.
Stearine	6½	,,
Asphaltum	2¼	,,
White wax	6	,,

The asphaltum is first melted and the other ingredients added gradually. This is mixed with an equal quantity of lithographic ink and made thin enough for use with turpentine after rolling up, the plate is slightly warmed and re-etched with an iron solution at 40°.

During the evening Mr. Denison demonstrated the preparation of the copper plate, the development of the resist, and the etching of the plate, and introduced Mr. Reardon, of Messrs. Brooker & Co., copper-plate printers of 78, Margaret-street, who printed from several plates.

Steel Facing the Plate.

At the conclusion of the lecture Mr. Denison described the method of steel facing a plate. It is as follows:—A wooden box has two brass rods running its whole length, and from them are suspended the copper plate and a plate of iron measuring one quarter of an inch, thick face to face. The solution in the trough is composed of one pound sal-ammoniac and one gallon of water. The electricity is supplied by a battery consisting of a stick of carbon in a porous cell, the latter being surrounded with a plate of zinc and the whole contained in an earthenware jar. In the outer cell is sulphuric acid solution 1:10, in the inner bichromate 3:20. The rod from which the iron plate is suspended is connected with the carbon anode and that supporting the copper with the cathode. The current is allowed to pass through the trough for two days before being ready. The plate should be carefully cleaned before steel facing, first with turpentine and a nail brush, then with benzole and rinsed under the tap, and then put in caustic potash solution 1:10 for half an hour. It is further rubbed and cleaned alternately with nitric acid 1:20 and with whiting and water, the operation being repeated until the plate is chemically clean. A piece of copper wire is soldered on to the back, and by this the plate is attached to one of the brass rods opposite the plate of iron. A sufficiently thick coating will be obtained in about half an hour.

The proceedings terminated with a vote of thanks to Mr. Denison, who, in acknowledgment of it, expressed his pleasure at the interest which had been taken in the lectures.

MULTIPLE-COATED FILMS IN PRACTICE.

The promptitude displayed by American dry-plate makers in placing multiple-coated films, primarily designed to resist halation, on the market so soon after the introduction in England by Messrs. R. W. Thomas & Co. of their double and triple-coated plates, as well as the many interesting discussions to which the points involved have given rise, says much for the acumen of Mr. J. T. Sandell in devising and taking advantage of this system for curing one of the commonest defects to which negatives on single coated films are liable. It must be obvious to the photographer that, by the superposition of a rapid film upon a very slow one, both back reflections and lateral spreadings of the light rays are largely, if not entirely avoided, and as it is conceivable that these phenomena are present in most subjects, not counting difficult interiors, upon which the lens is brought to bear, the gain in vigour and brilliancy of image, in the proper separation of tone and the better and truer rendering of gradation by the use of plates having this semi-catalytic substratum, so to speak, should be highly welcomed by those who are alive to the influence of halation, which Mr. Sandell, with considerable show of reasoning, regards as an almost omnipresent evil, in flattening and degrading the image. Extending the same principle a step further, a triple-coated film designed for interior work, which both dispenses with backing and gives a long range of exposure latitude, thus rendering it virtually impossible for the photographer to over-expose in this kind of work, should also prove a boon of great practical service.

It is with these two objects in view that Messrs. Thomas and Mr. Sandell have been working; but there is a third, which affects even the humblest and most incapable amateur. It is this:—That where the minimum normal exposure of the top film has not been under-estimated, the latitude in exposure (of course, to be followed by suitable develop-

ment), is bounded by such widely separated limits that, for all practical purposes, one may, by taking advantage of the image-forming properties of the lower film, ignore, or rather clear off, the fogged impression on the top film, with the happiest after-results, so far as the negative is concerned; or, where he has sufficient command over his developer, can produce a printable negative straight away. This, indeed, would appear to show that one can consistently over-expose with impunity with multiple-coated plates, without apprehending fatal consequences, and, within the limits spoken of, may be independent of exposure calculations.

As bearing upon the matter, we have lately, by the courtesy of Mr. J. T. Sandell, inspected a large number of 15×12 negatives, on Thomas's double and triple-coated plates, which that gentleman took during a recent visit to Italy and Switzerland. The subjects chosen embraced Alpine views, and exteriors and interiors of Roman, Venetian, and Milan churches, palaces, and monuments. The outdoor views were taken on the double-coated plates, and had a range of exposure of from a minimum of a quarter of a second to a maximum of many hundreds that length of time. In the Alpine views, the distance, which in all probability with an ordinary plate and an incorrect exposure would have been lost, was rendered with great force and strength; the exteriors of St. Mark's, Venice, St. Peter's, at Rome, two or three Venetian palazzi, the Doge's Palace, and other subjects exhibit, not only an almost ideal preservation of crispness in the relative translation of tones throughout the scale, but also where marble was contrasted with darker stones, and where, as in the case of St. Mark's exterior, the elevation is adorned with frescoes, a most faithful rendering of the respective colour values.

Mr. Sandell admittedly chose very difficult tests, and at the same time pitted himself against the best-known Continental photographers, several examples of whose work on the same subjects he also showed us, side by side with his own pictures. We must say that in the limited time at his disposal, Mr. Sandell, by means of his multiple-coated plates, produced pure photographs of his subjects where the Continental photographers had falsified the tone renderings to an alarming extent. But Mr. Sandell's success was undoubtedly the most striking in his interior exposures—particularly in the case of Milan Cathedral, which had five hours on a triple film. Commercial photographs of this subject are not to be had, so difficult is it regarded by photographers. Interiors of St. Peter's at Rome, the Jesuit's Church at Venice, St. Mark's, St. John Lateran, and many others all taken on triple films, and with long exposures, appeared to us to show this class of work to a degree of excellence seldom met with, the absence of halation, the tone renderings, and the wealth of detail being remarkable.

We understand that a public exhibition of prints from these and other negatives will shortly be given.

THE STEREOSCOPE AND STEREOSCOPIC PHOTOGRAPHY.

[Brixton and Clapham Camera Club.]

Many authors in ancient and more recent times have observed and commented upon the fact that the image of any near object seen by one eye differs very considerably from that seen by the other, although no blurring is apparent when the same object is observed with both eyes, and several writers in the last century and in the early years of the present surmised that it was to this that our impressions of the solidity and relative distance of near objects were principally due. Professor (afterwards Sir Charles) Wheatstone proved that this is the case by the invention, in 1838, of the stereoscope, which may be primarily described as an instrument by the means of which two dissimilar views of the same object may be simultaneously presented one to each eye. Professor Wheatstone's stereoscope consisted of a long board, at each end of which one of the two pictures was placed, one representing a solid object as it would be seen by the left eye, and the other the same object as it would be seen by the right eye. The pictures were placed in an upright position parallel to and facing each other, and midway between them were two plane mirrors adjusted so that their backs formed an angle of ninety degrees with each other, and their fronts angles of forty-five degrees with the front edge of the board. The observer had to place his eyes as near as possible to the mirrors, the left eye before the left-hand mirror and the right eye before the right-hand mirror, and then adjust the position of the two pictures by means which were provided until similar points in the two reflected images coincided with the intersection of the optic axes, when the two pictures blended into one, which had all the appearance of solidity. As this instrument has now been entirely superseded by a more convenient one, it is not necessary for me to enter deeply into its merits or demerits, and it will be sufficient to say that its principal defects were its clumsy and unmanageable size, the great loss of light by double reflection, and the difficulty that there was in securing an equal illumination of the two pictures.

The discussion to which the introduction of this instrument gave rise among scientific men led to the invention of several other stereoscopes in the course of a few years, and, among others, of the lenticular stereoscope by Sir David Brewster, who appears also to have been the first to suggest the application of the stereoscope to photography.

After this point in its history had been reached, the stereoscope rapidly emerged from the experimental stage, and became in a few years a most popular scientific toy. Since then it has lost favour a great deal, but now there are many signs that among amateur photographers at least it is about to achieve a greater popularity than ever, and deservedly so. It is not necessary for me to describe the lenticular stereoscope to you, as you are, no doubt, perfectly familiar with its appearance, but I will attempt to give an explanation of its mode of action.

If we look at any object through the centre of a double convex lens, such as an ordinary reading glass, and then, keeping the eyes fixed, move the lens slightly to one side, we shall find that the object will appear to move also, but in a contrary direction. This is because the rays of light proceeding from the object travel in straight lines while they pass through the centre of the lens; but, when the lens is moved so that they pass through its side, they are bent or refracted towards the centre, [the thickest part of the lens, and the object appears to have moved a distance equal to the refraction, because we judge of its position by the direction in which the rays reach us. The lenses of the stereoscope usually act in a similar manner. They are, as a rule, mounted, so that there is a greater distance between their centres than between the centres of the eyes, and one is therefore compelled to look through the sides of them. The consequence of this is, that the rays of light which reach our eyes from the pictures, having to pass through the side of the lens, are refracted in an outward direction, and the pictures appear to overlap each other more or less, according to the extent of the refraction. This will depend upon the extent of the difference that there is (if any) between the distance from centre to centre of the eyes, and the distance from centre to centre of the lenses, and also upon the difference (if any) between the latter distance and the distance of the pictures from centre to centre.

If the lenses are mounted at three-inch centres, and the pictures also at three-inch centres, the refraction will be just sufficient to cause the pictures to appear the same distance apart from centre to centre as are the eyes of the observer, *i.e.*, usually about two and a half inches. If the lenses are mounted at three-inch centres, and the pictures at two and three-quarter inch centres, the refraction will be greater.

There will be, first, the refraction due to the difference between the lesser distance of separation of the eyes and the greater distance of separation of the lenses, and, secondly, the refraction due to the difference between the greater separation of the lenses and the lesser separation of the pictures, and the result will be that the pictures will apparently overlap to the extent of about three-quarters of an inch. It is possible in this way, either by increasing the separation of the lenses or by reducing the separation of the pictures, to cause them to appear completely superimposed, and, when this is the case, no doubt most persons unaccustomed to the use of the stereoscope find it easiest to combine the pictures, but the best effects are not to be obtained in this way.

It is unnecessary for me to tell you that when we look straight at any object we unconsciously converge the optical axes, so that they would intersect upon that point to which vision is directed in order that its image may be received upon the most sensitive portion of each retina. It is because of this convergence that we are able to judge as closely and accurately as we do of the position and size of near objects. Many instructive and amusing experiments have been devised to prove that this is the case, and one of the most conclusive is to get some one to place a small object, such as a thimble, a short distance away from you, then, closing one of your eyes, attempt to pick it up. The result will be, nine times out of ten, that your first effort will be a failure. From this experiment, and others of a like nature, it becomes evident that, if we wish to arrive at a true conception of the size and distance of whatever may be the subject of a stereoscopic photograph, the two pictures must be so mounted, or the lenses of the stereoscope so adjusted, that when we are looking through them the convergence of the eyes shall be neither more nor less than it would be if we were looking at the view itself from the point at which the photograph was taken.

When we look at a distant object, we see it with so little convergence of the optical axes, that for practical purposes they may be considered parallel. This fact furnishes us with an easy guide for the mounting of stereoscopic photographs. They should be mounted so that when the eyes are directed through the lenses of the stereoscope towards similar

distant points in the two pictures, the optical axes are practically parallel, and this will be the case when the distance between such similar distant points in the two pictures is equal to the distance between the centres of the two lenses.

J. A. Butler.

(To be concluded.)

THE "INFANTS" AND THE PHOTOGRAPHER.

Simmonds v. *Edwards.*

Two young women last week brought an action, through their father, against a photographer at Worthing, by which they sought to recover the sum of 7*s.* 6*d.*, which they had entrusted to him under the following circumstances:—The elder of the girls informed the Judge that she and her sister were going to have some photographs taken, and engaged the defendant for that purpose. They paid 7*s.* 6*d.*, but their father, hearing of their intention, would not allow them to put it into effect.

The Judge: "I suppose the defendant is still willing to take your portrait?"

Mr. Edwards: "Yes. I never refused to fulfil the contract."

The Judge: "You decline to return the money?"

Defendant: "Yes."

The Judge: "But you have not had the trouble."

Defendant: "I have lost time; I kept the engagement open. Mr. Simmonds is so obstinate that he stands in the light of my doing business."

Plaintiff: "My daughters are both under seventeen; they are not of age to make a contract."

The Judge: "Very likely. If they had not paid the money, very likely I should have said he cannot recover."

Mr. Simmonds said his daughters were not going to be taken themselves, but made the engagement for his younger children, to which he objected.

The Judge: "Don't you like a little surprise?" (Laughter.)

Plaintiff: "When I have a family group I should like to pay for it myself."

The Judge: "You were not to be in it?"

Plaintiff: "No, sir." (Laughter.)

Defendant said the money was paid by the plaintiff's son.

The elder daughter said that was not so; "Jack" was going to contribute to the expense, and told them that Mr. Edwards would take the photograph, as his ("Jack's") name was good there. But he did not send any money, owing to the objection made by his father.

The Judge said it was a simple question of law, and, although he thought the plaintiff was entitled to recover, his daughters being both infants, he should like to have time to consider the case, an Act of Parliament having recently been passed which affected minors. He would give judgment at the next Court.

Our Editorial Table.

England's Film and Dry-plate Varnish.

This varnish of Mr. J. Désiré England possesses the advantage of not necessitating the heating of the negative to which it is to be applied. It flows smoothly, and dries quickly with a hard, tough film.

Payne's Crystal Cage.

Mr. J. H. Payne, Mexborough, Rotherham, has devised a modification of such crystal cages as we have previously seen. As the name implies, the "cage" is a porcelain vessel, perforated with holes, into which the crystals to be dissolved are placed. There is a flange, which may rest on a beaker, tumbler, or other vessel containing water, and by a series of projections on the cage and notches in the flange, the former may be lowered down to any desired depth. A small calico bag is supplied for inserting in the cage, which permits of solution and filtration proceeding automatically and simultaneously.

PATENTS COMPLETED.

Improvements in and connected with Photographic Apparatus.

No. 591. Edward Sledge, 46, Rural-vale, Northfleet, Kent. *December* 31, 1892.

My invention relates to a device to be used in connexion with an ordinary photographic camera, and has for its object a more rapid and inexpensive way of changing the plates of the dark slide of the said photographic camera. By its means, moreover, the use of more than one dark slide is obviated.

In carrying my said invention into effect, I make a slotted opening the width of the plate in the end of the dark slide. Over this opening, and securely fastened thereto to prevent the admission of light, is fixed an attachment called a receiver.

The said receiver is made of brass, or some similar metal, and possesses a mouthpiece, with lips curving outwards, so that a lightproof bag may be attached thereto for the purpose of introducing plates for exposure and removing the said plates from the dark slide after exposure without the operator being compelled to make use of a dark room where he can open the slide in the usual manner. In order to prevent ingress of light when the bag is removed, a long sliding piece, working within grooves in the receiver, below the mouthpiece, covers the slotted opening in the dark slide when the bag is not attached. When it is desired to introduce or remove plates, the aforesaid sliding piece can be pulled out by means of a lug, pin, or the like, after the aforesaid bag is attached. Although for the purposes of description I have mentioned a bag for carrying the plates, I do not confine myself to the use of a bag; any suitable receptacle for containing plates can be employed, for example, a box having two suitably slotted openings, corresponding to the opening of the mouthpiece of the receiver of the dark slide, the mouthpiece of the receiver of the latter being, of course, slightly modified for this purpose, the lips of the said mouthpiece being arranged to slide in corresponding grooves in a small metal receiver fixed on the box or plate-holder as shown, the said box being also provided with a sliding piece, similar to that on the mouthpiece of the dark-slide receiver to prevent the access of light.

The opening at one end of the box serves for introducing the plates into the dark slide, and the one at the opposite end for receiving the plates after exposure in the dark slide.

In order to prevent the plate being scratched or frayed during the process of transferring, small rollers or lugs are fitted to the corners of the slotted mouthpiece, so that the plate may only bear on its edges.

Improved Magic Lantern Slide carrier.

No. 2381. Barras Ramsay Reed, The Riding, Riding Mill-on-Tyne. *December* 31, 1892.

My invention consists of a shutter working vertically across the opening in lantern slide-carrier, and is capable of being applied to all slide-carriers now in use.

It is intended to give the effect of a curtain rising and falling upon the picture exhibited on the screen. It works independently of the lateral or vertical motion of the slide-carrier, and can be used at the option of the operator.

I take any ordinary slide-carrier, and at the opening provided for the purpose of throwing the light upon the picture, I cut a slot or groove in each of the top and bottom frames of the carrier, and opposite to each other, such slots or grooves being as long as may be found necessary.

Into these slots I insert my shutter, made of wood, brass, or other metal, talc, glass, vulcanite, or any description of material which may be thought suitable.

The form of this shutter consists of one part being so constructed to cut off the light of the lantern from the picture when placed in position in front of the condenser, the other part being a rectangular opening, which permits the light to be unobstructed when desired.

Improvements in and connected with Store Boxes or Change Boxes for Photographic Cameras.

No. 4886. John Rudolph Gotz, 19, Buckingham-street, Strand, London. *January* 14, 1893.

This invention relates to apparatus for storing the sensitive films or plates used in photographic cameras, for exposing the said plates in the camera one after the other, when required, and for storing them again after exposure.

The principal object of the improvements is to construct a simple and light change box suitable for holding a great number of films in a small space, and for exchanging the exposed films for new films without unnecessary manipulation or loss of time.

The store box may either be permanently fixed to the camera slide (dark slide), so that both must be attached to or removed from the camera simultaneously, or the slide may be separate, and constructed in such a manner that it can be attached alternately to the store box and to the camera.

If thin flexible films are used for exposure, each film is mounted on a light, but sufficiently strong and stiff, backing, preferably of aluminium or other suitable sheet metal, so that the film need never be touched with the fingers or removed from the backing during the different manipulations.

If the camera slide and the store box are made in one, the camera slide forms the face of the box, and the external width of the latter is slightly less than the clean opening in the camera.

The face of the box contains a sliding door similar to that used in ordinary camera slides. Behind the sliding door and parallel with the same the box contains a hinged frame, adapted to hold a film together with its backing or carrier mentioned above. The said frame is preferably hinged at its lower edge, so that it may be turned backward into the box, and is provided at its back with springs, which press it into position. The top of the box is provided with a door hinged on one of its edges, so that it can be opened outward into a flexible bag attached to the top of the box. The said top door has on its inside a ledge or other suitable detent, adapted to hold the edge of the film frame when the door is closed, and to release the same when the door is opened

The back of the store box contains a door, through which the box is charged with fresh films, the latter being placed upright between the back door and the hinged frame. The face of the hinged frame for carrying the films has a pair of ledges, one of which is slightly dovetailed, for holding the edges of the film when the latter is put into its place for exposure.

The box may contain a vertical partition or division plate for separating the unexposed films from those which have been exposed.

After the box has been charged with sensitive films and attached to the camera, the front door or slide is opened for exposure as usual. After exposure, the operator introduces his hand through the flexible bag, opens the top door, and thereby allows the film-carrying frame to drop backward into the box. He then removes the exposed film from the frame, places it at the back of the hinged frame, draws a fresh film out from the box into the bag, and places it on the face of the frame. Finally, he closes the frame forward into its normal position, and secures it by shutting the top door, after which the apparatus is ready for another exposure.

In the case of large store boxes the camera slide is made separate, as mentioned above, and consists of three principal parts, namely, the rectangular frame or body of the slide, adapted to be secured to the camera like an ordinary camera slide, a sliding door which closes the front of the camera slide as usual, and a hinged back door or frame which closes the slide at the back and serves to hold the film and carrier. This door may be provided with a spring, bolt, or other suitable locking device for locking it for the purpose of making an exposure.

The store box is a flat rectangular box provided with three doors, one in front, one at the back, and one at the top. The front door, or face of the box, may be an ordinary sliding door, or it may be flexible like a revolving shutter, so that it can be drawn from the back of the box. The top door is hinged on its rear edge, and opens into a flexible bag attached to the top of the box, as in the previous case. The back door is drawn for charging the box with plates. The front of the box has a pair of holders, or ledges, for holding the camera slide when an exposed film is to be changed.

After a film has been exposed in the camera, the slide is removed from the camera and attached to the front of the store box; the operator then withdraws the front door of the store box, introduces his hand through the flexible bag, opens the top door, and unlocks the hinged carrier frame, so that the latter turns back into the box behind; he withdraws the exposed film, takes a fresh film from the box, places it on the face of the hinged frame, after which he closes the latter and shuts down the top door. The camera slide is now removed from the box and again attached to the camera for another exposure.

Instead of placing the bag at the top, it may be on one side, and the position of the various slides or doors may be varied to correspond.

An Improved Dish or Case for Use in Photographic Development or other Process.

No. 22,633. Harry Rayner, 27, Francis-street, New Leeds, Leeds, Yorkshire. *January* 14, 1893.

The object of this invention is to construct a covered dish or case in, or within which, a photographic plate or film may be exposed to the action of a developing or other agent, or any similar process be carried on which requires to be performed in a non-actinic light, so that, by employment of the improved dish or case, which is made so that it is not affected by the chemicals used, any process of this nature may be carried on under inspection without the necessity of having recourse to a so-called "dark" room, or chamber, into which actinic light is not suffered to enter.

The improved dish or case comprises an inner dish, preferably made rectangular, and consisting of a bottom and sides, the whole being made of glass in one piece, and properly annealed. Near, or at one corner, is a projecting lip, open above, its upper edge being preferably about level with, or a little above the level of, the upper edges of the sides of the said inner dish. This lip or spout has free communication with the interior of the dish, and serves for receiving the developer, or other liquid which is poured into the dish, and for emptying the same therefrom. A vertical inner wall or screen, likewise of glass, lies in front of the lip inside the dish, and extends from the floor of the dish up to a level with the side walls thereof, and from the side wall of the dish next to which the lip is made for some distance parallel with the wall on which the lip is made, extending past the lip, and terminating so as to leave a passage way between it and the wall for entrance or exit, of the liquid from or to the lip. This screen is intended to intercept the actinic rays of light which might enter at the lip. The whole inner dish may be made of ruby or other non-actinic glass (that is to say, glass which prevents passage of actinic rays while permitting of the passage of visual rays, or a certain quantity or amount of the visual rays), or only the floor and the screen may be made of such non-actinic glass.

The inner dish aforesaid is enclosed within an impervious frame which will usually be made of tinned iron or other sheet metal varnished or japanned. This frame covers in the sides of the dish, and its upper face is cut out at the centre so as to leave a projecting flange all round, which lies horizontally at a slight distance above the upper edge of the walls of the inner glass dish, so as to leave a space for a sliding cover of non-actinic glass which may be slid into a slot in the frame left therefor, and so cover the whole dish while its edges are guarded by the frame. The central hole in the upper face of the frame is provided with a hinged cover for closing it, and the said frame has also a hinged cover which may be used to close the lip aforesaid. The frame does not extend far under the bottom of the glass dish, but leaves a free space thereunder, so that the plate or film or other object in the dish may be viewed by either reflected or transmitted light when under the process of development or other treatment.

Improvements in or appertaining to Printing Plates or Blocks formed by Photographic Means.

No. 5008. Joseph Hines, 20, Riding-street, Southport, Lancashire. *January* 14, 1893.

This process is designed to supersede known methods of photo-mechanical printing by the substitution of a quicker, simpler, better, and less costly mode of reproducing photographs in the printing press for pictorial illustration in newspapers, books, magazines, and other periodicals, and in job printing generally, than any which has yet been placed before the public.

It is intended to fulfil the function of supplying to the printing profession metallic plates to be screwed upon type-high blocks of wood bearing upon their surfaces photographs in a hard, durable substance capable of resisting the pressure of the printing press, so that they can be used equally by the newspaper and book press, and printed along with the type simultaneously with the descriptive matter accompanying it, in newspapers, periodicals, magazines, books, or any literary or artistic production of that class on any printing machine.

In carrying out my invention, I coat a metallic plate, preferably a stereotype plate, with gelatine, so attached that it will not ultimately strip off; then sensitise it chemically, so as to become sensitive to light, and allow it to dry. When dry it is ready for exposure under a negative. After being sufficiently exposed to light it is developed in a bath of hot sulphate of iron, which has the property of shrinking those portions of the gelatine not acted upon by the light, hence its name of intagliotype, and leaving the rest of the picture a raised surface, without swelling the gelatine or softening it, thereby enabling it to be printed as soon as the plate is dry, which only takes a few minutes. The plate is then screwed on to a wooden base, the whole making a type-high block ready for the printer.

One of the features of the invention is the preparation of the negative so as to break it up in such manner as to produce the effect of an engraving, and to enable it to print properly. This is effected by the use of thin sheets of transparent cellnloid previously printed with the lines, dots, cross-hatch or stipple, as may be required, and which are placed before the negative in order to impart their characteristics to the ultimate plate. The best effects are produced by taking reverse negatives with different screens, the last one, with all the desired effects upon it, being the one used with the final sensitised plate. (For rough-and-ready work, the screens may be dispensed with altogether by the use of a plate previously embossed with fine dots, but the results are not nearly so effective as with the screens, by which any effect of a line engraving can be readily reproduced.) The invention applies to either method employed, the treatment of the plates being the same, though the resultant picture is entirely different. The great value of the invention lies in the fact that it is simple, rapid, and effective, there being no delay arising from the drying of the gelatine, inasmuch as it does not require it, the action of the sulphate of iron not only shrinking it, but tanning it like leather, and enabling it to bear a prodigious pressure and print an incredible number of impressions without sensible deterioration.

In its simplest form, it consists of the photographic representation of any picture in lines or stipple, in imitation of a line drawing or engraving where there are half-tones.

The manipulation, when taking the negative, is the same as that of any ordinary photograph, and the finished negative requires simply to be placed upon the sensitised film of the metallic plate, and exposed for a short time, to effect all that is necessary, the resultant picture not requiring to be touched by etching tool, graver, or acid, but simply screwed down to a wood block ready for the printing press.

When the first negative is obtained, all that is necessary is to have at hand a few dry plates and transparent printed screens, developing solutions, dishes, &c., and a photographic printing frame. In order that the resultant picture may be right-handed, like the original, reverse negatives must be procured, and advantage is taken of this fact to introduce the transparent screens at these intermediate stages, two of these screens being of parallel lines ruled opposite ways, and one being of the dot-and-stipple order. They are so employed as to produce a hatch over the denser portions of the photograph, plain ruling in the half-tones, and a stipple throughout the lighter parts, breaking the whole up into variegated grains of distinct characteristics, corresponding in appearance to an ordinary engraving.

A metal plate, bearing on its surface a sensitised gelatine film, is placed under the negative last obtained, and both together exposed to light, natural or artificial, for the requisite time, which will depend on the strength of the light and the nature of the sensitised salts employed. After sufficient exposure, the plate is immersed in a hot solution of sulphate of iron, which shrinks those parts not acted on by the light, leaving the rest in relief, in addition to so hardening the whole that, when it is dry, which only takes a few minutes, it is quite ready for printing. The whole process is complete from start to finish in about an hour. The resulting block is remarkably durable, being far superior to other gelatine plates, owing to the developer causing shrinkage instead of, as in other processes, causing a swelling of the gelatine. The parts which are to receive the pressure of the printing press, so far from being softened, as would be the case if swelled, are converted into a tough, leathery substance by the double action of the sulphate of iron, which not only shrinks, but tans it at the same time. Its capacity to resist pressure without wearing or abrading is apparently due to the slight elasticity it still retains, but, at the same time, its hardness is so great that it can be taken direct out of the bath and printed at once.

The metallic plate employed as a basis for the gelatine film may be of any suitable metal, but stereotype metal is preferred, as not only cheap, easily cast and worked, but it readily forms a chemical combination with the acetic acid and gelatine. The stereotype plates are cast, varying from one-sixteenth to an eighth of an inch in thickness, according to size, the sizes chosen being those adopted by the photographic profession, and known as quarter-plate, half-plate, cabinet, full-plate, &c., as the idea all through the invention is to keep it within the scope of ordinary photographic manipulation for the sake of simplicity. It is easier to fall into these professional sizes, already in the market, than arbitrarily to fix others which might suit the printing trade better, for they will both have to work hand-in-hand together, and, as both the metal plate and the negative have to go into the same printing frame, they should both be the same size. There is nothing, however, to prevent the printer cutting the plate smaller after it is finished, as the metal is almost as soft as lead. The plates may be cast on either a smooth or grained surface. If the former, they must be scraped, smoothed, and polished, or otherwise brought to a fine, even surface. These plates are reserved for the best work, and very varied and

beautifully artistic effects may be obtained from them, depending entirely on the manipulation of the negative. The grained or embossed plates are for establishments where rough-and-ready cheap production is of more moment than artistic refinement. The newspaper overseer, in a hurry to get to press, will find them invaluable when time is precious, and they are grained or embossed beforehand.

The original negative is all that is required for these plates, nor is it necessary to use screens of any kind, because the pattern on the plate is partially reproduced by the gelatine film in contact with it. The operator, having procured any ordinary negative, places it at once on his sensitised plate, exposes it, dips it into a warm bath of sulphate of iron, and, as soon as the effects appear, withdraws it, screws it down on a wood block, and it is ready without any manipulation beyond mere handling, all the pronounced lines of the photograph come out distinct and clear, the half-tones exhibit the pattern on the plate, and the whites, if not clear enough, can be readily cut away with a penknife. In the case of the polished plate, which is better adapted for book and pictorial illustration of the higher class, the assumption is that the operator desires the best artistic effect he can get, and, therefore, he takes pains to select his screens with discretion and judgment. With his first negative, he uses a screen with fine parallel lines in a perpendicular or diagonal direction, as he may think fit. This results in a reverse negative, having all the characteristics of a positive, except that a thin white line appears throughout all the denser portions of it. He now introduces a dot or stipple, the purpose of which is to prevent the paper, when it comes to be printed, sinking down into the hollows, picking up the ink which may be lodged therein, and thus creating a smudge. These little pin points, as they ultimately become, bear the paper off the hollows. With the last negative he inserts a screen of parallel lines in a horizontal direction, or diagonal lines at right angles to those of his first negative, and the effects he requires are produced on the final plate in a mixed cross-hatch and stipple.

If he has any artistic feeling, and but a slight knowledge of retouching, he can obliterate lines or dots where he does not want them.

As to the method of attaching the gelatine film to the metal plate, a perfectly clean stereotype plate is made warm, and a warm solution of gelatine in glacial acetic acid is brushed over it in a thin layer. The acetic acid, having a strong affinity for the lead in the alloy of the stereotype metal, forms a close union with it, and, inasmuch as the solution of itself is a well-known adhesive cement, the union is perfect between them. Care must be taken not to mix too much acetic acid with the first coating of the gelatine, as the excess over what is taken up by the metal is liable to incorporate itself with the next film flowed over it to render it so soluble that, when it undergoes final development, it has a tendency to crinkle in those portions not exposed to the light. The plate, being floated with a solution of good gelatine, well strained, is put away to dry in a place free from dust, yet where a current of dry air can get access to it. The film need only be thin, but it should be level and even over all the plate.

The mode of preparing its surface to receive a photograph depends on the kind of light to which it is to be exposed. If for use with daylight or the electric light, it is simply sensitised in a bath of bichromate of potass containing a trace of bromide of ammonium. This soaks through the film and chromes the acetate of lead previously formed below it. It is then allowed to dry, and kept from the light till required. The bichromate must not be so strong as to crystallise on the surface. To prevent this, it is a good plan to lay the plates down on a level place and sensitise them by pouring a little of the solution upon the surface, rubbing it with the finger until the bichromate is absorbed by the gelatine, and finish off with a momentary wash in water.

If neither daylight nor the electric light is available, a plate prepared as described, but with the addition of chrome alum, and well washed, is coated (in place of the bichromate) with a sensitive silver salt emulsion, similar in character and composition to those employed in ordinary dry-plate photography. As this is a much more tender and delicate film than the bichromate, great care must be taken with it at the early stages of the process. It is necessary to employ chrome alum in the first coating of the plate to render it insoluble. The acetic acid and gelatine have, therefore, a small quantity of chrome alum added to them with this object. The ingredients are all mixed together, made hot, and brushed over the stereotype plate, which has previously received a wash of glacial acetic acid dried on. It is highly important, in the case of the silver emulsion, that not a trace of acetic acid be left on the plate in a free state, as it would seriously interfere with the future development of the picture. At the same time too much chrome alum must not be used, as it destroys the adhesive nature of the compound, and causes the film to strip off when dry. The proportions can only be ascertained by experience, as they vary with the kind of gelatine employed, strength of acid, &c. Of course with the silver emulsion process the same care must be taken to exclude all but non-actinic light as with a dry plate, the coating, drying, exposing, and developing being on all fours with other rapid photographic processes in vogue, the only difference being that, when the picture is taken and developed, it is not fixed in the usual way, but at once plunged into warm sulphate of iron, and as soon as the gelatine has shrunk sufficiently, it is wiped with a cloth, mounted on a wood block, and sent to the printer.

Just as the electric light serves the purpose of workers in the bichromate process on dull days when daylight is not available, so the silver process can be utilised where the electric light is not available, and thus it becomes possible to carry on the work by any light, gaslight or candle-light; in fact, the light of a match for a few seconds is ample for some requirements, everything in this particular depending on the sensitiveness of the salt employed. The invention is universal in its scope in this respect, and has the advantage that it can be carried on in the night contemporaneously with other journalistic work without the establishment, where it is conducted, requiring an expensive installation of the electric light, as has been necessitated hitherto. In the matter of time, also, it is an immense advance on all other processes for the same purpose, it being possible, by using embossed plates and a silver film, to obtain a picture capable of being printed in the press within a quarter of an hour of its being taken from the negative, there being no occasion to use screens, or manipulate the negative in any way, the process being purely and entirely automatic.

Where the best and most varied effects are desired, screens of transparent sheet celluloid, printed from engraved plates, must be used. They are cut the size of the plates, and may have any design upon them that fancy may dictate, but simple lines, hatches, dots, or stipples are all that is necessary.

The claims are:—1. The process of forming printing blocks, which consists in forming a gelatine photograph on the material of the block itself and exposing it to the action of sulphate of iron solution, whereby the unacted upon parts are shrunk and the acted upon parts hardened, substantially as described. 2. A printing block formed of a metallic surface almost type high, and a hardened gelatine photograph taken on the surface itself, substantially as described. 3. The improvement in making photographic printing blocks, which consists in forming a fine stipple photographically all over by means of a finely stippled plate, substantially as and for the purposes described.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
March 6	Camera Club	Charing Cross-road, W.C.
,, 6	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 6	Peterborough	Museum, Minster Precincts.
,, 6	Richmond	Greyhound Hotel, Richmond.
,, 6	South London	Hanover Hall, Hanover-park, S.E.
,, 6	Stereoscopic Clnb	Brooklands Hotel, Brooklands.
,, 7	Birmingham Photo. Society	Clnb Room, Colonnade Hotel.
,, 7	Bolton Photo. Society	10, Rushton-street, Bolton.
,, 7	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 7	Exeter	City Chambers, Gandy-st., Exeter.
,, 7	Hackney	206, Mare-street, Hackney.
,, 7	Herefordshire	Mansion House, Hereford.
,, 7	Keighley and District	Mechanics' Institute, North-street.
,, 7	Lewes	Fitzroy Library, High-st., Lewes.
,, 7	North London	Canonbury Tower, Islington, N.
,, 7	Oxford Photo. Society	Society's Rooms, 136, High-street.
,, 7	Paisley	9, Ganze-street, Paisley.
,, 7	Rotherham	5, Frederick-street, Rotherham.
,, 7	Sheffield Photo. Society	Masonic Hall, Surrey-street.
,, 7	York	Victoria Hall, Goodramgate, York.
,, 8	Ipswich	Art Gallery, Ipswich.
,, 8	Leicester and Leicestershire	Mayor's Parlour, Old Town Hall.
,, 8	Leytonstone	The Assembly Rooms, High-road.
,, 8	Munster	School of Art, Nelson-place, Cork.
,, 8	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 8	Southport	The Studio, 15, Cambridge-arcade.
,, 8	Stockport	Mechanics' Institute, Stockport.
,, 9	Birkenhead Photo. Asso.	Y.M.C.A., Grange-rd., Birkenhead.
,, 9	Camera Club	Charing Cross-road, W.C.
,, 9	Cheltenham	
,, 9	Glossop Dale	
,, 9	Hull	71, Prospect-street, Hull.
,, 9	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 9	North Kent	Gravesend.
,, 9	Oldham	The Lyceum, Union-street, Oldham.
,, 10	Bristol and West of England	Rooms, 28, Berkeley-sq., Bristol.
,, 10	Cardiff	
,, 10	Croydon Microscopical	Public Hall, George-street, Croydon.
,, 10	Halifax Camera Clnb	
,, 10	Holborn	
,, 10	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 10	Maidstone	"The Palace," Maidstone.
,, 10	West London	Chiswick School of Art, Chiswick.
,, 11	Hull	71, Prospect-street, Hull.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

FEBRUARY 28.—Technical Meeting,—Mr. Andrew Pringle (Vice-President) in the chair.

It was announced that, at a Council meeting held earlier in the same evening, Mr. H. Chapman Jones had been appointed Hon. Secretary, Mr. E. Clifton Hon. Librarian, and Messrs. H. A. Lawrence and James Cadett members of Council.

The Genie Hand Camera, &c.

Mr. T. P. Watson exhibited and described the "Genie" magazine hand camera of American design and manufacture, a feature of which is its compactness. The magazine is of metal made by machinery to gauges, takes twenty-four films, and the changing is effected by a simple "pull-out" arrangement. Mr. Watson also showed a simple catch arrangement for preventing a second exposure on an Eastman roll-holder, the invention of Mr. Rawley, an amateur.

A Paraffin "Bunsen" Burner.

Mr. Leon Warnerke exhibited a paraffin gas-stove for heating purposes, having the appearance of a Bunsen burner attached to an oil reservoir. It gives off as much heat as gas, and is worked by placing a few drops of spirit on the burner and lighting it. When the paraffin flame is alight, a lever pump increases the flame to any desired intensity. One movement of the pump suffices for two hours. The top part is made of non-fusible metal. The burner has been introduced in Russia, selling at 15*s.*, and Mr. Warnerke thinks it might be useful where a flame for heating purposes is suddenly required and gas is not available.

Acid Amidol.

Mr. H. Chapman Jones said there seemed to be an idea that amidol for development required an alkali. The makers say that the small amount of alkali with the sulphite suffices. There was, however, so little alkali present that he (Mr. Jones) did not believe that it could have any practical effect. By

simply acidifying with sulphurous acid, and giving an exposure of one second with *f*-64, he had produced with the acid amidol practically over-exposure. He could not see the difference between the alkaline sulphite and the developer as made acid, so that it was not the alkali which was practically effective.

The Panoram.

Colonel R. W. Stewart, R.E., read a paper on *Panoramic Photography—the Panoram*, in which, reviewing several of the cameras which had been previously brought out for panoramic purposes, he described his own, which consists of a rectangular box, a little more in length than the focal length of the lens, and a little higher than the width of the film. The camera rests on the head of the tripod stand, which is in the form of a circular disc, and revolves on ball-bearings in a socket. The camera opens so that access can be had to the roll-holder, in which are fixed four vertical rollers. The first has the tissue wound on it, the free end of the tissue is passed across the second and third roller to the fourth, or winder, the last two keeping the film in the focal plane. The winder is controlled by clockwork actuated by a ball and tube. A slit diaphragm is placed between the second and third rollers. In use, the camera is set on its stand and levelled, the clock wound up, the slit aperture adjusted, and a suitable stop put in; the camera is then turned round to point to the left hand of the view, the bulb squeezed, a needle holding the film in position withdrawn, and the camera begins to rotate. Prints of very great length may be developed on the periphery of a drum.

At the conclusion of the paper,

Mr. J. A. Harrison said the same principles were utilised in the Panoram as in the pantascopic camera, but in 1862 rollable films were not available for the purpose. He exhibited an old revolving camera which was actuated by hydraulic power.

The Chairman (Mr. J. Traill Taylor, who was moved to the chair after Mr. Pringle and the President had successively vacated it) said he had in his possession a panoramic picture of Red Lion-square which, with a microscopic object-glass of one inch power, revealed details that were invisible to the naked eye. Many years ago Rawlinson, of Windermere, sent him a panoramic view subtending the whole circle and about ten degrees more.

Mr. W. E. Debenham understood Colonel Stewart to propose that panoramic perspective was in itself truer than plane perspective. This was a mistake. Panoramic perspective would give views which could not be got in another way, therefore, whatever its faults, it came in useful for such views. Panoramic perspective is in itself false when the panorama is on a flat plane. No one could look at Mercator's projection without being struck at the extraordinary disparity in the size which Greenland bears to the tropical countries. As to the perspective being true if represented on a sphere like the eyeball, it was not so. If the photograph was seen on flat surface the only perspective which can give it truly is that of a flat-surface plate. If the photograph is that of a straight row of houses in cylindrical perspective, the effect is that of the outside of a rotunda. The plane of the plate is the same as that of the picture at which we look. As to the distortion of the foreground, as compared with the background, and the middle distance, not occurring in panoramic photography, the difference was between the margins and the centre. As to what Colonel Stewart had called distortion at angles of 80° and less, he (Mr. Debenham) thought he was mistaken. In wide-angle pictures this was the only perspective which would give the true relation of the various parts; he did not think it should be called distortion at all.

The Chairman said a picture subtending an angle of 80° on the base line with a wide-angle lens is very false in perspective. By photographing a row of spherical balls the centre ones would appear round, but as they approached to the margin they would be seen to expand laterally. They should be examined from a point of view equal to the focus of the lens. In a cylindrical picture the eye should be placed in a similar way and the picture looked at close, and then it would all be perfectly truthful. Both perspectives were wrong unless the pictures were looked at properly.

Mr. T. Samuels said the capacity of the panoramic camera was limited because its initial position must be level. At the same time such pleasing pictures could not be got with the ordinary camera. He had seen depth on these pictures which he attributed to the lens being so well shaded from the light. He suggested modifying the diaphragm slit so that differential exposures might be given where dark buildings, &c., came in.

After some remarks by Messrs. Warnerke, Gotz, and T. S. Davis, Colonel Stewart replied to the discussion, and a vote of thanks was passed to him for his paper.

North London Photographic Society.—February 21, Lantern Night, Mr. J. Brewer in the chair.—Slides were contributed by Messrs. Healy, Williams, Clarke, and others. The set of slides entitled *Places to be Visited by the* 1893 *Convention* were shown. They were disappointing, and are far from doing justice either to the Devon and Cornwall Camera Club or the Devon and Cornwall district. Next meeting, March 7, when Mr. A. E. Smith will demonstrate the photo-lithographic process.

Hackney Photographic Society.—February 21, Mr. J. O. Grant in the chair.—Messrs. Sodeau and Nunn showed reductions by flashlight and printing-out lantern plate. Mr. R. Beckett showed a lens made from two ninepenny meniscus spectacle lenses, and a portrait taken with it at full aperture, *f*-8. The Hon. Secretary asked why it was recommended to keep gold solution in the dark. Mr. Sodeau said *light* was likely to reduce the gold to a metallic form. He said, in answer to other questions, keep chemicals in moderately cool place—not too cool, for fear of crystallising. Every time a bottle of ammonia was opened some power was lost, hence it was better to use a small bottle, or keep stock bottle full up to the neck. The strength may be determined by standard solution of oxalic acid. Mr. Barker asked, "Can ferrous sulphate be recovered from iron oxidised by light?" Mr. Sodeau said "Yes, if organic acidifying matter be present; also recover by use of iron filings or nails." Mr. Avent asked how to harden gelatine films. Mr. Sodeau said chrome alum hardens more than ordinary alum; methylated spirit or aluminium chloride would also do. In answer to Mr. Poulson, it was advised to use boiled water for making solutions. Mr. Gosling asked about keeping of sulphite of soda. Mr. Sodeau said it went to powder. Mr. Beckett said sulphate was inert in developer. Mr. T. H. Smith asked which was the best kind of gloss to use, and was advised black for silver compounds.

South London Photographic Society.—February 20, the President, Mr. F. W. Edwards, in the chair.—Mr. W. Rice (Vice-President) read a paper on *Problems in Photographic Arithmetic*. The lecturer dealt first with the covering power of lenses, and proceeded to show how to calculate the circle of illumination required for the different sized plates in common use when the lens is central, and also when the front was raised. Angle of view was next dealt with. It was pointed out that photographic plates being made rectangular, a portion of the plate or part of the angle of view (covering power) must be sacrificed. Where the latter course was adopted, Mr. Rice defined the angle of the photographic image on the plate as the picture angle, which depended on the proportion of the field of view included in the picture. Tables for the simplification of the measurement of angles were given. Stops and the value of their focal ratio and exposure ratios were explained, and the lecture was concluded with a most simple method of calculating the measurements connected with the optical lantern, without committing the usual formulæ to memory. A considerable amount of discussion followed, led by Mr. P. Everitt, who endeavoured to show that the lecturer's method of calculating angle of view was not quite correct; but it appeared that he did not take the same starting-point as Mr. Rice, and it was ultimately decided to fix another evening to further consider the matter. To further elucidate his remarks, the lecturer distributed printed copies of his diagrams, with a number of questions illustrating the practical workings of the problems. By the courtesy of the manufacturers, samples of Cadett's "Lightning" plates and Schwartz's diamidophenol (developer) in powder and cartridges were distributed among the members present. Miller's "Unique" hand camera was exhibited by Mr. Ransom, and was very critically examined.

Aston Natural History Society (Photographic Section).—February 23, "Mutual Criticism." —The collection of prints and interest displayed by members spoke well for the success of similar future meetings. The works brought up included prints by the albumen, Solio, P. O. P., bromide, Alpha, and platinotype processes, the latter class being represented in some fine Jersey subjects by Mr. A. C. Townsend. Mr. Tylar showed some animal studies by Mr. Gambier Bolton, and some marine works by the Rev. F. C. Lambert. The interest evinced in the impartial criticisms made this meeting undoubtedly the most successful one held by this new association of amateur and professional photographers.

Liverpool Amateur Photographic Association.—February 21, Mr. A. J. Cleaver (President) in the chair.—Five new members were elected. Mr. G. A. Carruthers exhibited and explained his ingenious magnesium flash-lamp, and photographed a group of members as an experiment. He afterwards passed several slides through the lantern, the negatives being taken with the lamp. Mr. F. Clibborn then gave his lecture entitled, *A Little Tour through Ireland*, illustrated by a set of high-class slides made by Mr. G. E. Thompson. The lecturer gave a very lucid description of the various views, and frequently was very humorous.

Edinburgh Photographic Society.—Popular Lantern Night.—The second popular lantern-slide exposition of the Society was held on Friday evening, February 24, in Queen-street Hall. The Vice-President (Mr. J. C. Oliphant) in opening, said he desired to call the attention of this large meeting, many of whom must necessarily be still out of the pale of membership, to some of its benefits. The Society had an extensive membership, perhaps the largest of any similar body in the kingdom, and in earlier years it took one of the foremost positions in Britain. By some unaccountable laxity they had recently fallen into a slumbering state, a state from which the present Council wished to remove it. They had now secured good premises in Castle-street, where, for the use of the active members, they had an excellent dark room, with all its appliances; a large hall for ordinary meetings, as well as committee rooms; the nucleus of a photographic library, as well as all the conveniences of a club. They wished still further to increase these benefits, their numbers, and consequent usefulness. For amateurs, now that a great many of the risks and difficulties connected with the lantern and limelight were done away with, there was a wide field of usefulness, and the opportunity for a display of their work, besides that assistance derived from fellow-membership. All this only costs the active member ten shillings a year, leaving still the old subscription to those who did not wish to take full advantage of the benefits he had pointed out. This evening they were to have a selection from a large number of the recent works of the members, which would now be shown upon the screen. The pictures exhibited were all by members, including Messrs. Mitchell (of Dalkeith), J. S. Smith, J. Patrick Reid (of Wishaw), and many others, most of which were of the highest class. The portrait figure subjects were probably the least successful, but the landscapes, English cottage scenes, architectural work, interior and exterior, from Torquay to the north Highlands, were markedly fine. Those which comprised figures with animals, from lions and elephants and all those of the domestic type, were especially good. Several excellent songs, with music, were much appreciated and applauded. The lantern work was perfect, save where an occasional hitch between the speaker's descriptive notes and the pictures shown did not harmonise with each other. Mr. Oliphant called for an expression of thanks to their musical friends, who had so well aided them. This was heartily given, and the meeting dispersed.

Other Photographic Societies Please Copy.—Mr. R. E. Fenner-Kidson, the Hon. Secretary of the Brixton and Clapham Camera Club, writes: "If I might, I should like to call your attention to the fact that the paper recently read before our Club by Mr. J. A. Butler on *Stereoscopic Photography*, that by Mr. B. E. Pinder on the *Optical Lantern*, and that by Mr. W. Thomas on the *Hand Camera* (which have occupied the members for the last three meetings, and of which I think any club might be proud), have *all* been by members of the Club, the Committee having felt that in ordinary clubs of the type of our own there has been a tendency of late to rely upon outside aid for their meetings, instead of encouraging their own members to provide the entertainment."

FORTHCOMING EXHIBITIONS.

March 3, 4	*Blackheath Camera Club. Hon. Secretary, C. W. Piper, 46, Shooter's Hill-road, Blackheath, S.E.
,, 22, 23	Leicester and Leicestershire Photographic Society, Co, operative Hall, High-street, Leicester. Hon. Secretary-H. M. Porritt, 66, London-road, Leicester.
April 5–8	*Croydon Camera Club, Braithwaite Hall, Wellesley-road, Croydon. Hon. Secretary, G. R. White, 55, Albert-road, Croydon.
,, 12–15	*Bolton Photographic Society. Hon. Secretary, J. E. Austwick, 10, Rushton-street, Bolton.
,, 17–29	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.
May 4–6	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.

* Signifies that there are open classes.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

ANGLE OF VIEW.

To the EDITOR.

SIR,—"Free Lance's" pet sin seems to be disregard of the ninth commandment. In reference to my paper on Mr. Haddon's article in this year's ALMANACK, he states that I endeavoured complacently to show the absurdity of the *quoted table*. On the contrary, I distinctly stated in the first paragraph that by correcting the *rules* I hoped to make the table valuable. "Free Lance" also states that my concrete example is a false one, because Mr. Haddon referred to a plate and not a negative or view. But I think Mr. Haddon's remarks, reported on page 91 of your JOURNAL, show that this was not his intention, for he says:—"It is absurd to give a picture a fictitious value on account of a few trees, or twigs, or rocks at a corner, and so dignify it with an angle of 52° instead of, say, 42°."

"Free Lance" recommends photographers to keep to the rules as stated. Let us examine what the result may be. A photographer wishes to use a 12 × 10 plate for a view and decides to include an angle of 62°. By Mr. Haddon's rule he will employ a lens of ten inches focus. If the lens only covers 62°, the corners of the plate, when developed and fixed, will be bare glass. If he uses another lens of the same focus, which will cover the plate, it must be of wider angle, or about 72°. Consequently the angle included on the plate is more than 62°. Instead of half the length, half the diagonal of the plate should have been taken as the basis of calculation, if the lens is used centrally. Had "Free Lance" been less concerned with standing on his head, he would not have forgotten to take the cap off the lens, and would have discovered his mistake.

Cameras are provided with cross fronts and swing backs, and photographers make use of these conveniences. Under either condition the centre of vision is moved. If a photographer wishes to make a picture under a given angle, it is for special reasons, one such being that the perspective shall not be too violent in appearance. A rule to be of value should be correct, therefore I hold that the calculations for the purposes named should be based upon the distance from the centre of vision to the extreme limit of the plate.—I am, yours, &c., PHILIP EVERITT.

88, *Evering-road, London, N., February* 25, 1893.

WASHING CUT FILMS—BLISTERS.

To the EDITOR.

SIR,—Allow me to thank you and your correspondents, Mr. J. E. Hodd and Dr. J. Carter Browne, for their kind answers to my inquiries as published in your most valuable JOURNAL. I will try the suggestion for washing films, but I am afraid that for 12 × 10 plates the suction will not hold, especially when the washing water falls edgeways on the plate. I have used the following way, which I think very good. I drill on the smallest edge two small holes with a drill, and hang up the films to a cross wire over top of washing tank with an S-shaped wire of suitable length, and then let the water run. This may prove useful to other users of the films, and if the manufacturers of films could drill the holes beforehand so much the better.

Next I will answer in regard to blisters. Having used, since I wrote to you, pure alcohol and not the methylated stuff, I find I am always having the same trouble of scum after mounting, *but no blisters*. I am not positive of it as yet, but I think this scum comes simply from the tint with which the albumen paper is covered—pink, mauve, or whatever it is—being dissolved by the alcohol unevenly, and remaining on top through all ultimate washings without hurting it, otherwise than when dry. I will try white paper and then see the results.

As regards blisters and a warm hypo bath I must say that I cannot agree with Dr. J. C. Browne, having tried long ago hypo at any degree of heat, from 40° to perhaps 100° Fahr., and have generally found the higher the temperature the more blisters and the larger ones. Alcohol I have found the only sure remedy. Nevertheless, I am very much obliged to these gentlemen for their kind suggestions.—I am, yours, &c.,

4, *Avenue Pinel, Asnières, Seine, February* 25, 1893. ALBERT LEVY.

A QUESTION BOOK.

To the EDITOR.

SIR,—At a meeting of our Council, it was proposed that a question book be kept. I suggested that any photographic questions that could not be answered forthwith should be handed in to me, and I would enter them in the aforesaid volume, which would be placed on the table, and the query replied to by some of our abler members, such answers to be discussed at a future meeting, and the best entered opposite to the proposition. In due course, a compendium of useful information would result.

My purpose for encroaching upon your space is to see if other societies would take up the matter, so that at a subsequent date a temporary interchange of these records could be made.—I am, yours, &c.,

FRED. W. PILDITCH, *Hon. Secretary, Aston Photographic Society. Burlington Hall, High-street, Aston.*

A CORRECTION—FERROUS SULPHITE.

To the EDITOR.

SIR,—In my communication which you were good enough to publish last week, occurs a slight error, which has the effect of reversing my meaning. In the last paragraph but one I say, "I have been unable to get the clearest and best 'gratings,'" &c., whereas I meant to say, "I have been *able*," or just the opposite.

Some considerable time ago ferrous sulphite was recommended for restoring the ferrous oxalate developer when oxidised, or for keeping it in working order. I tried the method at the time, following the instructions then given, but cannot now refer back to them. I remember that I obtained some remarkably warm tones in development when using the sulphite, and should be glad to try it again for the express purpose of utilising the tone, if you could kindly give me details of how to prepare the ferrous sulphite, which I find is not an ordinary article of commerce.

Apologising for the trouble, and thanking you in anticipation,—I am, yours, &c., W. LINDSAY.

February 27, 1893.

[See an article in another column on the subject.—ED.]

PHOTOGRAPHING HORSES.

To the Editor.

SIR,—Referring to article on "Photographing Horses" in your issue of the 17th, I send by same post a few specimens of equine photography. The cart-horses were "handled" for the taking by Mr. G. M. Sexton, auctioneer to the principal horse societies, and I need scarcely say that it was an education to me to see and work for him. I prefer when taking horses, whether with a mount or not, to stand a little in advance of them, as it is then more easy to show the light between the legs, and I always expose with sky-shade instead of cap, that I may be able to keep my eyes on the animal.—I am, yours, &c., THOS. STOKOE.

Clare, Suffolk, February 27, 1893.

RAPID SOLUTION MAKING.

To the EDITOR.

SIR,—It is awfully amusing to see old and tried friends of the photographic dark room ("Lab." some people designate it now) popping up again under new parentage. The attention of Messrs. Baird, Ayres, and Webster has been drawn to the Doulton dipping jar, which has been in long use by the firm of Messrs. Martin & Co., and others. It has been long known to chemists and photographers (and especially to the chemist) as a most useful and indispensable article.

The writer has used the following rapid solution appliance from wet-collodion days to the present time. It is exceedingly simple, and is in some respects an improvement upon Messrs. Martin's plan. It is this:—Procure a small, round, fancy wicker-basket, from four inches diameter to any depth or size, costing sixpence each upwards. Cover the outside of basket with thin calico, permanently fixed. For use, simply fill the basket with the crystals to be dissolved, and suspend it in the jug or jar, filling up whichever utensil is used with water. It is surprising how long these baskets will last, especially if rinsed under the tap after use to remove sediment and impurities.

Of course, as in the "old days," the same care is paramount in the "new times," separate baskets must be used for different crystals. But in the wet-plate days (with certain exceptions), hypo and protosulphate of iron were used in large quantities, only two or three baskets were required.

In these modern days it takes away one's breath to be informed that the Doulton jar is used to dissolve pyro; yet so it is asserted in p. 668 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1893.—I am, yours, &c.,

February 27, 1893. ATTICUS.

AMIDOL AND PYRO.

To the EDITOR.

SIR,—I have been developing some instantaneous plates in the following manner, producing excellent results. I first brought out the detail with amidol developer, then washed the plate in water, and redeveloped with the ordinary pyro developer, well restrained with bromide. You can then get any amount of density without the slightest difficulty, and splendid printing negatives.—I am, yours, &c., H. COUCH.

February 27, 1893.

THE AMATEUR QUESTION.

To the EDITOR.

SIR,—We would respectfully call your attention to a little booklet enclosed, showing what we in Ireland are trying to do to meet the amateur question. We believe many professionals look askance on amateurs, but we think a little money might be made out of them. What think you?—We are, yours, &c., ALLISON & ALLISON.

14, *Queen's-arcade, Belfast, February* 20, 1893.

[Our correspondents, who are photographers, enclose a scale of charges for the use of dark room, developing, retouching, printing, &c., for amateurs.—ED.]

SPEED TESTING.

To the EDITOR.

SIR,—After my long reply to Mr. Williams last week, there is really nothing for me to say, for he does not answer the points of my letter. Messrs. Hurter & Driffield's system of testing is the outcome of their statement of the law relating to photographic exposures, and, in simple language, is, that the opacities are proportional to the intensities of the light by which they are produced acting for the same length of time. Photometric measurements show that this statement holds good in all plates for a period of exposure according to the plate, and, outside this period, either way, the law ceases to hold good. This statement, the pith of their system, is either true or false, and those who attack their system must attack this statement. Is any one prepared to do so? If not, it is quite useless to argue the matter further. Let me advise Mr. Williams to accept the kind offer of Messrs. Marion & Co. to practically demonstrate the system to him; I promise him he will learn something.

As regards "Arcanum's" remark, I think that he argues against himself. The fact that several people told us the plates worked well to the marked speeds only show that the latitude in their camera trials was sufficient to mask the error.

Perhaps Messrs. Hurter & Driffield will do as "Ignotus" asks, and expound their system in simple language. His remarks are good and to the point.—I am, yours, &c. JAMES CADETT.

February 21, 1893.

EXHIBITION OF PHOTOGRAPHS IN JAPAN.

To the EDITOR.

SIR,—You were good enough to make an announcement in your valuable journal of the collection of photographs we had the pleasure a short time ago of bringing together from English and foreign photographers for an Exhibition in Japan.

It may now be of interest to state that we have just received information from Professor W. K. Burton, which tells us that the Exhibition will shortly be opened, and will be held both in Tokyo (the capital) and in Yokohama (the principal open port); that the enterprise is taken up with much enthusiasm (shown by a general desire to have the honour of guaranteeing the expenses of the undertaking); that the original idea of appointing three leading Japanese artists to adjudicate may have to be extended to selecting ten, as there are so many "schools" of art in Japan that it is proposed to give the designing of a bronze medal for the occasion as a competitive exercise to advanced students of the Government Art College, and that the exhibits (which were all sent out unframed) will be framed in a quiet way, and the Exhibition made attractive in every possible manner. We may add that a very fine collection of about three hundred English and foreign photographs, probably never before surpassed, was kindly contributed, in answer to our requests, by the following exhibitors:—Messrs. Horsley Hinton, Lyd. Sawyer, E. Beck R. H. Lord, Alfieri, Hollyer, Keene, Scott, H. M. Hastings, H. Baker H. P. and R. W. Robinson, F. Evans, Snteliffe, H. W. and L. C. Bennett Manafield, Harding, Douglass, Cole, Burchett, Davison, Crooke, Halford, Gregor, Wilkinson, jun., Clement Williams, Keighley, H. Stevens, Bright, Ennis, Lange, Bhedwar, Briant, Guardia, Wellington, Tyser, Smith, Van der Weyde, Calland, Lee, Bergheim, Ulrich, Dumont, Bedford (the late W.), Bridson, Terras, Cassela, Dresser, Alexandre, Colls, Strakosch, Cobb, Gale, Ramsay, Rigaux, Colard, Loppé, Cameron (including some of Mrs. Cameron's pictures), Lyonel Clark, Andræ, Watzek, Blechinger, Gèruzet, and Count Primoli, Baron Nathaniel Rotchschild, and Mrs. Main. In many cases the contributions consisted of the best work of the exhibitor, so that it will be seen that everything has been done to make a representative exhibition, and one likely to interest our Japanese co-workers in photography. We shall hope to be granted the favour of the insertion of a note or report of the Exhibition in your columns when further information is forwarded to us.—We are, yours, &c., G. DAVISON.

February 27, 1893. A. PRINOLE.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Exchange good tricycle for camera, 8½×6½, 10×8, 12×10, or hand camera.—Address, R. H. BLYTH, 4, Oxford-grove, Ilfracombe.

Will exchange a 42s. Kodak, complete (except film), for quarter-plate camera.—Address, J. W. YOUNG, Lower Gornal, Dudley.

Canvas camera case for 10×8 apparatus, new; exchange for background or studio accessories.—Address, WILLIAM HARE, Windsor Studio, Sutton, Surrey.

Will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, 1890-2, complete, not bound, good condition, for half-plate landscape lens.—Address, E. KRAUSS, 162, King's-road, Reading.

Will exchange four backgrounds and various accessories for 10×8 rapid rectilinear lens and twelve or fifteen-inch burnishor.—Address, T. F. EYLES, Marlborough Gate Studio, Marlborough-row, Portsea.

Will exchange 12×10 camera, with three Tyler's metal slides, in good condition, for whole-plate studio camera, or portrait lens to cover whole-plate.—Address, G BROWN, High-street, Ibstock, near Ashby-de-la-Zouch.

Exchange box of transparent colours for photographs or lantern slides, not used, and three show-cases, hinged fronts, red cloth backs, painted black, about twenty inches by twenty-five inches each, for a 10×12 tripod (folding), or a single-view lens.—Address, LONDON PHOTOGRAPHIC COMPANY, New Brompton, Kent.

Will exchange a splendid folding tricycle, electro-plated throughout, fine 15×12 quick-acting portrait lens, three full-size artistic canvas backgrounds, and lecturer's stock of specially selected lantern slides, screen, frame, reading-desk, &c., for a first-class modern 12×10 landscape camera, rapid rectilinear and wide-angle lenses for same, and 8½×6½, also 3D and 5D group lenses, and 3D (Dallmeyer's).—Address, LONSDALE & Co., 45, Stroud Green-road, N.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

J. J.—Apply to a photographic dealer.

G. G.—Received and noted. *O tempora*, &c.

INK STAINS; J. BRIAN; and others.—In our next.

DEAF.—We do not see any objection to your inscribing the cards as you suggest.

J. GOULD.—The new chemical formulæ are given in the 1883 edition of Hardwich.

M. A. R.—Ordinary silver prints placed together cannot be used for stereoscopic purposes.

E. EDWARDS.—Received. While the case is still pending, it would be improper for us to publish your letter.

W. H. WALLACE.—The camera and lenses named are excellent. We do not recommend particular makes.

PHOTOMETER wishes to know the maker of a printing-out bromide paper for testing the actinic value of the light.

A. L. S.—Consult the advertisements in the ALMANAC, where you will find descriptions of sets of apparatus at all prices.

PETER.—Schlippe's salt is not much used. It is to be had at most dealers in photographic material; it is very inexpensive.

R. SIMCOE.—There is no secret about the transfer ink used in photo-lithography; it may be obtained from every dealer in lithographic materials.

W. GOULD.—A single lens will do quite well for a hand camera, provided it is of such a focus as to cover the plate with a large aperture with the requisite definition.

BROMIDE.—1. We do not know where such gratings can be obtained. See an article last week by Mr. W. Lindsay, which may give you a hint as to their preparation. 2. Not worth the trouble on a small scale.

EASTER HOLIDAYS.—Will any gentleman give particulars of a tour in Holland—Rotterdam to Amsterdam—going and returning by different routes; five clear days there, museums and picture galleries excluded?

B. N. J.—Prints received. If they received a prize it will prove that the standard fixed in the so-called "competition" is very low. However, we have known awards to be made to pictures in no way better than these—indeed, not so good. Hence so many successful pot-hunters. The pictures returned as desired.

LINCOLN.—It is quite a mistake to surmise that rain water can be used for the same purposes as distilled water. It would be the case if it were collected where it would not be contaminated with impurities from the atmosphere; but this is never the case when it is collected from the roofs of houses, more especially in large towns.

R. ROBBINS.—If the camera has not been patented before, or previously made or described, you can obtain a patent for it. Even if it has been, you can still, under the present law, obtain a patent for it unless the sealing of it is opposed by some one. But the patent, like very many others, would turn out to be invalid if contested.

E. H. DEBENHAM (York) writes of gelatino-chloride paper: "Some photographers may be deterred from using this paper by the fear that there are difficulties connected with toning, &c. Let me assure all such that if the manufacturer's simple instructions are adhered to, there is no difficulty whatever in obtaining first-class results."

A. MCLENNON.—Almost any adhesive may be employed for mounting carbon pictures; the same with collotypes. If you prefer dextrine, there is no objection to its use, as in the case of silver prints. Flour paste may be used as well as starch paste. The latter is the mountant in most general use for carbon and collotype pictures. For large sizes the starch is made very thick and applied with a sponge.

OPERATOR.—So far as we are aware, there is no trade union society amongst photographers. An attempt, we believe, was made some years ago to form one, but it ended in failure. We quite agree with you that the system of taking "articled pupils" or apprentices with good premiums, so as to obtain labour at merely a nominal cost, if not for nothing, is very unfair alike to skilled workers and the so-called "articled pupils."

ALPHO.—Unless the apprentice's indentures are duly stamped they are not binding, and he can leave the same as any other *employé*; in fact, he is not legally apprenticed at all. So far as we can see, there is no remedy. Agreements, such as that in question, should be prepared by a duly qualified solicitor. There is an old proverb, often quoted, that the man who acts as his own solicitor has a fool for a client. This, we imagine, will turn out to be the case in the present instance.

R. REED.—White hard varnish, diluted with methylated spirit, makes a varnish that is very useful for negatives that are to be carefully handled, and is given in the ALMANAC. Being soft and brittle, it is easily abraded by rubbing with the ball of the finger, and then it forms a good medium for retouching upon. By the way, "white hard varnish" is a very indefinite article, and varies with every maker. Sandarac is its recognised basis, but in many of the commercial articles common resin predominates.

PAPIER.—If the wooden vessel were lined with gutta percha there would be no advantage in coating the gutta percha with paraffin, which, by-the-by, would not be easy of application. Either material by itself would answer perfectly. We, as a matter of economy, should prefer the paraffin. It will have no injurious action on the silver solution, and some say that gutta percha has. Certainly some samples of the common commercial article does quickly deteriorate a silver bath for the collodion process, and the pure article is not easily obtainable nowadays.

NEMO ME IMPUNE LACESSIT writes: "Last season I secured some pretty negatives of men carting, ploughing, and felling trees, &c.; also rustic houses and bits, with figures at doorways and elsewhere. I wish now to publish these. Can the persons represented stop me? They understood at the time I was a professional and intended to do so. I gave them a copy each for their trouble. This seems to me to be different from a portrait taken in the studio."—So far as we can see, the publication of the pictures cannot be legally prevented. It would, however, only be cautious to ask the permission of the parties whose portraits are included, and they will doubtless raise no objection.

PIGEONS.—"My studio has an iron roof, and I am troubled with my neighbour's pigeons settling on the same, making a noise about as pleasant as setting a saw. Can you suggest a remedy? I have used a squirt with water (large one), but to no purpose. I thought I would tar the roof, and mix tar with some ingredient, so that it would not dry, and so it would make the feathers messy. You see, people want to fly the pigeons, but I don't want them if I can avoid it."—We can quite sympathise with our correspondent, but a remedy is not so easily suggested. But still it just occurs to us that cats are rather partial to pigeons, and the latter do not like cats. Now, if "Pigeons" were to keep one or two of the feline tribe, and give them free access to the roof of the studio, and further accommodate them with a board fixed along the ridge, the trouble might cease.

C. WILTON.—The majority of copies of paintings seen in the shop windows of London, that are made on the Continent, are by the wet-collodion process. This is the process almost exclusively employed for this class of work by our Continental neighbours. The process is an orthochromatic one, of which those who employ it do not publish the details.

J. B. writes as follows: "If I entrust negatives to any person or firm for process printing for my own publication, with the understanding that the negatives are to be returned to me, is it implied that they are to be returned in the same condition, or would trade custom admit of their being stripped and reversed without my permission, and have I any legal claim against any person who, under these circumstances, returns my negatives reversed, cut down in size, and injured in other ways, so as to render them unfit for ordinary work?"—Unless permission was given to strip the negatives, they should have been returned intact. So far as "trade custom" is concerned, we know of nothing that will justify tampering with negatives without the owner's consent, therefore an action for damages might be successful. Perhaps some of our readers commercially interested in the subject will favour us with their experience.

R. O. S. says: "I wished to obtain a piece of finely ground glass, and obtained from the oil shop some of the finest flour emery, and ground a piece of glass with it and water, using a piece of thick plate glass as a muller; but when a ground surface was obtained, and the emery washed off, there were innumerable deep scratches, almost cuts, in the glass, and not the even surface of ordinary ground glass. Is not the emery I used the right kind?"—The finest flour emery will give a fine, even, ground glass surface; but it is clear that in the sample used there must have been some very coarse particles from some accidental cause or other. If a more reliable sample of emery cannot be obtained, the present one can be made available. Stir it up with a tolerably large quantity of water, and allow it to rest for two or three minutes. In that time the coarser particles will have settled to the bottom. The major part of the water and the finer particles of the emery can then be decanted, and afterwards allowed to subside. With emery so treated, though it may not be suitable in the first instance, a fine surfaced glass may be obtained.

RECEIVED:—E. Dunmore, J. Pike, and G. Gosling.

PHOTOGRAPHIC CLUB.—March 8, Mr. A. Brooker's Slides. 15, Smoking Concert.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, March 9, Mr. J. Traill Taylor will read a paper on *Investigations in "Spirit Photography."* Visitors welcome.

THE Sutton's Process Syndicate, Limited, inform us that they have taken commodious premises at 91, Blackfriars-road, with studio and electrotyping plant, &c., and are going in for supplying half-tone blocks to the trade cheaply and quickly.

THE Bolton Photographic Society will hold an exhibition of photographs on Wednesday, Thursday, Friday, and Saturday, April 12–15, 1893. Six silver and six bronze medals will be offered for competition. Competition sheets and all other information can be obtained from Mr. J. E. Austwick, Hon. Secretary, Exhibition Committee, 10, Rushton-street, Bolton.

ON Thursday evening, February 23, the London and Provincial Photographic Association gave their annual ladies' entertainment at the Champion Hotel, Aldersgate-street, when a capital programme of songs, recitations, and instrumental music, interspersed with lantern-slide displays, was given. A feature of the entertainment was the exhibition of live objects on the screen, shown by means of a vertical lantern arrangement with a prism lent by Messrs. Newton, of Fleet-street.

MR. HORSLEY HINTON writes: "So many photographic friends have for some years past correspondeed with me at 45, Charterhouse-square, and 91, Graeechurch street, London—the photographic businesses of Messrs. W. B. Whittingham & Co., Limited (late The Photographic Artists' Co-operative Supply Association, Limited)—that I shall be obliged if you will spare me space to make known that I am now no longer in any way connected with the above business."

CHANGE OF ADDRESS.—Messrs. Hunter & Co. have acquired large manufacturing premises, containing over 10,000 square feet of floor space, situated in Dermody-road, Lewisham. The new factory comprises two distinct portions, one of which will be set apart for the manufacture of dry plates and films, and equipped with the best modern appliances, while the other will be devoted to the production of Messrs. Hunter's photographic requisites and specialities, to which will be added an electrical engineering department, embracing the manufacture of hand and power dynamos, arc lamps, and requisites for studio and other installations.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1714. Vol. XL.—MARCH 10, 1893.

NOTICE—THE "LANTERN RECORD."

Adverting to an announcement made last week in the "Lantern Record" (the monthly Supplement to The British Journal of Photography), it may be convenient if we here repeat the substance of what was there said. During the past winter the "Lantern Supplement" has met with such appreciation at the hands of readers and advertisers, that, instead of confining its appearance to the months from October to March, as was originally intended, we have decided to issue it monthly throughout the year, without intermission. The next Supplement, therefore, will appear with the Journal of Friday, April 7, and will be continued every month.

Although during the summer the lantern, among photographic societies and at public entertainments, is not so largely employed as in the winter, its uses for enlarging, and for scientific and experimental purposes are still very extensive, while the preparation of negatives for lantern slides, improvements in the optics, mechanics, and construction of the lantern, and its many accessories, and, in brief, lantern matters generally, are of constant interest to photographers and others. It will, therefore, be the aim of the "Lantern Record" to devote itself to the treatment and discussion of the optical lantern and its allied subjects as fully as possible during the forthcoming summer, so as to form a complete and unbroken record of lantern progress and practice.

HOW BUSINESS MAY BE REVIVED.

Depression in the photographic profession appears to be almost universal, not only in the Metropolis but throughout the whole of the Kingdom. So far as we have been able to ascertain, there appears to be little prospect of an immediate improvement, at least, so far as portraiture is concerned, and that has hitherto been, and still is, looked upon as the most important branch of professional photography. It is not necessary just now to speculate as to the cause, or causes, of the depression—it undoubtedly exists. It is the remedy that may, at the present time, be more profitably considered. It has been suggested that a revival of business could be brought about if some new style or size of picture could be introduced that would take the public fancy. But we fear there is but little prospect of this being done at present.

Let us see if there are not other channels into which professional photographers may profitably turn their attention. In doing so we shall, however, have to show that a very large amount of business, which ought to be and is legitimately that of photographers, has been diverted into other trades, such as lithographic and other printers. Just let us take two or three cases by way of example. Photo-lithography, to which we refer elsewhere: here a photographic negative has first to be made, then from that an image in fatty ink is obtained by the action of light on bichromated gelatine. The work is purely photographic, and up to this point is simply equivalent to that of the lithographic draughtsman when he places it in the hands of the printer—a different business altogether. Relief or "process" blocks: this is purely a photo-chemical process up to the time that the block is ready for the press. So far as separate crafts are concerned, it is exactly parallel to the work of the wood engraver. Photogravure, too: here we have to produce a negative, then make a reversed transparency, and afterwards obtain from that a negative in carbon on the copper-plate. The remaining operation is entirely a chemical one. Photography entirely takes the place of the engraver or etcher. Collotype is still more entirely a photographic process, inasmuch as the finished plate cannot, like the process block, engraved plate, or litho-transfer, be placed in the hands of their different printers. A special training for the work is necessary; for although the method of printing is analogous to that of lithography, we are given to understand that lithographic printers cannot deal with collotype plates. Woodburytype is even yet more completely a photographic process throughout. Still, all these processes are being neglected by photographers generally.

All the photo-mechanical processes that are being worked at the present time were, with the exception of some slight modifications, in the possession of photographers twenty or thirty years ago, and full details of them were published in the journals; but they did not avail themselves of them at the time, nor have they, to any extent, done so since. Other trades have, however, during the past few years taken them up, and are turning them to very profitable account.

Talbot's method of photographic engraving, for instance, was published in 1858, and that is the basis of, and differs but slightly from, the process now most in vogue. Further, the identical method described as the Talbot-Klic process, which was demonstrated the other night by Mr. Denison, was published nearly ten years ago in this country, yet it has received but little attention at the hands of professional photographers up to the present, though largely worked by others. Again, collotype, precisely as it is worked at the present day by some firms who produce the best work, was, in its entirety, fully described in the English journals more than twenty years ago. But how many really professional photographers have taken it up? Should this state of things continue to exist?

Would it not be well for many of those photographers who are now so loudly complaining of the lack of trade, to turn

their attention to some of the mechanical processes in their own businesses? None of them require much space or costly appliances for their practice beyond what is found in every portrait establishment. We surmise there are few photographers, especially in manufacturing districts, but who could often have materially increased their returns, had they the means of turning out mechanical prints at a short notice and at a moderate price. Hitherto, as a rule, when an ordinary photographer accepts an order for mechanical work, it is put out to be executed, sometimes even sent to the Continent. This generally means a delay of some weeks, and sometimes with the result that in the end the work is not done as it should have been, whereas, if it could have been executed on the premises, it could have been done in a few days, and, what is of still greater importance, would have been in accordance with the photographer's and his client's requirements.

The processes that would be most generally useful to the ordinary professional photographer are photogravure and collotype. The former is eminently suited for portraits and landscapes. There is little doubt that, if people could have veritable engravings of themselves, they would prefer them to silver prints, and would willingly pay a considerably enhanced price for them. Collotype is also good for portraiture, though it must be confessed that portraits hitherto produced by this process in England are not of a very high class; but that is not the fault of the process. It is, however, for views, reproductions, book illustrations, and for trade purposes that the photographer will find collotype most useful. Some have the idea that this process is not capable of yielding results equal to silver prints, and the notion is somewhat supported by the quantity of inferior work that is to be met with; but this, as we have just said, is not due to the process. Collotype is capable of yielding prints as good as those in silver, or those from engraved plates.

The collotype process requires no expensive plant for its working on a moderate scale. The most expensive item is the printing press. One of the form most generally in use in Germany to take plates ten or twelve inches wide costs only about twelve or thirteen pounds, and the other necessary items may be had for something less. The cost for installing photogravure was referred to last week.

PHOTO-LITHOGRAPHY FOR AMATEURS.

The full attendance at the Photographic Society's lectures on photogravure, and the evident interest evinced in every detail of the process, testifies to the awakening appreciation for this and similar processes of reproduction on the part of amateurs and photographers generally. But, while photogravure may be taken as representing the highest artistic form of such processes, as well as the most difficult to master, there are others of a similar nature which, if not capable of producing similarly artistic results, are, at any rate, applicable to a variety of utilitarian purposes, and, at the same time, form stepping-stones in a certain measure to the practical mastery of the more difficult methods. Foremost amongst these is photo-lithography.

By this title we mean to refer only to the simpler kinds of photo-lithographic reproduction, those in which photography is called in to assist in making "transfers" from line subjects, or others in which there is no natural half-tone, to be printed from an ordinary lithographic stone or its substitute. The higher branches of photo-lithography—or "collography" as it is called technically—include processes which are not only capable of yielding the most artistic results attainable by any methods, but in which the rendering of half-tone is even more perfect than in photogravure of the highest class. But these are even more difficult to work successfully, and require such an array of special materials and appliances that they are almost beyond the capabilities of the amateur or worker on a small scale.

Not so, however, the more modest methods of line reproduction, the applications of which are numerous and useful in the hands both of amateurs and professionals. For instance, we are acquainted with one amateur who executes all his own note-paper headings, monograms, and suchlike, making the transfers himself by reduction in the camera from carefully prepared originals on a larger scale, the printing being performed by a skilled litho-printer. In the same way we have seen concert programmes and similar things that have been rapidly and economically reproduced from pen-and-ink sketches, while an endless variety of similar uses will suggest themselves.

For the production of the transfers themselves scarcely anything is required that is not found in the average photographer's laboratory, lithographic transfer ink being perhaps the only special requirement. For the printing it will be better in the majority of cases to utilise the services of a practical lithographic printer, as, although the process is not a difficult one to learn, it is seldom that the practical photographer and lithographer are found combined in one individual. It is by no means an unlikely occurrence, if the photographer himself undertakes the printing, that though his own proper share of the work may be efficiently performed, it is spoilt as soon as he attempts to get into the ground of another, whereas a skilled printer would have known how to make the most of it. Some years ago, having access to a lithographic machine and the assistance of a skilled lithographer, we made, by the simple process about to be described, a series of reduced copies of line engravings, which on the smaller scale were generally said to be superior to the cheap originals from which they were made.

The first requirement is, of course, a suitable subject for reproduction—that is to say, one in which the half tone or gradation is represented by lines, dots, hatching, or mechanical grain of some sort. But this is not all; the grain, of whatever character it may be, must not be too fine, especially if it is to undergo reduction, or it will not bear inking up with the lithographic roller without clogging. In this matter a skilful lithographer would often succeed with a class of subjects that would be impossible to the mere photographer, who will do well to confine himself—at first, at any rate—to tolerably open subjects, and to altogether eschew any attempts at extremely fine work. When he has acquired some experience in making and washing up the transfers, he may, perhaps, venture on to a better class of work, and with the assistance of a practical printer he may then, perhaps, succeed in producing what might pass for fairly good line engravings or etchings.

The next step is the production of a suitable negative, and this, perhaps, forms the chief difficulty in the process. For this purpose, perhaps more than in any other process, a negative of great density and perfectly clear-glass shadows is required, the latter condition being, if anything, the more important of the two; at least, any decided veil over what should be the clear parts is far more objectionable than a little falling short of absolute opacity—if there be such a condition—in the deposit. In the old collodion days this type of negative was not at all difficult to produce, and for that reason

the wet collodion still remains in use wherever "process" work is done; but, except under special conditions, it is not by any means easy to attain to the requisite clearness and density with gelatine plates—that is to say, with the ordinary commercial rapid plates.

In order to make the best of matters as they stand, let a "slow" plate be selected. There are special photo-mechanical plates in the market, but any reliable slow plate will answer with careful treatment. Let a full exposure be given—that is to say, avoid *under*-exposure; but, on the other hand, do not go to the opposite extreme. Develop with hydroquinone, using bromide, or, better still, with pyro and ammonia, mixing the developer with a saturated solution of gallic acid instead of plain water, as described in these columns some few years back. If the latter plan be adopted, the exposure may be very much increased with advantage, and the development will be gradual, resulting in any desired degree of density without appreciable loss of clearness.

The basis for the actual transfer is paper coated with gum, gelatine, starch, glucose, albumen, or any similar substance, or a combination of them, sensitised with bichromate of potash, and carefully dried. If a special paper be prepared, a solution of gum arabic, with a little sugar or glucose to remove its brittleness when dry, may be spread thinly but evenly, by means of a brush or by floating; or a small proportion of gelatine may be mixed with the gum if a more robust layer is desired. But for our own part we prefer to use an article easily obtainable, ready to hand, namely, ordinary albumenised paper, as used for silver printing. Here we have a product in every way suited to the purpose—the chloride contained in the film does not interfere in any way—and more evenly and carefully coated than the photographer is likely to do himself, and which only requires sensitising.

This is effected by floating the paper, *plain* side downwards, on a solution of bichromate of potash, of the strength of one ounce to the pint of water, for three or four minutes, or until it has entirely lost all tendency to curl. The albumen surface should not be brought in contact with the solution, or it will be partly dissolved, and rendered uneven. As it is, great care must be observed, as the solution penetrates the paper and softens the albumen, which is thus extremely liable to injury. After floating, the paper is hung up to dry, being finished off by heat, to ensure perfect desiccation.

The exposure is made in the printing frame in the ordinary way, and is continued until a strong brown image is formed and appears to grow no darker. The object is to harden the whole thickness of albumen in the insolated parts, without allowing the white lines of the picture to be touched. If the exposure is insufficient, there is danger of the transfer washing off the paper in development; on the other hand, in the case of over-exposure, the whole image will be dirty and "smudgy."

After exposure, the surface of the print is covered as uniformly as possible with lithographic transfer ink. This is best done, if the means be at hand, by rolling it upon an inked stone, but, failing this, the ink may be applied by means of a chamois leather or silk "dabber," and spread as evenly as possible. When the surface of the print has been reduced to an even tint of black, it is transferred to a basin of clean, cold water, and allowed to soak for a few minutes. Gradually the unchanged albumen dissolves and leaves the paper, carrying with it the ink attached to the white lines of the picture, the dark lines represented by the hardened albumen remaining intact. The process may be assisted by means of a camel's-hair pencil carefully applied, but it is better to allow the development to proceed as far as possible without interference. Every care must be taken, under all circumstances, to avoid letting the dislodged ink attach itself to the paper to form smudges. If gelatine has been used in the preparation of the paper, or in case of over-exposure, it may be necessary to use slightly warm water, but it is not advisable to resort to this course unless absolutely necessary.

When the development is complete, the superfluous moisture is removed by gentle pressure between blotting-paper, taking care that the surface of the transfer is not rubbed at all. It is then ready for application to the stone or printing surface, which, as we have said, will be better done by a qualified printer, or it may be allowed to dry. The method is similar to that followed with an ordinary transfer; it is laid on the stone, damped, and passed once or twice through the press; then, as the ink is not separated from the paper by a soluble film as in an ordinary transfer, it is a desirable plan to pass a hot iron over the back of the paper once or twice, to melt the ink and cause it to sink into the surface of the stone; then redamp, pass through the press again, and strip in the ordinary way.

We have necessarily given but a brief sketch of the process, leaving the printing entirely for other hands. Our remarks are intended to be chiefly suggestive, and our readers will be able to elaborate them in such manner as best to suit individual cases.

Another "Largest" Photograph.—It seems as if this country will be well represented in the matter of large photographs at the Chicago Exhibition. The Autotype Company have just produced, for a well-known firm of photographers, an enlargement something over seven feet by four feet six inches, which is to be sent to the World's Fair. This, we are informed, is the largest carbon picture that has yet been produced on one piece of paper and printed from a single negative.

The Determination of Plate Speeds. — The recent correspondence on this subject in our pages, provoked by Mr. G. F. Williams' articles, has excited very general interest; and, as Mr. Williams is at an early date to read a paper before the London and Provincial Photographic Association in defence of his standpoint, we may expect an animated and profitable discussion, at the hands of the supporters and the opponents of Messrs. Hurter & Driffield's theories.

The Sun's Ultra-violet Radiation.—In reference to the recent experiments on this subject chronicled by us, it may be stated that the measurements were made by an electrical actinometer. The instrument was based on the fact that the ultra-violet light accelerates the dissipation of an electric charge from a cathode of amalgamated zinc. The portable instrument devised is in the form of a cylinder, which is to be directed to the sun, a charged sphere of amalgamated zinc being first inserted, and the rate of its dissipation being gauged by an Exner electroscope. Experiments were made at various heights, and it was found that of the perpendicular rays falling at Sonnblick (3100 metres above the level of the sea) forty per cent. reached that level, twenty-three per cent. of these were absorbed before reaching the next station (1600 metres), and only forty-seven per cent. of the remainder reached the level of Wolfenbüttel (80 metres).

Amateur Astronomical Photographs with an Ordinary Telescope.—At the last meeting of the British Astronomical Association, a paper by Mr. Lawrance Richardson was read, describing how these could be produced with a very simple arrangement. The need for the use of an astronomical clock is the great

drawback, but granted possession of this necessary instrument in astronomical observation, Mr. Richardson showed how the only apparatus he used was a home-made arrangement of cardboard, gummed together and fitting on to the draw-tube, by means of which he took four photographs on a quarter-plate. The telescope was not corrected for photographic purposes, but by putting the plate about a quarter of an inch outside the visual focus he obtained sharp results. He tried the effect of stopping down the aperture, and the results were at one end of their range very singular and contradictory of photographic experience. Thus, the instrument was a 4½-inch objective; when he stopped down to 3½ a sharper image was obtained; a still sharper at 2½ inches, still further improved by a 1-inch stop. But when he arrived at a half inch, the image became less sharp. By using an eyepiece, he obtained photographs of the moon 2⅓ inches in diameter. For photographing the constellations, he used an ordinary landscape camera strapped on to the object-glass end of the telescope. He stated that this was by far the easiest mode of taking astronomical photographs.

Electric Spark Photographs.—The lecture delivered at the Edinburgh meeting of the British Association by Professor Boys on this subject is now being published with illustrations in the pages of our contemporary, *Nature*, and those of our readers interested in some of the most remarkable experiments in instantaneous photography hitherto made will do well to read the paper in its entirety. Professor Boys is known as the originator of a variety of most ingenious experiments for showing the results of certain rapid, or almost instantaneous, effects of motion—his explanation of how soap bubbles burst, and so on, are to be found in his interesting *brochure* published by the Christian Knowledge Society; but the photographic representations of a bullet travelling at a speed of about two thousand feet a second are startling. The lecturer modestly called the part he had taken in producing them a subordinate one, but those who read his account will soon be aware of the ingenuity of the methods he adopted, and the originality of his ideas. Practically, the method adopted is, to cause the light of an electric spark to be diffused by a lens, opposite to which is placed an ordinary camera. The bullet passes across this field of light, and a photographic image is instantaneously secured. The details of the arrangement for ensuring that the very moment the bullet passes across the field the light shall be there cannot be put in a brief paragraph like this, but they will well repay perusal in the complete paper we quote. They are interesting, and marvellous in the highest degree.

Home-made Electric Light by Battery. — There are many who would like the opportunity of an occasional use of an incandescent electric light, but who do not care, or who have not the means, for setting up a dynamo and power engine. No doubt, battery power can be and has been used for the purpose, but this means of using electricity is open to the objection of its variability, and the mess and trouble of setting it up whenever required. But it is possible to get a very even quality of light from a storage battery (which, after all, is only a form of chemical battery, though the name of storage battery so well indicates its power that it is not likely for some time, at all events, to grow into disuse), and it is also possible to "charge" a storage battery by means of a set of bichromate cells. How to make a "Home-made Storage Battery" is recently described in an article in the New York *Electrical World*, and the paper is quoted *in extenso* in the *English Mechanic* last week. The ingenuity, and power of using tools to advantage, required to construct such an arrangement are decidedly less than what would be needed for making cameras and camera appurtenances such as numberless photographic amateurs construct. Hence, after reading the instructions alluded to, it is quite possible that in the near future our amateurs may show us not only photographic apparatus of their own construction, but also dark rooms lighted by electric lamps, fed by batteries, alike made by the same hands. The lamps themselves are now to be had at such a cheap rate that it would not be worth while to attempt their manufacture, the vacuum producer needed for their construction being a most elaborate arrangement, not to speak of filament making.

STUDIO-BUILDING.

A WRITER in these pages has, in so complimentary a letter, asked for my views on studio-building, that, much as I dislike intruding my personality on questions where great diversity of opinion exists, I cannot but respond to the best of my ability. The Editor informs me that, in a further letter, "H. L." thinks I can put the matter in a nutshell—quite an impossibility. In entering upon this subject it may be said at the outset that the conditions favouring the design of such buildings at the present day are far less restrictive than in the times when we had no quick gelatine plates. Then we had to consider how to get as much light as possible to ensure rapidity on dull days; now we have rather to arrange how to diminish the light. Hence, the battle of lean-to, ridge roof, sloping front is almost ended, for the chief factor in determining one or the other was the angle at which the dominant light struck the glass on its path to the sitter, much light being lost by reflection when the angle was considerably divergent from a right angle. Hence we may be guided by conditions of convenience alone.

As *to the shape of the studio*, the "nutshell" idea will be perhaps carried out when I say that, granted a lofty building, and plenty of skylight and sidelight, it is the blinds, and the blinds alone, that govern the light. The common plan is to make them run close to the glass, but to do this is quite unnecessary. They may run in any direction most easily managed, whatever the shape of the roof, and at any distance from it. But it should always be borne in mind that, the farther they are away from the sitter, the less the variation in the light, and when a sitter changes his position, and also when a group is taken, the more even will be the illumination over the individual sitters composing it. To emphasise this idea, let us imagine a sitter placed in the middle of a roofless room with four opaque walls. Whatever the shape of the roof, supposing it all glass, the lighting of that sitter would be, for all practical purposes, identical. As to the aspect of the main light, the north has universal preference on account of there being least disturbance from the sun. By a north light is to be understood one which falls from that quarter on one side of the sitter when he faces due east or west.

For simplicity, and consequent cheapness, of construction, a ridge roof is to be preferred, and I will therefore describe such a one, and mention the conditions to be considered in erecting it. In building any studio whatever, it will be a mistake to be governed by the mode the light falls at the time of construction, unless it be near midsummer. Many studios built in spring or autumn, or in winter, which act admirably in those seasons, may be found to be greatly inconvenient when summer arrives, the sun then being so high in the heavens that it falls upon the glass and in front of the sitter, causing fogs and streaks through, perhaps, unnoticed sunbeams that are difficult to combat.

One of the most important considerations in arranging a studio is to be able at will to illuminate by a main light either the right or the left side of the sitter. It is not always enough, if one side of the face is found the best, to turn the sitter to the light if the side turned to the shadow is the one preferred. Power must be taken to cast the chief light on either side of the face. This may be effected in two ways. The studio may have a light on each side, one to be always screened off by blinds, or its fittings may be so arranged that the subject may be placed at either east or west end. I have tried both ways. The former I have found so objectionable in summer time, owing to the difficulty experienced in keeping the studio cool, one of the sides in such studio necessarily being south, and exposed to the full sun rays almost all the day, that I have abandoned it entirely, and gain all the effects I need by using either end of the studio at will. This arrangement, it will be seen, puts out of court the once famous "tunnel studio." My present studio is built with this double light, the south being much smaller, yet I have practically disused the south light. The glass on that side is nearly wholly roofed over with opaque covering placed *outside*, and ceiled inside under the glass to improve its appearance.

Another very important matter to be thought of in selecting the position of the studio is the direction of the surrounding buildings. If the studio be built in a garden with high buildings around it, it is evident that they may fatally obstruct light in one or more directions: but, as a counterbalance, these structures may also obstruct the sun's rays,

and prevent their entering the room. When, for example, they lie at the west end, they will, if lofty, quite keep out the sun's rays after noon, and greatly assist in cooling the studio, a most important thing to be attended to. But another aspect of the case then presents itself. If they do so obstruct the sun's rays, they will also obstruct the more front light from falling upon the sitter when he is placed at the east end. I name all these points, as they will assist in forming a conclusion as to the best aspect. If such buildings prevent the due use of a north light, a studio built to face the east—sitters placed at north or south end—will answer well, for, by ten o'clock in the morning, the sun will be well away from the east end, and will not fall inconveniently into the room. If, however, there are no tall buildings at the south, it will be found that sunbeams will be painfully prominent at work. A studio I once had was built in this direction early one spring, and it was not till the summer months approached that trouble was experienced. I got rid of it by erecting a tall wood screen at the sitter's end, outside (this was a tunnel studio built thirty years ago), and between the sitter and the camera was placed, just so high as to escape the range of the lens, a wooden false ceiling to intercept the direct rays. I was some little time in discovering the cause of certain streaks on the upper part of the plate, they being confused (this was in wet-plate days) by the streaks produced when a wet plate during development is held up to the light for more than a brief moment, but eventually they proved to be sunbeams.

I think I have now thus far so dealt with general principles as possibly to aid any one in forming his own plans when on the actual site of a proposed studio, and in a succeeding chapter I will enter more into practical details.

G. Watmough Webster, F.C.S.

A NEGLECTED DEVELOPER.*

Some years ago I tried a number of experiments with a view of adapting the hydrosulphite developer to gelatine plates without in any material way altering its original form and its simplicity of preparation, but I failed to secure any very conspicuous success, as the less energetic solution formed with sodium sulphite proved too slow, and the objectionable zinc salt formed an obstacle in the way of the other. Since that period, however, there have been introduced a large number of substitutes for pyro, and it is by no means impossible that, by the use of one or other of these instead of pyro, the objectionable precipitation may be obviated. This, at any rate, forms one direction in which it may be worth while to experiment.

But, failing success in that direction, we may look in another, that is to say, we may try the use of a solution from which the zinc has been eliminated or which has been produced without the assistance of zinc or other metal capable of forming insoluble deposit. For this purpose we have fortunately the choice of two or three different plans.

First of all we may employ the hyposulphurous acid itself, which is easily separated from the zinc, though its extreme instability scarcely renders that plan worth trying. Or we may separate the hyposulphite of sodium from the objectionable zinc-sodium compound, and this, though not a very easy process for those not accustomed to chemical manipulations, at least supplies us with a tolerably definite and stable product, which, if the demand arose, would, no doubt, become an article of commerce. Lastly, we may use, instead of zinc, a metal which forms no basic compounds similar to that of zinc.

The exact composition of the hyposulphite does not seem to be thoroughly agreed upon. In Watts' Dictionary I find it mentioned as Na II SO_2 while in a recent edition of *Fownes*, edited by Watts, the same authority speaks of it as $Na_2 SO_2$; the former has the composition of an acid, the latter of a neutral salt. The fact that either the acid or neutral sulphite, when submitted to the action of zinc, produces a solution possessing developing powers, renders it possible that there may exist two hyposulphites analogous in composition to the sulphites. The following is the method of preparing the salt in a state of isolation.

Let the concentrated solution of acid sodium sulphite be submitted to the action of zinc for half an hour, and then decanted into a flask containing about three times its volume of strong alcohol, and closely stoppered. The zinc-sodium salt, being insoluble in alcohol, is thrown down almost immediately, and, when the crystals have separated themselves from the liquid, the latter must be again decanted into a flask which it quite fills, and once more closely stoppered or sealed. In the course of a few hours the flask will be filled with a mass of fine colourless crystals, which must be rapidly separated from the liquid, pressed between folds of linen, and dried in a vacuum, as so strong is their affinity for oxygen whilst moist that they become quite hot, and are reconverted into acid sulphite. When dry, however, they are comparatively little affected by oxygen.

The solution of this salt possesses all the decolourising and reducing action of the free acid, than which, however, it is much more stable, although, when in solution, it rapidly reverts to the condition of acid sulphite. If it be desired to use the acid itself, it may be separated from its sodium salt by means of oxalic acid. It forms a yellow solution, which rapidly loses its power, being converted into sulphurous and thio-sulphuric acids with liberation of sulphur. Or the acid may be prepared by digesting zinc in the aqueous sulphurous acid of commerce, in which case, however, it will most probably be useless for gelatine plates owing to the presence of zinc in solution.

Probably the best plan of preparing a solution which does not cause a veiling of the gelatine film, and which yet obviates the trouble of preparing the crystallised hyposulphite, will be to reduce the bisulphite by means of another metal than zinc, which does not form the objectionable precipitate. For this purpose nothing seems better suited than sodium itself, the only objection to it being its comparatively high cost, which, however, at the present day, is not an insurmountable difficulty. In such a solution, instead of the zinc-sodium sulphite accompanying the sodium hyposulphite, we should, of course, have only sodium salts, none of which would be likely to cause any trouble in the direction mentioned, unless, perhaps, it be the thiosulphate. This, however, would, we think, require the presence of some free acid, other than hyposulphurous or sulphurous, to cause any deposition of sulphur during the period of development, although it is not quite safe to predicate what might or might not occur with the oxidation of the liquid.

At least the experiment is worth trying. I some months back obtained very promising results with the crystallised hyposulphite, and only relinquished my experiments in consequence of the trouble involved in its preparation. I have more recently been induced to take the matter up again, and shall probably have more to say on the subject at no distant date.

The advantages to be anticipated in the use of such a developer are, chiefly, cleanness of action, freedom from stains, and good quality of image, together with most excellent keeping properties in the solution itself. For be it understood, although the hyposulphite itself may quickly revert to its former condition of bisulphite, its extraordinary preservative action upon the pyro or other reducing agent protects that from oxidation, so that it is not impossible that a stock solution of pyro may be made which only requires the contact with zinc or sodium to supply it with energy without the addition of alkali.

But, beyond these, I believe a far more energetic developer for short exposures may be the outcome of the inquiry, while the possibilities that surround an acid developer form as yet entirely new ground.

I see in last week's issue, in the report of the Photographic Society's meeting, that Mr. Chapman Jones has pointed out the fact that amidol is capable of development in the acid state. This is one of the points on which I have been relying in my search for a more energetic developer, but the bad weather and the state of my health have not allowed me to pursue my experiments recently. Amidol, like pyro, is incapable of development alone, but both in the presence and with the assistance of a sulphite even if acid, possess developing power. How far the vastly greater reducing action of sodium hyposulphite will work in with amidol to make it *really* the most energetic developer extant remains yet to be seen, but from what I have observed already amidol seems to offer a far better look-out than pyro, and to work in a more cleanly manner than the latter in the combination.

W. B. Bolton.

* Concluded from page 117.

ON THE TONING OF SOLIO PAPER.

[Photographic Club.]

I HAVE thought that, instead of giving you a paper on the combined toning and fixing, it would be preferable to give you a few hints on the general toning of Solio paper, in the manufacture of which I am personally interested.

We have now arrived at that point where the new printing-out paper is no longer in the experimental stage. It is largely used by the best photographers, both here and in America, and all speak in glowing terms of its superiority over albumen. This dear old friend albumen has had its death-bell tolled many a time before—certainly it has been the case every year during the last ten years—and yet it has lingered on, dying hard at the last. I think every one must see around them that albumen is giving place not only to the new printing-out papers, which must resemble it in appearance, but also to platinotype, bromide, and kindred processes.

As this is to be a practical paper, I do not intend to dwell too much upon the *pros* and *cons* of the process. With this paper we have the greatest range of tones that the most fastidious can desire. Of course, as with albumen, it is of the first importance to have a good negative. Having secured this, it is easy to secure a good print; but there is no doubt that with the new printing-out paper there is a far greater range to be obtained than with any other process. We have also at our command the capability of giving to our prints either a glazed or dead matt appearance with but very little trouble.

On the question of permanency, there can be no doubt there is a greater chance of achieving this than with albumen, which we all know is so liable to go wrong; but to attain this, as with all photographic manipulations, it is necessary that due care be exercised with the various stages through which the print has of necessity to go. To say that a Solio print is absolutely permanent would be taking a great responsibility upon myself, for in this mortal world of ours anything on paper could not be so; however, I will say we can obtain a reasonably permanent result. The fading of prints is, I believe, more often caused through unsuitable mounts and bad mountants than through any inherent defects in the prints themselves.

As with all new processes, it is necessary that we take some trouble to understand the little peculiarities incidental to its working; and, when these are once mastered, you will be surprised at the simplicity of the whole thing. In the printing paper before us we have chloride of silver, in conjunction with a definite organic salt of silver, held in suspension in a vehicle composed mainly of gelatine, and this is coated on a paper with a baryta surface, which prevents it sinking into the fibres of the paper, and we have a more brilliant print, and the elimination of the hypo is more easily effected. To get even prints, and to prevent uneven toning, it is absolutely necessary that the paper should not be allowed to become damp before printing, and, when separate toning and fixing baths are employed, care should be taken that the hands are not contaminated with hypo during the preliminary washing and toning, otherwise red stains will inevitably be the result.

As this paper is peculiarly susceptible to a diffused light, great care should be exercised in handling it in a very subdued light, both before insertion in the printing frame and during examination of the print, otherwise the high lights and purity of the resulting picture will soon be destroyed. It is not necessary to carry the prints to such a depth in printing as is the custom with albumenised paper, as the loss is not so great in the subsequent toning and fixing.

Now we come to the all-important question of toning. What bath shall we use? I think the first to engage our attention is the combined toning and fixing, about which there is such a divided opinion as to the permanency of the prints produced from it. There certainly is a distinct charm in the use of a combined toning and fixing bath, especially as no previous washing is required, the prints being taken direct from the printing frames and immersed in the one solution. There are amateurs who do not, and will not, use separate fixing and toning baths when there is one to be had that will do everything that is required in one bath. As long as too many prints are not toned in one bath, there is no danger of less permanency than with any other bath; but, if the gold is exhausted, the toning proceeds with the lead, and probably sulphur also, in which case the prints *may* possibly change, but I do not think they would fade. The chances are they may become darker, especially should there be any sulphur in the atmosphere, and I fancy there is a good deal in London. This will probably attack the lead, and form sulphide of lead. The opinion of any chemist here to-night on this matter would oblige. I have prints here which have been standing about on the mantelpiece of my sitting-room for over six months, and show no signs whatever of any change.

The formula recommended by the Eastman Company is as follows:—

Stock Solution No. 1.

Hypo	6 ounces.
Potash alum	1½ „
Sodium sulphate (Glauber's salts)	4 „
Water, make up to	60 „

First dissolve the hypo and alum in the water, then add the sodium sulphate.

Stock Solution No. 2.

Gold chloride	15 grains.
Acetate of lead (sugar of lead)	50 „
Water	7½ ounces.

Note.—An orange precipitate is formed in No. 2 solution, which, however, redissolves on its being added to the No. 1 solution.

To form a combined bath take of—

Stock solution No. 1	8 ounces.
Stock solution No. 2	1 ounce.

Do not use until the mixture has become quite clear.

In all solutions composed of hypo and alum it will be found that there is always a slight white precipitate. This, however, does not interfere with toning. This bath is very useful indeed for giving soft prints from hard negatives. It is not advisable to attempt to produce purple or black tones with this bath.

For those who prefer a separate toning and fixing bath, and one that will produce warm black tones, there is nothing better than the sulphocyanide bath. In order to have this bath under greater control, the addition of acetate of soda is of very great advantage; not only does it slow down the toning action, but the prints are not so liable to take that very objectionable blue surface tint which sulphocyanide, *per se*, is so apt to produce; the tones of the prints can be more closely watched. Where possible, it is certainly better to tone by daylight rather than by artificial, as with the latter it is far more difficult to watch the various changes of tone. Of course it must be done in very subdued light. As I said before, no hypo must come anywhere near the prints during the toning, otherwise the prints will be irretrievably ruined with red stains that will refuse to tone.

Owing to the softening action of sulpho-cyanide on the prints, they should be washed in two changes of water, and then passed through a bath of alum water (alum half an ounce, water twenty ounces). After this they should be well washed in three changes of water, and then placed in the toning bath, as follows:—

Stock Solution A.

Sodium acetate	600 grains.
Water	20 ounces.
Gold chloride	15 grains.

Stock Solution B.

Ammonia sulphocyanide	50 grains.
Water	20 ounces.

For use, take of A two ounces, B two ounces, water four ounces. Allow to stand one hour before using.

The toning may be stopped at any stage by immersion in a bath of salt:—

Common salt	1 ounce.
Water	32 ounces.

For securing still greater control and regularity of toning, it is advantageous to use two-thirds of an old bath and one-third of a new one, omitting the water.

After removal from the salt bath, the prints should then be transferred to the fixing bath. This should not be made too strong.

Fixing Bath.

Sodium hyposulphite	3 ounces.
Sodium sulphite	1½ „
Water	20 „

The addition of sulphite is to preserve the purity of the tones.

There are some amateurs, in contradistinction to those who will have the greatest simplicity, who prefer formulæ of the greatest complication (take, for instance, some of the developing formulæ published), and it is for these that I bring forward the following not too complicated method of toning, in two toning baths, the second being a toning and fixing combined.

First tone very slightly indeed to a light brown in the following the prints having been previously washed, as usual):—

Potassium chloro-platinite	5 grains,
Sodium chloride	40 „
Citric acid	40 „
Water	20 ounces,

and immediately transfer direct to the combined toning and fixing bath as first mentioned in my paper until the desired tone is obtained. This produces tones of a rich, warm black; but, if purple tones are desired, tone first in the sulphocyanide, and then follow with the combined bath. Certainly the tones produced by it are very fine.

Where prints are desired of a nice sepia, tone a little deeper in the platinum bath, and fix as usual in the ordinary way. Care must be taken not to go beyond the brown stage. Prints produced in this platinum bath only are best finished off with a matt surface. As my paper is intended to be devoted to toning only, I will leave the subject of finishing, &c., to some other member to take up.

J. B. B. Wellington.

DEVELOPMENT OF ROLLABLE FILMS.

Before the Putney Photographic Society on Monday, February 20, Dr W. J. Sheppard in the chair, Mr. J. B. B. Wellington, of the Eastman Company, gave a demonstration on *Development of Rollable Films*. In a short preface he gave a history of the improvements of these films, culminating in those manufactured by the Company at the present time. The chief advantages claimed were extreme lightness, portability, and the convenience of being able to carry 100 exposures, very great advantages when travelling. Having brought a roll of exposed films, Mr. Wellington showed how very plainly their new roll-holder marked the divisions between the exposures, thus getting rid of a difficulty which had been experienced with the earlier patterns. Proceeding with the demonstration, he first soaked the films in water, which certainly caused them to lie quite flat during development. At least a dozen films were treated simultaneously, being placed face downwards, and care taken to keep them constantly moving by transferring those from the bottom to the top, in the same way as prints in a toning bath. This treatment is essential to ensure even development. The developer used was the pyro-soda recommended by the Company. Mr. Wellington stated that, in cases of under-exposure, better results would be obtained by long development than by increasing the quantity of soda. After development, the negatives were rinsed and placed in an acid and alum clearing bath, washed thoroughly, and fixed. The final washing completed, the films were placed face downwards on an opal slab or glass plate, and squeegeed to get rid of the superfluous moisture. They were then pinned down at the corners and allowed to dry spontaneously. The best way to store them was under pressure between the leaves of an album or book. During the discussion, Mr. Wellington stated that various marks which undoubtedly occurred in their films some time ago would not now appear, as great improvements had been introduced in their manufacture.

THE STEREOSCOPE AND STEREOSCOPIC PHOTOGRAPHY.*

No doubt some persons will at first find considerable difficulty in combining the two pictures when they have been mounted in this way, and this is because, as a rule, the eyes have a greater tendency to a near convergence than to a more distant one. When this is the case, the lenses of the stereoscope, if they are adjustable for separation, should be separated slightly until the pictures can be combined, and then slowly brought together again to the required positions. If the lenses are not movable, the best plan will be while looking through the stereoscope to push back the pictures as far from the lenses as the instrument will permit, and it will be found that while this is being done they will appear to approach one another. When they are apparently superimposed, pull them forward again slowly, and if the eyes are kept intently fixed upon them while this is being done, they may be drawn forward until the view is seen quite sharply without appearing to separate again. In many of the cheaper forms of stereoscope, instead of a pair of lenses, the two halves of a single lens are employed mounted so that their thin edges are together. Whole lenses are preferable, but they must be of equal focus. Sir David Brewster recommended the use of halves of a single lens, not only in the stereoscope, but also in the binocular camera, for taking the photographs, because of the difficulty of obtaining two lenses of equal focus. He contended that it was impossible to obtain the necessary mathematical accuracy unless this was done; but, whatever may have been the case then, there is no difficulty now in obtaining lenses that are sufficiently accurately paired for all practical purposes.

* Concluded from page 138.

The earlier stereoscopic photographs were taken, as you are no doubt aware, with a single camera and lens, the apparatus being moved a suitable distance between the exposures; and if it is not desired to photograph moving objects, this plan may still be adopted. It is not necessary to move the whole camera and stand. All that is required is that the tripod should have a rather larger top than usual to permit of the camera being slid about three inches between the two exposures. Even this is not absolutely necessary. Mr. Traill Taylor has pointed out that it is sufficient if the camera be slightly rotated after the first exposure. I have tried this myself, and find a very slight rotation is all that is necessary; but I would not recommend this method in preference to the use of a divided camera and a pair of lenses. This is no doubt the apparatus that all those will use who, like myself, wish to obtain their results with the greatest ease. Such a camera may be used either in the hand or upon the tripod, but in either case it must possess several good qualities in order to be satisfactory in use. If it is for the tripod it should have a swing-back and rising front, and some means of adjusting the separation of the lenses. It should open out to focus when eight or nine inch lenses are required to be used, and close into three inches or less when a pair of wide angles are necessary. If it is to be used in the hand, many of these advantages may be sacrificed to lightness and portability; but special attention should be directed to the shutter and the view finder. In both forms it is, above all, necessary that a good spirit level should be fitted, and careful attention paid to its use, for although in a single photograph we may easily trim the top and bottom to correspond with the horizon line, it will be found not nearly so simple a matter to counteract the effect of carelessness in this respect in a pair of stereoscopic pictures.

Opinions are somewhat divided as to the size of plate that it is desirable to use. Personally, I think that the advantage of a plate larger than the standard size, $6\frac{3}{4} \times 3\frac{1}{4}$, will not often be found, but I must tell you that some gentlemen of very great experience recommend a larger. Mr Traill Taylor advises 8×5, which certainly permits a greater separation of the lenses when it is desired. Other sizes which may be used are $7\frac{1}{2} \times 4\frac{1}{4}$, $6\frac{1}{2} \times 4\frac{3}{4}$, and $6\frac{1}{2} \times 4\frac{1}{4}$. It is generally conceded that for all ordinary purposes of stereoscopic photography a pair of single lenses will answer equally as well as the more expensive doublets, even disregarding the somewhat theoretical advantage of the former of giving greater brilliancy because of the smaller loss of light by reflection. But, of course, where a large angle of view has to be included, a pair of short-focus doublets will be necessary, and there will be a slight gain in the use of doublets where it is desired to obtain the maximum amount of definition with a large aperture of lens, as, for example, in photographing moving objects.

It will be found that those pictures which have been taken with lenses of about five-inch or six-inch focus, present in the stereoscope the most natural appearance, and for this reason, that the eyes of the observer are then placed at about the same distance from the pictures as the lenses were from the plate when the view was taken, viz., about five or six inches, and the perspective therefore coincides with what we observe in nature.

If shorter focus lenses are used, as they must be for many subjects, then the perspective is bound to appear somewhat exaggerated, and objects will appear smaller than they should do.

It may be suggested that for the examination of these pictures lenses of short focus should also be employed in the stereoscope, and I know of no reason why this should not be done. The amount of separation that there should be between the lenses by which the photographs are taken has been the subject of much discussion. Three to three and a quarter inches is the usual distance, but I am of the opinion myself that it should not so much exceed the distance between the centres of the eyes, usually about two and a half inches; and it will be found that if a very near object, eight or ten feet away, is photographed with a greater separation than this, a strained and altogether unnatural appearance of relief will result when the pictures are seen in the stereoscope. Of course, if it is desired to represent distant objects with the relief due to those near at hand, it is necessary that the points of view should be very widely separated; but, if it is desired merely that the pictures when seen in the stereoscope shall present the same appearance as the view itself presented from the position at which the photographs were taken, then the rule may be laid down that for an ordinary landscape with near foreground the distance of separation should not be more than three inches nor less than two and a half inches.

As a stereoscopic camera makes its two pictures independently by separate lenses, it will be seen that each picture is inverted independently of the other. Therefore it is necessary, if the negatives are to be printed from by contact, either to divide and transpose them before printing or to divide and transpose the prints, unless each end of the negative is printed from alternately. Which is the most convenient way will depend

upon whether it is desired to make prints upon paper or transparencies upon glass. If paper prints are wanted, then it is generally recommended to print from the two negatives in the usual way on to one piece of paper, and when the toning, fixing, washing, or other processes have been gone through, and the prints are dry, to divide and transpose them, mounting the print which appears on the left-hand side, as they lay together on the table before you, on the right-hand side of the mount, and the right-hand print on the left-hand side of the mount.

If it is glass transparencies that are required, then it will be found easiest to print alternately from each of the two negatives; that is, to print from the left-hand negative on to the right-hand side of the transparency plate, and from the right-hand negative on to the left-hand side of the transparency plate. By means of a printing frame which is specially constructed for this purpose, and which may be procured from any dealer in photographic apparatus, and by using with it a set of cardboard guides, such as I have here, and which you may easily make for yourself, this may be done rapidly and easily.

Care must be taken that each of the pictures is given an equal exposure, and I find, myself, that this may be done with sufficient accuracy by burning one inch of magnesium ribbon at a measured distance from each negative. Stereoscopic transparencies may be made in this way that will be good enough to satisfy the most particular; but there is another way in which they may be produced that is, perhaps, superior in some respects, and is equally convenient when the work can be done by daylight. This is by copying the negatives with a divided camera, and a pair of short-focus lenses. This method obviates the necessity for transposing the pictures, for each negative is independently inverted by each lens, just as the picture itself was inverted when the view was taken. Another advantage of this method is, that one is able to arrange, with the most perfect accuracy, the desired distance of separation between similar points in the two pictures, which it is practically impossible to do exactly when they are printed by contact, owing to the fact that the glass of the negative and the glass of the transparency plate is seldom cut to the exact size. It is hardly necessary to mention that, when this way is adopted, the pictures may also be slightly enlarged or reduced in copying if it is desired. It is not necessary to have a special copying camera for this purpose. The camera and lenses with which the pictures were taken will answer almost equally well if it is attached to a board, at the end of which the negative is supported in a divided box. The arrangement which I use myself is, as you see, made on this principle.

The effect of a stereoscopic picture is very much enhanced if, when it is seen through the stereoscope, it presents the appearance of being viewed through an opening. This may be produced in a transparency by having the openings in the mask at somewhat nearer centres than are the pictures themselves, and with paper prints by so trimming them that, when they are mounted, there is a little more of the view on the left-hand side of the left-hand picture than there is on the left-hand side of the right-hand picture. The reason why doing this should cause the picture to appear as if it were viewed through an opening will be seen if it is remembered that we estimate the distance of an object by the amount of convergence of the optic axes necessary to see that object, which becomes greater when the object is near at hand than when it is remote. The openings in the mask, being at nearer centres than the pictures themselves, are seen with greater convergence, and consequently appear some distance in front of them. The same may be said of the edges of paper prints; when they are at nearer centres than the pictures, the mount appears to be in front of them.

The amount of separation determined upon between the centres of the pictures should, for the reasons I have before mentioned, always be measured between two similar points in the distance, altogether disregarding the foreground; and here I am sorry to say that I find myself at variance with a gentleman who has by his persistent advocacy done a great deal in the last year or two towards bringing the stereoscope into favour again, Mr. Chadwick. In his *Stereoscopic Manual*, in which will be found much practical and useful information, he says: "It must be observed in these instructions that in all measurements it is the foreground which must be taken into account, and the distance will take care of itself." I claim that what should be done is the very reverse of this. All measurements should be taken between similar points in the distance, and the foreground will then take care of itself. The foreground must be right if the distance is correctly placed.

The difference may be a small one, and it may be that when Mr. Chadwick's instructions are intelligently followed the results will not be greatly different.

There is, however, this to be said. If a view was taken in which was included a very near foreground indeed, it is quite conceivable that if Mr. Chadwick's instructions were followed we might find similar points in the distance so widely separated, that for the images of them to fall on corresponding points in each retina the optical axes would have to diverge if the pictures were examined in a stereoscope of the usual pattern.

It should always be remembered that the stereoscope shows us its most remarkable effects when the photographs that are seen by its aid are placed at such a distance of separation that they are seen with the same convergence of the optic axes as the actual view itself was from the position of the camera in taking them, and when the lenses of the stereoscope are of such a suitable focus that the pictures are seen sharply, clearly, and easily at a distance from the eyes equal to the focus of the lenses that produced them. When these conditions are complied with, and they will be complied with if the methods I have indicated are adopted in the production of the photographs, then it is impossible to imagine a more perfect realisation of the view represented than that which will be seen when the pictures are examined by the aid of a suitably adjusted stereoscope.

J. A. Butler.

A CHAT ON LENSES.

[Before the Photographic Section of the Croydon Microscopical and Natural History Club.]

On March 3 Mr. W. Low-Sarjeant delivered *A Chat on Lenses*. After a brief explanation of the elementary laws of optics, Mr. Sarjeant described the properties of the six varieties of lenses, and also of a seventh, called a "crossed" lens (a double convex lens, having its two curved surfaces of different radii).

In photography, the use of a lens composed of a single element was attended with two great disadvantages, viz., chromatic aberration, or the non-coincidence of the visual with the chemical focus, shown by a want of definition in the photograph; and spherical aberration, producing a similar result, owing to the rays of light passing through the margins of the lens intersecting at different points instead of at one and the same point. The first-named was corrected by the addition of another element with a different refractive index (crown and flint glass were the two elements commonly used), and the latter by the addition of a second lens, reversed, to correct the aberration of the first, as in a rectilinear combination; or it could be practically eliminated in the single or landscape lens, by using a diaphragm of relatively small size compared with the diameter of the lens.

The purpose and uses of the stops were then explained. With a single lens, owing to the office performed by the stops, it was advisable to focus with the same stop it was proposed to use in exposing.

The focal length of a lens was measured from its optical centre, the position of which, in the several forms of lenses, was shown by diagrams. To find the focal length of a lens—information often desired for various purposes—several methods of obtaining an approximately correct result were given. Focus a distant object in the camera, and the distance between the screen and the optical centre of the lens would be, roughly, the focal length; or, focus some object, getting the image the same size, and the distance between the screen and the object would be about *four* times the focal length.

The comparative advantages of the use of long and short-focus lenses were then discussed. A long-focus lens was most suited for ordinary outdoor work, as the natural proportions between near and distant objects was better preserved in the photographs taken with it.

The "chat" was illustrated by a large number of diagrams, and was listened to with much attention by the members. The questions which were afterwards discussed showed that they had been enlightened on many hazy points, and would, consequently, be enabled in the future to use their lenses to better advantage.

PRACTICAL REMARKS ON LANTERN-SLIDE-MAKING.

[Dundee and East of Scotland Photographic Association.

At the fag-end of a meeting last session, Mr. Baird passed through the lantern for me a number of my slides, interesting chiefly because made by some of the less-used processes; and, as I have been repeatedly asked by members of the Society to show them again, I have extended the idea somewhat, and pose to-night rather as an experimentalist than a practical slide-maker.

When I take up a process, I generally keep at it until I have made what appears to me the most of it; in any case, I never stop short of being able to produce presentable results by it. In many instances I have gone on until such time only as I had mastered the process and produced one or two slides by it. It frequently happens that a process may be capable of giving very fine results at times, and yet not such a process as one would care to work constantly. In such cases, it is excellent practice to make a small study of the subject, and after attaining success to "leave it for fresh fields and pastures new."

You will please understand, therefore, that the slides which are to be shown you are not shown as models of what slides ought to be, but merely as fair specimens of the various processes they are to illustrate.

Almost every process requires (if one is to make the most of it) a

special quality of negative. It follows from this that I have had to pick out from my negatives one suitable for the process in hand rather than one artistically good. Let no one, therefore, go away, saying there is nothing special in this slide or that slide; the production of a pretty picture was not always the aim of the experiment.

While, therefore, safeguarding myself against the imputation of putting these slides forward as being something specially fine, I, nevertheless, claim that they represent fair average work of the various processes touched upon, and such as any one designing to work any of these processes may attain to, with the moderate care which the average amateur bestows on his work.

As to the precise practicability in every-day work of these out-of-the-way processes, I will speak more particularly later on. My remarks will apply to slides in collodion wet and dry (but not with collodion emulsion, with which I have done very little), carbon, gelatino-chloride, gelatino-bromide, powder process slides, Alpha and albumen. I include the better known processes for comparative purposes.

As conclusion to this introduction, I may say that most of the slides have been made quite recently, that is to say, I have prepared the most of them to refresh my memory for, and to serve as illustrations to this, paper.

Collodion Slides.

With the exception of slides done by the Woodburytype process, collodion is the process adopted by probably ninety-nine per cent. of the professional slide-makers. It seems absurd, therefore, to include this as one of the "out-of-the-way" processes. It is so, however, in reality as far as the amateur is concerned. From time to time attempts are made to show how simple the whole thing is, and how unobjectionably simple it truly is, but not unobjectionable. What are the claims made on behalf of the collodion slide? They are these:—First, absolutely pure high lights; second, vigorous shadows; third, good gradations; fourth, agreeable colour. These good qualities a collodion slide generally has, but there is one good quality which a slide ought to have which the vast majority of collodion slides have not, that is, transparency in the shadows. I maintain that with *suitable* negatives gelatino-bromide does come within measurable distance of a collodion slide with a tithe of the trouble. To test this point, we will ask Mr. Baird to place the two slides marked 1 and 2 in the lantern. No. 1 is a collodion slide by Wilson of Aberdeen, a master of the art of slide-making; No. 2 is a gelatino-bromide slide from one of my own negatives on a commercial gelatino-bromide plate.

I maintain, and I think you will agree with me, that, while there is a difference, the collodion slide is not immensely better. If collodion cannot do *very much* better than gelatino-bromide, I hold that, to the amateur, the extra mess and trouble simply exclude collodion.

My remarks heretofore have related to wet collodion, but very fine slides may be made on dry-collodion plates, bath prepared.

Slide No. 3 was made as follows:—A plate of glass was cleaned, and coated with collodion, dipped in a bath of silver thirty grains to the ounce, and then washed, flooded with an infusion of pure coffee, and dried. After exposure under a negative to gaslight, the transparency was developed with acid pyro and silver. It came up the colour you see it, no toning being necessary. Of course, it was fixed in hypo.

Various preservatives, other than coffee, may be used, and different colours obtained in the slide. An infusion of tea gives a brownish tint, and tannin gives a very fine purple-blue—better, I think, than a wet-collodion plate toned with a sulphide.

I sometimes wonder why it is that dried bath plates are not supplied by the dealers. They are extremely easy and certain of preparation, would compete with gelatine plates in cost, and, preserved with a solution of albumen, are hardy enough to stand pretty rough handling.

My best collodion slides have been prepared by this dry method. I selected this one to show the peculiar colour got by a coffee preservative. For those who care to try the collodion process, I would advise a preservative of ten grains of tannin, and ten of sugar candy, to an ounce of water. Plates so prepared give excellent slides.

Carbon Slides.

We pass on now to the consideration of carbon slides. Carbon is said to be *the* process for producing slides of the two extremes—best and worst. I must say that no process in photography came so near to going up my back (as the saying goes) as the production of carbon slides. The Autotype Company, in their manual, say that *very fair* slides may be produced by the carbon process. I think that this is over-modestly stated. Of course, a good deal depends upon what qualities one likes in a slide; but, for myself, I only wish I could produce all my slides in carbon.

Scattered throughout photographic literature are articles on the production of slides in carbon without number. According to most of the writers, it is an easy process, according to all a beautiful one. To read the commonplace and general directions given would lead one to suppose that mistake was impossible. Methinks some of those who have written on the subject have never made carbon slides. I cannot give you a better idea of the troubles one may meet, and how they may be overcome, than by giving you a short history of my own experience.

When I first determined to try the making of carbon slides, I was even then a fairly efficient printer in carbon, and had plenty of material by me. I had no special transparency tissue, it was true, but had I not read again and again that ordinary tissue would do excellently—indeed, in some cases, better than the special transparency tissue? I made the experiment. Result, universal flatness and weakness. I tried a denser negative. Improvement, but not much. Then I would intensify the slide. How I laboured at this! At last, after a great many failures, I got one good picture. Mr. Baird will show it as slide No. 4. This slide, after development, was soaked in an infusion of logwood, lightly washed, and soaked in a weak solution of sulphate of iron.

The great trouble in this staining process is this, that, do what you will, your high lights take on the stain. I am aware that, theoretically, the high lights in a carbon slide ought to be bare glass; but, practically, there is an imperceptible skin—enough, when stained, to spoil the slide.

The picture on the screen is absolutely the only one I ever got with pure high lights by this staining methods. I then sent for the special transparency tissue, and wish I had done so at first.

The special transparency tissue carries much more pigment, and pluck and density are now with suitable negatives quite possible.

My method of producing carbon slides is as follows:—I cut a dozen or so pieces of tissue by means of a tin shape to exactly three and one-eighth inches square. I make a solution of bichromate of potash, one ounce in thirty ounces of water, and place the tissue in this—"over the head," so to speak. When they are quite soft and limp I take them out one by one, and place them face down on a piece of plate glass, and by means of a roller squeegee drive off the free solution hanging about them. I then take them from the glass, and place them face up on a blotting pad. Upon this they are placed in a locked press, and in the morning they are generally dry and ready to print. Much stress is laid upon the rate of drying, and being in a room free from fumes of gas. Working in this way, I have never had any trouble, and even in a moderately small press, if it is not damp, the tissue will dry in a night's time, and be out of the way of light, fumes, or any other injurious influence. I have never found it necessary to dry the tissue on collodion plates. In the morning the tissue is printed under the negative. In mounting the tissue on the glasses for slides I had two troubles. First, the tissue would sometimes wash up and, secondly, air bells would get between the tissue and the glass in spite of everything I could do. I cured these faults as follows:—If the glasses are thoroughly scoured with a clean rag and common whiting under the tap, and the surface not touched again with anything under the sun till the tissue goes on, it will stick like glue. As for the air bells, mount the tissue on the glasses under water which has been heated and then allowed to cool, and there will be no more trouble. *En passant*, I may say that to those who are annoyed with air bells under their gelatino-chloride prints the same method will put an end to their troubles.

In developing carbon slides, beware taking too hot water to them. I am convinced that we would hear less of reticulation if more caution were used in this particular. As I am making no pretence to a complete guide to carbon slide-making, I content myself with these few practical remarks on the process. Even a suitable negative (and too much stress cannot be laid upon this), carbon slides, in my opinion, cannot be beaten. If it be asked, What is the special kind of negative? the answer is, that the negative must be extremely dense, with good gradation and very clear shadows. A hard black and white negative useless for any other process is about the thing for a carbon slide.

I may say that transparency in the shadows is the chief virtue in a carbon slide as against the other processes. Mr. Baird will pass through one or two carbon slides unstained.

Gelatino-chloride and Bromide.

I have little to say on the gelatino-chloride slide. Altogether, I have not used more than four or five dozens of this plate, and, while the results were generally very fine, the developers were a pest to make up, besides being somewhat expensive. The variety of colour is very considerable, but not very thoroughly under control—at least, that was my experience. I was not so much taken with the process as to take to it as a standard method of slide production. Mr. Baird will show a few on the screen.

As to gelatino-bromide, that being the general method of slide production in use by the great bulk of amateurs, I would make a few general remarks only. In the first place, given a good negative, I have produced first-class slides by almost every advertised brand of lantern gelatino-bromide plate. At this moment, if I had to produce a slide specially fine, I would only stipulate to have the information of the maker's name. I have gone into this question pretty thoroughly, and am convinced there is little to choose between the various brands—I mean in the possibility of getting good slides from them. When I hear many complaints about bad plates, I always feel inclined to ask for a sight of the negatives which are being printed from.

There is a very widespread idea that a good slide can be made from any kind of negative by simply timing the exposure properly. This, I think, is erroneous. If you want clear, sparkling, high lights with rich luminous shadows, you must have a tolerably vigorous negative with the necessary gradation in it.

However it comes about, I find I get better results by intensifying my negatives first. I bear this in mind in development, of course, and am content with a somewhat feeble image. I think I see all through better what I am doing this way. So long as you can see easily through

the plate during development you are not working in the dark, but long before the negative is thick enough to do without intensifying the most of the plate is absolutely opaque, and you cannot tell how far the process has gone, perhaps much further than you want. I think the great secret of slide-making is in having a good negative. To keep up a kind of consistency, Mr. Baird will pass a few gelatino-bromide slides through the lantern.

The Powder Process.

The next process upon which I would make a few remarks is known as the powder process. I am not aware that any one actually makes his slides by this process; but, as it has a certain interest and is an exceedingly beautiful process, I have made a fresh slide and will say a few words on the subject. To those who do not know anything about it, I may briefly say that the process is this:—A clean glass slide plate is coated with a watery solution of gum arabic honey, and bichromate of potash. The plate is dried on the top of the dark-room lamp, and immediately exposed to daylight under another transparency. After a variable time depending on the light, from twenty seconds in direct sunlight to minutes in the shade, the plate is taken to the dark room, removed from the frame, and a small quantity of impalpable powder placed upon the surface. A fine soft camel's-hair brush is now used to spread the powder over the plate, and in a few minutes it will be observed that the powder begins to adhere to the surface of the plate in an irregular way, in fact it is a picture that is being developed. The explanation of this apparently extraordinary phenomenon is simple enough. The solution of gum arabic and honey is ordinarily very much prone to absorb water from the atmosphere and become sticky. When the bichromate of potash is added to it and the sun acts upon the mixture, it loses this property of becoming sticky. It follows from this that a plate coated with the mixture and exposed under a transparency loses its adhesive nature in proportion to the effect of light upon it, so that those parts exposed to the sun take on no powder but remain pure glass, which makes your high lights on the contrary, the shadows having been protected from the light room get adhesive when exposed to the air and hold on to the powder when it is brushed over it. Since a transparency must first be produced by some other means, the powder process would seem to be "a round-about road for a near cut;" but do not forget that a powder picture is first permanent; second you may develop at one part and leave another soft and hazy; and, thirdly, you have absolute control over the colour.

Having nothing else beside me at the time, I developed the picture shown with common soot from the chimney, which, as you will see, gives a kind of sepia tint. If any of you have not worked this beautiful process, let me urge upon you to spend some of your spare time upon it when the light gets good. I can promise you a real "eye-opener," as the Americans would say, when you see the picture develop the first time. It is simply astonishing. Please do not judge the capabilities of the process from this specimen. When I was working at it three years ago, I made two or three dozen of beauties, but have since given one away here, and another there, till I had not one slide left. I had, therefore, to make this one, and one cannot be expected to turn out a perfect slide at the first shot. Plumbago is often used as a developing powder; to my mind it gives an unpleasant colour to a transparency. There used to be sold a powder for this process, for the production of burnt-in enamel—just the very thing for transparencies. I wish I could have shown you a transparency developed with it—a beautiful, rich, soft photographic purple. I do not, for a single moment, imagine that any one would adopt the powder process as a regular method of making lantern slides, but a trial of this beautiful process would well repay the time and trouble spent on it.

Alpha Plates.

I have done a good deal with Alpha plates, and like them immensely. I have two practical hints to give which might be of service to those intending to try them; and the first is, that a very much softer and superior image is developed with carbonate of potash and hydroquinone than when the caustic soda is used. The second point is, that superior tones are got by simply adding a little gold to an alkaline fixing bath than by using a separate toning bath, or even the combined toning and fixing with sulphocyanide.

I had intended to say something on albumen slides; but it occurs to me that already this paper is long enough, and the days of albumen too long past to be of much interest. It is a difficult process to work, but yields magnificent results; not, however, better than some of our modern processes, which are infinitely less trouble.

In conclusion, the opinion which I hold at the present time is that, for the amateur, commercial gelatino-bromide in skilful hands is everything that can be desired for cold tones. If warm tones be required, let him make his negatives suitable for carbon, or, failing that, use Alpha plates. I have already said that I attach ten times the importance to the negative that I do to the method of slide-production.

J. K. Tulloch, M.B.

BLACKHEATH CAMERA CLUB EXHIBITION.

This Exhibition was held on Friday and Saturday, March 3 and 4, the Judges being Messrs. Cembrano and Pringle, and the Rev. F. C. Lambert. In the Members' Class Mr. E. Hawkins took the silver medal for *Autumn at Frognal*, in which, to our thinking, the effects were more wintry than autumnal. Mr. A. W. Young's bronze medal for *An Interior* was honestly earned, lighting, exposure, development, and printing of the subject combining to produce a technically faultless photograph. Mr. W. F. Butcher's Parisian enlargements, Mr. Sydney Spencer's small Swiss views, and Mr. Henry Sandland's animal studies, lent excellence to a class which is generally most in need of it. In Class C (open; landscape, seascape, &c.) Mr. Spencer obtained honourable mention for some small Zermatt Valley views, in which the detail and truth of gradation were very noticeable. In the same Class Mr. F. L. Parsons showed the *Blowing up of a Pontoon Bridge at Tewkesbury by a Torpedo*, the fragments being cleverly caught. We liked Mr. Leslie Selby's view of a corner of *Greenwich* as showing what good pictorial effects may be often secured out of unpromising materials. A bronze medal went to Mr. S. J. Beckett for *Gudvanger, Norway;* he also showed several of his Hackney exhibits. We admire the tastefulness Mr. Beckett displays in his mounting and framing. Mr. H. E. Farmer's Rochester Cathedral views struck us as being a little chalky. Mr. Charles Moss obtained honourable mention for a capital little *Surrey Brook* meandering across a well-selected bit of landscape, the silver medal going to Mr. T. M. Brownrigg for a *Winter Sunset on the Shore*, quite in the style of Mr. Gay Wilkinson. In Mr. Brownrigg's *Early Morning on a River*, however, the sun seemed uncommonly high in the heavens.

In Class D, Mr. H. W. Bnsbridge's *Portraits* were uncommonly good, and Mr. Bhedwar's *Fair 'Fruit-seller* and *To Think and Ponder When Apart* were in his best style. For the first-named he received a silver medal.

The bronze medal was gained by Mrs. S. Frances Clarke for a charming study, *Sympathy*, one lady condoling with another over the intelligence contained in a just-opened letter. The attitudes of the figures were capital, while the facial expressions were perfect. We should be inclined to regard this delightful picture as by far the most meritorious in the Exhibition. Mr. C. F. Archer's *Grandpa* was a most natural study of a venerable old gentleman.

In the class for hand-camera work, Mr. J. H. Anderson secured the silver medal for some river views printed on rough paper, and Mr. W. Thomas the bronze for similar subjects. The class was small but good.

The gold medal in the Championship Class went to Mr. B. Gay Wilkinson for *The Peaceful Evening Hour*, the class including Mr. Tavener's flower studies, Mr. Byrne's portrait of Dr. W. C. Sellé, Mrs. Clarke's *Aha!* Mr. Warncuke's Pall Mall *Portraits*, Mr. F. W. Edwards *Westminster Abbey*, &c., Mr. Brownrigg's *Storm on Derwentwater*, Mr. Lord's *How's That?* several of Mr. Dresser's, Mr. Gear's, Mr. Ralph Robinson's, Mr. Bhedwar's, and Mr. C. Court Cole's pictures.

In the Open Lantern Slides Class the awards were Mr. Brooker (silver medal), Mr. George E. Thompson (bronze), Mr. E. G. Lee (hon. mention); Mr. Hawkins (silver), Mr. Field (bronze) being successful in the Members' Class. The loan collection of pictures comprised a large yacht picture by Messrs. West & Son, several of Mr. Birt Acre's Barnet Fair cattle studies, and the ubiquitous but always welcome Wave picture (lent by Messrs. Elliott & Son).

The limited space at our disposal this week not only obliges us to omit mention of many other admirable pictures that were on view, but also to be as brief as possible in our remarks upon those we have noticed. In closing our reference to this capital Exhibition, however, we must not omit mention of the useful and compact little displays of apparatus, lanterns, &c., by Messrs. Butcher & Son, Messrs. Noakes & Son, and Messrs. Platt & Witt, which were on view in the Hall.

FILLEBROOK ATHENÆUM PHOTOGRAPHIC EXHIBITION.

This Exhibition, which was held at Leytonstone on Wednesday and Thursday last week, differed from most others, in that there were only two classes, namely, one for exhibits which had not previously gained medals, and one for those which had. Both classes included lantern slides, for which, however, the Judges (Messrs. Cembrano, W. L. Colls, and J. A. Hodges) declined to make any awards. A third class of non-competitive exhibits, which included such works as H. P. Robinson's *Dawn and Sunset*, several of Mr. Horsley Hinton's pictures, and contributions from Dr. P. H. Emerson, Mr. B. G. Wilkinson, Mr. Alex. Keighley, and others, materially helped to enhance the quality of an Exhibition already excellent from the circumstance that most of the competitive pictures were fit survivals from the innumerable exhibitions which have been held since last autumn.

In Class I Mr. L. C. Bennett received a bronze medal for *The Cress Gatherer*. In *The Pet Peacock* (a lady toying with one of those gaudy

fowls), *In Love with her own Wondrous Voice* (a Parsee lady accompanying herself with a guitar-like musical instrument), Mr. Bhedwar showed his customary command over graceful poses and technique. But the downward-turned foot of the lady on the top of the step in *Home from the Well* was so distorted as to detract from the merits of the picture as a whole. The Exhibition was so poor in portraiture that Mr. Byrne's ever-delightful *Studies of Children*, and a large direct picture of two young people passing as *Sweethearts*, were very welcome. Mr. C. A. Brightman's Gloucester and Wells interiors and exteriors struck us as being very fine, even in the presence of some of Mr. F. W. Edwards' best work, that gentleman taking a bronze medal for a large Westminster Abbey interior, and the choir at Canterbury. It is a pleasure to examine such careful, conscientious architectural work as the two gentlemen named, Mr. C. H. Oakden, Mr. H. E. Farmer, Mr. W. Howell (who gained a silver medal for a view of the South Entrance at Canterbury Cathedral), and others showed here. By judicious printing, Mr. A. Jeffreys had produced quite a realistic and chilly effect in his riverside study of a *February Morning* (silver medal), a similar award going to Mr. A. Keighley for *The Breath of Winter*, and to Mr. Leslie Selby for *Evening Calm*, both subdued-toned studies of the subjects. Mr. Keighley's *His Little Joke* (an old fellow exchanging smiles with two women) had the true spirit of humour; but the same gentleman's *Sunlight and Soap* (an outdoor washing scene) was scarcely worthy of him in any sense. The last remark applies, with some qualification, to Mr. Ralph Robinson, who, in *A Sudden Squall* (an old woman retreating before the wind on the seashore), *In Summer among the Flowers* (a small, uninteresting child against a background of flowers), and *All Illumined with a Rustic Glory* (a lady seated in the open, in company with a dog), hardly soared above the commonplace. Mr. Robinson, however, made ample amends in *Making Friends* (silver medal), a farmyard scene in Normandy, presumably, where the efforts of the woman to soothe a startled calf and a frightened child, half hiding behind her dress, tell a simple story forcibly and directly. The composition and general treatment of the picture were excellent. In addition to the gentlemen named, other exhibitors of good and generally well-known work were Messrs. J. H. Avery, Golding, Gottlieb, C. S. Roe, J. Kidson Taylor, &c.

In the champion class, Mr. Ralph Robinson was successful with his picture of Mr. G. F. Watts; the class included Mr. Bhedwar's *Feast of Roses* and *Naver* Series, Mr. Dresser's *At Work: Ploughing*, Mr. Lord's *How's That*, and other well-known works. On the whole, the Exhibition, especially to local residents and those unfamiliar with exhibition photography, must have been highly appreciated. A better average of quality it is not often our lot to encounter.

THE NEW CENTRAL PHOTOGRAPHIC CLUB.

On Monday evening last, March 6, a public meeting of those interested in the formation of the New Central Photographic Club, which was referred to in our issue of the 24th ult., was held at the Memorial Hall, Farringdon-street, E.C. Mr. John Howson was voted to the chair, and the attendance, which was a large one, included Messrs. J. H. Avery, A. F. Stanley Kent, E. J. Hughes, R. G. Fenn Kidson, W. E. Ward, H. Snowden Ward, H. Ransom, T. E. Freshwater, F.R.M.S., F. W. Hindley, A. Dolland, G. Lamley, R. Child Bayley, A. Cowan, W. Fenton Jones, H. E. Farmer, E. J. Wall, J. A. Hodges, C. H. Oakden, B. J. Edwards, A. C. Edwards, T. E. H. Bullen, A. E. Hayman, T. Samuels, J. O. Grant, L. Medland, A. S. Newman, R. Beckett, J. S. Teape, G. H. James, R. P. Drage, E. Benest, W. H. Barnes, W. D. Welford, Charles Bilton, and many others.

Mr. Thomas Bedding (the Hon. Secretary, *pro tem.*) having laid the outlines of the proposed Club before the meeting, a long discussion on the details of the scheme took place, and finally an Executive Committee was appointed to (1) draw up a set of rules; (2) to arrange for suitable premises; (3) to determine the financial basis upon which the Club is to be floated; and (4), generally, to arrange a working scheme to be submitted to a future public meeting.

The Executive Committee have already met to carry out the terms of the instructions given at the above meeting, and in the course of a week or two another public meeting will be called for the purpose of considering the decisions at which the Committee will have arrived.

Numerous promises of membership were received in the room, making a total, with others sent by letter, of about eighty—a remarkably good number for one evening.

The following comprise the Executive Committee:—Messrs. Birt Acres, Robert Beckett, R. P. Drage, A. C. Edwards, T. Fall, T. E. Freshwater, F.R.M.S., John A. Hodges, J. Howson, William Fenton-Jones, Charles H. Oakden, E. J. Wall, H. Snowden Ward. The Hon. Secretary (*pro tem.*) is Mr. Thomas Bedding, 2, York-street, Covent Garden, W.C.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 3699.—"Improvements in Stand for Photographic Cameras." H. W. Taunt.—*Dated February* 20, 1893.

No. 3791.—"Improvements in Gratings or Screens for Photo-mechanical Printing." Complete specification. M. Levy.—*Dated February* 21, 1893.

PATENTS COMPLETED.

Improvements in Means for Raising and Lowering and Securing in Position Studio Camera Stands and Other Objects.

No. 5672. Walter James Boughton, King-street, Thetford, Norfolk. *January* 28, 1893.

My invention, a studio camera stand for photographers or others, or any article required to be raised up and down, to be kept in position wherever wanted without the aid of set screws. My invention consists of two upright standards grooved for cords, with cross feet, connected by two cross bars; in between the bars is a spindle, with cords connected, to raise and lower the platform between the two standards, a wheel on spindle to raise and lower with wedge arrangement.

Improved Portable Photographing Apparatus.

No. 6631. Jules Carpentier, 20, Rue Delambre, Paris, France. *January* 28, 1893.

This invention has reference to a small portable apparatus for taking photographs, which has the general configuration of a binocular opera-glass, the one barrel of which serves as the photographing camera, while the other serves for sighting, the glasses at the small ends of the barrels being the object lenses. The two barrels are connected at their small ends by a cross frame, in which is a sliding shutter, by means of which the object lens of the camera can be momentarily uncovered for taking the photograph.

This shutter has for this purpose an opening, which, when in its inward position, is situated on the inner side of the object glass, while, when in its outward position, it is on the outer side thereof.

The shutter is acted upon by springs tending to draw it into its inner position, and when drawn out into its outer position it is held by a trigger catch, on releasing which with the finger it is drawn rapidly by the springs into the inner position, thereby momentarily exposing the sensitised plate in the camera. In order to prevent such momentary exposure from also taking place when drawing the shutter outwards, there is provided a small slide on the shutter, which covers the opening thereof while the shutter is being drawn outward until the opening has passed beyond the object lens, when a stud on the shutter comes in contact with the end of a slot in the frame, and it is thus held while the outward motion of the shutter is completed, whereby the opening becomes uncovered by the slide, which, on the inward motion of the shutter, moves back with it, leaving the opening uncovered.

The two barrels of the apparatus are fixed on to a rectangular box, in which is a sliding drawer, to which is attached a stem, projecting to the outside, where it has a button, by means of which the drawer can be drawn from that side of the box which is opposite the camera barrel to the other side.

The end of the drawer opposite that to which the rod is attached is not closed, but from the opposite sides two small claws near the top project into the open end. The bottom of the drawer is also open, and two slightly curved blade springs extend from the closed end of the drawer along the open bottom.

In this drawer are stored a number of sensitised plates, each of which is contained in a thin sheet metal frame, which frames separate the plates from each other. Each of these frames carries a number marked on a recessed part thereof, and the number of the bottom frame in the draw will be visible through a red eyeglass fixed in the bottom of the box opposite the sighting object glass, when the drawer has been drawn to that side. The frame carries a light spring which presses the sensitised plate against the rim of the frame, and thus holds it securely in position. For introducing the frames with their sensitised plates into the drawer, the bottom part of the end of the box on the camera side is made as a door, and, on opening this, the frames are then slid in, one on top of the other, over the before-mentioned curved springs at the bottom, which, when the box is full, press the uppermost frame and its plate slightly into the larger open end of the barrel which constitutes the camera, stops being provided for preventing the entrance of the frame to an extent exceeding its thickness. The door of the box being closed, the apparatus is ready for taking a photographic impression on the said plate, after which the drawer is drawn outward by its rod, whereupon the uppermost frame with its plate, being held by the stops as described, will remain in position while the others slide from under it with the drawer, and when this is entirely withdrawn the said frame, losing its support, will fall to the bottom of the box. On now pushing the drawer back again, the said frame will pass in between the curved springs and the undermost frame of the pile in the drawer, and will thus become the bottom plate, while the second uppermost one will at the same time be pressed into the camera as above described, in order to be exposed at the next operation. In this way, by moving the drawer backwards and forwards after each exposure, each plate is in its turn brought automatically into the camera, while the preceding one is brought automatically to the bottom of the box.

The sighting barrel of the apparatus is, by preference, constructed with a concave object glass, and with the before-mentioned semi-convex red eyeglass in the bottom of the box for observing the object to be photographed.

It may, however, have a photographic lens and a transparent screen, like an ordinary camera.

The negatives taken in the above-described instrument are, of course, on a miniature scale; in order to obtain therefrom positives on an enlarged scale, I provide an apparatus of the following construction:—

A rectangular box has at bottom a frame in which is a movable plate, and which can open away from the box on hinges, like a door, being held close by a spring catch. The sensitised paper is placed upon the movable plate, and is held in position by being pressed by the plate against projecting ledges on the box by the closing of the door. On the upper side of the box is fixed a metal tubular extension, the upper end of which is adapted to receive the small negative taken in the first-described apparatus. At a suitable distance from the negative the tubular extension carries a partition, in the centre of which is an object lens, by means of which an enlargement of the picture of the negative is thrown on to the sensitised paper at bottom.

The top of the tubular extension is closed by a cap, which is removed for the length of time required for the exposure, and is then replaced while the apparatus is being taken to the dark room, where the sensitised paper is removed and treated in the usual manner.

For making this apparatus more compact for carrying, the tubular extension is made removable from the box, and is fixed in position by a bayonet joint or other fastening.

Improvements in or relating to the Regulation of Photographic Shutters.

No. 19,581. Joseph Thacher Clarke, Boston, Massachusetts, United States.—*February* 4, 1893.

My invention relates to photographic shutters of that class in which the duration of the exposure is governed by a pneumatic piston and cylinder, acting as a brake of variable effect.

Hitherto the differentiation in the action of such pneumatic brakes has been attained in two ways, either by varying, by means of a tap or of a movable cap valve, the orifice through which the compressed air is permitted to escape from the cylinder, or by so shifting the position of the piston arm in relation to the working parts of the shutter that the leverage exercised by the shutter spring upon the piston is changed, and the length of the piston travel is thereby altered.

My invention has for its purpose to provide an improved pneumatic shutter in which the requisite differentiation of the brake is effected in a third and novel manner. While dispensing with the valve for regulating the outflow of air from the cylinder, and while leaving the leverage between the shutter spring and the piston unchanged, and the length of play of the piston unaltered, I obtain the variable speeds of my pneumatic brake by sliding the air-compressing chamber or cylinder to and fro along the axis of the piston rod in such wise that the piston is caused to plunge to a greater or less depth into the cylinder, the retarding effect of which is thus restricted to a longer or shorter part of the travel of the piston. In this movement of the air-compressing chamber, relative to a piston of fixed travel, lies the gist of my invention.

The movable air-compressing chamber, or sliding cylinder, being provided with no variable outlet, is preferably made to fit the piston somewhat loosely, so that the air compressed therein by the movement of the piston may gradually escape between its inner walls and the sides of the piston. In the event of the leakage thus provided between the piston and the cylinder being found insufficient, a further outlet may be provided by piercing one or more small apertures in the walls of the cylinder. These apertures may be so arranged as to gradually cut off the outflow, and consequently to increase the resistance of the air remaining in the cylinder, as the piston passes them on its travel.

The air-compressing chamber may be constructed as a plain cylinder closed at its base, like a stopped organ pipe, so arranged as to slide along the line of play of the piston, permitting this to move, at the one extreme, both forwards and backwards without entering it, and thus without compressing the air within it, or, at the other extreme, to traverse its entire course within the closed cylinder, under pneumatic restraint. Or, while arranged to slide in the manner indicated, the air-compressing chamber may be made with a slightly conical bore, so as to gradually alter the amount of air leakage between its walls and the sides of the piston as this latter is caused to penetrate more or less deeply within it. Such a slightly conical bore will render the pneumatic retardation more or less appreciable, according as the piston travels along a more or less constricted portion of the bore.

In either case it is preferred (although the principle of the invention is in no wise dependent hereupon) to make the air-compressing chamber greater in length than the travel of the piston, cutting out longitudinal slots or otherwise perforating all that portion of the tube through which the piston travels when the cylinder is so withdrawn as to exercise the least possible restraining effect. Through these slots or perforations the air, displaced by the movement of the piston, finds free escape, and hence exercises no retarding influence. The rails formed by the strips remaining between the slots may serve as guides for the piston during that portion of its travel in which it does not enter the unperforated portion of the air-compressing chamber.

The piston may be connected with, and receive its motion from, any portion of the shutter worked by the shutter spring. Thus, if the shutter plate be of that type which performs an entire revolution for each exposure, the piston may work upon a cam or eccentric, the position of which in relation to the centre of revolution will determine the play, forwards and backwards, of the piston. If, on the other hand, the shutter be of a type moving to and fro across the lens aperture, the piston may be advantageously made to work in a slot in the shutter plate, or be connected therewith in any other convenient manner. The piston can, if preferred, be directly connected with the operating spring of the shutter plate, as is well understood. In shutters of the type last mentioned the piston will be moved backwards, *i.e.*, away from the air-compressing chamber, by the act of winding the shutter spring, and will differentiate the length of the photographic exposure only during its forward travel.

The adjustment of the air-compressing chamber, for the purpose of setting the speed of the shutter, may be performed in any convenient manner, either by direct action of the fingers upon the cylinder itself, or, as in the case of hand cameras with closed fronts, by means of an intervening lever or other shifting device. A scale, indicating the speed to which the shutter is set, may be engraved, or otherwise marked, either in connexion with the cylinder or with the moving lever.

It is obvious that the principle of my invention may be retained, although the relative positions of cylinder and piston be so reversed that the former is connected with some moving portion of the shutter and the latter adjusted by sliding along the line of travel.

One of the notable advantages of my improved pneumatic shutter is that, even in protracted exposures, the lens aperture is opened (and in the case of shutters of the before-mentioned circular type is likewise closed) with the maximum rapidity of the shutter. This is due to the fact that the piston is permitted to commence (and in shutters of the circular type likewise to terminate) its movement without restraint from the pneumatic brake, the retarding effect of which is not brought into action until after the shutter has been passed aside from the lens aperture by the unrestrained force of the shutter spring. The character of the photographic exposure is hereby greatly improved.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 2.—Mr. W. H. Harrison in the chair.

Mr. Edgar Clifton, being unwell, was unable to deliver his promised lecture on *Cameras, Tripods, and Dark Slides*, and it was postponed accordingly.

THE QUESTION BOX.

1. "Are ferro-prussiate prints permanent? if not, can their permanency be increased in any way?"

The CHAIRMAN said blue prints were very much affected by alkalies.

Mr. G. W. ATKINS had some by him which were made ten years ago; they had been varnished, and were as good as ever.

2. "A dry plate, developed, fixed, and washed in the usual way, was dried off with spirit; when dry, large patches of a whitish deposit were noticed on the film next to the glass. Is this detrimental to permanency of negative, and what is the cause? This has only been found when working with the new spirit, and does not appear to affect the printing of the negative."

Mr. W. E. DEBENHAM thought that insufficient washing was the cause.

Mr. G. T. HARRIS had been troubled in the same way, but found, however, that the deposit disappeared in varnishing.

3. "What would be the best printing paper to send to the Gold Coast, as platinotype, silver, and bromide paper are spoilt by damp in less than a week?"

Mr. T. E. FRESHWATER said he had seen prints which had been done on silver paper set out ready sensitised to India, and which seemed to stand well.

Mr. DEBENHAM would suggest the use of collodio-chloride paper.

Mr. J. S. TEAPE said that if the silver prints were coated with a weak solution of gelatine on both sides, left to dry, then again coated on both sides with a spirit varnish, he thought they would be as permanent as could be desired, even in a climate like that of the Gold Coast.

Messrs. P. Everitt and F. W. Pask were again appointed delegates to represent the Association on the Affiliation Committee.

The HON. SECRETARY announced that on March 16 a large collection of lantern slides (including some astronomical), illustrative of South Africa, would be shown.

North Middlesex Photographic Society.—March 1, First of a series of Elementary Technical Classes, Mr. J. MCINTOSH taking charge.—He explained the different sorts of lenses, their uses, and how to test them; the stops, their uses, and their relation one to another as regards exposure, the camera, swing-back, rising front, showing and explaining various tests; he also touched upon plates, and made a point of the advantages gained by backing the same. These classes are given expressly to help beginners, free of charge; any gentleman wishing to attend should make application to the Hon. Secretary, Mr. G. Gosling, 13, Lausanne-road, Hornsey. An outing has been arranged to Hampstead for Saturday, March 11, which will be attended by several members of the Society to give practical instruction in the use of the camera in the field, and will be followed on Wednesday, March 15, by an evening for developing the plates exposed.

Harringay Photographic Society.—March 2, Mr. Towers occupied the chair.—Mr. MORGAN, representing Messrs. Fuerst Brothers, gave a demonstration with amidol. In introducing this comparatively new developer, Mr. Morgan said its advantages were extreme energy, its very small bulk, and it does not require an acid clearing bath for bromides. The demonstrator successfully developed a half-plate (Edwards' isochromatic plate), and Thomas's lantern plate, and some bromide paper. Mr. DENNETT said he liked the brown tones as produced by pyro for the ordinary negatives, and Mr. Towers said, though the lantern slides and bromides were perfect, he should prefer pyro for ordinary negatives. Some excellent enlargements, done by Mr. A. R. Dresser, and developed with amidol, were shown. Mr. Morgan strongly recommended the concentrated stock solution, and he also said there was quite as much control with amidol as any other developer.

Hackney Photographic Society.—February 27, Mr. F. Houghton in the chair.—Mr. Hudson handed up a home-made shutter. The working was, however, too too stiff in its action. Mr. A. Barker presented slides to the Society for lending out. Mr. Grant showed some print-out opals. A discussion ensued on the desirability of the Society being represented at the forthcoming Crystal Palace Exhibition. The matter was referred to the Council to be thrashed out. Mr. VINING asked: "What is a simple way of obliterating portions of a negative so as to omit some in printing and without leaving a hard line?" Mr. GRANT said that Mr. H. P. Robinson described the method in his book. Mr. AVENS asked: What had the Society done about the proposed new lantern lenses? Through the kindness of one or two members it was decided to purchase two, made by Messrs Swift. A series of prize slides were then shown, after which slides by Messrs. A. Barker, S. J. Beckett, Dean, Grant, Hull, Moore, Harvey, Roofe, Tavener, and G. W. Wilson, of Aberdeen, were shown.

Croydon Camera Club.—February 27.—It was announced that the Judges appointed for the forthcoming Exhibition were Colonel J. Gale and Mr. T. J. Bright.

Halifax Camera Club.—February 28.—Mr. J. E. Jones introduced the subject of *Landscape or Tourist Photography*. Mr. JONES described at some length the apparatus best adapted for the tourist. He did not believe in the long-focus camera when on tour; the double extension was never required out of doors, and every ounce of *impedimenta* weighed heavily at the end of a day's journey. A small lamp, with non-actinic medium, was very useful for changing plates, with the window covered up with the focussing cloth. He had found the best way to store plates or films after exposure was to place a thin sheet of non-actinic paper, cut to size of plate, between every two plates, films to the paper. Films have an immense advantage over plates on account of weight. A very slow plate had certain advantages in landscape work, but for all-round work a moderately quick one was more desirable. He always carried a bottle of Kay's Coaguline, which he found very useful in cases of accident, such as the breaking of the focussing screen, &c. He had used various kinds of lenses, including the single landscape, but he found nothing like Ross' rapid symmetrical, which he invariably used at about *f*-22. He considered the legs of the tripod and the focussing cloth great nuisances, and, as a partial remedy for the latter, exhibited Houston's focussing cloth holder. His plan was always to use a normal developer, and, if a picture did not come out without all sorts of dodging, he did not think the plate worth further trouble. He had often been annoyed by crowds of people standing round when about to expose, and recommended, as a remedy for this, that one's wife should be sent round with the hat, which he considered would be effectual in making them move off. Mr. Jones also described the difficulties he had experienced in passing his apparatus through the Customs on one of his Continental tours.

Leeds Photographic Society.—March 2, Mr. John H. Walker (President) in the chair.—Mr. W. D. WELFORD read a paper on *Practical Hand-camera Work*. While he agreed with most workers that the hand camera should not take the place of the stand camera for really fine work, it had its place and department in which it excelled, such as street scenes, character and life on the sands, in the market-place, &c. He got about seventy slides passed through the lantern illustrative of this, which were pronounced excellent. Mr. Welford, like many others, is often asked: "What is the best hand camera?" but, like most men of experience, states that there is no universal pattern, but that nearly all (of the better class, at any rate) in the market are good, each possessing special merits of its own, but he has a preference for those having automatic changers for either slides or films.

Dundee and East of Scotland Photographic Association.—March 2.—A paper, entitled *A Few Practical Remarks on Lantern-slide Making*, was read by Dr. J. K. TULLOCH (see page 152.) During the lecture a large number of slides were exhibited, illustrating the various processes referred to. A series of American slides were sent for exhibition, as were also a number of members' slides. Beginners' Slide Competition:—1. J. S. Lawson; 2. Rev. E. J. Gough. Special (each competitor having had the same three negatives):—1. T. L. Wynd; 2. J. D. Cox.

Glasgow Photographic Association.—February 17, Mr. William Lang, jun., F.C.S., President, in the chair.—To a large and appreciative audience Mr. W. LAMOND HOWIE, F.C.S., delivered his well-known lecture, *To Ober Ammergau and Back in* 1890. March 2, Mr. J. CRAIG ANNAN gave a practical demonstration of carbon printing, and developed several prints on paper, glass, and opal. A new printing-out lantern plate was shown to members, and a series of new standard lens fittings was exhibited and explained by Mr. W. S. HOBSON, of Messrs. Taylor, Taylor, & Hobson, Leicester.

Leith Amateur Photographic Association.—February 28, Exhibition o members' work taken during last year.—The PRESIDENT (Mr. William Dougal) said that this entertainment had now become an institution in their midst which was eagerly looked forward to by those interested in art. The Association, although numbering only forty members, was looked upon in the photographic world as one of the most go-ahead societies in Scotland. The works to be shown were, in his judgment, superior to those of any previous Exhibition. Some 213 slides would be exhibited on the screen, being an average of thirteen to each exhibitor, or fully five for each member, while in the largest societies in the kingdom the average per member was one only. The views were of the usual varied character—Newhaven fisher-wives and men in their picturesque garbs and occupation, landscapes and architectural subjects, together with fine sea pieces, a thrushes' nest with eggs, &c. One set of copies of engravings after Turner, Wilkie, &c., seemed to please many of the large audience. The Exhibition, which was assisted by instrumental and vocal music, was brought to a close with a couple of dozen from the Hon. Secretary's fine collection of slides of the series "Burns, his Homes and Haunts," which received well-merited applause.

Hobart (Tasmania) Photographic, Science, and Art Association.—January 20.—The SECRETARY read a letter from Dr. T. J. Barnardo, the founder of the Homes for Destitute Children, in which that gentleman thanked Mr. F. J. Paterson (a member of the Association) for his kind donation of Tasmanian lantern slides. Dr. Barnardo said that the slides will prove a source of great interest, and he will take care that they are exhibited throughout his Homes. Mr. PATERSON delivered a lecturette on *Ilford Printing-out Paper*, and stated that he had never had a single failure. The beautiful pictures shown by the lecturer were greatly admired, and proved that Mr. Paterson was an expert in this particular style of photographic printing. Mr. N. OLDHAM followed with an instructive lecturette on *Photographic Chemicals*, in which he described their manufacture and various uses, also pointing out how to avoid impure varieties and overcome failures. A number of new styles of cameras were placed upon the table for inspection, as well as a good number of lenses and shutters.

FORTHCOMING EXHIBITIONS.

March 22, 23	.....	Leicester and Leicestershire Photographic Society, Co, operative Hall, High-street, Leicester. Hon. Secretary-H. M. Porritt, 66, London-road, Leicester.
April 5–8	.....	*Croydon Camera Club, Braithwaite Hall, Wellesley-road, Croydon. Hon. Secretary, G. R. White, 55, Albert-road, Croydon.
,, 10–29	.....	*Crystal Palace. The Executive, Crystal Palace, S.E.
,, 12–15	.....	*Bolton Photographic Society. Hon. Secretary, J. E. Austwick, 10, Rushton-street, Bolton.
,, 17–29	.....	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.
May 4–6	.....	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.

COLLOTYPY—A HINT TO PHOTOGRAPHERS.

To the EDITOR.

SIR,—It seems remarkable that photographers as a body have not taken to this process as a means of increasing their business. I think that I am not far from the truth when I state that at the present time photography as a business is not very remunerative. I am well aware, however, that there are a great many who can command high prices for the excellent artistic work which they produce, and who know nothing of the fluctuations of the trade which is the worry of their less favoured brethren. The average photographer who has to depend upon the ordinary public finds considerable difficulty in making ends meet; and to such a new style or a new process proves a veritable godsend.

Now, collotypy is purely a photographic process, and the operator who knows his business thoroughly has little to learn to enable him to prodnce good work; all the apparatus and materials are already at hand, with the exception of the printing press.

The dark room with its sink and dishes require no alteration; the manipulation of the gelatine, glass plates, &c., is at the finger-ends; and the same light which prints out the picture on the P. O. P. makes ready the printing plate for the press; and, moreover, the fashion has set in long ago for black-and-white pictnres.

Not many weeks ago a paragraph went the round of the photographic magazines, in which the writer spoke of collotypes as superior to silver prints. I have no hesitation in stating that, when they are carefully produced, they are much superior to platinotypes, and not to be mentioned in the same day with those flat grey and white things which are often exposed in show cases as samples.

There are a thousand-and-one ways in which a good business man could turn this process to account. Suppose, for instance, that the local team has succeeded, after several protests, in bringing home the Challenge Cup, it follows that it must be photographed, and the photograph put up for sale. Now, if it is produced by any of the ordinary processes, the price is so high that only a very few are bought, perhaps not more than a dozen; indeed, when the fire of enthusiasm begins to die out, it requires hard pushing to induce even those members of the club whose kicking won the honour, to purchase a copy. Whereas, if they be produced to sell at a sixpence, the thousands who paid that sum for admission would readily buy them up. It is well known that the cheaper an article can be produced the greater the number of sales will be effected; and it does not require much of a business eyesight to perceive that the cheap article invariably admits of a larger margin of profit than the costly article, which only covers working expenses.

I have no intention of taking up space in multiplying examples, yet how easy it would be for the wide-awake photographer, with a press which takes a large plate, say 16 × 20 ins., to put down ten or a dozen different negatives, and by a series of masks produce with twelve pulls of the press as many dozen C.D.V. or cabinet portraits.

I trust that these few words will prove a useful hint to some of your readers, who, from the state of the trade at present, are sometimes sailing in shallow waters.—I am, yours, &c., GILBERT CLARKSON.

March 4, 1893.

DETERMINATION OF PLATE SPEEDS.

To the EDITOR.

SIR,—Since my original communication hereon, I notice that more than one of the dissentient writers invite me to discuss with them on matters of theory which are irrelevant to the subject of my experiments as set forth in my articles.

I considered I had already disproved any assumed concordance between the theory and the practice of determining speeds of plates by the Hurter & Driffield method, and such was the courage of my opinions that I offered to submit *everything* to impartial jurors. This challenge has not been taken up.

Lest it might be thought I was making a "safe" or "empty" offer, I propose to carry the matter still further, and I have to-day written to the Secretary of the London and Provincial Photographic Association, offering, if the subject is of sufficient interest, to read a short paper, and illustrate it by the experiments I scheduled in my original article.

This will show your readers that I, at any rate, have faith in my convictions to determine me to carry this matter to an issue.—I am, yours, &c., G. F. WILLIAMS.

March 7, 1893.

To the EDITOR.

SIR,—Messrs. Hurter & Driffield have been good enough to explain their views and conclusions, so that they can be "understanded of the people," in a little pamphlet which may be obtained from Messrs. Marion for the asking.

For fuller information we are referred to the original papers in the *Journal of the Society of Chemical Industry*; but this publication is not sold in parts, and it is necessary to buy a whole volume (or, maybe, volumes).

If Messrs. Hurter & Driffield would enlarge their pamphlet so as to contain the details of their methods (the mathematical reasoning we will take on trust), and, at the same time, deal with the commoner criticisms and misunderstandings, they will add to our many obligations.—I am, yours, &c., AN AMATEUR.

March 6, 1893.

AMIDOL.

To the EDITOR.

SIR,—Rather late, I have been perusing the discussion on amidol which occurred at the Photographic Society of Great Britain's meeting, as printed in the January issue, of the transactions, some remarks on which may not be misplaced.

Mr. G. L. Addenbrooke, after relating that he "had had a good deal of experience with amidol," made some remarks thereon, in which he attributed to the free sulphurous acid in a developer, prepared with meta-bisulphite of potassium, restraining powers. This was objected to by Mr. Mackie, who "could not understand how free sulphurous acid could act as a restrainer in a developer, as, on adding alkali, it would combine with it, and no longer remain in a a free state." In reply to which, Mr. Addenbrooke said, "The sulphurous acid was too weak to combine."

It seems to me a pity that no better-informed member took part in this discussion, the gentlemen above quoted evidently not having watched the reports of experiments by photographic experts, which put quite a different aspect on the development with amidol than that apparently existing in their minds.

They evidently have no knowledge of the recent examination of acid development by Messrs. A. & L. Lumière, which shows that certain organic developers, derivatives of Mars yellow, certainly develop in acid formulæ. These are diamido-phenol, triamido-phenol, pyrogallic acid, oxidroquinone, and diamido-naphthol.

Many years ago Captain Abney proved acid development possible with a pyrogallic acid formula, rendered distinctly acid with hydrochloric acid.

I may perhaps be permitted here to refer to an amidol formula for transparency work which I gave in the last issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC which is very distinctly acid, and efficient, nevertheless, for its purpose—in fact, it seems to me, that certainly for transparency development an acid formula is preferable. I am under the impression, from the moderate experience I have had with it, that it very much adds to the brilliancy of the clear parts of the transparency.—I am, yours, &c., HENRY E. DAVIS.

Camera Club, Charing Cross-road, March 7, 1893.

NATIONAL PHOTOGRAPHIC EXHIBITION JUDGES.

To the EDITOR.

SIR,—We have the pleasure to inform you that the following gentlemen have consented to act as Judges at the above Exhibition, which opens on Monday, April 10, at the Cryatal Palace:—

Hon. Slingsby Bethell,	F. Stanley Little,
Valentine Blanchard,	Peter Macnab,
J. Pattison Gibson,	H. L. Noel-Cox,
F. Mason Good,	Francis Powell, R.W.S.,
Richard Keene,	F. P. Slingsby Roberts,
Dr. Lindsay Johnson, M.A., BSc.,	Leslie Thomson,
W. Lang, Jun.,	F. York.
Edgar G. Lee,	

Your kind insertion of this letter will be esteemed by—Yours, &c.,

S. G. BUCHANAN WOLLASTON, CHARLES W. HUSTINGS, } *Executive.*

Crystal Palace, March 6, 1893.

SCULPTURESQUE PHOTOGRAPHY.

To the EDITOR.

SIR,—I read with interest your able article on "Sculpturesque Photography" which appeared in the JOURNAL of January 27, since which I have been devoting my attention to practising the same. I have tried various means; among them the one advised by the editor of one of the papers devoted to photography, and with moderate results, its great drawback being the trouble to the sitter and the time which it occupies in getting ready, which is against its practicability.

This last few days I have been trying the method patented by Messrs.

G. B. Bradshaw & Co., Altrincham, and am delighted with the results, and would call the attention of more practical workers to it.

In your issue of December 3, 1892, you call attention to the inquiries of a correspondent for a new style of photograph which amateurs could not produce. Your answer was, that the idea was excellent; but where was the picture to be found beyond the scope of the amateurs? Now, sculpturesque photography is a beautiful art, and could be easily made fashionable. Is this the long-wanted picture which amateurs could not imitate? If they were refused patent rights, it might be.—I am, yours, &c., W. TIPPING.

Sutton, Notts.

THE LANTERN SOCIETY.

To the EDITOR.

SIR,—I read in the "Lantern Supplement" to your JOURNAL of March 3 that a correspondent has been inquiring as to the existence and prosperity of the Lantern Society. May I be allowed, as President, to inform him, through your JOURNAL, that it is progressing very steadily and surely, and doing active work? Our fortnightly meetings since October have been very well attended. Several learned and scientific men have most generously given us lectures and papers on varied and interesting subjects, not necessarily or always connected with lantern work, or even photography in its different phases. On these occasions our lantern has been requisitioned to assist the lecturer as far as possible. Our public meetings and exhibitions of slides, in a very large and fine room at 20, Hanover-square, appear to give great pleasure to our members and their friends. Ladies attend frequently, and, I may remark, *en passant*, are eligible as members. Mr. E. M. Nelson, F.R.M.S., now President of the Quekett Microscopical Club, our able chairman, as well as our Honorary Secretary, Captain C. E. Gladstone, R.N., spare no pains to make both our formal and informal meetings as instructive and entertaining as possible. I had the pleasure at our last meeting of thanking Colonel Gale, Mr. Edgar Lee, and several other gentlemen for so kindly giving our Society the opportunity of admiring some of their most beautiful pictures; so true were they to nature in her most difficult aspects, and so perfect in photographic teaching, &c. We shall have pleasure in welcoming your correspondent to our next meeting open to visitors, in order that he may judge of our activity and earnestness in the work which we have undertaken. Captain Gladstone and our curator of slides will be happy to furnish any applicant with our rules, &c., as well as particulars of our loan collection of slides, &c.—I am, yours, &c., SLINGSBY BETHELL.

Brooks' Club, St. James's-street, March 6, 1893.

PHOTO-INTAGLIO ENGRAVING IN THE UNITED STATES.

To the EDITOR.

SIR,—In the issue of your JOURNAL dated December 2 is published a review of a communication recently made by me to the Franklin Institute regarding a certain improvement or innovation in the matter of photo-intaglio engraving, the tenor of which is of a nature to call for a reply.

The assumption, made on the basis of my reference to the retouching of intaglio plates, that I am, or have been, ignorant of the state of the art in Europe, is unfounded. I have before me specimens of unfinished and finished work of this character from a number of European establishments, showing the work of the retoucher; but this should be superfluous in view of the fact that the retouching to which I adverted is recognisable by an expert eye in practically all published work of this character.

The statement made on the basis of my having applied for a patent on the method in question that my communication "reads very much like an advertisement" is scarcely just. Permit me to reply that I have many excellent British precedents in that respect, including the names of all the foremost English contributors to the advancement of the photographic arts.

It is furthermore predicated of me that I am ignorant of the state of the art even on this side of the Atlantic, because it is "certainly a novelty to be told that a dried gelatine film can be printed from as an intaglio plate." What I stated is an absolute fact. I have myself frequently printed from a gelatine relief plate—it could scarcely be called a film—dried after washing out, in which condition such plates of gelatine have both depth and firmness enough to stand many impressions in the printing press. Both the "wash-out" and "swelled" gelatine methods were regularly employed in my daily practice up to 1881, and then replaced by the etching processes. I have not, indeed, utilised such gelatine films as intaglios, but there is nothing in the nature of the case to render such procedure impracticable for, at least, a limited number of prints. To any one familiar with the "wash-out" gelatine process, my statement will not be a novelty.

With regard to my reference to Paris as leading in the production of intaglio work, I will only say that the question at issue is largely a matter of opinion and of taste, "*De gustibus non est disputandum.*"—I am, yours, &c., LOUIS EDWARD LEVY.

Philadelphia, December 29, 1892.

[Owing to defective postal arrangements, the above communication only reached us a few days ago. We shall have a few remarks to offer on the subject in our next number.—ED.]

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Alfred H. Scott, Twickenham.—*Photograph of D. Alder, veteran postman of Twickenham.*

John Stuart, Glasgow.—*Three photographs of the interior of the late Dr. Bonar's study at 20, India-street, Glasgow.*

Simeo & Holme, Wellingborough.—*Two photographs of Hind Hotel, Wellingborough, in 1856. Two photographs of Market-street, Wellingborough, in 1856. Four photographs of Princess Kaiulani of Hawaiian Islands.*

WOULD-BE MEMBER.—See "Lantern Notes and News," last week.

SPRING.—Return the films to the makers; they will, doubtless, give you fresh ones for them without demur.

F. R. E. (Weymouth).—The Pamphengos lamp is made by Mr. W. C. Hughes, Brewster House, Kingsland, N.

J. W. C.—Mr. Denison is not a professional photo-engraver, and does not work for the trade as you have been erroneously informed.

HECTOR MACLEAN, MARCUS P. FUCHS, J. R. SINGER, C. RAY WOODS, PERPLEXED, and others.—Received; thanks. In our next.

INK STAINS.—Try the effect of a dilute solution of either citric or hydrochloric acid for removing the ink stains from the photographs.

EXPERIMENT says: "Can any reader give the formula for white ink for writing on glass so that it will not only write, but etch the surface?"

SOLE RIGHTS.—If you have copyright in the picture, then by registration you can proceed for damages if another person makes copies thereof.

RUPERT HOLLETT.—It is the object-glass of the telescope that must be used; and, of course, the camera must be erected at the eyepiece end.

AJAX.—The iodo-albumen process is described in the JOURNAL for June 17 of last year. So far as we know, it is not now worked commercially.

"LANTERN RECORDITE."—You were misinformed; the "Lantern Record" will appear during the summer months. See editorial announcement elsewhere.

"H. LEWIS" ("Brooklyn, U.S.A.").—You are too deliciously simple if you imagine that we cannot penetrate such a poor disguise. Try again.

C. PORTER.—You would be rendering yourself liable to prosecution by making and exhibiting lantern slides of the engravings named without permission.

TALC.—Mica is being introduced by Mr. Rudowsky as a support for negatives and positives, and therefore would answer for lantern pictures. It is, however, very expensive yet.

PUZZLED PHOTOGRAPHER.—However much their admirers may like fuzzy photographs on paper, we do not think they are likely yet to introduce lantern slides from the negatives to a general audience.

R. O. S.—If the mounts were guaranteed by the vendor, or his agent, to have no injurious effect on the photographs, and you can prove that they have had, you have a good cause of an action at law for damage to your reputation.

W. J. CLUTTERBUCK.—Solutions of ferrous oxalate and mercuric chloride may be ordered of any dealer. For use, employ the latter at the strength you receive it, and dilute the former with three times its volume of water. If you desire to make the solutions yourself, the quantities are given in the ALMANAC.

B. W. C.—1. An attachment for keeping the tripod perfectly steady has been patented by Messrs. George Mason and A. L. Henderson. Send us a description of yours, and we will say if it is patentable. 2. Apply to Mr. H. N. King, 4, Avenue-road-villas, Goldhawk-road, W.

STONE & WILKINSON asks: "What is the best reagent to use to precipitate the silver in the washing of P.O.P.? Have tried H.Cl. and Na Cl without effect."—If the substances used do not throw down the silver, though we should have thought they would, use sulphide of potassium—liver of sulphur.

J. WAITE.—The pictures are very good, but they would have been infinitely better if they had been printed by the platinotype process. Winter effects are never well represented by being printed on albumen paper and toned to a warm brown tint. The cold tones of platinum are best suited for winter pictures.

F. BRAIN.—If you have proper retouching medium and pencils, and have read all that has appeared in the JOURNAL during the last few years, and yet do not get on, we should advise you to have a few lessons from a practical retoucher. We cannot, of course, without seeing examples of the failures, indicate the causes of them.

J. LANE.—We cannot tell what your slides are like as regards quality, from such a vague—or, indeed, any—description. Join a photographic society that has lantern nights, and exhibit your slides among those of the other members. Volumes of criticism would be worthless as compared with that way of finding out whether the slides are good or bad.

W. A. T.—1. The formula given in the ALMANAC is the best published. 2. Many professional photographers sensitise their own paper because they consider they get better results than buying it ready sensitised. It is also, to them, more economical. 3. Yes, if the wooden vessels are coated with paraffin or other impervious material that has no injurious effect on the silver solution.

P. CASEY.—Your local chemist and druggist is in error. Sulphate of soda is not what you want, and it is not the same thing as sulphite of soda. It is the latter you must have. Better obtain it from a dealer in photographic material. If you succeed in obtaining it from a village druggist it is very doubtful if it will be of good quality, and unless it is it is useless for photographic purposes.

A. HORTON.—1. Expose the cleaned surface of a glass plate to the fumes of fluoric acid, which are generated from fluor spar and sulphuric acid in the bottom of a lead or guttapercha dish. 2. There is no rule for placing the stop in your lens. 3. The rays from opposite sides cross the axis after transmission through the first lens of the combination. Axial rays meet only at the focal plane.

C. SLADE.—In photographing an interior, if the camera is placed directly facing the mirror at the end of the room, so that it is reflected in it, the apparatus will necessarily show in the photograph; but, by a little judgment, the camera may no doubt be so placed that its image is not reflected on to the lens. An alteration of a few inches in its position will often be sufficient to get over the difficulty.

OMICRON.—The stains are caused by the prints being stored so long in a moist condition. Stains precisely the same as these can be produced at will by keeping prints in a pile closely pressed together for two or three weeks according to the temperature. The more perfect the washing the quicker are the stains likely to appear, particularly if the conditions favour mildew. In future, we suggest the prints be dried prior to delivery.

A. Y. E.—The design for the studio is so good, that we can suggest no real improvement upon it. With regard to the other question, we can offer no opinion, as the law, as regards building is not the same in different districts. As the erection will be a conspicuous one, we should advise you to consult, with the plans, the surveyor to your local authority before commencing to build. By doing so you may save yourself a lot of trouble and delay.

A. S. BONE.—An ordinary typographic press, such as the "Albion press" you possess, will answer quite well for collotype printing. Indeed, this is the form of press that is extensively used by collotype workers in this country. Power machines are necessarily expensive. They vary from about two hundred and fifty pounds to double that sum, according to size and maker. The power required to drive them is not great. A gas engine of one horse power would be equal to working a couple of moderate size.

LIONEL HARTMAN asks: "How can I obtain particulars of a kind of photograph introduced many years ago? It was a crystal cube, with portrait inside, and I believe it was called the 'Casket Portrait,' and done only by the inventor at a studio at Charing Cross. If it was patented, what year about was it?"—The Casket portrait was the invention of Mr. H. Swan, and was patented by him in 1862. The number of the patent is 3249 for that year. The specification, giving full particulars, costs eightpence.

EDMUND STIRLING (Philadelphia) writes: "I was greatly interested in the letter of Mr. Haes in your issue of February 10, in which reference is made to flexible steel tubing and its uses in connexion with the lantern. I would be under renewed obligations to you if you could advise me where I could get samples and specific information as to such tubing. Do you know whether it can be had in this country?"—In reply: Particulars of the tubing are given in the "Lantern Record (Supplement)" for March 3.

T. MATHIA writes: "1. I have a set of moist water colours, which have become too dry to work easily. Will it do to mix them with honey or glycerine? I might say that I use them for colouring bromide prints. 2. How to make them transparent for lantern slides? 3. Where can I get lantern slides on hire?"—1. It would scarcely be worth the trouble to attempt to remix the colours. Possibly, if they were kept for a few weeks in a very damp place, they would absorb moisture, and somewhat regain their former condition. 2. Unless the pigment is a transparent one, there is no means of making the colours so. The colours generally employed for lantern slides are oil colours, specially prepared for the purpose. 3. From those who let lanterns and slides on hire.

PHOTOGRAPHIC CLUB.—March 15. Smoking Concert. 22, *New Cameras* Adjourned Discussion on *Combined Toning and Fixing Baths.*

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Ordinary Meeting, March 14, at 50, Great Russell-street. *Naturalistic Photography*, by Mr. P. H. Emerson, B.A., M.B.

WE have received the price list of Mr. C. F. S. Rothwell, who has opened premises at 8, St. Mary's-street, Deansgate, Manchester, as a general dealer in photographic apparatus and chemicals.

THE Harringay Photographic Society are arranging for a public lantern night. Admission will be free by ticket, to be had of all dealers or by enclosing ½*d.* stamp to Mr. C. Frith, 8, Cavendish-road, N.

MR. E. G. LEE writes: "In the list of awards in your issue of February 10 last, *re* the Photographic Society of India's Exhibition, held in Calcutta, the award to me of a silver medal for twelve lantern slides is not included. I received the medal from Calcutta this morning (March 6)."

MESSRS. R. W. THOMAS & CO. have appointed Mr. S. Herbert Fry to demonstrate the virtues of the Sandell plate, their new multiple-coated and patented film. Secretaries of photographic societies who wish to fix a date for a demonstration should write to Messrs. R. W. Thomas & Co., Thornton Heath, Surrey.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 16, Monthly Lantern Night, 200 slides illustrating South Africa, to be exhibited for the first time in this country. Visitors welcomed. 23rd, Technical Lecture. Mr. Edgar Clifton on *Cameras, Tripods, and Dark Slides.* 30, Mr. W. J. Rawlings on *Reversed Negatives for Process Work*, demonstration.

THE Imperial Dry Plate Company, Limited, inform us that during the past twelve months they have been continually enlarging their premises and purchasing every modern labour-saving machine. These alterations and additions have been pressed forward, so that their factory, in its finished state, will compare favourably with the best-fitted plate factories in existence. The management offer, during the present month, to send samples of their plates to any one on receipt of the mere cost of postage.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A meeting of Committee was held in the rooms of the Photographic Society of Great Britain on March 3, Mr. A. Mackie in the chair. There were four applications for assistance by loans or grants, all of which, after careful consideration, were granted. Messrs. A. Mackie and R. Child Bayley were appointed to wait upon the husband of one of the applicants with a view to inducing him to go into a hospital, and so give his wife an opportunity of resuming her work as photographic spotter and mounter, and so recovering from their present extreme poverty. One loan was to enable an operator, who had been long out of work, to pay his arrears of debt at his lodgings, and to take a situation which he had already obtained; another, to enable a process worker, who had been out of work for many months, and who was penniless, to obtain camera and apparatus whereby he could undertake work for which he had already orders sufficient in quantity to ensure him a living. In the fourth case, of an operator out of work and with a large family dependent on him, a small grant was made for immediate necessities, with a promise of more if he should be unable to obtain work. The total grants amounted to a little over 10*l.*

EFFECTS OF IMPURE OXYGEN ON THE LIMELIGHT.—Mr. Kenneth S. Murray, of Brin's Oxygen Company, writes: "In your article on these works (see 'Lantern Supplement,' March 3) there is one subject referred to, viz., the effect of impure oxygen on limelight, with regard to which I am afraid I could not have expressed myself clearly to you. What I intended to convey was, that in the tests mentioned, although there was an inferiority in the illumination of the disc thrown by the lime supplied with the low-quality oxygen, this inferiority was less than had been anticipated from the disparity in the quality of the two samples employed. The increased consumption which you mention was most marked. I may, perhaps, emphasise the point by stating that, in a test made between two samples of oxygen of 92·4 °/₀ and 67·0 °/₀ quality respectively, the consumption of the low-quality oxygen was just 50 °/₀ more than that of the high-quality gas, and the illuminating power was even then considerably less, and this was especially marked in the delineation of shadows thrown on the illuminated disc. I consider the difference in qualities of oxygen is more appreciable in the actual consumption of the gases than in their illuminating effect on the lime; but, apart altogether from the question of consumption, I consider a gas of only 60 °/₀ purity would spoil any lantern show. I am conscious of not having explained myself sufficiently on this point, and shall be much obliged if you will kindly put the matter right in your next issue."

ROUND WEST LONDON WITH CYCLE AND CAMERA.—Before the West London Photographic Society, on February 28, Messrs. Stein and Varden read their joint paper on *Round West London with Cycle and Camera.* After detailing how a few members of the Society had banded themselves together into a cycling division, the authors dwelt on the advantages of combining cycling with photography. The cyclist did not feel the weight of his camera, for it was carried on his machine. The paper was profusely illustrated by the lantern, the slides being from photographs by the joint authors, commencing with a short series of pictures illustrative of the evolution of the modern cycle. The authors described very happily a circular cycle trip that could be easily managed in one day, starting from Chiswick and taking their audience, in imagination, through Acton (or Oaktown), Ealing, Hanwell, Perivale, Greenford, Northolt, Harrow, Pinner, Eastcot, Northwood, Ruislip, Hillingdon, Uxbridge, Cowley, West Drayton, Longford, Harlington, Hayes, Heston, Osterley, Isleworth, Brentford, Boston Road, Strand-on-the-Green, and back to Chiswick by way of the Mall, Hammersmith, and Stamford Brook Green. The journey thus indicated was described in detail, with much interesting information about the places visited, both as regards their past history and present appearance, and, in the interests of those members who require a plentiful supply of landmarks to guide them, the authors mentioned by name the many wayside inns they encountered on their journey. The run described included but a part of the Western District of London, and there were other routes of equal interest, embracing such places as Esher, Weybridge, Ripley, Virginia Water, Windsor, Kingsbury, Roe Green, Preston Green, Stanmore, and Whitchurch.

JOURNAL OF PHOTOGRAPHY.

No. 1715.. Vol. XL.—MARCH 17, 1893.

MIXED DEVELOPERS.

It occasionally happens that a batch of plates is met with which, without being actually bad, requires some special kind of development to secure a satisfactory image. This is far less frequently the case at the present day, since the manufacture of commercial plates has been brought to a degree of uniformity, than was the case a few years back, for it is the practice in most of the large establishments to test each make of emulsion before spreading any considerable quantity, and any such doubtful lots are either rigorously rejected, or, if the quality be such as to admit, mixed with other lots of opposite character.

We came across such a sample of plates a few days back, a small lot which had been made for experimental purposes, and which, according to a memorandum on the package, had been found wanting in density, though otherwise good. This seemed a favourable opportunity for testing the capabilities of some of the newer forms of developers which had not been available at the period the plates were made, an opportunity of which we at once availed ourselves.

The particular batch of plates was some seven years old, a fact which in itself would be considered amply sufficient to throw doubt upon the quality of the films; but we may remark *en passant*, that, given a good plate to start with, that is to say, a plate that has been properly treated in manufacture, more especially in the removal of all soluble matter from the emulsion, age alone does not necessarily produce any deterioration. We say "*age alone*," because it is obvious that, if the conditions of storage have been such that other complications are introduced, any sort of change may be anticipated; but, if properly cared for, we have never found mere age to appreciably deteriorate a good gelatine film. With dry-collodion plates the case was altogether different, as by the gradual decomposition of the collodion itself, frequently aided by the nature of the organifier or so-called preservative, a constant change or decomposition was going on.

At the time the plates were made the only developers practically available or, at any rate, in general use were alkaline pyro and ferrous oxalate, and we presume that both these, but certainly the former, in its various modifications, had been tried before the plates were put away as faulty. These were again tried just in order to ascertain if the original qualities of the films remained, and so far as the mere density, or rather want of it, was concerned, they answered directly to the character appended to them; that is to say, while very rapid —rather remarkably so—and perfectly clean in working, they were absolutely useless for printing purposes, owing to the want of vigour. This was more particularly the case with ferrous oxalate, and the best result—if a scarcely appreciable difference in density can be so called—was obtained with pyro and potash.

The first of the more modern developers tried because the first in order of introduction was hydroquinone, and with this a very decided increase of density was produced at first attempt, and with an ordinary formula. But the improvement was accompanied by an alarming reduction in sensitiveness, not, be it understood, a mere prolongation of the time required in development—a not unusual feature of hydroquinone—but a direct impossibility, with a given exposure, of obtaining anything like the same amount of detail, even though the development was extended over a couple of hours.

Nor was this the only difference in the behaviour of hydroquinone. Instead of the clean, delicate, image produced by pyro or iron, the newer solution gave in every instance a coarse and patchy effect, which at first sight seemed to arise from stains, but which on closer examination proved to be due to the form of irregular development for which hydroquinone is remarkable, especially with paper positives. We have no record of the composition of the particular films under treatment; but, as at the period of their manufacture chloride of silver was not an unknown or unusual component of the negative emulsion, it is very probable that the presence of some chloride would account for the irregularity.

Eikonogen and amidol both failed in producing any appreciable increase of density as compared with pyro, indeed the former appeared, if anything, inferior in that respect. As regards sensitiveness, there was no apparent falling off as in the case of hydroquinone.

As, after ringing the changes on the variations of the different formulæ, hydroquinone proved to be the only one capable of any increase of density, but accompanied, as we have described, by loss of sensitiveness and other defects, it occurred to us to try a double or combined development in which hydroquinone played the part of intensifier. Mixed solutions of hydroquinone with pyro and eikonogen have been employed with a certain amount of advantage—especially in America—in cases where one or other alone has failed to produce adequate vigour; but, before trying the mixed solutions, they were applied separately, pyro, eikonogen, and amidol respectively being first applied with a view of getting out the detail, and hydroquinone following as the intensifier. The behaviour of the particular batch of plates under this treatment was peculiar, for it was found in every instance that the solution first applied stamped its individual quality upon the image, and the subsequent application produced literally no

effect. In other words, hydroquinone failed entirely as an intensifier when thus attempted.

In another set of trials, in which the hydroquinone was used first in order to get a certain amount of vigour, while eikonogen was subsequently applied to bring up the detail, the effect of the first solution was the only one that was apparent; for the hydroquinone not only still exhibited its want of energy or capability of bringing out detail with a short exposure, but actually prevented the eikonogen doing so — in fact, it appeared to act in very much the same manner as a strong dose of bromide. Such being the effect of separate applications of these two solutions, it was not considered worth while to try others in conjunction with hydroquinone in the same manner.

The mixed solutions were, however, finally tried, and, while there was no practical advantage apparent in the case of pyro and hydroquinone, pyro and eikonogen, or any combination of amidol, eikonogen, and hydroquinone, in conjunction gave a decidedly better result, so far, at least, as the production of density without loss of sensitiveness was concerned. So far as that, indeed, was concerned, all was as it could have been wished; but unfortunately the irregularity in development which characterised hydroquinone alone still prevailed, though to a lesser extent. The point, however, to be specially noticed is that the retardent action of the latter disappeared when it was used in the presence of eikonogen, although it existed when the two were used separately.

Another peculiarity in the action of the mixed solution upon the old sample of plates under experiment was the production of what at first appeared to be dense fog, but which proved to be a deposit of very fine *loose* matter that was easily and perfectly removed by rubbing the film with the finger. This, together with the irregularity in development, we take to be due, in great measure, to the composition of the films, for on repeating the last experiment (with the mixed solution) with a sample of commercial plates rather wanting in vigour, the beneficial action in securing additional density was again noticeable, while the other peculiarities were altogether absent.

It seems, as far as we have gone, that any advantage there is to be gained from a combination of developers will be in the use of mixed as distinguished from separate solutions. This being the case, it will be desirable to inquire how such mixed solutions will keep, especially as the practice seems to be gaining ground of using the same quantity of solution for a succession of plates.

LENS FOG.

Of all subjects important to the production of clear, crisp photographs, that which forms the title of this article has had perhaps the least attention. Yet, in its many forms, it is the cause of as many defective negatives as any that can be named, short of those inevitable to absolute want of experience. The one example most familiar is that of flare, which, as all know, arises from the diaphragm being improperly placed; but the number of lenses still sent out by makers of position in the optical world which yet suffer from this defect is, to say the least, something remarkable. It is merely localised fog, arising from the lenses, and so embraced in our title; any lens possessing the defect should be returned to the maker at once upon its being noticed, with, if possible, a print taken by its means and showing the flare.

Another potent fog-producer is the presence of a single scratch on a surface of one of the lenses. Many plates may be taken, and the effect of the scratch be imperceptible, yet on some particular day, under conditions favourable to the performance of this defective portion of the instrument, it is possible for a negative to be hopelessly ruined; the vagaries a scratch is capable of indulging in are occasionally most singular. The most favourable condition is seen to be when the lens is exposed to a great flood of light; and, again, will fog be produced when taking interiors if a strong beam of light impinges upon the lens from some unnoticed side-light—a window or otherwise. We have seen fog brought about by a reflected light from some bright object in the field of view striking the surface where the scratch lies. It is, however, but to draw attention to the evil to discover a remedy. If the scratch be painted over with opaque paint—black varnish is as suitable as anything—all danger is obviated. The performance of the lens will not be interfered with, except to the extent of reducing the light passing through it. As a scratch whould be an exceedingly large one that would occupy the hundredth part of the surface, it follows that the consequent loss of light in such case—a hundredth—is not worth discussing.

Akin to this cause of fog is that condition brought about by careless use and handling; the surface is covered with a multitude of fine, almost invisible, scratches, and these, when the lens is flooded with light, will cause the image to lose considerably in brilliancy and crispness. It is remarkable that we do not hear more of such defects than we do, for the carelessness with which some operators dust and polish the lenses of their objectives is simply appalling. When a lens is damaged in this way, there is no remedy but to send it to the maker. It is a mistake ever to attempt, as is sometimes recommended, to polish it up with rouge, putty powder, &c. If the polishing is sufficient to remove the scratches, it means removing the surface to the depth of the deepest scratch, which, slight though it may be, is quite sufficient to alter the original curves, on the correctness of which the performance of the lens depends.

Another frequent example of lens fog is brought about by the brass mounting near the lens showing through the original coating of black given to it by the maker, the result being that the rays of light entering or leaving the lens suffer reflection or refraction at the bright part, and cause veiled images; for it must be remembered that a very slight amount of light is sufficient to act upon the plate. When this reflected light falls upon the shadows, as it does equally with the lights of the picture, it may easily be sufficient to cause fog, at a time, too, when the real cause may have remained unnoticed. When large portrait lenses are in question, this wearing away of the dead black of the instrument is usually seen in the outer rim of the back cell. Let any one, with camera set ready for exposure, remove the ground glass, insert his head under the focussing cloth, and examine the state of the lens. He will often be surprised at the amount of light reflected from this rim, and it is self-evident that all extraneous light visible inside the camera to the eye placed in such a position must fall upon a plate, and produce a greater or less amount of veiling, according to its intensity.

But both for portrait and landscape work, where the quicker kind of lens is used—that in which the posterior and anterior compounds are separated some considerable distance—there arises a frequent cause of fog, before which this last-mentioned cause becomes absolutely insignificant. We refer to the state of the inner surface of the brass mounting. Whether from the gradual entry of dust through the diaphragm slot, the interior being often thus coated; whether from the original

coating being insufficiently matt—a by no means infrequent condition—or from occasional wiping of dust from the interior, it very frequently happens that the light falling through the lens upon this imperfectly blacked surface illuminates the whole of the plate, and it is rigidly impossible to produce a perfectly clear negative with rich shadows, the often discussed "clear glass in shadows" being then uniformly conspicuous by its absence. We should advise every possessor of a large lens to examine it in a suitable manner when the instrument is pointed to the view or portrait. We shall be surprised if the condition of the surface, and the amount of light it reflects, will not often be a revelation. The subject is one of the very greatest importance, and we find cannot be completely treated in a single article; hence we propose shortly to return to it with some practical suggestions bearing on the disease and its remedy or remedies.

Daguerre's Cook.—In the last number of the *Paris Photographe* there is given a reproduction of the portrait of his cook, taken by Daguerre. It was one of the first photographs he executed, and was presented to the Académie des Sciences in 1844 by M. Arago.

Antidote for Cyanide of Potassium.—The records of suicides in recent years show that cyanide is still the fashionable poison among photographers. Dr. Kossa says that permanganate of potash transforms the cyanide into cyanate, which is said to be inoffensive.

Antiquity of Amidol or Diamidophenol.—According to an article in the *Wochenblatt*, diamidopenol or amidol, both as chlorhydrate and sulphate, was originally prepared by T. Gauche in 1869 by the reduction of dinitrophenol by means of iodide of phosphorus Since then the body has been extensively studied, Hemilian, in 1875, showing that by the reduction of the dinitrophenol the salts of diamidophenol were formed, and, not as Gauche thought, those of diamidobenzole.

Photographic Properties of the Salts of Cerium.—According to the *Moniteur*, Messrs. A. & L. Lumière have obtained photographs by the aid of the salts of cerium. Cerium, it is said, forms two series of compounds like iron and manganese, the ceric and the cerous, the ceric salts having the property of being reduced to the cerous state under the influence of light. It will be remembered that Messrs. Lumière have taken advantage of a similar property of the manganic and cobaltic salts to produce positive impressions.

The Synoscope Wide-angle Lens.—At a meeting of the Société Française de Photographie on February 3, M. A. Gorde exhibited a wide-angle lens of very short focus, called the Synoscope. The lens, he says, embraces an angle of 135° (!!), its focus for a plate 13 × 18 cm. (7¼ × 5¼ inches about) being about 3¼ inches, for 18 × 24 cm. 10 cm. (about 4 inches). M. Gorde says that these foci are about the shortest known for the sizes of plates covered. The largest aperture available is about *f*-20, which being, he says, relatively large, allows of instantaneous pictures of interiors with magnesium being taken.

Fine Art in America.—According to a daily contemporary, out of nine hundred and fifty paintings, by western artists, that have been offered for exhibition at the World's Fair at Chicago, the Committee have rejected no less than eight hundred and forty. Unless the Committee have set a very high standard for the work, this does not say much for the ability of American painters. That our American cousins do appreciate fine art there is no question, as is proved by the high prices they sometimes pay for the works of European artists, also by the large sale that photogravures of high-class paintings, that are produced in France and Germany, meet with in the States.

How to Disperse a Crowd.—Every out-door worker has, at times, experienced the annoyance of small crowds of people collecting in front of the camera when ready for exposing. Many dodges have, from time to time, been published for getting rid of them; the latest, however, which is certainly original, comes from the Halifax Camera Club, where, at its last meeting, Mr. J. E. Jones recommended "that one's wife should be sent round with the hat, which he considered would be effectual in making them move off." Very likely it would. But the method suggested presupposes one to have a wife—and, having one, that she would or could be made to go round with the hat. We should advise some of our married friends to try it on, and report the result.

The Forthcoming Solar Eclipse.—It is to be hoped that the two British eclipse expeditions—the one to Brazil, the other to the West Coast of Africa—will be favoured with fine weather on the 16th prox. The work on this occasion, we are told by Mr. E. W. Maunder, is to be almost exclusively of a photographic nature—photographs of the corona itself and its spectrum. One of the advantages of this eclipse is its unusually long duration, over four minutes and a half. This, if the weather be propitious, will enable a greater number of negatives to be secured than on other occasions. It would be exceedingly dispiriting to the astronomers to make such long journeys without result. Such, however, has been the fate of some expeditions as far as photography is concerned.

Art in the Lantern.—At the present time lantern exhibitions are restricted almost entirely to photographs from nature, such as landscapes, street views, and the like. This frequently renders a long exhibition somewhat monotonous before it reaches the close. Now, if the slides from nature were occasionally interspersed with a few copies of works of fine art, it would often prove a relief to the audience. One cannot help thinking, when looking at the magnificent copies of painting to be seen in the shop windows, that are produced on the Continent, what excellent lantern slides could be made from the negatives. Although it might not pay commercially to have to take negatives specially for lantern purposes, there is no reason why the negatives now in use for contact printing should not be employed with camera printing. On the Continent the lantern is not in such extensive use as it is here, and it is for that reason, perhaps, slides of the kind are not forthcoming. If those enterprising houses that publish the popular reproductions of paintings were convinced there would be a sale for lantern slides of the same subjects, there would soon be a supply in the market. Any how, the matter may be worth consideration.

"Trusting to Honour." — A correspondent directs our attention to the following advertisement of a provincial photographer:—"Trusting to honour. A bold experiment never before tried. Can only succeed by the result being so beautiful that you cannot resist it. Send me any portrait, no matter how old or faded, of yourself or friend, that you really value, and I will return you, entirely free of cost, one of my new style large porcelain-type portraits—an exact reproduction, artistic, lasting, beautifully finished, and handsomely framed—entirely on approval. If you do not wish to possess it, I will trust to your honour to return it to me; but, if you do (of which I feel sure), I will accept the very reasonable sum of 1*l.* 1*s.*, and trust to your honour to remit the same. I will stake my honour and 50*l.* that I will not damage your copy to the slightest extent, and return it post free and safely packed. Address, ——— Cabinet portraits copied same size, or enlarged from *cartes-de-visite* on same terms, viz., approval. Specially note.—This is not a two-guinea free pastel portrait, which may be a take-in, but exactly the opposite in every way. Give us a trial, as there is no risk to yourself in any way whatever, and you will have the opportunity of purchasing, at about half its value, a portrait that will be certain to please, and which you will probably find a joy for ever." We have only one

remark to make, and that is, that we should like to see the element of "honour" entering more largely into competition among professional photographers than this and other recent advertisements would indicate as prevalent.

Photo-Intaglio Engraving in America.—In our last issue Mr. Louis E. Levy has a reply to our comments on a paper of his that appeared some time ago in the *Journal of the Franklin Institute*, the greater part of which, as we said, was devoted to decrying the methods of photogravure as at present followed in Europe, and belauding an alleged new method of his own, which he did not describe, but said it formed the subject of a patent. Mr. Levy seems hurt at our suggesting that he appeared ignorant of what is being done in the matter of the highest-class photogravure on this side of the Atlantic, particularly as to the amount of hand work there is on high-class modern plates. His letter now confirms our previous impression, for we cannot imagine him making an intentional misstatement. We have had many opportunities of examining plates immediately the photo-chemical operations in some processes, and the photo-electro in others, were completed, as well as seeing them carried through from the beginning, in some of the best houses both in England and on the Continent. These have disproved Mr. Levy's ideas as to the amount of hand work that is now required. Until our correspondent told us, we were unaware that European establishments issued "unfinished and finished work." Those we know let no unfinished work leave the premises. With reference to the practicability of a gelatine film being printed from as an intaglio plate, Mr. Levy says: "I have not, indeed, utilised such films as intaglios." Possibly, when he attempts to do so, he will find there is a difference between reliefs and intaglios, even when only a limited number of impressions are concerned. Regarding the statement in the paper, "In only one establishment, and that in Paris, has the work been brought to a high degree of quality," our correspondent now quotes an old Latin proverb, "De gustibus non est disputandum." But we were not dealing with questions of taste, but matters of fact. Probably Mr. Levy is unaware that this is not the only journal that commented on his belauding his process without saying anything at all interesting about it.

SOLUTION-MAKING.

This subject seems to be very attractive: but if every one who, in response to our esteemed Editor's wishes, contributes to the British Journal Almanac what he considers to be useful memoranda of practice, is to be exposed to covert sneers and openly expressed accusations of making false claims, the responses would quickly fall off. As a matter of fact, when the Photographic Convention met in Chester, and a considerable number of members did me the honour to go through my place, studio, dark room, laboratory, toning room, and various workrooms were open to them. Most of them saw the Doulton dipping bucket, and in use for dissolving sulphite of soda, and expressed themselves highly pleased with the action of what, to them, was a novelty.

The principle of the method of solution is of historical age (I used it myself over thirty-five years ago), and it goes without saying that the particular application of the dipping bucket is only one of a hundred plans that may be adopted for the same end. It is not every photographer who possesses such acquaintance with laboratory work as, like Messrs. Martin & Co., to be able to look down upon the rest of their photographic brethren as "needing instruction in the elementary operations of their business," if the perforated dipping bucket should be a novelty to them. I am, however, surprised that the mere fact of "thoughtless assistants" breaking off the handle of the buckets should oblige such a talented firm to adopt another course, which they call simpler and more efficient, in lieu of repairing the breakage. If those who have any thought of acting upon this recommendation will take my advice, they will not adopt it. I long ago tried the plan (but in a more workmanlike way, the canvas being attached to a ring of cane, and thus quickly shipped and unshipped), and dismissed it for the dipping bucket, which is a far quicker and simpler method, and to be preferred, especially when *rapid* solution—the point of the original recommendation—is desired. I will not insult the intelligence of the readers of this Journal by supposing it is needful to explain how to form a substitute for a broken handle when the original support is knocked off.

The most striking point about Messrs. Martin's communication is their own statement that they make their hypo solution fresh every day. Every one practically familiar with the chemistry of hypo is aware that it is quite easy to keep the solution free from injurious decomposition for several weeks. The best way of arranging for fixing operations is not to make the solution daily, but to store a large quantity in a tank, and convey it in pipes provided with taps—"lay it on," in fact, like water. I claim no originality for this plan, but it would be far better for a "general photographic works" than the primitive hand-to-mouth plan of making it daily, and carrying about the place. A hundredweight cask of hypo has a few holes bored by a brace and bit round the sides at one end, and is then placed in the tank, supported, partly immersed, at the perforated end. Solution is soon made, and a tank with sides little over two feet square will suffice for a twenty per cent. solution of a hundredweight of the salt.

"Atticus" appears to be one who is readily amused: but, as he is ignorant of the difference between a dark room and a laboratory, and from his letters it would be inferred does not use sulphite in making stock solutions of pyro, and when he does make it uses his dark room for the operation, he is evidently of no account! Surely the readers of The British Journal of Photography take no interest in the amusements of this kind of person, who, further, seems to have a specially original copy of The British Journal Photographic Almanac, for it contains, according to his letter, statements on a particular page not to be found there in any other copy.

G. Watmough Webster, F.C.S.

JOTTINGS.

The unalterable ass who beats the drum for the *Shoptician and Spectacle-sellers' Gazette* seems to be in doubt as to whether the owner of the *nom-de-plume* at the end of these "Jottings" is a lady or a gentleman. It is so agreeable to the anonymous journalist to be taken for one or the other, that I am peculiarly pained to have to deny the compliment of a choice to my critic—who is neither.

Mr. Jones—the only Jones, I should think—has been giving the Halifax Society his ideas on landscape or tourist photography. "He did not believe in the long-focus camera when on tour." Why? Has Mr. Jones never experienced the want of a long-focus lens out of doors? "The best way to store films or plates after exposure was to place a thin sheet of non-actinic paper between every two plates." Why *non-actinic* paper? "He considered the legs of the tripod . . . . a great nuisance." Where does the "nuisance" come in? and why not include the camera, the dark slides, and the lens in the same category, Mr. Jones, or use what the Irishman would call a one-legged tripod? "He had often been annoyed by crowds of people standing round when about to expose, and recommended as a remedy that one's wife should be sent round with the hat, which he considered would be effectual in making them move off." If *I* were among the crowd, my readiness to move off would be largely governed by the lady's personal gifts; but I should like to have the ladies' views on the suggestion. On the whole, Mr. Jones's photography is superior to his gallantry—but not very much.

I hear a meeting of Exhibition Judges is to be held, with a view, I suppose, of arriving at a common basis of action for their future guidance, and the preparation of rules to be observed by societies holding exhibitions. The ridiculous airs and graces which several judges have given themselves lately proves that there is as much need for rules and regulations for *them* as for societies and individuals: and I hope therefore that the search lights of the photographic press will be turned on their proceedings, so that the game of mutual admiration does not go too far. It seems to me that in late years the principal qualifications for a judge at photographic exhibitions are two, namely, (1) that he should have produced a few passably well-selected and composed photographs, indifferently focussed and exposed,

and printed to look as much unlike a "photograph" as possible; and (2) that he should have foisted lengths and lengths of nebulous twaddle on Art—with a capital A—on the readers of the photographic papers. The worst of it is that people of this kind get so imbued with the notion that their way of making pictures by photography is the right one, that any one who thinks otherwise, and proves the faith that is in him by exhibiting, stands very little chance of an award against those who prefer to look at nature through a ring stop.

Contact photographs, with the tones broken up by the interposition of ruled gratings between the negative and paper when printing, are, to my mind, so distinctly effective, that I should not be surprised if the public, being gently inclined thereunto by a little of the push and assiduity with which, alas! so few modern photographers are endowed, did not take kindly to them, and the oft-expressed aspiration for a new style of portrait, which has appeared in these pages of recent years, be fulfilled. During a brief visit to the States last year I saw several grated photographs, produced, I think, by a New York photographer. They were on albumen paper; but I can conceive that on bromide or platinotype, where, as a rule, the contrast between the lights and the shadows is more accentuated, much more effective results can be secured. The preparation of suitable screens is no easy matter for the ordinary photographer, and it would, I think, be worth somebody's while to take the matter in hand commercially and supply screen negatives with a small variety of grains. But I would not give much for Mr. W. Lindsay's idea of securing the grain by sifting powdered emery on a gelatine surface, however much it might effect a resemblance to photogravure on albumen or gelatino-chloride. It seems to me that more evenness and regularity of grain would be likely to be obtained by mechanical ruling, while I am doubtful of the artistic success attending any attempt to impart the dominant features of a photogravure to a "surface" print.

The great Amateur *versus* Professional controversy seems to die a hard death. No professional photographer worth his salt need be alarmed at the progress of amateur photography, for if a man who devotes his days and nights to photography, and has the wholesome knowledge that his daily slide and the Sunday's dinner depends upon the measure of his application to his profession, cannot acquire a range of ability fifty times greater than the non-professional photographer who simply follows the art as a hobby, then has he mistaken his vocation, and is only fit for the hod. The sneering at amateurs as such by several of your recent correspondents strikes me as in the highest degree puerile. I applaud Messrs. Allison, of Belfast, who, on March 3, write you that they are endeavouring to make a little money out of amateurs by issuing a scale of charges for the use of dark room, developing, &c.; but I have no patience with W. Tipping, who, on March 10, appears to yearn for a new style of picture which amateurs could not "imitate." As if that, *per se*, would popularise portrait photography with the general public one tithe more than at present! If your correspondent wants a process which amateurs do not work, why does he not turn his attention to the neglected processes which you described a couple of years ago, among which he will find several admirable methods suitable for portraiture? By the way, I wonder if Mr. Byrne, Mr. Winter, Mr. Vanderweyde, Mr. Crooke, and Mr. Warnenke care a rap how much amateurs "imitate" them. Not likely.

Advance, Australia! An enlargement, fourteen feet six inches by six feet three inches, for the Chicago Exhibition, quite snuffs out the big enlargements which have recently been executed in this country for the World's Fair. I wonder if anybody buys—and pays for—these mammoth pictures? A man who could afford space for hanging them could afford to have big paintings, I suppose, and would have them. I like enlargements—"not too much enlargement, just enlargement enough"—but, when they are measured by the yard, I fail to see their beauty or utility for ordinary purposes. Still, "sweet are the uses of advertisement."

COSMOS.

GEORGE WASHINGTON WILSON.

One by one, and in an increasingly rapid sequence, the men who made photography are passing away.

There is no one whose name has ever been associated with all that is excellent in the art department of photography that stands so high as that of George Washington Wilson, of Aberdeen. When he first issued his singularly beautiful stereoscopic views, it was at once universally felt that a real artist had arisen, one who would aid in elevating landscape photography from the somewhat low state of mediocrity in which it existed. In his pictures were concentrated the highest development of

artistic beauty and technical skill, and they became models for imitation; and it is to this, in many cases slavish, imitation that we owe a marked and rapid progress as soon as his gems of art came to be known and studied. "Quite Wilsonian" was, and still is, a term frequently applied to photographs having a certain style of technique. Imitation is rightly said to be the sincerest form of flattery, and we know of some who did not disdain to follow Mr. Wilson's footsteps in such a literal fashion as, having one of his views in hand, and observing the relation of one portion of the scenery to the other, to eventually by this means discover the identical spot where his camera had been planted, and there also plant their own tripods.

In early life Mr. Wilson studied in the Art School, Edinburgh, and for some years he followed the profession of miniature painting, an avocation in which he attained a considerable measure of success. His reason for abandoning that art is rather remarkable. We learn from a local paper that just as he had begun to make a name for himself photography was discovered, and the impression became common that portrait painting as a profession was doomed. Mr. Wilson was apparently of that opinion, and threw aside palette and easel for the camera. He became one of the pioneers in photography, and was among the first to apply it to landscape. It is said that he had the honour of taking the first photograph of the Queen and the Prince Consort at Balmoral in 1850. His services were frequently requisitioned at Balmoral after that; and one notable group of Royal personages includes the late Emperor Frederick (then the Crown Prince of Prussia) at the time he was courting the Princess Royal, and so gratified was the Prince with the character of the work produced

by Mr. Wilson that he commissioned him to execute a series of water-colour sketches representative of Deeside scenery for presentation to the Princess Royal. When passing through Aberdeen in the Jubilee year, the deceased Emperor (still Crown Prince) paid a visit to the premises of the Messrs. Wilson, and, recalling the circumstances referred to, entered into a long and friendly conversation with the deceased.

After commencing business as a photographer he made numerous expeditions to notable parts of Scotland, and his views obtained on these occasions became widely celebrated. They were taken by the wet-collodion process (which he worked in a little portable tent), and in which he was an adept. By this he secured admirable instantaneous effects with fine skies. About seven years ago he retired from the active pursuit of photography, leaving three of his five sons to manage the large business now established. This, within the past few days, has been formed into a limited company, the necessary negotiations to that end having only been brought to a termination on the 9th inst, on the morning of which day he died very suddenly at his residence, Queen's Cross, having been in town on business the day previous. He was seventy years of age when the sad event occurred. When he retired to bed the previous evening he was in his usual health, but at one o'clock in the morning he had an epileptic seizure and expired soon afterwards.

After his retirement from active business, he once more took up the brush, and painted the portraits of several citizens of eminence. Mr. Wilson was a member of the Chamber of Commerce, and had represented one of the wards of the City in the Town Council. He was also a Director of several companies in Aberdeen.

It is needless to speak in terms of eulogy of his works—that has been done by the world during a long term of years; and through them, although now dead, he yet speaketh. As we have said, he was seventy years of age at his death, which took place on March 9. He is survived by a widow, four daughters and five sons, to all of whom we tender our sympathy.

The portrait we here give is a striking likeness, and was among the last that was taken of the eminent photographic artist.

ON THE PRODUCTION OF BLACK AND WHITE NEGATIVES BY MEANS OF ARTIFICIAL LIGHT.

III.

The great aim in black and white work being to produce negatives having much contrast, *i.e.*, clear glass for the blacks and the utmost density for the whites, it follows that the greatest care requires to be observed in the matter of development. A worker, however, will often be puzzled to account for the varying behaviour of the plates he exposes on what at first sight appear to be almost identical subjects. There is, however, a great difference in the behaviour of various samples of white paper. This can be easily proved by taking a sample of snow white, upon which some design or handwriting has been effected by means of Indian ink, and alongside of this place, say, a sheet of printed matter from any ordinary book or publication, and exposing the plate on both simultaneously. On development a considerable difference may be apparent in the densities. There is a golden rule, however, to follow in all cases, viz., to stop development before any reduction in the blacks begins to take place. This is not by any means a difficult thing to do, but it means the utmost care must be taken to give a full exposure, but not by any means an over-exposure for the method of development it is intended to adopt. Full density is seldom or ever acquired by development alone. Provided, however, sufficient attention has been given to the proper lighting, and a small stop used in the lens, with a correct exposure, a very considerable amount of density will be easily acquired before there is the least sign of any veiling over in the blacks or transparent portions of the negative. This must be carefully looked for, and development arrested the moment the least signs are noticed.

A worker will now see how necessary it is that the utmost precautions be taken to guard against any strong light entering the camera, except that which is conveyed to the sensitive plate by the lens and which forms the image. This I pointed out in a previous article. Sometimes unsuitable lenses are employed for copying. No lens should be used that conveys any light to the sides of the camera, or, in other words, that considerably more than covers the size of the plate being used. When it is considered that exposures of minutes' duration have frequently to be given, it will be at once obvious that any reflected light from the sides of the camera would be certain to cause deterioration to the transparency of the negative. This is a very frequent cause of defect, even in ordinary work; but in black and white subjects it is one of the most insidious defects met with, and when it occurs no perfect results can be obtained.

Whenever, after due attention has been given to the matter of correct exposures, &c., it is found that degraded negatives are still being produced, this defect should be looked for.

I have said that it is but seldom sufficient density is acquired by development alone. This means that all, or nearly all, negatives intended for black and white prints require to be intensified, and this being so means that the utmost care should be bestowed in the treatment of the plate during development.

With so many excellent formulæ for development in the hands of every worker, it might seem unnecessary for any one to recommend one in preference to another, because it is quite possible for a worker to turn out as good negatives by a certain formula, the working of which he daily practises and is therefore conversant with, as any one else can do by a different formula entirely. This undoubtedly is so in the all-round working of photography, but I find in black and white work I have succeeded in getting quite different results by the employment of a formula different in many respects from that used for other classes of work.

Some years ago I was forcibly struck, when reading a formula which I think was first given to the world by Mr. Leisk, that it appeared to me to be just the right one for black and white negatives. I can strongly recommend this. Here it is :—

Make up the pyro by adding nine ounces of saturated solution sulphite to one ounce of pyro, then add sixty grains of citric acid; label A.

Dissolve four ounces of carbonate of soda, 288 grains of sulphite of soda, forty grains of bromide of ammonia in thirty-two ounces of water; label B.

Attention must be given that these quantities are carefully weighed.

In conjunction with this formula, a clearing bath should be provided, as follows :—

Add two drachms of strong acetic acid to one pint of water.

Most workers of any experience will readily understand that some plates require considerably more pyro to gain extra density than others; therefore, practice alone will show the quantity of pyro to use to each ounce of soda solution. As a rule, however, it will be found that when the developer is very strong in pyro and bromide, and the exposure has been so regulated for such, the best results are got. I have frequently gone as far as two drachms of pyro to each ounce of soda, with an addition of bromide of ammonia over and above the quantity in the formula.

With a good isochromatic plate, this will yield plenty of density to allow of complete opacity when the plate is intensified. The great advantage of this formula is that it never stains the plate. When it is seen that the utmost range of density has been acquired without any reduction in the blacks, the plate is sponged gently by means of a plug of cotton wool with a quantity of the clearing solution. This will remove all developer from the surface. Do not wash the plate at this stage, but, after sponging off the developer, place it straight-away in the bath of clearing solution above given. This prevents any staining that would probably occur were cold water applied to the plate, the surface of which still contained some portion of the pyro developer. The plate should be kept in the clearing bath for at least some minutes.

From the clearing bath the plate is well washed under a running tap, and is then fixed in *freshly* mixed hypo.

If strict attention is paid to these particulars, a beautifully clean bright negative is the result.

A dirty or previously used fixing bath should be avoided. It may not be generally known, but a discoloured fixing bath will stain a plate, provided it remains in such only a very short time.

Some workers use a clearing and fixing bath made up by adding to about twenty ounces of hypo solution of proper strength two ounces of saturated solution of sulphite of soda, to which has been added one drachm of hydrochloric acid. This is a very useful fixing bath for ordinary work, and keeps the bath free of discolouration for some time after being used; but I fancy I never get such good clean results when the intensification stage is reached, after plates have been fixed in such. An alum bath also is better dispensed with when plates have to be intensified.

Some workers advocate the use of a gallic acid bath for the exposed plate previous to development, and claim that by its use the utmost amount of density and contrast is obtained. I know one worker who speaks very highly of its use in conjunction with a certain brand of plates, but I can confidently recommend Mr. Leisk's formula, which I have described. It is cleanly in its results, and yields bright and sparkling negatives.

So much for the formulæ. Now let me refer to a very important factor in development that is seldom or ever taken into consideration even by experienced workers. I refer to the important influence a

variation of temperature in the developing solutions has in the results obtained. We often hear expressions of dissatisfaction made about this or that plate being bad, or this or that developer being all wrong, or the light must have been awfully bad to-day, or some other such ejaculations having reference to the difficulty experienced in getting a plate to develop up with the usual amount of detail; or it may be the other way about, such as, after getting into a certain way of working with some particular brand of plates, all at once things get into a different groove, and quite a change comes over the behaviour of the plate, although, as far as can be judged, everything has been conducted just as before. I am quite sure this puzzle has bothered many an amateur who looks upon himself as a full-fledged worker, and yet somehow they cannot discover the reason of the different behaviour of the plates.

To those having experience of this, and who would like to solve the problem, let me suggest the following experiment:—

Take two plates, and expose them on any given subject under exactly the same conditions in every respect; proceed into the dark room and mix up sufficient developer in one cup to develop both plates, they being placed in different dishes. Proceed to develop with the formula I have given one of the plates with the developing solution at a temperature of about 38° Fahr. Mark how slow the development proceeds, and how for a long time only the high lights put in an appearance, and in many instances, even with a full exposure, the utmost difficulty is experienced in bringing out the shadows, the result being a negative violent in contrasts, with every appearance all through of being under-exposed, although such has not been so by any means. Now take the other plate, which has been exposed under exactly similar conditions, and with the other portion of the developing solution exactly the same proceed to warm the porcelain developing dish by placing it in hot water, and whilst the dish is warm pour in the developer, so as to raise its temperature. Now place in the dish the plate and proceed to develop, and mark what a distinct difference at once becomes apparent. There is now no talk of under-exposure, but, on the contrary, the plate will very possibly come rushing up and show every sign of being over-exposed.

Here, then, in the matter of altered degrees of temperature of the developing solution, we have a considerable power for ringing the changes in the way of getting violent contrasts when desired, and in the production of negatives from black and white subjects. We can do much in the way of keeping clear glass for the blacks by a judicious use of developing solutions of a low degree of temperature, at least, for a portion of the time the plate is being developed, and if desired, the temperature can be raised by merely flowing the solution into another dish, which is standing in warm water. In my hands this alteration of the temperature of the solution *during development* has proved a great boon in many cases, for, by a judicious use of such, not only can density be got to begin with, but the amount of detail that will eventually be brought out is sometimes quite surprising. When copying ordinary photographs, or other similar subjects, it is very necessary to get pluck and vigour in the high lights before detail is out, and it is got better by this means than any other I know of.

In winter-time, much may be done by warming the developing dishes, for in such weather as we get up here in Scotland, where we have a long spell of cold weather, often for weeks together the developing solutions will stand as low as 38° Fahr., and sometimes even lower; whilst in summer-time a supply of iced water, to cool the dishes at the start, helps wonderfully in gaining various ranges of tone in the negatives.

T. N. Armstrong.

"SPIRIT PHOTOGRAPHY," WITH REMARKS ON FLUORESCENCE.

[London and Provincial Photographic Association.]

The presence of smoke may be considered as implying the existence of flame. Spirit photography, so called, has of late been asserting its existence in such a manner and to such an extent as to warrant competent men making an investigation, conducted under stringent test conditions, into the circumstances under which such photographs are produced, and exposing the fraud should it prove to be such, instead of pooh-poohing it as insensate because we do not understand how it can be otherwise—a position that scarcely commends itself as intelligent or philosophical. If in what follows I call it "spirit photography" instead of psychic photography, it is only in deference to a nomenclature that extensively prevails, and not as offering a surmise from any knowledge of my own as to what is matter and what spirit, or the distinction between mind, spirit, and matter, for in truth I don't know. I approach the subject merely as a photographer.

Origin of "Spirit" Photography.

Before I proceed, a few words on the origin of spirit photography may not be out of place. In March, 1861, W. H. Mumler, the principal engraver in the employ of Bigelow Bros. & Kennard, the leading jewellers of Boston, when whiling away an idle hour as an amateur photographer, had a form other than that of any one present developed on his collodion plate. He surmised that it arose from an image having been previously on the plate, and its having been imperfectly cleaned off. Subjected to a more thorough cleaning, the form again appeared more strongly marked than before, and he could offer no other explanation than the one given. It got noised abroad through the press that a spirit had been photographed, and although Mumler strove to suppress the misrepresentation, as he regarded it, yet he eventually succumbed to popular demand, and took two hours a day from his regular work, devoting them to photography. This he had to extend to the whole of each day, entirely discarding his regular profession. Many men of eminence sat to him, most of whom he did not know at the time. He seems to have encouraged his sitters in the adoption of such test conditions as they deemed satisfactory. The figures that usually appeared on the plate with the sitters were, if I rightly infer, those on whom the sitters' minds had been set. That eminent portrait photographer, Mr. Wm. Black, of Boston, so well known all over the world as the inventor of the acid nitrate bath, undertook to investigate the *bona fides* of Mumler's methods. Through a friend, who had just previously sat and obtained a figure, Black offered fifty dollars if Mumler would operate in his presence and obtain a picture. Invited to come, the acute Black critically examined camera, plate, dipper, and bath, and had his eye on the plate from the moment its preparation began until it was sensitised and locked in the dark slide, removing it himself from the camera and carrying it into the dark room, where, on development, a figure of a man was seen leaning on B.'s shoulder. Black was wonder-stricken, and got away the negative, no charge whatever having been made. Mumler now claimed publicly to be a spirit portrait photographer, and as such he eventually opened a studio in New York, having previously satisfied Silver, Gurney, and other photographers as to the genuineness of his claims, never hesitating to operate in their galleries if required, and with their apparatus and chemicals. Mumler was arrested in New York; whether on the ground of witchcraft or of endeavouring to obtain money under false pretences, I am at present uncertain, but his trial was the sensation of the day, and numerous witnesses were examined. He was honourably acquitted.

Some Investigators of the Subject.

In this country, several who are amateur photographers have investigated this subject with more or less success. These include some F.R.S.'s, scientists, artists, and others. I question whether any have so persistently done so as the late Mr. John Beattie, of Clifton, and his friend, Dr. Thompson. Mr. Beattie was a skilled professional photographer of the highest eminence, who sometimes, prior to his death, had adopted the views of the spiritualistic school. The figures he obtained on his plates were much blurred in outline, some being misty in the extreme. I possess some two or three dozen of these taken by, or in the presence of, Mr. Beattie, whose intelligence, honesty, and powers of observation no one would venture to doubt. Many such photographs are claimed to have been produced by Hudson, a professional photographer, formerly of the Holloway-road, and I submit for examination a work by the late Miss Houghton, containing fifty-four of Hudson's spirit photographs.

There are many ways by which, assuming the genuineness of only one of all spirit photographs hitherto produced, the spurious article may be made even better than any alleged real ones I have yet seen. A plate secretly impressed previous or subsequent to being placed in the camera fulfils the condition; so does one at the back of which is placed a phosphorescent tablet in the dark slide. Pressure on the surface, such as by that of a Woodbury relief film, also causes a developable image; in short, trickery in a whole variety of forms may and has been impressed into the service.

Photographing the Invisible.

The higher department of fluorescence may with success be employed. Here is something to which believers in the visibility of spirit forms to a camera are quite welcome. At the time, and *apropos* of the Mumler trial in New York, I wrote that a good many absurd things have been said *pro* and *con* on the subject; but a writer in the latter category, who asserted that anything that is visible to the eye of the camera, and thus capable of being depicted by photography, must therefore necessarily be visible to the human eye, was surely ignorant of that important branch of physics popularly known as fluorescence. Many things are capable of being photographed which to the physical eye are utterly invisible. Why, for that matter, a room (visually dark) may be full of the ultra-violet rays of the spectrum, and a photograph may be taken in that dark light. Objects in a room so lighted would be plainly visible to the lens of the camera—

at any rate, they could be reproduced on the sensitive plate, while at the same time not an atom of luminousness could be perceived in the room by any person possessing ordinary or normal vision. Hence the photographing of an invisible image, whether it be of a spirit or a lump of matter, is not scientifically impossible. If it reflect only the ultra-violet rays of the spectrum, it will be easily photographed, although quite invisible to the sharpest eye.

Again, Cromwell F. Varley, F.R.S., well known as one of the most eminent of electricians, says (*Eclectic*, June, 1871), when passing a current of electricity through a vacuum tube, the results of which were indicated by touches of light about the poles: "In one instance, although the experiment was carried on in a dark room, this light was so feeble that it could not be seen, and the operators doubted if the current were passing. But photography was at work, and in thirty minutes a very good picture was produced of what had taken place. This," he says, "is a remarkable fact; indeed, it borders on the wonderful that a phenomenon invisible to the human eye should have been, so to speak, seen by the photographic lens, and a record thereof kept by chemical agency. It is highly suggestive, and we may anticipate that it will be turned to good account by practical philosophers."

Fluorescence.

Some very striking phenomena in photographing the invisible may be produced by the agency of fluorescence. Figures depicted upon a background by one or other of certain substances I shall presently name, although invisible to the eye, may become visible to the camera. Of these, the best known, although not the most effective, is disulphate of quinine. Such a solution, although to the eye it is colourless like water, is to the camera as black as ink. Fill three phials respectively with water, quinine, and common writing ink, and you have two whites and one black; but photograph them, and you have two blacks and one white. The camera has reduced the transparent quinine solution to the colour of the ink. Those of you who may care to experiment in this direction, please take notice that the quinine must be acidulated with sulphuric acid, and that hydrochloric acid, even a small trace, will destroy this property. Among other substances that are fluorescent, or that change the refrangibility of rays of light, are mineral uranite, certain salts of uranium, canary glass, alcoholic solution of chlorophyll, æsculine, tincture of stramonium seeds, and of turmeric. There are others known to be still better, but my experiments in this direction are yet too incomplete to warrant my even indicating them.

Let me for a moment enter the realm of speculation, and assume that there are really spirits invisible to the eye but visible to the camera and to certain persons called seers or clairvoyants only. Might we not suggest that there is some fluorescent compound in the eyes of such persons not present in those whose eyes are normal, and that it is to this they owe their seeing powers? Some of you may probably be aware that Dr. Bence Jones and other philosophers have actually established the fact of such fluorescent substances being found in some eyes. May this throw any light upon the recognised fact of certain animals being able to see in the dark?

When the subject of fluorescence is more thoroughly investigated (it is a discovery of Sir D. Brewster, who was followed by Herschel and Professor Stokes, and is as yet but of yesterday), we may hope for a vast accession to our knowledge of subjects as yet very slightly understood.

At the Bradford meeting of the British Association for the Advancement of Science, in 1873, Dr. Gladstone, F.R.S., demonstrated before the Mathematical and Physical Section what I have said respecting invisible drawings on white cards having produced bold and clear photographs when no eye could see the drawings themselves, and I brought away back to London these photographs, and, for aught I know, may have them still.

A Lady's Joke.

To prevent this disquisition from being too dry, I will here introduce a fanciful sketch I wrote *apropos* of Dr. Gladstone's demonstration at the time mentioned:—

A mischievous young lady of scientific proclivities who attended the meeting of the British Association, and who was addicted to practical joking, listened attentively to Dr. Gladstone's observations upon the properties of quinine referred to, and having carefully noted the discussion that followed, reasoned within herself thus: If solution of quinine can make invisible marks upon paper which will come out black in a photograph, it ought to do the same when applied to the skin. So she procured some of this solution, and upon her fair brow she painted with it a death's head and cross bones. These, of course, were invisible to human vision. Thus prepared, she went to a photographer to have her portrait taken. All went right until the operator went in to develop the plate, when she soon heard an altercation between the photographer and the attendant boy, in which it was evident that the latter was being charged with having coated an old or dirty plate.

A second negative was taken, with this result, that the operator, after bestowing a puzzled, affrighted look at the lady, rushed downstairs to the principal of the establishment. Both returned to the dark room, and a third negative was taken, when it became evident that intense excitement was being produced in the dark room. After an excuse to the lady about there being electricity in the atmosphere which had affected the chemicals, she was requested to sit once more.

Scarcely had the plate been developed when both photographer and assistant rushed out from the dark room, pale and excited, and explained that on the brow of the sitter in each negative was emblazoned the insignia of the King of Terrors. The negatives were produced, leaving no doubt of the fact. What was to be done?

The sitter hinted something about not being disposed to be made a fool of by one who she was satisfied was a spirit photographer, and that she, for one, would not allow herself to become the victim of such absurdity. This upset the equanimity of the photographer, who expressed his earnest conviction that she was an emissary and personal friend of the common enemy of mankind.

"I shall look in again to-morrow," said the lady, in her sweetest tones, "if you promise not to play any of your silly ghost tricks upon me."

"Not for ten thousand worlds," said the artist, "shall you ever set foot within my studio again."

"Oh," she laughingly rejoined, "I shall drop in through the roof and visit you some day when you are disengaged;" and with that she departed.

"I knew it!" gasped the photographer. "I felt a sulphurous odour the moment I came near her. Send immediately for my friend, the Rev. ——, and get him to offer prayer, and free the studio from the evil influences remaining after a visitation from one whose feet, although clad in boots, would, if examined, be found to be cloven."

Some Personal Experiments.

For several years I have experienced a strong desire to ascertain by personal investigation the amount of truth in the ever-recurring allegation that figures other than those visually present in the room appeared on a sensitive plate. The difficulty was to get hold of a suitable person known as a sensitive or "medium." What a medium is, or how physically or mentally constituted to be different from other mortals, I am unable to say. He or she may not be a photographer, but must be present on each occasion of trial. Some may be mediums without their being aware of it. Like the chemical principle known as catalysis they merely act by their presence. Such a one is Mr. D. of Glasgow, in whose presence psychic photographs have long been alleged to be obtained. He was lately in London on a visit, and a mutual friend got him to consent to extend his stay in order that I might try to get a psychic photograph under test conditions. To this he willingly agreed. My conditions were exceedingly simple, were courteously expressed to the host and entirely acquiesced in. They were, that I for the nonce would assume them all to be tricksters, and, to guard against fraud, should use my own camera and unopened packages of dry plates purchased from dealers of repute, and that I should be excused from allowing a plate to go out of my own hand till after development, unless I felt otherwise disposed; but that, as I was to treat them as under suspicion, so must they treat me, and that every act I performed must be in presence of two witnesses, nay, that I would set a watch upon my own camera in the guise of a duplicate one of the same focus—in other words, I would use a binocular stereoscopic camera and dictate all the conditions of operation. All this I was told was what they very strongly wished me to do, as they desired to know the truth and that only. There were present, during one or other of the evenings when the trials were made, representatives of various schools of thought, including a clergyman of the Church of England; a practitioner of the healing art who is a fellow of two learned societies; a gentleman who graduated in the Hall of Science in the days of the late Charles Bradlaugh; some two extremely hard-headed Glasgow merchants, gentlemen of commercial eminence and probity; our host, his wife the medium, and myself. Dr. G. was the first sitter, and, for a reason known to myself, I used a monocular camera. I myself took the plate out of a packet just previously ripped up under the surveillance of my two detectives. I placed the slide in my pocket, and exposed it by magnesium ribbon which I held in my own hand, keeping one eye, as it were, on the sitter and the other on the camera. There was no background. I myself took the plate from the dark slide, and, under the eyes of the two detectives, placed it in the developing dish. Between the camera and the sitter a female figure was developed, rather in a more

pronounced form than that of the sitter. The lens was a portrait one of short focus, the figure being somewhat in front of the sitter was proportionately larger in dimensions. I submit this picture. It is, as you see a lady. I do not recognise her or any of the other figures I obtained as like any one I know, and from my point of view, that of a mere investigator and experimentalist, not caring whether the psychic subject were embodied or disembodied.

Many experiments of like nature followed; on some plates were abnormal appearances, on others none. All this time Mr. D., the medium, during the exposure of the plates was quite inactive. After one trial which had proved successful, I asked him how he felt and what he had been thinking of during the exposure. He replied that his thoughts had been mainly concentrated upon his chances of securing a corner seat in a smoking carriage that night from Euston to Glasgow.

How the Psychic Figures Behaved.

If the precautions I took during all of the several experiments, such as those recorded, are by any of you thought to have been imperfect or incomplete, I pray of you to point them out. In some of them I relaxed my conditions to the extent of getting one of those present to lift out from the dark slide the exposed plate and transfer it to the developing dish held by myself, or to lift a plate from the manufacturer's package into the dark slide held in my own hand, this being done under my own eye, which was upon it all the time; but this did not seem to interfere with the average on-going of the experiments.

The psychic figures behaved badly. Some were in focus, others not so; some were lighted from the right, while the sitter was so from the left; some were comely, as the dame I shall show on the screen, others not so; some monopolised the major portion of the plate, quite obliterating the material sitters; others were as if an atrociously badly vignetted portrait, or one cut oval out of a photograph by a can-opener, or equally badly clipped out, were held up behind the sitter. But here is the point: not one of these figures which came out so strongly in the negative was visible in any form or shape to me during the time of exposure in the camera, and I vouch in the strongest manner for the fact that no one whatever had an opportunity of tampering with any plate anterior to its being placed in the dark slide or immediately preceding development. Pictoirally they are vile, but how came they there?

The Stereoscopic Camera in Use.

Now, all this time, I imagine you are wondering how the stereoscopic camera was behaving itself *as such*. It is due to the psychic entities to say that whatever was produced on one half of the stereoscopic plates was reproduced on the other, alike good or bad in definition. But, on a careful examination of one which was rather better than the other, and which is now about to be projected on the lantern screen for your examination, I deduce this fact, that the impressing of the spirit form was not consentaneous with that of the sitter. This I consider an important discovery. I carefully examined one in the stereoscope, and found that, while the two sitters were stereoscopic *per se*, the psychic figure was absolutely flat. I also found that the psychic figure was at least a millimetre higher up in one than the other. Now, as both had been simultaneously exposed, it follows to demonstration that, although both were correctly placed vertically in relation to the particular sitter behind whom the figure appeared, and not so horizontally, this figure had not only *not* been impressed on the plate simultaneously with the two gentlemen forming the group, but had not been formed by the lens at all, and that, therefore, the psychic image might be produced without a camera. I think this is a fair deduction. But still the question obtrudes, How came these figures there? I again assert that the plates were not tampered with by either myself or any one present. Are they crystallisations of thought? Have lens and light really nothing to do with their formation? The whole subject was mysterious enough on the hypothesis of an invisible spirit whether a thought projection or an actual spirit being really there in the vicinity of the sitter, but it is now a thousand times more so. There are plenty of Tycho Brahes capable of supplying details of observations, but who is to be the Kepler that will from such observations evolve a law by which they can be satisfactorily explained?

In the foregoing I have confined myself as closely as possible to narrating how I conducted a photographic experiment open to every one to make, avoiding stating any hypothesis or belief of my own on the subject generally, and it only now remains to exhibit the results, bad and fraudulent-looking as they are, on the screen.

J. Traill Taylor.

ON DIVERS SUBJECTS.

The Panoram.

I suppose that no less than a hundred or so inventors have exclaimed, on reading the account in the last British Journal of Photography of the "Panoram," "Why, I have had that in my head ever so long." I am one of the hundred or so, and congratulate the practical inventor for carrying out an idea which occurred to me the first time I used the Eastman roll-holder, having in my possession an old Johnson Pantascopic camera, which, in the days when I had time to use it, gave me great satisfaction. Of course, it brings up the question of perspective again, and will make discussion hot. It will be impossible to make the general public accept the perspective of the "Panoram" as correct, for the presentation of a line known to be straight as a curved one will be at once denounced as a falsehood; but the fact is that, in the case of horizontal lines, only that one which is on a level with the eye appears to it as a straight line, the lines above that level being bent down at the extremities, and those below it bent up; and in their finest temples the Greeks, who had no idea of scientific perspective, recognised this phenomenon, and, to give the buildings greater apparent dimensions, exaggerated the perspective effect by making the horizontal lines curve slightly, in the same sense that the effect of perspective made them seem to curve. The reason of it is apparent. If you stand opposite the central column of a long colonnade, the apparent height of the more distant columns diminishes in an increasing ratio, and, if the most distant were twice as far away as the central one, it would appear half the height; and this is the true perspective, as it is the true aspect of any natural object. Scientific perspective is a pure fiction, and the action of rectilinear lenses is so arranged as to confirm this fiction. It renders perfectly the facts on any given plane, but in no case gives the actual appearance to the human eye. As the Editor has shown, a sphere in extreme perspective becomes an ovoid, while the capital of a column is, in the case of a very wide-angle view, distorted most unnaturally, while to the eye, looking directly at them, they are of the same shape as the central ones.

Perspective.

In talking of the relation of perspective to photography, whether the scientific or real perspective is to be treated of, we must remember that there is a complication not easily adjusted in the equation, which is the fact that the photograph itself has to be seen in perspective, no matter how near it is held to the eye. Suppose, for instance, a photograph taken with a rectilinear lens of fifteen-inch focus of a façade of a building presenting a line of columns, the point of view being opposite the centre of the façade. By measurement the extreme columns will be of the same height as the central one; but, look at it from what distance we may, the photographed column which is most distant from the eye will be shorter than one in the centre, always on condition that we hold the photograph so that the eye is opposite the centre of the façade. If it be held at the distance of fifteen inches from the eye, the distant column in the photograph will be just as much smaller than the central one as it would be in the building itself, and the horizontal lines will have the same curvature that they have in nature. But in practice we cannot look at photographs from the distance of the focal length of the lens, and it is only comfortable to look at them from a much greater, so that in those taken with short-focus lenses we are always seeing them falsely. But the eye is educated to these compensations, and we accept what we know to be the fact even when it is not in accordance with the true optical impression. It is as in many more serious matters, we accept recognised illusions as conveying a better idea of the truth than the absolute reality would give. Everybody knows the old story of Queen Elizabeth objecting to the shadows in her portrait, as representing her with dirty patches on her face which she knew not to exist there; but, when we look at a portrait in which the light and shade are ever so strong, we do not take exception to the actual colour being different on one side of the face from that on the other, for without this difference the greater truth of the rotundity of the head could not be expressed. The simple fact is, and it can be easily proved, that any photograph can be shown in one way true and in another untrue. Taking one thing with another, I am inclined to think that the perspective which comes nearest to the truth in general is that of the panoram or pantascopic camera, for it agrees best with the method by which the eye takes in its vision.

Film Photography.

I have been seeing and hearing a good deal lately about the flexible film, as used in the roll-holder, and have seen the results of many exposures, with some results which make me doubt if it is possible to teach certain people to take a photograph even on the "pull-the-string, press-the-button" principle. I have known an amateur, in

spite of all warning, to make a snap-shot at an old picture in a church, and, on being remonstrated with, to reply, "Why, I thought' you had got the taking of photographs down to instantaneous!'. Last winter, when the light was at its very lowest, and an instantaneous picture could only be hoped for in the mid-day hours of bright day and with a powerful lens at that, a roll of film exposures was brought to the Club for development, some of which were interiors, some late afternoon and over-cast day exposures, all being snap-shops, and on opening the camera I found that the smallest aperture had been used throughout. And a literary friend, whom I had fitted out with a roll-holder camera and minute instructions, came back with a roll of exposures running over six months, all taken with a medium stop, and at the same focal distance, some interiors and some sunsets! It is not uncommon even to get a time exposure with the camera held in the hand entirely unsupported by any fixed support. I once gave instructions to and outfitted an amateur who was anxious to take photographs of a picnic party, and brought back his exposures to me for development. The first plate showed three bands of unequal density across its length; puzzled, I threw it away, and tried the second. Same result. An idea flashed on me: I said, "Did you not put your camera in a boat out on the river?" "Yes," said he; "was that not right?" And he had given a time exposure with a small stop. My experience with Kodak-users is that not half have learned, perhaps are incapable of learning, the conditions under which the Kodak must be used. I never attempt an exposure without a bright sunshine, and then, in the winter, only in the middle of the day, say, from ten to two, and in summer only when the sun is at least two to three hours above the horizon. In my experience of wandering Kodakers I am convinced that at least one-half the films are wasted through insufficient exposure and utter inattention to the conditions necessary for success. Many negatives are spoiled by carelessness in development, and generally in the following ways:—First, the negative is not thoroughly and equally wetted before applying the developer, and develops unequally. Second, the operator tries to develop half a dozen negatives at once, and they either stick together in the bath or protrude from it, and show similar inequalities. Third, they are thrown carelessly into the hypo and hold bubbles under them, or lie partly out of the solution, in both which cases they show brown patches when finished, printing more intensely. A certain amount of shrewdness is imperative even for those who only pull the string and push the button, for a judgment of the nature and intensity of the light precedes success even with the Kodak.

The Sandell Plates.

I have seen some of the results of the use of the Sandell plates on our Roman church interiors, and I must say that I have never seen such negatives of any interior by any other process; but the question which puts itself to me is, whether the absence of halation is due to the use of emulsions of various degrees of rapidity, or simply to the thickness of the aggregate of the coatings? Is it not probable, or even certain, that the chemical qualities of the under coating are immediately reacted on by the subsequent coats? and is it possible, chemically, to isolate them when in the moist state, as the prior coatings must be as soon as the later coat is applied? Is not the success of the operation due to the fact that the light has not the power to penetrate the mass of haloid presented for its action, and therefore never reaches the point at which the reflection, to which halation is due, commences? However this may be, the Sandell plate is certainly capable of producing such interior negatives as I have never seen here. My own experiments with them were not so successful, probably because I did not try them correctly. W. J. Stillman.

NOTES FROM THE CAPE.

It is some time since any notes from my pen appeared in these pages, but a cloudy night affords me an opportunity of a clearing a few items from my notebook; a few items of no startling character, but just a few of those little experiences which occasionally come handy to others.

Keeping Sensitised Paper.

Some two years ago I had occasion to order a few quires of a well-known make of ready-sensitised albumen paper. I was very well satisfied with it at first, and noted, with satisfaction, that each quire was in a tin tube, well soldered down. Six months later a second tube was opened, and the paper found to be considerably discoloured, but was fit for use, the discolouration disappearing in the toning bath. I placed it in a larger tin case, using small quantities of it at intervals, until a short time ago I found I had got to the last sheet, which showed spots and streaks that did not trouble me unless I used negatives with a large space of sky. I then opened the third tube. The paper smelt considerably, but I was astonished to find that it was very brown—two or three times as dark as the paper that had access to air at intervals. Very little of this discolouration disappeared in the toning bath, the whites coming out very brown. I have little doubt as to what was the cause; the albumen had decomposed, compounds of sulphur had been emitted, and these, having no outlet, had acted on the free silver, converting it into sulphide of silver. I can only advise shippers, therefore, not to pack sensitized paper in sealed tubes, but to roll it up in blotting and brown paper only. To those photographers who, like myself, only use small quantities of paper at a time, I say, cut it up in suitable sizes, and pack it between blotting-paper, treated with carbonate of soda, as has been so often recommended.

Packing Plates.

Whilst on the subject of packing, let me request plate makers not to pack their plates with sheets of "papier Joseph" or other paper between them. I have tried several brands of plates packed in that manner and before I have had them many months paper marks have appeared and rendered them useless. On the other hand, plates packed with a slip of thin card at the edges deteriorate very slowly, and any packing marks appear at the edges only. When I purchase plates here I like to see the word "slipped" written on the label.

A word too on the subject of packing plates in tin foil. A carefully prepared plate when new should give no trace of "light fog," and any chemical fog produced by energetic forcing should be even over the plate. But plates on keeping show fog first at the edges, and then this gradually creeps over the plate according to the time it has been stocked. A great part of it may be removed by gentle friction, but prevention is better than cure, and for some time past I have had all plates for astronomical use packed in tinfoil with most beneficial results. I have met no plate that does not sensibly degenerate with time, but now my complaints on that score are reduced to a minimum. By the way, it is hardly fair for a plate manufacturer to advertise that they supply plates to the Cape Observatory, on the strength of the occasional purchase of a few boxes at a local dealer's. Our stellar plates have for some time past been specially prepared for us by Mawson & Swan, and are a model of even coating and clean working, with rapidity and fine grain.

Landscape Photography at the Cape in 1892.

Two novelties during the past year are worthy of special notice under this heading. We had a severe winter, which extended far into the summer months. Ice was found on Table Mountain, although we had but little frost below, and on the mountain a little sleet fell; but on the distant mountains to the north and east of the peninsula snow fell in abundance, and at Worcester, a town fifty miles from Cape Town in a straight line, a party of climbers ascended to a height of 6000 feet, where one of their number—Mr. Isaac Meirig—took some photographs, which are perfectly Alpine in character, and that, too, at a time of the year when we are usually experiencing the commencement of the summer heat. The other novelty consists in the views of the Zambezi Falls, brought down by Mr. Ellerton Fry, who exposed a large number of plates there under considerable difficulty, the chief trouble being the showers of spray that obscured his lens, nearly spoilt his camera, and fogged his plates. Only one in every twenty plates he exposed does he consider a perfect success, but these are pretty numerous and unique in their way.

Indecent Photographs.

A much-needed law was passed last session stringently prohibiting the sale of indecent photographs, not that we are fastidious. The photographs prohibited are seldom the work of Cape photographers, for the ordinary run of photographs of natives cannot be classed under the above heading. They may be made indecent, and in that case their sale would be rightly stopped; but the photographs aimed at are those displays of nastiness frequently sold at foreign seaports. Port Said has an unenviable notoriety for such works, and so have some Western ports of North and Central America, and most of the Southern American ports as well. When going on shore at Guayaquil in South America in 1883, we strolled into a photographer's and asked to be shown some photographs. He opened two large drawers of—well, we blushed, and it takes something to make men do that, whilst the photographer was surprised to find that we wanted landscapes, and had very few to show us. Now that a law has been passed here on the subject, it is to be hoped that on my next visit to England I shall have less annoyance with the Custom authorities. My experience at Plymouth has been that, on the arrival of the steamer from South Africa, the appearance of anything photographic in one's

baggage has furnished occasion for rigid cross-examination and a strict search for anything nasty.

PERMANENCY OF PRINTS—GELATINE *versus* ALBUMEN.

An instructive sight here is to watch the show-cases put up by photographers in the principal streets. You see a group of sparkling landscape specimens, which you stop to examine. A week or two later you notice that the blazing sun is effecting a change in them. Soon the should-be whites have turned to an intense gamboge, then the shades appear mealy, and at last out comes a batch of new specimens. Printing-out paper is having a run here, and it was soon noticeable that photographers were taking advantage of it in hopes of obtaining greater permanency. And yet the other day I noticed that the gelatine prints were going like the rest. I remarked to a member of the profession that the gelatine prints were as little permanent as albumen, but he differed from me. "Look on this group of prints and on that," he remarked. "Printed at the same time, exposed outside together, got damp together, as witness the water stain on the cardboard. Yet, you see, the albumen are fast going, and the others are almost unchanged." Under the circumstances, it is difficult to come to any conclusions. Time alone and the collated experiences of many will tell. C. RAY WOODS,

Photographic Assistant at the Cape University.

LIGHT, SHADE, AND PICTURE COMPOSITION.

BEFORE the Aston Society, on March 9, Mr. C. T. Cox, head master at the Birmingham School of Landscape Art, delivered a lecture on *Light, Shade, and Picture Composition* to the members and friends of the above Society.

In his opening remarks he said he knew that much unkindness existed between devotees of the camera and lovers of the brush, and that many of the latter always tried to depreciate work of the former; and before commencing his lecture he should like to say that he was no party to such feelings—in fact, he considered the photographer equal to the artist, however high, and that in many cases the camera could produce effects that would be otherwise beyond the skill of an artist to obtain; in short, he thought the two should work together. He then dealt with laws relating to chiaroscuro, and showed in many ways how the laws relating with art were equally applicable to photography, and how the violation of such laws led to failure.

The members present were here asked to take down the nine rules governing the proper representation of a picture, and were as follows:—(1) Principality, (2) Repetition, (3) Continuity, (4) Curvature, (5) Interchange, (6) Contrast, (7) Radiation, (8) Consistency, (9) Harmony. After explaining the first principle, he showed, by means of specimens, how far the law of repetition was carried out in the works of Rembrandt, Turner, Edward Watson, and others; how the chief image was again represented by a similar but minor study, not competing with the chief object of interest, but only repeating it. Then, again, *continuity*, as in the case of the outlines of mountains, pillars, trees, &c., would also be seen not competing with repetition, but only repeating it. The speaker here asked who had not noticed the graceful curves of motion of the human figure, the exquisite curvature of the movements of body, the dainty toss of the head, and from these he went to those of Cader and Snowdon, and pointed out that the whole of nature presented these curves to the users of those valuable twin lenses, the eyes. He had seen and painted old Welsh cottages whose chronic curvature of the backbone of the roof and tumbledown gables lent a charm to the whole scene. Contrast and interchange were then fully dealt with, effects in the former being chiefly obtainable in April, when days of tender light and soft, flickering shade were always present; and here the lecturer showed how the general rule of contrast was laid down in the works of Ruskin, viz., "the shadow thrown was always deeper than the shaded side of the object throwing the shadow." Again, most of the famous works of Claude Lorraine were all based upon the division of his canvas diagonally into light and shade, with an interchange of both from one to the other, and the larger the picture the greater was the half-tone of each introduced.

Ruskin asserted that the shadows in photography always appeared three times as dark as they were in nature, but the lecturer said he had adjudicated in photographic exhibitions in which he had seen shadows depicted far truer to nature than could have been portrayed by the brush, owing to their transient character. Relating to consistency, Mr. Cox asked who would think that "a lovely sylvan scene—a poem without words, one that draws out the soul and appeals for response to everything that is beautiful in the mind," would be consistently represented in a thunderstorm? he said that "rocky crags and frowning dark ravines" would be more consistent with the battle of the elements. Radiation and harmony were next dealt with, and herein he advised that photographers should follow the lines of the old masters and obtain an oval character for their views, although this was often exaggerated, as in the works of Bonnington, one of which was shown in which the clouds appeared as if placed in order to fulfil the ovality, as it were. He said, if the camera screen were divided medially through the sides, and an ellipse sketched round the points of contact, we should have a guide to good picture, making if we avoided placing objects of interest in the corners or on the margin of the diagram. He (the speaker) concluded with some splendid remarks on clouds, those things which bothered photographers, and more especially artists, but things which were invaluable to the production of a good view. Finally, he was pleased that Aston had formed a photographic society. He wished them every success, and offered to give advice gratis to any member at any time that they may feel they would like to have his opinion or criticism.

MANCHESTER PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THIS Society, whilst not following the practice which has now become common amongst kindred associations of inviting exhibits from the general body of photographers, was able to display a very pleasing and interesting collection of photographic work, fairly representative both of the progress made by individual practice and the development of new processes.

The Exhibition was open on March 9 and 10, and was well attended both days. An improvement made in the hanging of exhibits over previous years perhaps in a manner added to the satisfactory character of the show; still, as a rule, the contributions were of excellent quality. Prizes were offered for the best exhibits in various classes; but for the instantaneous *genre* pictures and home portraiture the result was disappointing, especially as regards the first-named, it being either an indication of the waste of energy displayed on "snap-shots," or the unfavourable conditions during the past two years for this class of work, for only one member sent specimens. In portraiture, too, a good set by Mr. J. Wood was alone, so that in these two classes prizes could not be given. The *genre* pictures were only two in number, and neither very striking as compositions. Mr. J. Wood's *Taking Milk to Market* gained the prize; the title, as far as "taking milk," was well expressed, but the destination of the said milk not very obvious. Mr. Higson's picture, *Father Adam*, was a good photograph, but not very expressive. Two classes for Landscape (over half-plate and smaller sizes) were, as a matter of course, well represented, two bits of local scenery, *Morton Bottoms*, by Mr. J. Wood, and *In the Bollin Valley*, by Mr. W. G. Coote, taking the prizes. Interiors were all good, *Lyme Hall Entrance*, by Mr. M. W. Thompstone, being adjudged first. Stereoscopic and lantern slides were not as numerous as the number of workers in this class could warrant, Mr. J. Higson, with stereoscopic transparencies, and Mr. H. M. Whitefield, with lantern slides, taking first places.

The enlargement class was very prominent both by number and quality. The Judges highly commended two pictures exhibiting very opposite treatment, one a bromide, by Mr. J. Brier, *At Tivoli*, being a well-defined, perfect enlarged reproduction of the negative; the other, also bromide, a Norwegian harbour scene by Mr. F. Edwards, a very clever and artistic enlargement of a hand-camera exposure. Mention might also be made of Mr. E. G. Wrigley's seascape enlargements for brilliancy.

The scientific or experimental photography class was responded to by Mr. B. Robinson and Mr. H. Smith, the former with a frame of photo-micrographs of great technical excellence, and the latter by perhaps the most interesting exhibit in the room, namely, the treatment of gelatino-chloride printing-out paper by short exposure and development. The results of evident patient experiment were shown by a number of prints, different tints (from red to blue-black), being obtained by varying the exposure and development, no gold or other toning being employed.

The Judges were Mr. Geo. Perkins (artist), Mr. J. W. Wade, and Mr. J. W. Leigh.

The platinum, gelatino-chloride, and bromide were the processes used by nearly all the exhibitors.

THE CENTRAL PHOTOGRAPHIC CLUB.

THE Executive Committee appointed by the public meeting on March 6 has already got to work, with the result that suitable premises and Club rules are under active consideration. Another meeting will be called in a few days to consider the propositions of the Committee. The Hon. Secretary *pro tem.* has received a large number of applications for membership, particulars of which will be sent in due course to the applicants.

Our Editorial Table.

ROUCH'S IMPROVED "EXCELSIOR" HAND CAMERA.

INGENIOUS in every way as Messrs. Rouch's now well-known "Excelsior" hand camera is known to be, the march of improvement has still further added to its usefulness and excellence. It has now a sliding as well as a rising front, and a rack and pinion adjustment allows of lenses of varying foci being used, an index scale being, as heretofore, placed on the top of the instrument. In addition to two

finders, there are spirit levels on two sides—a great convenience. The camera may be used on the stand with slides and a focussing screen, and the firm's well-known changing back can be employed instead of slides. To the changing back is now added an indicator, so that by simply touching a small lever at the side, the number of plates exposed may be seen at a glance. The camera we saw (made expressly for Mr. E. Hawkins, a successful hand-camera worker) was fitted with the Thornton-Pickard focal plane shutter, and this in such a neat way as not perceptibly to increase the bulk of the instrument. Altogether, the Excelsior remains the perfection of a practicable, workmanlike instrument, that must be a pleasure for the photographer to handle.

Marion's Cartridges for Developing and Fixing.

Messrs. Marion & Co., Soho-square, have submitted to our notice pyro and soda developing cartridges, together with similar cartridges for fixing which they have recently introduced. The various contents of these form an impalpable powder which dissolves almost immediately after being thrown into water. The pyro-soda cartridges are in form of plain glass tubes closed at one end and well corked at the other, two of these forming a complete dose for ten ounces of water. As might be surmised, the contents of one is pyrogallic acid, that of its companion being sulphite of soda and carbonate of soda. The proportions of these are so accurately adjusted as, with the above quantity of water, to form a perfect developer. The fixing cartridges, like the others, contain the active agent in form of a fine powder; and, according to whether they are to be used for negatives or prints, so is the quantity of water determinable. For negatives, the contents are dissolved in five ounces of water, while for prints ten ounces form the correct quantity.

This is a most excellent form in which to keep these necessary agents, not alone convenient for those who go to the country or seaside during the summer, but also for those who stay at home and like to have things ready to hand.

Andresen's "Diamidophenol" and "Combined Toning and Fixing Bath."

Messrs. Arthur Schwarz & Co., the agents, have sent us samples of diamidophenol which, used with alkali in the proportions of the formula given, develops rapidly and cleanly, and renders the density well. The toning and fixing cartridges should prove extremely useful—they impart a deep but pleasing rich black tone to prints.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
March 20	Camera Club	Charing Cross-road, W.C.
,, 20	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 20	Fillebrook Athenæum	Fillebrook Lecture Hall.
,, 20	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.
,, 20	Hastings and St. Leonards	
,, 20	Leeds Photo. Society	Mechanics' Institute, Leeds.
,, 20	Richmond	Greyhound Hotel, Richmond.
,, 20	South London	Hanover Hall, Hanover-park, S.E.
,, 21	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 21	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 21	Exeter	City Chambers, Gandy-st., Exeter.
,, 21	Hackney	206, Mare-street, Hackney.
,, 21	Keighley and District	Mechanics' Institute, North-street.
,, 21	North London	Canonbury Tower, Islington, N.
,, 21	Paisley	9, Gauze-street, Paisley.
,, 22	Leytonstone	The Assembly Rooms, High-road.
,, 22	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 22	Southport	The Studio, 15, Cambridge-arcade.
,, 23	Camera Club	Charing Cross-road, W.C.
,, 23	Glossop Dale	
,, 23	Hull	71, Prospect-street, Hull.
,, 23	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 23	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 23	Oldham	The Lyceum, Union-street, Oldham.
,, 24	Cardiff	
,, 24	Croydon Microscopical	Public Hall, Georgo-street, Croydon.
,, 24	Holborn	
,, 24	Maidstone	"The Palace," Maidstone.
,, 24	West London	Chiswick School of Art. Chiswick.
,, 25	Hull	71, Prospect-street, Hull.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

March 14,—The President (Captain W. de W. Abney, F.R.S., D.C.L.) in the chair.

Messrs. E. Collins, E. J. Garwood, H. W. Hughes, W. E. Pond, T. P. Watson, and the Duchess of Sermoneta were elected members.

The North Surrey, Hastings, Derby and Manchester Photographic Societies, the Croydon Camera Club and the Photographic Section of the Chester Society, were admitted to affiliation of the Society.

The Hon. Secretary announced receipt of a supplementary communication from Colonel Waterhouse on Gaiacol, of which he had tried a fresh sample. It had distinctly weak developing powers, and it was quite possible that it was not a developer, although practically it was one apparently inversely to its purity. He had also tried other derivatives of creosol, and thought their developing power might be due to oxidation products. A minute quantity of impurity might impart developing powers.

Naturalistic Photography.

Owing to Dr. Emerson having sustained a bereavement, his paper on *Naturalistic Photography* was read by Mr. T. R. Dallmeyer. In the paper (which we shall give *in extenso* on a future occasion), Dr. Emerson said that two years ago his researches into the subject of vision and perspective drawing were responsible for the withdrawal of his book. When he took up photography he was told by all that if the photographic observer closed one eye and placed the other eye at the focal distance of the lens he would see the picture true to nature. He felt that this was not the case, and he maintained that the sharp photograph was not true to nature; hence years of long and inky warfare. Opticians were right from the mathematical standpoint and he from the physiological. He had laid it down that truth to nature was obtained by throwing the background out of focus. There was no connexion here between want of sharpness or pinhole pictures; it was a deliberate and conscious act to be modified according to circumstances, and not a hap-hazard dodge. He had found his method of focussing justified by psychology. As to what was true in nature from the visual standpoint, he thought the tele-photo lens a most useful tool to put into the hands of the decorative photographer. The position he and Mr. Goodall had taken up in their pamphlet on drawing and vision was still unshaken. There was no absolute truth to nature from the visual standpoint, for as each man's sight was different, the only absolute truth to nature was in his own view of it. From the mathematical standpoint there was an absolute standard, which was the sharp photograph. Having said that the shapes of things, such as table-tops and wall-paper patterns, are perspective distortions, the transition from one to another being infinite and continual, he said that it was evident that no photograph gives things as we see them with two eyes; some photographs gave results nearer to what we saw than others, but were not naturalistic photographs. How true must the photograph be that it may be considered naturalistic? It must be true in fundamentals to the point of illusion, that is, a man's boots must not be twice as big as his head. He did not consider photography was an art, it was a mechanical power. Its results were sometimes more beautiful than art, but were never art; just as nature is sometimes more beautiful than art. Photography was a mechanically recording representation of nature. Having defined nature as the fountain-head of sensuous impressions but not necessarily of ideas, he traced the relation of realism, idealism, and naturalism to nature. He said that, under the same physical conditions, the same results would always be obtained in photography. Art was personal, however; photography was a cross between nature and a machine, art a cross between man and nature. There was a link binding art, photography, and nature together. Photography was decorative, and photographs must be decorative to appeal to artists. The decorative photograph was a mechanical reflection of nature when she sings in tune, and a good photographer is required to know when she does sing in tune. It mattered not for merely decorative photographs what lens was used, what exposure given, what developer employed, what developer applied, provided the result be decorative, as no photograph could be said to have any art qualities without being, first of all, decorative. That was the quality which differentiated the few photographers from the thousand. It had been said, photography would do works of art when they got soul into their photographs; this and all sorts of similar rubbish had been said by second-rate artists and third-rate photographers. The paper concluded with a series of nineteen propositions, which attempted a definition of art and its relation to photography.

Mr. T. Bolas thought the paper involved a great deal of thought, although it was given in difficult phraseology. It enabled those who had studied Dr. Emerson's previous remarks to understand the full bearing of his recantation. He appeared to have changed his fundamental views as regards photography, but not as to his method of working. The paper corresponded with the tendency of thought at the present time in regarding the beautiful as subjective rather than objective. Mr. Emerson's figure of an artist's ideal changing during the progress of a picture had considerable interest as bearing on the subjective idea of the beautiful rather than the objective. There were undoubtedly a great many ideas in the paper which were quite new.

Mr. Andrew Pringle did not understand the paper, but he was perfectly willing to believe that it was extremely able. The subject was a great deal discussed—perhaps too much to be profitable, and it contained many truisms which were as old as the hills.

Mr. W. E. Debenham defended mathematical perspective as the only true perspective, and also thought that an artist's idea of sharpness, in contradistinction to the photographer's, meant harshness of outline. Mr. Emerson had said that a great deal of pretentious rubbish had been written about art; they might retort and call this paper Emersonian rubbish. Dr. Emerson had said that a representation of nature on a plane surface was impossible. Were they then to condemn paintings, and were stereoscopic views to be accepted?

The Rev. F. C. Lambert said the paper wanted three months' careful reading, it contained so much that was old and true, and so much that was debatable. He was not at all sure that he understood the greater part of it. Dr. Emerson had, it seemed to him, taken up the same position as Mr. Pennell—that because a photographer places between his brain and what he sees a machine, the product had no stamp of individuality. The mere question of tools did not affect individuality.

Mr. Birt Acres disputed the view that half a dozen photographers taking the same view would produce identical results, as each would have his own idea as to how the view struck them as a picture, and their ideas would differ as to brilliancy or softness of results. Again, he did not think the best workers in photography called themselves "artists," though they produced artistic

results. He did not think photographers should be ashamed to call themselves photographers.

Mr. T. R. DALLMEYER said the subject involved very deep study. Differential focussing had come forward a great deal since Dr. Emerson first laid it down. It appeared to him (Mr. Dallmeyer) that Mr. Debenham had gone away from the real intent of the paper, as Dr. Emerson was not discussing mathematical perspective. Psychology was not a science yet, but we did not see things in mathematical perspective for psychological reasons. He thought the term decorative a good one in regard to photography.

Rev. F. C. LAMBERT agreed with Mr. Dallmeyer as to the importance of linking physiology and psychology together to appreciate works of art. As to the use of the term decorative, it seemed to him all pictures were decorative.

Mr. PRINGLE, in the course of further observations, said that, in spite of all Dr. Emerson's changes of position, no person had a right to deny that photography owed a great deal to him. He had done a great deal towards turning the attention of photographers into an improved artistic line. The results of his work were before them now, and though many of his pupils and disciples had thrown him overboard, the fact remained that he had inaugurated great improvement not only in specific but in general artistic work.

Colonel GALE said that it was pleasant to find Dr. Emerson coming out of his seclusion, but he was disappointed to find that he was still drawing comparisons between the artist and the painter. They were always getting into trouble with painters, and he did not see the necessity for it, as photography could be carried on without reference to painting.

The PRESIDENT, in closing the discussion, said that he himself was only a plain maker of "photographic maps," but it seemed to him that, whatever might be the outcome of the paper, Dr. Emerson himself was the outcome. Whether the fuzzy school would last was a matter for the public to say. He (the President) would continue to take sharp photographs, as he thought the fashion for them would come back again.

Votes of thanks were passed to Dr. Emerson for his paper, to Mr. Dallmeyer for reading and deciphering it, and an expression of sympathy with Dr. Emerson in his bereavement.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 9,—Mr. J. Weir Brown in the chair.—There was a very large attendance.

"SPIRIT PHOTOGRAPHY," WITH REMARKS ON FLUORESCENCE.

Mr. J. TRAILL TAYLOR read a paper on this subject [see p. 167], after which several slides from the negatives he had obtained were exhibited by the aid of the lantern. A series of "Spirit Photographs," the work of Mr. Hudson, of Holloway-road, and some French photographers, were also shown by Mr. Maltby, a visitor.

In the discussion that ensued, Mr. DOWNEY asked Mr. Taylor if he thought there were such things as "spirit photographs?"

Mr. TAYLOR replied that the question was outside the subject.

Mr. P. EVERITT asked if Mr. Taylor had any choice of a room—was it of his own selection?

Mr. TAYLOR replied that the room was the only one, so far as he could see, in which he could conduct the experiment.

Mr. EVERITT said that undoubtedly vitiated the experiment. Had Mr. Taylor control over the arrangements in the room?

Mr. TAYLOR said he placed the sitters and his camera, and arranged the light himself.

Mr. A. GLENDINNING explained that it had originally been intended to have had the photographs taken in a photographer's studio, but the photographer had withdrawn from the experiments on the ground that the latter were dangerous. The photographs, therefore, were taken in the drawing-room of a house in Dalston.

Mr. EVERITT asked whether that house was inhabited by a spiritualist, or any medium, or any one of spiritualistic tendencies? Did Mr. Taylor go as a sceptic?

Mr. TAYLOR said that he went with a perfectly open mind.

Mr. EVERITT pointed out that in the paper Mr. Taylor said that he considered himself as acting as a detective upon those who were present when the photographs were taken.

Mr. TAYLOR explained that on the morning of the day on which the experiments were made he received a letter asking him to bring a reasonable man with him—in fact, he had the option of taking any one he chose.

Mr. W. E. DEBENHAM asked if it would be possible to repeat the experiments in the presence of the same medium and two members of the London and Provincial Photographic Association?

Mr. GLENDINNING said that he had been interested in this subject for twenty-eight years, and had spent both time and money over it. He would like to ask whether the members of the Association then present believed that Mr. Taylor was competent for the investigation he had recently undertaken? He did not mean, were they prepared to endorse his statements; he did not mean, did they consider him an honest investigator? Many honest men would not be considered sufficiently qualified for such experiments; others, as honest and upright, skilled in the ordinary routine of photographic work, might possess little knowledge of chemistry and optics; others, again, might be honest men, and well acquainted with chemistry and optics, but too opinionative to undertake such experiments. He would put it to them in this way: His own belief and strong conviction was, that Mr. Taylor was well qualified in every respect for the important and solemn task which he undertook—a man with an open mind, watchful to detect the slightest attempt at trickery; of integrity of purpose, independent, and who would denounce those who would so far forget themselves as to palm off a miserable counterfeit of a grand reality. Did they uphold him in his views that Mr. Taylor was the right man? He did not wish to corner them—he desired to be perfectly frank; but, supposing for a moment that Mr. Taylor's report was an accurate statement, that he had obtained images on his plates which could not be accounted for by any known agency, it seemed to be a fair conclusion that persons were present on the occasion of the experiment who could not be seen by the normal vision, but who, by their presence, had co-operated to produce those images. They might call them by any name which might commend itself to them, but he (Mr. Glendinning) would call them spirit friends, excarnated human beings. He would call the pictures spirit photographs, because they were portraits of persons who had cast off the earthly tabernacle.

Mr. F. A. BRIDGE said they were bound to believe Mr Taylor's statements; but, as practical photographers, though the pictures shown *might* be spirit photographs, he thought they gave them the idea of cut-out prints, but as to who cut them out he did not know and did not care.

Mr. GLENDINNING remarked (ironically) that he was the gentleman who "cut them out."

Mr. DOWNEY regarded the photographs as a "clever trick."

Mr. EVERITT remarked that Mr. Glendinning had drawn attention to the capacity of Mr. Taylor as a witness, and they could not have a better representative of photographers for such experiments; but Mr. Glendinning had gone a step further, and said that Mr. Taylor, having witnessed all the persons in the room, they were entitled to infer that the appearances were due to "other persons" present. He (Mr. Everitt) would say that nobody had a right to infer the presence of "other persons." It was no doubt true that Mr. Taylor had got images he did not expect to find, but to say that they were due to "other persons" present was another matter. If they were entitled to infer that those appearances were due to persons they did not know, they were also entitled to infer that they might be due to other physical phenomena they did not know. They might be due to copies of other photographs which had got on the plates in some unaccountable way. Then as to the room—all the other conditions but this were under Mr. Taylor's control. It was a pity it did not suggest itself to him, with each successive exposure, to remove to another room. By varying the conditions for each photograph, he might have traced out the conditions under which they were produced, and have had some means of arriving at a conclusion. Mr. Taylor's experiments had been vitiated to a large extent by his not having the whole of the conditions under his own control.

Mr. A. COWAN said that about fifteen years ago—before dry plates were used—a lady of title and a member of the Stock Exchange came to him in London and asked him to go to Mr. Hudson with them, to see if they could get some spirit photographs. He took plates marked with a diamond. They went and paid half a guinea for a sitting. The plate was coated, exposed, and developed, two mediums being present in front of an ordinary background. There was nothing on the plate; another one was tried, and there was nothing on that. In all, six exposures were made, and on the sixth plate was a curious effect. A "mysterious operation" was said to have gone on between the sitters; but the explanation was that Hudson had poured the iron in the centre of the plate, so that no silver was deposited. While in the studio he (Mr. Cowan) found a good many of the draperies in the spirit photographs had the key border which was on the table-cloth in the room.

Mr. DEBENHAM added his testimony to Mr. Taylor's fitness for the experiment, but he (Mr. Debenham) really thought while he was reading his paper that he was going to tell them "how it was done;" he did not understand him to be serious. In spite of Mr. Taylor's assurance, however, they must all see that the "spirits" were copies of photographs, though they did not suggest *mala fides*. The thing had been managed in the usual way of spirit photography, and, if there was any fraud in the case, Mr. Taylor had not detected it.

In reply to a question, Mr. TAYLOR said that the room in which the photographs were taken was not absolutely dark.

Mr. A. HADDON observed that if "spirits" gave out ultra-violet rays it would be advisable to use lenses made of quartz, as they would have a far better way of rendering such subjects on the plate than with ordinary lenses, which cut off ultra-violet. Again, had different eyes different powers as regards the taking in and cutting out of different rays? Mr. Friese Greene had shown how it was possible to allow an impression to be made on the retina, and then to be transferred to a plate. Most probably only certain people possessed this power, for it was curious no one had repeated the experiment with success.

In reply to a question,

Mr. COWAN suggested that these spirit photographs could be made by scraping out positives on glass and exposing them on the negative before development.

Mr. R. CHILD BAYLEY asked whether it had been appreciated that the "ghost photographs" had only height and depth?

Mr. HADDON asked why the figures should have drapery?

Mr. DEBENHAM objected to the assumption that the things were genuine because they could not be explained. Messrs. Maskelyne & Cooke's trick could not be explained by many people.

Mr. EVERITT suggested that in future experiments a mirror should be placed behind the sitter at an angle so that a photograph of the back of the spirit as well as the front should be obtained.

Mr. J. S. TEAPE, in regard to the appearance of the photographs, said any one accustomed to the appearance of stump work would recognise some of the images as having been produced by the stump. They were not photographs from nature in the first instance.

In reply to a question as to whether, when he was out of the room developing, it would not have been possible for somebody to stamp an image in relief with fluorescent chemicals on the front of the camera, Mr. TAYLOR said it was impossible.

Mr. HADDON pointed out that the spirits seemed to be able to double themselves, as Mr. Taylor took a stereoscopic picture with some on both halves. One of the "spirits" was at the back of the sitter, yet some of the high lights were on the shadows. He did not think any one would say that the ultra-violet rays could pass through the human frame and a piece of wood.

Mr. T. Shorter and Mr. Maltby (visitors), Mr. A. Mackie, and other gentlemen, having spoken, Mr. Glendinning said he would endeavour to use his influence to allow some members of the Association to make experiments in the presence of the medium (Mr. D.) at a future date, and the proceedin closed with a vote of thanks to Mr. Taylor for his paper.

North London Photographic Society.—March 7, Mr. G. J. Clarke in the chair.—Mr. A. E. SMITH gave a demonstration of the photo-lithographic process. Explaining the necessity of a previous knowledge of carbon printing, he first developed a carbon print by single transfer. Some prints on bichromated gelatine films from wet-collodion negatives were then coated with photo transfer ink, soaked in water for a few minutes to soften the film where the light had not acted. The ink on the soluble part of the film was then cleared away, leaving the printed image ready for transfer to the stone, and the transfer thereof and method of printing were then explained. At the next meeting, at Canonbury Tower, on March 21, a Lantern Entertainment will be given in the reading-room.

Hackney Photographic Society.—March 7, Mr. S. H. Barton in the chair.—The library was augmented by about a dozen more new books. Mr. J. O. GRANT recommended that the Society exhibits at the forthcoming Crystal Palace Exhibition, and, after it was carried, he said that the Committee would draw up and send a circular to all members. Mr. BECKETT stated that the Committee had decided on purchasing two nine-inch lenses by Swift for the new lantern. Mr. Houghton presented the Society with a new form of carrier for the lantern. Members' work was then shown by Messrs. Cross, Sodeau (Arachoidus ornatus, photo-micrograph), Hudson (lantern slides), and Roder (two slides developed with amidol). Mr. GOSLING asked how many sheets of tissue paper were necessary to reduce or enlarge by (diffusion of light) in sunlight. It was stated that it would depend on light; in any case, the paper must be put out of focus. Mr. BROOKER, of Hastings, then gave a lecture on *Winchelsea and Rye*, illustrated by the lantern. Much care had been bestowed by Mr. Brooker on it, as it was very instructive and interesting to all, and that the slides were good goes without saying. Whilst the scientific side was treated upon, likewise the historic, the art side of photography was certainly to the fore, and a great treat was given to the Society. Mr. Brooker must be complimented on the fine quality of his slides.

South London Photographic Society, March 6, Ordinary Meeting, Mr. F. W. Edwards in the chair.—Mr. LEON WARNERKE demonstrated his method of printing, developing, and toning gelatino-chloride paper. He said his process was somewhat similar to that used in 1848 for the preparation of waxed paper negatives before gelatine plates were invented. While staying last winter in St. Petersburg he had to contend against an almost entire absence of light in carrying on photographic work. This led him to make certain experiments with Ilford P. O. P., Eastman's Solio, and Liesegang'a Aristotype papers, exposing them for a short time, and then developing with gallic acid. The exposure of the paper could be made at night, using magnesium ribbon. He considered "Solio" paper the best suited for the process. If daylight was used, the paper could be exposed until the image was just visible, or until it was completely printed out. Good results could be obtained either way. With a short exposure, development took a longer time. He then exposed a piece of Solio paper by burning about two feet of magnesium ribbon in front of the negative. On examination, a faint image was found on the paper. He gave the following formula for development:—Water, 1000 parts; acetic acid, 10 parts; acetate of soda, 10 parts; gallic acid, 5 parts. When dissolved, 10 parts of a ten per cent. solution of acetate of lead, after filtering, were added to the above. For development, 1 part of the solution to 5 to 10 parts of water were used. The print, on being placed in the developer, gained in detail and density, as if printed out in the ordinary manner. It was then placed in a dish of water, to which a pinch of table salt had been added to stop the action of the developer. The print was then placed in a combined toning and fixing bath, composed of—water, 1000 parts; hyposulphite of soda, 100 parts; acetate of lead, 10 parts; chloride of gold (one per cent. solution), 20 parts. Uniformity of tone was very easily obtained. Toning could be stopped at any stage thought desirable. It was impossible to distinguish prints developed by this process from those printed, toned, and completed in the usual manner. The lecturer believed that the prints would be more permanent than those prepared by the ordinary methods. In reply to questions, he said a beautiful sepia tone could be obtained by using a platinum toning bath. A weak negative required a more concentrated developer, and a hard negative a dilute one, to obtain good results. He did not advise the use of separate toning and fixing baths. Lead acetate kept the whites clear, and did not affect the permanency of the prints.

Croydon Camera Club.—Third Annual Dinner.—The above was held on the 8th at the "Greyhound Hotel," when a considerable proportion of members met together to enjoy gastronomical, oratorical, and musical entertainment. "Prosperity to the Club" was proposed by Mr. CHARLES W. HASTINGS in a neat and effective speech, to which the PRESIDENT replied with a series of remarks which induced sustained merriment, the definition of "*a human being*" and an explanation of "*why Diogenes was not a club man*" being specially punctuated with salvoes of laughter. The violin solos of Mr. Joseph Beckwith were the most keenly appreciated of the musical items, and the healths of Messrs. Oakley, Tuckham, and White the toasts which were most enthusiastically received.

Leicester and Leicestershire Photographic Society.—March 8.—The details of arrangements for the forthcoming Exhibition of the Society on March 22 and 23 were considered, the Hanging Committee elected, the Excursion Committee also arranged, and various other matters in connexion with the Exhibition received attention.

Liverpool Amateur Photographic Association, March 9.—Mr. J. SHEARD delivered his new lecture on *Our Members of Parliament and Something about some of Them*, illustrated by limelight portraits of present members of the House of Commons. The lecturer dealt in a racy manner with the personal reminiscences and peculiarities of about fifty members, and exhibited about 300 portraits, together with a reproduction of a number of lifelike *silhouettes*.

Preston Camera Club.—March 9, Annual Meeting, Colonel Oliver, J.P. (President), in the chair.—The Secretary's report and balance-sheet showed a satisfactory state of affairs for a Society not yet two years old. It was decided to affiliate with the Photographic Society of Great Britain in order to be able to procure the members technical instruction of a class superior to any that can be locally obtained, and at the same time to keep in touch with the chief centre of photographic activity. Colonel Oliver was unanimously re-elected as President and Mr. Frank Ketton took the combined position of Hon. Treasurer and Hon. Secretary, the previous holders of these offices having resigned. Altogether the Club seems in a prosperous condition, and a successful season is anticipated.

Rotherham Photographic Society.—March 7, Dr. Baldwin (President) in the chair.—The President and Hon. Secretary (Mr. Hemmingway) were appointed delegates to the Photographic Society of Great Britain, under the Affiliation of Societies scheme.

FORTHCOMING EXHIBITIONS.

March 22, 23	Leicester and Leicestershire Photographic Society, Co, operative Hall, High-street, Leicester. Hon. Secretary-H. M. Porritt, 66, London-road, Leicester.
April 5–8	*Croydon Camera Club, Braithwaite Hall, Wellesley-road, Croydon. Hon. Secretary, G. R. White, 55, Albert-road, Croydon.
,, 10–29	*Crystal Palace. The Executive, Crystal Palace, S.E.
,, 12–15	*Bolton Photographic Society. Hon. Secretary, J. E. Austwick, 10, Rushton-street, Bolton.
,, 17–29	*Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.
May 4–6	*Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.

* Signifies that there are open classes.

MR. PRINGLE AND THE SANDELL PLATES.

To the Editor.

SIR,—I shall be glad if you can find space for what must constitute my reply to Mr. Andrew Pringle's opinions on the "Sandell" plates, as published in the *Camera Club Journal* of December last, and which I should have dealt with earlier but for a prolonged absence from home. These opinions, emphatic as they were (I am advised from several quarters) have tended to do the interests of the plates considerable harm; but I should be first to admit that this result was altogether foreign to Mr. Pringle's intention. The experiments spoken of, although expressly described as of quasi-scientific character, have been regarded as having special interest for the practical worker, and, therefore, the necessity for my pointing out wherein I consider they are at fault.

To fully discuss all the points involved in Mr. Pringle's arguments would require a lengthy dissertation on photographic theories and practice, and a too great intrusion on your space, so I will endeavour to take the vital points only. Mr. Pringle seems certainly to fail to grasp the capabilities of the plates, and, were he an authority of lesser calibre, I should be tempted to say there was a failure in his appreciation of the potentialities of the single sensitive film.

Speaking of the photography of an interior, he says, "If the exposure be only long enough to affect the upper film, the result is in no way

different from that on an ordinary plate." This reminds me that it would be more convenient if it was made manifest from the commencement that the position I take up regarding the plates is this: I assert and challenge the contrary proof, that the plates are an absolute cure for halation from support reflection, in all practical photography, and that their latitude in exposure is practically unlimited. Reverting to the interior, I submit that an exposure should not be quoted unless accompanied by the development given to render obvious the work done in the film or films during the exposure; now, this is a most important item in considering the utility of the new plates. Can Mr. Pringle imagine an exposure on any interior with a clear glass window, admitting direct skylight, where the inside details are even poorly rendered on the single film, where the light from window has not gone through and through the film? he must have surely forgotten that halation is not unknown in snap-shot work. Mr. Pringle remarks in one place, he was surprised how little light passed through the single film; it has been a matter of surprise to myself how much passes the film. On more than one occasion have I, in trying the experiment of stripping off the top film, found a printable image of the highest lights of a snap-shot developed in the second film. It may be remembered that the finer emulsion of the latter is more amenable to development than the more sensitive one, and the image formed although apparently having a similar density, has a better printing value. To these qualities I attribute the characteristic softness of the prints from all exposures on the plate. Mr. Pringle also asserts that two or three times the exposure of an ordinary plate produces a failure with the "Sandell" plate, but if the higher lights of the snap-shot have so penetrated the plate how much more so will the exposures in question. I can quite understand his failures in this case if he relied on the preposterous operation (for practical work) of stripping or a total clearing away the upper image. But I think I can demonstrate that for this, and even a greater increase on the normal exposure, the image-forming capacity of the lower film is not a necessity; and, leaving out of consideration latitude obtainable by developer modification, Mr. Pringle seems to ignore the constitution of the ordinary film, and treats of it as if it were a single molecule of silver haloid; but I am sure on reflection he will agree with me that the latitude of the ordinary plate is really due to the superposition of many molecules, and also that only the molecules to a certain depth can be utilised effectively for the image formation, the remainder being simply serviceable as a screen. If development be pushed into this screen, the result is halation. Now, in the multiple plate, the whole of these molecules can be used up to the last line, and this I maintain will admit of a greater increase in exposure than that which caused failures in Mr. Pringle's experiments.

Then, as to Mr. Pringle's joke (for surely it was such), when he spoke of the plates making him miserable, he said, "I do not think they are of any real value unless you give them enormous over-exposure." This is very comical, and smacks much more of a desk emanation than a dark-room one; their latitude for prolonged development would seem to indicate superior advantages for the quickest exposures, as well as for the longest, and I can assure Mr. Pringle that he is mistaken in fancying that any intermediate exposure between maximum and minimum necessarily yields a failure; the amount of exposure to be given, above the minimum allowable, by an experienced worker, depends entirely upon his own tastes, as to how much of his shadows he wishes to render. There is no occasion for the merest tyro to consult an exposure machine.

Before I close, I must express my surprise that Mr. Pringle could have been informed that half-second *f*-64 under trees was the correct exposure for the plates. His informant could scarcely have consulted the prospectus sent with each box. In this he is directed to give the exposure of our table for the cyclist plate as a minimum. This, under trees, would be four minutes sixteen seconds; and for landscape, with heavy foliage, three seconds. I do remember making the first of a series of experimental exposures with Mr. Pringle, and giving half second on heavy foliage, but I assure him he is mistaken if he understood me to suggest that I considered this sufficient; I did it simply to show the amount of reduction that could be effected in the film as a result of this short exposure.—I am, yours, &c.,

J. T. SANDELL.

Thornton Heath, March 11, 1893.

CHEAP MOUNTS—A PLEA FOR QUALITY.

To the EDITOR.

SIR,—"Cheapness" is the tendency of the age. It is the natural right of every man, which no one can ever think of denying, to try to obtain what he desires for as small an equivalent as possible. It is impossible to decide with mathematical exactness the relative value of things. Usage and competition fix what may be called the real or market value of the various articles, and still this fixed value may be doubtful according to the different prevailing circumstances. What is "cheap" from one point of view may be "dear" from another, depending upon that with which it may be brought into connexion. However, opinion will hardly differ on this one point: the less of an equivalent of the medium of traffic—money—is demanded for a certain article, the less it is actually worth; and the cheapest is surely never the best, nay, often hardly sufficiently good for the purpose it is intended. And I must say it is to the credit of the public that it is not so much *the mass of buyers* which raises the cry of "Cheapness! cheapness!" it is more the dominating element, the clamour of the *selling individuals*. Is the public asking for cheap mounts—it barely asks for cheap photographs—and what is the ratio of cost of a mount, even if it be the best, to that of a photograph, even if it be of the cheapest? In general, as one to ten! In view of this, will any one dare to maintain that the price of photographs is in any way affected by the cost of the cards on which they are mounted?

I stated at the beginning of this letter that "cheapness" is the tendency of the age, but, I must also add, "progress and improvement" not less, though these two tendencies go in different directions. Nevertheless, there has been a vast progress and improvement in the quality, and especially in the finish, of photographic mounts. As regards the latter, it shows that a refined, artistic taste is an indispensable element in the manufacturing of such mounts, and still they have become cheaper in proportion. On the other hand, if we behold what is now also being offered by native and foreign mount-manufacturers in material and finish, it reminds us of the time when photography was still in its infancy—I mean the modern photography—being but little superior to what at that time the photographers, as a rule, "manufactured" themselves. These manufacturers are the "Rip Van Winkles" of the photographic trade; they have slept during the "revolution," and appear on the market with something which one should think belongs to the dead past.

Is it necessary to bring forth arguments to convince that any photograph appears more advantageously on a good, nicely finished mount? Just look at the show-cases of photographers, and compare the one with the other. Is it surprising when we see the mount crumble to pieces when the photograph itself has lost but little of its original value? I must confess it is humiliating to the trade that this degeneration is gaining ground, and apparently gains an overwhelming influence over the photographers, and, as a necessary consequence, over the photographic dealers. There is but little hope of retarding the progress of the inundation of this "cheap" element, unless the public revolts against it, and demands, at any rate, a good, durable mount, pleasing to the eye and in harmony with modern taste.

I do not plead in my own interests, but in the interests of the card-manufacturers of a higher level. We shall follow degree by degree downward if it must be, yet continually keeping the reins upwards as long as our strength does not fail; we have nothing to fear, and only little to lose, but I am pleading in the interest of *the photographic art*.—I am, yours, &c.,

A CARD-MANUFACTURER.

March 7, 1893.

THE CRYSTAL PALACE EXHIBITION.

To the EDITOR.

SIR,—Mr. F. P. Cembrano, jun., having been the first gentleman to consent to act as Judge at the forthcoming National Photographic Exhibition, we deeply regret that, owing to an oversight, his name should have been omitted from the list sent you on the 6th inst. We shall be extremely obliged if you will kindly note this in your next issue.—We are, yours, &c.,

S. G. BUCHANAN WOLLASTON,
CHARLES W. HASTINGS, } *Executive.*

Crystal Palace, March 13, 1893.

BEWARE OF GLYCERINE.

To the EDITOR.

SAR,—A word or two of caution to those using glycerine for the purpose of mixing with the oxalate solution employed in the development of platinotype. Be sure that it is quite free from citric or other acid.

Quite recently I have had the mortification of seeing the image on several prints completely disappear, due solely to acidulated glycerine. I find on inquiry that a large proportion is thus sophisticated, and on sale at various druggists. It is said to be, like many other shams, "made in Germany."—I am, yours, &c.,

HECTOR MACLEAN.

34, *Birdhurst-road, Croydon, March* 13, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange fifteen monthly parts of Cassell & Co.'s journal *Work* for finder for hand camera.—Address, J. K. EWART, Marine House, Banff, N.B.

Will exchange Adams's twelve-inch club burnisher, and 15×12 Ross's wide-angle lens, for rolling press.—Address, STONE & WILKINSON, 3, High-street, Devizes, Wilts.

Wanted half-plate landscape camera, or studio accessories, in exchange for two negative cupboards to hold 2000 quarter-plate negatives, one whole-plate, and two half-plate negative boxes.—Address, R. SMALLEY, 139, Euston-road, Morecambe.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

R. Y. T.—It is, we believe, an ordinary solution of rubber.

J. C. RUTHVEN.—We should be pleased to have the communications.

CONSTANT READER.—Apply to Messrs. Winstone & Sons, of Shoe-lane, E.C.

GREAVES.—The mottling may disappear if the solution is warmed slightly.

HUSSAR.—Swell thirty grains of gelatine in water, drain, and add one ounce of caramel.

R. S. O.—Consult the ALMANAC. The three formulæ about which you inquire are given with others of a similar character.

DEVONSHIRE.—Yes; the photograph can still be registered; but it is doubtful if it will be of any use as regards those copies already issued.

A. R. T.—You will see a reference is made to the subject in another column. Of course, the copies must be good, or they would not meet with success; also the subjects must be of a popular character.

T. STEELE.—The one is a more modern lens than the other, but will answer your purpose no better. The triplet is an excellent lens for copying, and is largely used by commercial copyists, some of whom prefer it to lenses of the "rapid" type.

B. W. C.—1. The stand attachment is identical with that patented by Messrs. Mason & Henderson. 2. It is not necessary to coat gelatine negatives with collodion prior to varnishing them; but it is better to do so, as it affords greater protection.

PYRO.—Try the effect of a strong solution of cyanide of potassium and pumice stone if the other things fail. If the nails are badly stained, they are very difficult to clean. Stains, by the way, are easily avoided, but not so easily removed when once they are formed.

T. CROWE asks how he can know when he has washed all the nitrate of silver out of the prints before they are toned?—If the last washing water is clear and does not become turbid on the addition of a pinch of salt, it may be assumed that all the free silver is removed.

W. McC.—You will see by Mr. Wellington's paper on the subject that the Company do not apprehend any injury to Solio paper by the use of the combined toning and fixing bath. If you carefully follow the instructions in making the bath, no fumes should be given off.

L. S. D.—There is no regular rule with regard to resittings in first-class establishments in London. The custom is to satisfy the sitter whenever it is possible. We quite sympathise with you, and other portraitists, in the matter of the unreasonableness of some persons. For that there is no panacea.

R. TREMERE.—For portraiture an arc light of from five to six thousand candle power is desirable; but, for copying from small-size originals, one of two or three thousand candle power will suffice. Of course, such a light could be used for portraiture, but the exposure would be proportionately longer than with the more powerful one.

C. WELTON.—If you can obtain a current from the mains, it would certainly be more advantageous to take it from that source than to go to the expense of the necessary plant for generating it yourself. The current from the mains being of so high a voltage is of no moment. That may easily be reduced to anything that may be required.

E. HAMILTON.—The trouble arises from the tissue not being in the right condition when it was squeegeed on to the plate, or maybe from the squeegeeing not being properly done. If the tissue be too moist, or not moist enough, this difficulty may be expected. Master the details of carbon printing, and the trouble will not be experienced.

A. W. ALLARD.—1. Instead of diffusing the light, it wants more concentration on the sitter. There seems to be too much top light for that form of building. Stop off all direct front light, and two feet or more of the extreme top light. What light then remains will be ample and easy to control. Any quiet, unobtrusive colour, such as a greyish blue or green, will do for the side wall.

S. A. T. asks the best way of reproducing negatives. There is no best way, because all the recognised methods are equally good in the hands of skilled workers. The simplest method is, make a transparency by contact printing on a dry plate, and from that produce the negative by the same means. Excellent negatives are made daily by making a carbon transparency, and from that the negative by the wet-collodion process in the camera.

W. A. T. writes: "Will you kindly say—1. What fuming with ammonia does to sensitised albumen paper? Does it make it keep better, or what? 2. Also are the following brands of albumen paper the best to be obtained?"—1. Fuming with ammonia does not add to the keeping qualities of the paper. It is said by those who employ the method to improve the quality of the prints. 2. It is quite against our rule to recommend any particular make of material. All the brands named however, are good.

WIDOW.—By no means pay such a sum as a premium for your son to be "articled" for three years to learn the portrait photography as a source of livelihood. The whole business is at present in a very depressed state, and there is, we fear, little prospect of any immediate improvement. Furthermore, the labour market is, and will be for some time to come, overstocked. If he must follow photography, the photo-mechanical branches just now are the most promising; but these are fast being overdone. Have nothing to do with the so-called crystoleum and similar styles of colouring.

T. M. says: "I have a quantity of old silver plate, which I have, as executor, to dispose of to the best advantage. There are over seventy ounces of it, and it occurs to me that if I were to dissolve it in nitric acid, and crystallise it, I could sell it to photographers, and so realise more than by selling the metal to a refiner. Will you please give me your idea on the subject?"—By all means sell the metal as it is. Supposing the metal were pure, it would not pay for the time and material required to convert it into nitrate; but, as silver plate is alloyed with copper, the nitrate of copper that would be formed must be separated before the nitrate of silver would be marketable.

RECEIVED.—*Dry Plates*, Shapoor N. Bhedwar, C. G. Ablett (Port Elizabeth), and others.

PHOTOGRAPHIC CLUB.—March 22, *New Cameras*; adjourned discussion on *The Combined Toning and Fixing Bath; The Sandell Plate*, by Mr. S. Herbert Fry. 29, Lantern Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 23, Technical Lecture, by Mr. Edgar Clifton, *Cameras, Tripods, and Dark Slides*. 30. *The Sandell Plate*, demonstration by Mr. S. H. Fry; *Stripping Gelatine Plates for Collotype Work*, by Mr. W. J. Rawlings. April 6, *Determination of Plate Speeds*, by Mr. G. F. Williams.

On March 23 the Woolwich Photographic Society will hold a Lantern and Musical Entertainment.

RICHMOND CAMERA CLUB.—March 20, Demonstration on *Printing, Toning, and Developing Gelatino-chloride Paper*, by Mr. Gotz.

BOLTON PHOTOGRAPHIC SOCIETY'S EXHIBITION.—We are informed that the Society will pay carriage on all exhibits in the Champion Class.

WE have been shown several examples of Messrs. Morgan & Kidd's machine-collotype process, which attest the remarkable readiness with which this firm has thus early achieved excellence of results with the process.

HACKNEY SOCIETY'S FUTURE ARRANGEMENTS.—March 21, Demonstration of *Sandell Plate*, Mr. S. H. Fry. 28, *London Street Cries*, Mr. E. Scamell. April 4, *Photogravure*, Mr. A. Dawson. 11, Members' Lantern Night. 18, *Record and Survey*, Mr. W. Jerome Harrison. 25, *After-work of Hand Cameras*, Mr. A. R. Dresser. May 2, Annual Meeting.

ON Saturday afternoon a new photographic studio, to be known as the Delmen Art Studios, Limited, was opened at 470, Holloway-road, N. Messrs. Downey and Mr. Mendelssohn, on behalf of the Directors, received the visitors. Although scarcely yet finished, the suites of rooms are elegant and nicely planned for a photographic business. All the rooms are fitted with the electric light.

MR. J. SMALL, of Dartmouth, writes: "This last week or two mention has been made of mammoth enlargements. I was not aware they were novel, as the celebrated firm of Marion & Co. made me, from a *carte* negative, an enlargement, seven feet six inches by four feet six inches, of Lord Northbrook's son, who was drowned in H.M.S. *Captain*. This was in December, 1870. The enlargement was painted by the Hon. Graves, of Bond-street, at a cost of 600 guineas. The Autotype Company have made me several enlargements 48×36, so that I rather read the announcement with a little surprise."

WE have received from Messrs. Perken, Son, & Rayment their wholesale and export illustrated Catalogue of lanterns, slides, gas bags, jets, and everything else connected with the lantern, together with an illustrated Catalogue of cameras and the numerous and varied appliances of photography. Their new lecture sets for the lantern are so comprehensive as to afford highly suggestive matter for those who contemplate making camera trips during the approaching season. As regards the numerical strength of this department alone, it is such as almost to defy counting. The quality of such of these as we have seen is of the very highest order of excellence.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A Committee meeting was held at the registered offices of the Association, Memorial Hall, E.C., on March 13, Mr. Alexander Mackie in the chair. Three applicants for assistance appeared to state their cases, and in each instance the assistance asked for was granted. It was in small sums—one pound to set up a roadside worker with apparatus, a few shillings to help an out-of-work man to reach his next situation, and a few shillings to redeem a man and his wife from actual starvation. A couple of pounds covered the whole of the grants, but the investigation of the cases occupied over two hours. Thirteen new subscribers, who had been introduced by Mr. Birt Acres, were accepted, and a hope was expressed that other managers and employers would introduce the subject of the Benevolent to their *employés* as Mr. Birt Acres had done.

JOURNAL OF PHOTOGRAPHY.

No. 1716. Vol. XL.—MARCH 24, 1893.

ELEVATING THE POINT OF VIEW.

The view of a place which will be most familiar to the observer is that which is obtained from a height approximating to that of the human eye, or, say, a little over five feet from the ground. Numerous camera stands fall far short of fulfilling this requirement—a fact readily perceived when one watches a party of camera men in the field, and notes how they stoop when focussing or arranging their subjects on the ground glass of the camera. To obtain a view as seen by the eye, the camera stand ought to be elevated to such a degree as to permit of the focussing screen being brought directly opposite the eye. This is a truism which requires no elucidation.

While "'tis well to have a giant's power," there are numerous occasions on which it would be exceedingly unwise to take advantage of it. A lakelet, a stream, or a flat meadow in the near foreground might, from the usual point of view, assume a magnitude of expanse so pronounced as to detract from—nay, eclipse—that of the scene beyond, unless thrown into subordination by lowering the point of sight to within one or two feet of the ground, so as to foreshorten these obtruding and undesirable commonplaces. The photographer, who is also an artist, understands full well the value of selecting a point of sight that will ensure him getting all the pictorial effect necessary, and it is fortunate that the mechanical construction of most of the camera stands enables this to be done without difficulty.

But there is another view of this question of height, and that is, when it is found expedient that the point of sight be higher—in oftentimes a considerable degree—than that capable of being attained by our ordinary appliances, What is to be done when a tall fence, or other equally tall obstruction intervenes between the only *locus standi* for the camera and the subject that is to be taken? It is now about twenty years since we saw among the outdoor *impedimenta* of a photographer in the provinces (Mr. Bottomley, Leeds) a camera stand constructed expressly for meeting such contingencies as those just hinted at. Each limb of the tripod was fourteen feet in length, and formed a ladder, up which the adventurous photographer had to climb with his camera until he reached the top, which formed a small platform, from the centre of which rose a stout piece of wood, supporting the table on which the camera was planted. Think of the advantage possessed by a man perched on such an elevation over another nine or ten feet nearer the ground! Foreground obstructions have for him no existence.

There are other subjects for which a tall stand is an absolute necessity. A photograph in our possession, received from Dr. Le Plongeon, shows that intrepid traveller and explorer engaged in the act of photographing the details of carvings on the wall of one of the temples in Yucatan, Central America, this being done from the great elevation necessary to bring the camera opposite to the architectural tracery which is being depicted. On this occasion he employed a stand, the legs of which were twenty feet long. It was composed of a ladder and two other supports, formed of bamboo.

While such tall stands are only required for special purposes, and are not necessary to the amateur, portability being quite out of the question, yet would we put in a strong plea for portable stands, by which the camera could, when required, be elevated to, say, seven feet when required. We have tried the effect of extemporising an additional joint to each leg of one by which this height is attained, and find that it places a great power in one's hands. With the camera at the usual elevation, much prominence was given to trivial foreground objects; with the greater elevation these disappeared, their places on the plate being occupied by others at a greater distance. Incidentally, we experienced a slight difficulty in arranging and focussing the subject on the ground glass, and in inserting the slide and withdrawing the shutter. But by the adoption of a portable stool, about eight inches by twelve inches, the legs of which fold underneath, this difficulty is entirely overcome. A stand of this nature is so useful, and may be constructed at a cost so little in excess of one of the length now usually made, that we strongly recommend its adoption.

Apropos, many users of hand cameras err in holding their cameras so low as they do. We can readily understand that an excuse for this is to be found in the fact of the assumed necessity for having to allow a certain space to intervene between the eye and the finder, upon which the user looks down; but, as we have shown on former occasions, direct finders may now be obtained, which may be placed so as to be used opposite the level of the eye, by the use of which the point of sight is considerably elevated.

Since writing the foregoing we have learned that a tall stand, such as we desiderate, has been exhibited by Messrs. Houghton & Son at the Photographic Club, and, from subsequent examination, find it fulfils every reasonable requirement. We hope that the manufacture of such stands will become universal.

THE WELSBACH LIGHT FOR STUDIO WORK.

Exactly two years ago (p. 193, vol. xxxviii.), we described an arrangement which we were shown by Mr. Atkinson, of Liverpool, for the utilisation of common house gas as the illuminant in studio portraiture. Briefly, it consisted of placing the sitter

inside of a portable room, and directing the camera towards him through an aperture. The light was obtained from a row of gas jets, with reflectors, placed above the sitter, where the top light might be supposed to be, and another row behind a diffusing screen, as the side light. By the system and power of light used, an exposure (with a portrait lens, of course), of ten seconds, was practicable.

We suggested at the time that, by increasing the illuminating quality of the gas, the duration of the exposure might be diminished, while we regarded, and still regard the idea of utilising house gas for portrait purposes as capable of being turned to great practical account in the hands of photographers. A similar idea is evidently entertained by the Incandescent Light Company, of Palmer-street, Westminster, who are adapting their well-known Welsbach light for portrait work in the studio. An opportunity for observing the capabilities of the light was recently afforded us in the studio of Mr. Charles F. Treble, of Clapham Junction, who has had it in use for the last three months.

The arrangement adopted by the Incandescent Company may be described as follows:—As the top light, and placed behind a translucent screen, is a row of jets with the now-familiar incandescent mantles, burning gas from the main, protected by glass chimneys and having metallic reflectors. On the side from which the side light comes, two other rows of lights are placed behind the same kind of screen, one system of gas piping being employed throughout. On the shadow side, and as a background, a large rectangular portable screen of a tint reflecting as much light as possible, is placed, conditions which, we were informed, are also necessarily applicable to the floor and the ceiling.

In all, some seventeen lights are used, the estimated candle power of each being about 120. This large volume of light allows of the exposure, under favourable circumstances of lens aperture and sitter, being so short as six seconds. A considerable but not uncomfortable degree of heat is given off, and the lights, although powerful, do not emit any inconvenient glare, or dazzle the eyes as other illuminants do. The flames, besides, are perfectly steady and noiseless.

From personal observation of a sitter, we had opportunities of noticing that the light cast on the face is of a soft, agreeable nature, and such as, by its inherent properties, ensures the negative falling short of hardness. Moreover, we ourselves sat while several trial negatives were taken, so that we can attest its lack of discomfort so far as the sitter's eyes are concerned. The charmingly lighted work which Mr. Treble himself has produced by the illuminant, points to its high capabilities in the hands of the photographer. We gathered that the consumption of gas involved is, all things considered, not so formidable as might have been supposed from the number of burners.

The employment of house gas for studio portrait work, in accordance with the above-described system, should be welcome to photographers, not only in winter time but at other seasons of the year, and at evening, when natural light is unobtainable of sufficient actinic force, or magnesium and electricity are either unsuitable or too expensive.

COMBINATION PRINTING.

It may seem a little strange at the present time to have to say anything about such a simple matter as double printing; but, if we may judge from the letters we are constantly receiving, not only from amateurs, but from professionals even of some few years' standing, asking how one or more figures in a group that may be unsatisfactory in one negative, from a movement or expression, may be replaced by more satisfactory ones from another, information on the point may be of general value. To do such a thing in several different ways would give no trouble whatever to a printer of the old school, and that, too, without showing the slightest indication of a join. At one period in the history of photography, as some of our older readers will remember, almost the first question put to a printer seeking employment was, Can you mask well? For at one time it was rarely that a portrait was printed with the background that was in the negative, as a new one, nicely shaded, was generally substituted. Nowadays, there are few printers who are skilful at double printing

Combination printing may be classed under two heads vignetting and masking. By the former method the juncture is made by vignetting the edges of one picture into similarly shaded ones of the other. This was the system followed by Rejlander in producing his once well-known picture, *The Two Ways of Life*, which was printed from upwards of thirty different negatives, and so skilfully was the work done that the junctions of the various printings could not be detected. The same principle was also adopted by M. Lambert in the "Lambertype" process. This method requires considerable skill on the part of the operator for its successful working, and it is better adapted for large sizes than for small ones.

The more generally practised method of double printing is by masking, and it is the one the novice will succeed best with. Let us take, by way of explaining it, two negatives of a group of several persons—usually, in taking a group, a couple of exposures are made—and one or two figures in one are unsatisfactory, while in the other they are perfect; but it is the first picture, as a whole, that is preferred. Now it is required to substitute the approved figures for the faulty ones. Portrait negatives have been taken by way of illustration, simply because recent queries have applied more particularly to them; but it will be obvious that the same systems are applicable to all classes of subjects. Take, say, first the negative with the figures to be substituted, and stop out neatly all portions, with black varnish, except these figures, so that they will print with a perfectly white ground. In the other negative these figures only are stopped out by the same means, leaving the other portions of the negative intact. After the first negative has been printed, it is quite easy to place the print in its exact position on the second negative for the second printing, so that no junction will show when finished.

Instead of painting out with black varnish, the old method was to make a light print from one negative—sometimes from both—and then cut out neatly with a penknife the different portions, and then, after the paper had been blackened by exposure to light, cementing them as masks in proper position on the different negatives. The cement generally used was indiarubber solution, as that did not cause an expansion of the paper as an aqueous cement would do. This plan has also the advantage that the paper can be taken off, and the negatives restored to their original condition. This is not always possible with black varnish containing bitumen when it has become insoluble by exposure to light. It is a very important point in double printing, especially in the case of portraits, to have the paper in the same hygroscopic condition for the two printings. Paper, it is well known, expands with moisture, and it is manifest that, if one printing is made with it very dry and

the other after it has been allowed to absorb a certain amount of moisture, accurate registration will not be obtained. Further, if the paper is not in the same condition as regards moisture in the two printings, a uniform tone will not be obtained in the finished result.

Here is another system of double printing which is exceedingly satisfactory, and requires even less skill in its working than that just referred to, as, with it, the masking of only one negative is necessary. It is therefore better suited to the requirements of the novice. It is based upon the plan introduced many years ago by Mr. Edge. The first negative has all stopped out—either with black varnish or a paper mask—except the figures to be introduced into the other. It is then printed. Then these figures are neatly painted over with a non-actinic water colour—such as gamboge—and allowed to dry. The colour protects the printed image from any further action of light. The print is then placed in position on the second negative, which is readily done, and printed. After the second printing, the toning and fixing is, of course, done in the ordinary way. The gamboge readily dissolves off in washing the free silver out of the paper. With this method, as we have just said, only one negative need be masked. It has also this further advantage, that, as the first printed image is perfectly protected from light by the pigment in the second printing, therefore it will not be affected by any little inaccuracy in the registration.

As described, this method would only do for albumen paper, as it would be undesirable to apply water colour on gelatine paper, because it might soften the coating and be absorbed by it. However, gamboge is soluble in spirit, and gelatine is unaffected by that; therefore the gamboge should be mixed with alcohol instead of water. Then, after printing, the colour can easily be removed by a sponge charged with spirit prior to washing out the silver for toning.

Photographs of Jupiter.—The Royal Astronomical Society at its first meeting of the new Session, in enumerating the present received, referred to some exceedingly beautiful photographs of Jupiter from the Lick Observatory.

Solidified Air.—The latest and most remarkable outcome of the experiments upon the compression of gases, recently popularised by Professor Dewar, is the solidification of air, a product described by the learned professor in a communication to the Royal Society a fortnight ago. The exact condition of this solid matter is yet a matter of doubt. It may be solid air in which both constituent gases are frozen and pressed into solid air; or, it may be, a kind of jelly of nitrogen with liquid oxygen entangled like solid gelatine holding water. Hitherto, though nitrogen has been frozen, oxygen has resisted all attempts to pass it beyond the liquid stage.

Recognising Metol by its Smell.—Writing of metol in the current number of the *Journal of the Photographic Society of India*, Colonel Waterhouse says: "I have not worked further with metol since my last paper on it. I have, however, noticed one fact regarding it which may be worth recording, and that is, that old metol solutions can easily be recognised by the strong smell of phosphorus they evolve. I observed this smell in testing it with various reagents. Metol is said to be the sulphate of mono-methyl para-amido-meta-kresol, but is possibly a phosphate or phosphite of this compound. The smell of phosphorus is most decided and unmistakable."

Simple Specific-gravity Apparatus.—An exceedingly simple and, evidently, roughly correct contrivance for quickly taking specific gravities is described in a recent number of the *Wiener Berichte*. It consists of two glass tubes joined by an indiarubber tube. One of the former is thirty centimetres long, and about one wide. There are scratched upon it two marks twenty centimetres apart. This tube is immersed up to the lower mark into the liquid to be examined, and at the same time the other tube is immersed in water. Upon withdrawing the tubes the water rises in one, and the other liquid in the other tube. When this latter reaches the upper mark, the height of the water column is noted on a suitable scale, and its height measures the density of the liquid under examination.

Orthochromatising Gelatine Plates.—Colonel Waterhouse says: "For some time past I have been orthochromatising my gelatine plates by bathing them for one or two minutes with the tincture containing erythrosin silver and ammonium picrate used for the orthochromatic collodio-bromide emulsion process described in the February number of the *Journal of the Photographic Society of India* for last year. The formula is as follows:—Erythrosin, 1 part; silver nitrate, 1 part; picric acid, 1 part; ammonia (s.g. ·880) about 30 parts; spirit of wine, 500 parts; water, 500 parts; one part of the above solution being diluted with nine parts of water to make a solution containing about one part of dye in 10,000 of fluid. More ammonia may be added, in the proportion of one part to 100 parts of diluted solution. This works exceedingly well for most purposes when orthochromatic plates are required, and for landscape work with the telephoto lens no yellow screen seems to be necessary, unless there is much blue haze in the distance. The quantity of ammonium picrate may also be increased in such cases."

Photography versus the Eye in Photographs of Clusters.—Dr. Isaac Roberts recently read a paper on this subject, and brought out in a remarkable manner the contrast that was to be found in these two classes of records. Thus, while Sir John Herschel described a particular cluster as "bright, round, rich, and composed of pretty large stars down to the eleventh magnitude," the photographs of Dr. Roberts, taken with an hour's exposure, show the cluster to be composed of stars of very different magnitudes, ranging from the eighth to the fifteenth, and not round or symmetrical in shape. An interesting question arises from another photograph of Dr. Roberts's, whether some stars in another system, not hitherto catalogued, but found on the photograph, are a system in motion? A further photograph, taken some years hence, may show whether the possible motion takes place or not. During the discussion on Dr. Roberts's paper, a question was put as to whether it was possible that the nebulous appearance seen in the plates was due to photographic action rather than stellar images? But Mr. Ranyard stated that this was almost impossible, seeing that negatives taken by Dr. Gill at the Cape exhibited, down to the minutest details, the same appearances as Dr. Roberts's. It might be expected, if the appearance was not really a representation of a telescopic image, it would differ according to the instruments and processes employed.

Weinek's Enlarged Lunar Photograph.—This photograph continues to excite considerable discussion, and many experts declare its details in parts to be due to something other than simple enlargement. Many details of surface structure are visible which hitherto have escaped detection in eye observations—winding rills, valleys, and hairlike markings. These were quite sharp and distinct, and in contrast with the larger-surface pictures—a condition which has led to their being challenged. In contrast to the usual experience with enlargements, sharpness being then diminished, we have in this lunar photograph minute details after an enlargement of twenty diameters, while other larger portions are "fuzzy." In the *Observatory* of this month Mr. Elger says: "If these curious markings represent actual features on the moon's surface, ought they not to be easily seen in any good telescope that shows the formation and its principal details with far greater sharpness than the twenty-times enlarged negative, and many small craters, &c., in addition, which are scarcely traceable upon it? One does not understand why this should not be

so, unless these objects make an impression on the sensitive plate that they fail to do on the retina, which is hardly likely to be the case." Many experts, it appears, are reserving their judgment. To us the simplest method of solving the matter would be to have the original negative enlarged by a second photographer, a preliminary examination of the original for technical defects, and a comparison of a second enlargement even on a smaller scale would at once show whether Weinek's picture was a true photograph or not.

TEMPERATURE IN THE DARK ROOM.

Although it is but a few weeks since attention was called to the importance of maintaining a uniform temperature in the dark room during the winter months, it is more than probable that the sudden change of last week has brought trouble into very many photographic establishments. A spell of fine weather, more resembling summer, in the matter both of light and temperature, than late winter, or even early spring, has been suddenly succeeded by a sharp "snap" that would have done credit to mid-winter, and photographers—good, easy men, who have fondly imagined the cold season had departed, and have become careless in consequence, have no doubt suffered correspondingly.

The danger to which we wish more especially to direct attention in the present article is not connected with the mere warming of the studio and dark room, though that, of course, if neglected, will contribute materially to the seriousness of the visitation, should such occur; we have at present to deal with a more insidious foe, more dangerous, perhaps, from the fact of its, in many cases, being unsuspected—namely, the fall in temperature of the water supply. That the water is colder after a sudden fall of temperature, such as that of the past few days, becomes painfully apparent to those who have to dabble in it, in either developing or printing operations; but, so long as the studio and developing or printing rooms are kept properly warmed, the tendency is to suppose that everything has been done that is necessary. Such, however, is not the case, as we have repeatedly tried to show in years gone by, and, as the danger lurks during the summer months, though perhaps to a less extent, as well as in the winter, we make no excuse for pointing out in what way inattention to this important point may cause serious trouble.

We need scarcely repeat the truism that chemical action of every kind goes on more rapidly, as well as more energetically, at a high temperature than a low one. We employ hot water instead of cold in such simple operations as solution-making, in order to hasten the process, and every one knows that a warm developing solution acts not only more rapidly, but also far more vigorously, than a comparatively cold one. And yet, in spite of these obvious facts, many photographers are content to use their developing, fixing, sensitising, and other solutions, as well as the water they employ in washing, at nearly freezing point, and expect them to behave in the same manner as when they are thirty, forty, or perhaps fifty degrees warmer.

The chemist is careful in performing any experiment or operation in which uniformity of results is necessary for comparative or other purposes at a uniform or standard temperature, knowing well that it is only under such conditions that a proper and accurate comparison can be made; and it is equally important that a similar course should be followed by photographers, though it is scarcely needful to observe the same rigid uniformity as the chemist. The general principle should be borne in mind, though the latitude permissible in photographic operations permits of considerable variation without materially affecting the results. Let us point out one or two instances in which carelessness in this respect may work injury.

It has been remarked that the temperature of the developing solution seriously affects its energy; this applies not only in a chemical, but also in a mechanical way; or, in other words, not only does an abnormally cold solution act less powerfully as a developer, but it also penetrates into the film of gelatine with far less rapidity, so that we have a double retarding action. This was brought forcibly to our own notice a few days back, when, on attempting to develop one of a series of exposures, several of which had already been developed successfully, we could obtain no trace of an image after several minutes, although the conditions were apparently identical. The idea arose that it was a case of having forgotten to draw the shutter, until we remembered that the plates previously developed had been treated before the sudden fall of temperature.

On procuring a supply of hot water with which to raise the temperature of the developing solution itself to a normal of 58° or 60°, and reapplying, the image at once commenced to appear, and progressed regularly and precisely as the previous ones had done. A still more remarkable result accrued, and one which shows more forcibly where danger may arise when an assistant neglected to raise the water used to the proper temperature—an omission we failed to discover for some time. Two plates had been exposed, one after the other, on the same subject, the light having practically not changed in the slightest, the second exposure, however, being about four times as long as the other, which had been cut short owing to the movement of a portion of the subject. The shorter exposure was developed first, and proved, with suitable development, a fairly satisfactory negative.

It was on the finish of this that a fresh can of water was brought in, the temperature of which was some ten or twelve degrees lower than what we had been using. Unconscious of this, we proceeded to develop the duplicate exposure, treating it in accordance with its increase of time and the result obtained from the other. The progress of development was much slower, and the contrast obtained much greater, owing to the shadow details hanging back while the lights were gaining density. On discovering the mistake, it was too late to remedy the matter, for, though unnecessary detail was obtained in the shadows, the high lights under the modified treatment became too dense, and the second image appeared to have had much the shorter exposure. This, of course, is a result that could only ensue from carelessness, but it shows in a marked manner the absolute need for uniformity of temperature from day to day if equality of result is desired.

It also shows, what it was attempted to demonstrate in a leading article in these pages some years back, that the temperature of the developer alone may have an effect on the character of the image that no variation of the proportions of the ingredients will alter. It is not necessary to recapitulate all that was said in that article, but it may be stated in brief that the results of experiments showed that cold developing solutions conduced to brilliancy and clearness, while a higher temperature produced greater softness. This general result could not be altered by variations of the ingredients within the bounds permissible for successful development. It appears, in fact, as if the cold developer is incapable, with a given, or even with an increased, exposure to search out details that are readily brought out by a solution a few degrees warmer.

GLYCIN.

[Journal of the Photographic Society of India.]

Glycin appears to be identical with *p.* oxy-phenyl-glycocoll, or para-oxy-phenyl-amido-acetic acid, with the formula—

$$C_6H_4\begin{cases}OH\\NH,\ CH_2,\ COOH.\end{cases}$$

and is prepared, according to Vater, by the action of chloro-acetic acid upon para-amidophenol. It is therefore a chloro-acetate of para-amidophenol.

The sample I have is a light cream-coloured granular powder, not altering readily in the air. It is not very soluble in water or in alcohol, but dissolves easily by the addition of caustic alkalies or their carbonates. The watery solution has a strongly acid reaction, but it is quite colourless. Alkaline solutions take a yellow tint, which disappears on the addition of sodium sulphite.

It is easily soluble in dilute nitric, sulphuric, and hydrochloric acids, the solutions being quite clear and colourless. It is not so readily soluble in weak bromine water, but the solution becomes colourless. Nitrate of silver first turns the glycin solution a turbid, dirty greenish-black, but it afterwards takes a violet tint, like slightly darkened chloride, and silver is precipitated, but not in the bright metallic form distinctive of metol. The same change takes place if the glycin solution be acidified with nitric acid before the addition of the silver salt; the silver precipitates, and leaves a clear solution of a beautiful purple colour. With a solution of glycin made alkaline with potash, nitrate of silver gave at once a thick brownish precipitate.

The manufacturer recommends two solutions for developing, ac-

cording as the negatives are required to be soft and detailed, or hard and dense, and glycin is said to be especially suitable for reproductions of all kinds, photomicrography, &c. The formula for the first developer is:—

1.

A. Glycin	4	parts.
Potash	1·5	„
Sodium sulphite (crystals)	12	„
Water	100	„
B. Potash	10	„
Water	100	„

For use, one part of A is mixed with two parts B.

Heat is required to dissolve solution A; but I find that, on standing, the salts have crystallised out in very pretty, thin, long hexagonal plates.

The second developer, for dense negatives, is as follows:—

2.

Glycin	5	parts.
Potash	25	„
Sodium sulphite (crystals)	25	„
Water	100	„

diluted for use with three parts of water.

In preparing this, it is well to first dissolve the potash in the water, then the glycin, and add the sulphite. The solution is nearly colourless, or a dirty white, and does not readily change by keeping, either in colour or in its developing power. I have not yet ascertained its full keeping powers.

Both of these formulæ give powerful and effective developers, yielding images of great density and brilliance, with clear shadows and perfect freedom from stain. Like other para-amidophenol developers, they require good exposure, and the density depends a good deal upon the length of time the plate is left in the solution, as is also the case with ferrous oxalate and and the sulpho-pyrogallol developers. The action of glycin is slow compared with amidol and metol, but not inconveniently so, and there is not the same tendency to a general veiling over the image.

I find both developers quite suitable for ordinary landscape work, the first formula being, perhaps, the better, while, for copying, the second is more suitable. They also work very well with orthochromatic plates. I have not yet tried them for instantaneous work, but with a suitable very rapid plate, and a large aperture of a quick-acting lens, they would probably answer. Several plates can be developed in a batch of developer without any marked change in it. The stability of the glycin, both dry and in solution, the density and clearness with which it works, and the latitude that appears to be permissible in exposure, seem likely to give it a very great advantage over para-amidophenol hydrochlorate and other new developers lately introduced. Largely diluted, it would probably be an excellent developer for lantern slides or for bromide paper.

A voltametric examination of the developer, made up according to formula 2, shows that it evolves hydrogen more vigorously than any other developer I have yet tried, and this would appear to favour the hypothesis that developing power is dependent, other conditions being suitable, on capacity for evolving hydrogen.

The dilute solution, made up in the above proportions, contained:—

Glycin	1·25	parts.
Potash (anhydrous carbonate)	6·25	„
Sodium sulphite (crystals)	6·25	„
Water	100·00	„

This solution was first electrolysed in the tube voltameter, described in a previous paper, with platinum electrodes, using, as before, a battery of four gravity cells, the current being 280 milliampères, with a pressure of 4·2 volts, the resistance of the galvanometer being one ohm. The current through the voltameter at starting was eighty milliampères, with a pressure of 3·2 volts, and in twenty minutes it had decreased to about seventy-five milliampères, and 3·15 volts. At starting, the solution in the tubes and the outer vessel was quite clear and colourless, the temperature about 72·5° Fahr. When the current was turned on, the evolution of hydrogen was very brisk, and the yield was, in five minutes, 2·5 c.c.; in ten minutes, 5·4 c.c.; and, in fifteen minutes, 7·6 c.c.

This corresponds very closely with the results obtained from an ordinary ferrous-oxalate developer containing four drops of a ten per cent. solution of potassium bromide to 120 c.c., or about one drop to the ounce. In this case 5 c.c. of hydrogen were evolved in ten minutes, the current, with the same four-cell battery and voltameter, being about seventy-five milliampères, with a pressure of 3·25 volts.

The solution in the oxygen tube turned a bright yellow, and the anode was surrounded by a dense layer of yellow solution. The general body of the solution in the outer vessel did not change colour, nor did that in the hydrogen tube. At the end, when the oxygen tube was removed and the solution in it mixed with the remainder, the whole was a bright yellow with a slight blue fluorescence.

With silver electrodes, the evolution of hydrogen was not so brisk, possibly owing to the immediate formation of a film of oxide on the anode.

With the same battery the current through the voltameter at starting was about eighty milliampères with a pressure of 2·7 volts, and in twenty minutes it decreased to seventy-five milliampères with 2·5 volts. The yield of hydrogen was, in five minutes, 2·2 c.c.; in ten minutes, 4·5 c.c.; and in twenty minutes, 9·3 c.c. The anode was covered with a flaky deposit of silver oxide (?), and ribbon-like streams of a turbid yellowish solution were given off above and below the anode plate. As in the case of the platinum electrodes, the colour of the solution in the outer vessel was not much changed; and, when the solutions were mixed at the end, the mixture was slightly turbid and not such a bright yellow, but it was also fluorescent.

Dr. Eder, who reports on glycin in the *Photographische Correspondenz* for October, 1892, speaks highly of it, and gives a formula for a glycin-soda developer as follows:—

Glycin	3	parts.
Sodium sulphite	15	„
Crystallised soda	22	„
Water	200	„

The solution can be used at once, and keeps unchanged for a long time in closed bottles. It gives clear and soft negatives, and, by lessening the quantity of soda or diluting the solution, the negatives will be more transparent. By adding bromide of potassium, even decided over-exposure can be remedied.

Baron von Hübl has found glycin a very valuable developer for collodion-emulsion plates when made up according to formula 1, diminishing the water to 80 if greater intensity is required, or mixing one part of solution A with three to five parts of B, or diluting the normal developer if less density is required. He says that this developer gives, with collodion-emulsion plates, perfectly clear shadows, a good and very compact deposit, rich half-tones, and a surprisingly beautiful gradation. This agrees with my own experience of para-amidophenol hydrochlorate as a developer for collodio-bromide emulsion plates.

COLONEL J. WATERHOUSE, I.S.C.,
Assistant Surveyor-General of India.

AMERICAN NOTES AND NEWS.

The Medal Question in California.—Our sprightly young contemporary, *The Pacific Coast Photographer*, says: "We wonder why the English photographic journals are so constantly quarrelling over the disposition of medals—whether an already medalled picture should be allowed to compete again in the form of a lantern slide, or else in some other exhibition, or whether a contributor with a string of medals as long as his arm has or has not the right to enter his pictures and hunt for more 'honours;' and, wondering, we are rather led to think that this is about all for which English clubs are organized—holding exhibitions and distributing medals. However, a liberal ray of truant light seems to have started our foreign friends in a—to them—new direction, for there is now a movement to establish a central photographic club with meeting rooms, dark rooms, and work rooms. Out here, on the frontier, we have had such an organization for a number of years. It is called the California Camera Club. They have had only one public print exhibition, and that was simply a quiet little time, and there were no medals. The photographic press ought to use its space to better advantage than squibbling about the awards of medals. As a pointer, however, the way the matter would be settled over here—when a man showed the disposition of greed to such an extent that, after receiving three or four medals, he still wanted more—his desire would probably be settled with the explanation, 'Do you want the earth?' But then, of course, we are merely an isolated and unpolished community."

Medals and Medals.—The *Journal of the Photographic Society of Philadelphia* has the following very sensible remarks on the medal question:—"The photographic journals of recent issue seem to be unanimous in deploring what has been termed the 'medal nuisance.

A small deluge of 'metallic honours' has apparently been poured on the heads of English photographers, and it does look as though the matter had been overdone. Is this a reason, however, why medals should be abolished? To us it seems that, if our leading societies treat the evil in the right manner, it will cure itself. If little exhibitions continue to award big prizes in large numbers to 'toy photographers,' will not the public quickly appreciate the fact that these awards are of no value, and, instead of asking an exhibitor, 'How many medals have you won lately?' the question will be, '*What* medals have you won?' The medals at our most important exhibitions here and abroad are still as hard to win as ever—or probably harder—as the amount of fine work produced increases each year. In this country, three of the leading societies have made an agreement which limits, so far as they are concerned, the number of 'open' competitions to one each year. All photographers of the world are invited to take part, and each year the invitation is more generally accepted. At these exhibitions the very highest standard of excellence is maintained, and the awards have a value which will never grow less so long as this aim is kept in view. The question may be asked, however, 'Are not the conscientious and diligent workers, who are not quite up to the 'highest notch,' entitled to awards of some kind?' This point has been met, where it should be, within the 'domestic circle' of the societies. Local annual exhibitions are now held in our principal societies, the competition being confined to their own members, and awards of diplomas, or, in some cases, medals, are made. These awards should not be numerous enough to become cheap or easily won, and should always be awarded for decided merit of some kind."

Viewing Photographs by Transmitted Light.—A recent American invention embodies "a simple and improved method of treating photographs, drawings, crayons, prints, &c., whereby the picture is protected, and is adapted for exhibition, either as a surface picture or as a transparency. A photograph, drawing, or print, is imposed upon a sheet of translucent material, such as paper or thin cardboard. Over the surface of the picture is secured, by means of a suitable translucent adhesive substance, a protective sheet of mica or other suitable material, which will not destroy the flexibility of the mount, and which is sufficiently transparent to render the picture at all times clearly visible. Upon the rear side of the translucent sheet upon which the picture is imposed is placed another sheet, preferably also of translucent material, upon which is printed or painted the natural or desired colours of the picture subject. The colouring is visible unless the picture is viewed, by transmitted light, as a transparency."

Fluorescence.—Professor L. H. Laudy, before the Society of Amateur Photographers of New York, recently entered into a discussion of fluorescence, and described the experiments of Sir John Herschel with an acid solution of sulphate of quinine. It was found that such a solution, colourless by ordinary light, was opaque when viewed by violet light. Professor Stokes made many experiments on this subject, and found that in fluorescence the length of the light wave is increased, and its velocity of undulation is diminished. The vibrations of the ether in the incident ray appear to excite disturbances within the complex molecules of the fluorescent medium, whereby new vibrations are excited in the ether, different in period from those of the incident ray. The portion of the light which has produced this molecular disturbance is used up or absorbed, and thereby lost to visible perception. By this means we are enabled to make the invisible visible, to bring out that portion of the spectrum that, to our eyes, produces no visible image. A design, traced on a card by means of such an acid solution of sulphate of quinine, when dry, is scarcely visible, but a photograph of the same reveals the design in sharp contrast.

What a Retoucher Should Know.—In the course of a paper in *The Art Amateur* on "An Occupation for Women," Mr. George G. Rockwood says: "A retoucher should have some knowledge of light and shade in pictures. He should know something of the value of a high light or a mass of dark, and should note carefully how the light has fallen on the sitter, also whether it is a direct light or a reflected one. This knowledge is especially necessary where he is to supply lights that are entirely lacking in the negative. Suppose he finds that his print is flat and tame: clearly, the way to improve it is to put in some lights here and there. Perhaps the hair may need a few sharp lines, being careful to follow the curves of the locks, or the modelling of the face may be strengthened by a delicate lightening of the prominent portions. Accessories, such as drapery or furniture, often need little skilful lights, to give them character or to add to the general effect of the composition."

The American Customs and American Dry Plates.—We read that, when Miss Barnes took back her American plates from her recent trip to England, the Surveyor of the Port decided that she must pay a duty of 60 per cent., as they came under the head of "American Glass Manufactures Improved Abroad." The duty was paid under protest, and a letter written to the Secretary of the Treasury at Washington brought about a reversal of the ruling, on the ground that the exposure of a plate did not constitute sufficient evidence of its improvement, many of them being ruined by this treatment.

RULED *VERSUS* GRANULAR GRATINGS.

I see, in your last week's issue, "Cosmos" alludes to the method I recently described of making gratings by photographing a grained surface under suitable conditions of lighting. I feel inclined, with another of his admirers a few weeks back, to say, "Oh, that I could write like 'Cosmos!'" but, as I cannot hope to do that, I must try and explain in plainer language why I described that method, and why I use it instead of—I will not say "prefer" it to—the ruled screen. If my cosmopolitan friend does not agree with me, I trust he will not write me down an "unalterable" one, to use his latest term of endearment.

I am prepared to admit that a properly prepared mechanically ruled screen is better for the purpose I had in view, and to which "Cosmos" also refers; but I cannot agree with him that "more evenness and regularity of grain would be likely to be obtained by mechanical ruling" than by the method I described, in the hands of an amateur, at any rate. Mechanical ruling requires machinery or appliances of the most delicate and perfect character, and these are not found in the possession of photographers, either amateur or professional; and, if they were, something more is required than the mere ruling to produce a usable screen.

Some years ago an acquaintance of mine, who was connected with the photo-mechanical printing business, showed me a ruled copper plate, not larger than a quarter-plate, which he had had specially prepared, and which had cost him, he said, 10*l*. The difficulty was that, perfect as was the plate itself—and it was the finest piece of ruling I think I ever saw—he was utterly unable to use it, mainly on account of its extreme fineness, and he came to me to help him to do it by photographic means. But I too failed, for ink impressions upon the most highly surfaced paper were too fine to copy, the contrast between the lines and paper being so faint. We tried printing direct on to thin sheets of gelatine, and even on to stripped collodion films; but here the difficulty was to get the ink to "take" evenly to the support.

I have seen samples of very fine ruled screens on thin, transparent, flexible films, but do not know how they are produced, and their price is prohibitive, running to about two shillings per square inch, or, say, about twenty-five shillings for a quarter-plate size. I should think they must be photographed direct from rulings on a much larger scale, which means a tremendous amount of labour and the extremest skill.

I need not say that for this purpose absolute regularity—using the adjective it its strictest sense—is necessary; the slightest error in spacing even a single line, or the least variation in pressure, spoiling the whole screen. The difficulty of producing even a quarter-plate grating with 100 or 120 lines to the inch by hand ruling, even with the aid of a machine, may be imagined even by those who have never tried it, which I have not. Possibly "Cosmos" has.

I have tried a method described in the Journal two or three years back, consisting in making a line of minute perforations in a strip of tinfoil, using a finely cut file upon which to lay the foil while a sharp point is passed over it with slight pressure in the same manner that the printing *cliché* is made in Zuccato's papyrograph, and using this

perforated strip to form a series of fine lines by drawing it across the surface of a sensitive plate. The principle is perfect, but in practice it is extremely difficult to avoid missing one or more perforations in a line of any length, and, as I have said, the least irregularity spoils the whole thing.

Now, in my makeshift method, there is no attempt at regularity, in the sense of mechanical or mathematical regularity, but a grain of a fairly uniform character, in which, from the absence of any attempt at mathematical precision, the faults, if any, are not so noticeable. The grain, too, when photographed, is represented by a vast number of minute points *with softened edges*, which act as minute "vignetters," and so help to add perfection to the gradation, even when the grain is comparatively coarse. In other words, one of these minute "holes," when printed under a *high light*, would be represented by the merest pin point, but, if submitted to the far longer exposure it would receive under a transparent *shadow*, would perhaps increase to the dimension of a decided dot. In printing on albumenised paper, with an evenly ruled screen, a similar, though not so marked, effect is produced.

Such is my reason for using the plan I described, not because I consider it superior to a ruled grating, for I do not, for the purpose, at least, to which I apply it. In conclusion, I agree with "Cosmos," that, if photographers only appreciated the effects that can be obtained in this manner, they would be inclined to introduce them as a stimulant to business.

W. LINDSAY.

AERIAL PERSPECTIVE.

(American Journal of Photography.)

THE matter of focussing the image upon the ground-glass or focussing screen of the camera, with regard to a determination of the amount of definition in the photograph, is so important a one in its relation to artistic effect, that we feel we may, without apology, be permitted to supplement the excellent article by Professor W. K. Burton, "The Stop to Use," published in the November number of this JOURNAL, by a few remarks which may make more intelligible what Professor Burton evidently feels to be the case, but it is not clear enough upon to assert as definitely as he perhaps should.

Objects, as we see them in reality, in addition to extending on a plane parallel to our eyes, also extend towards us and from us, and as one object after another is added to those constituting the scene before us, there is an actual recession which, as in the case of landscape scenes, if we would travel from our point of sight to the extreme boundary of our scene, would often take us very many miles away from our starting-point. This continual receding of parts, which is often spoken of as the natural perspective of a view, is so common to us that it does not form a matter of thought, or arrest the attention in any way, until we come to see a representation of such scene or view upon a flat surface, as in a drawing, or painting, or photograph. Then it is that we feel the shortcoming of art, which cannot in any way advance or recede beyond the surface plane of the canvas or paper, except as in the case of scenery in theatres; and yet this very shortcoming contributes one of the greatest beauties and features of attractiveness in a well-executed work of art, because by the art of the painter is overcome the appearance of want of relief, and the very deceptiveness of that which he presents to our vision adds to its charm. It is the knowledge of this fact, and the effort of the higher class photographer to vie with the painter, which has given rise to the discussion which we see continually in progress of the effect of certain alterations of focus in portraying scenes with the camera to bring about, if possible, this perspective effect.

There are two things upon which the painter mainly relies to bring about the appearance of recession. The one, perspective, which is really the diminishing in size of objects, under certain absolute laws, as they recede from the eye, which is called linear perspective. The other, the intervention of atmosphere between the receding passages, which is known as aerial perspective. The former is unvarying, the rules being the same under all conditions, whilst the latter is simply accidental, varying with the conditions of the weather and other uncontrollable circumstances. In addition to these two means within the power of the painter to produce his perspective deception are others, of minor importance, though often made use of, such as the choice of bold features in his foreground, brilliant lights, deep shadow touches, and coarser or more vigorous handling with his brush or pencil. Some of these may be made available by the photographer, others not.

The chief reliance of the landscape photographer for the attainment of the effect of retirement in the receding passages of his picture must be the intervention of atmosphere; and here, again, is a nice point, for there must be just enough of such haze to bring about the desired effect. He cannot, as the painter does, at his will, change and vary, perhaps bringing in more here and clearing away there, thus sharpening and heightening his effects—he must choose a time when there is such a prevalence of haziness as precisely suits his aim. Not too much, because then it will be impossible to attain a sufficient amount of detail in his foreground before his distance will have been irrevocably over-exposed, and not too little, or he will find his distant features failing to retire, and his perspective effect will be lost.

There is a continual complication in this matter of effect of recession, between studio or group photography and that of open landscape views. In the former much more may often be conveyed by alteration of focus than in the latter, because the effect of blurring is much greater in looking at an object a few feet from the eyes, of other objects in the rear of it, than is the case in taking a comprehensive out door view. Therefore the act of vision is better accommodated by the nature of circumstances.

In the case of groups, and what are known as picturesque foreground bits, wherein the whole subject pertains comparatively to the foreground, atmosphere can have little or no influence in the matter, and a blurring of the background may do much in the way of accentuation of the principal feature of the work. Let us especially note here, however, that such blurring by unaccentuated focus can have little benefit when the background features, are very marked in light and dark, or vie in size and form with the principal feature, or are ill-shapen. When a really fine picture is desired, such must be avoided.

Some painters, more especially modern, have done much in giving relief to their figures by finishing the latter highly and painting whatever may have formed the background, even though it were near objects, in a blurred manner. We recall some work by De Koninck as especially happy in the effect of relief produced in this way, but the background features were so chosen as not to vie too much with the subject figure.

Backgrounds so treated—that is to say, blurred by being put out of focus—must be of such a character as to be considered background solely. Whenever any of the background objects assume sufficient importance to be in any way a prominent part of the picture, it becomes necessary to accentuate the focus sufficiently upon them to make them distinct.

To return to landscape work: In order to attain the best perspective effect, we must necessarily choose a time for taking our views when there is just that nice amount of haziness which will give a due softening of each retiring passage of the work. Only the most careful observation and continual practice will train the photographer in this matter; not only, as we said before, because the precise amount of obscurity must be determined, but also because its character will make much difference, there being a certain bluish-white, smoky atmosphere prevailing sometimes, which will much more potently affect the sensitive film than will be the case under other conditions of murkiness.

There can be no attainment of this desired artistic effect so perfect as that of taking a view under the most favourable atmospheric conditions. No simple blurring of distance by imperfect focus will attain the desired aim when atmosphere is entirely absent.

Our remarks must be taken in the true artistic sense. We are well aware that this quality of atmospheric perspective is understood by but few in this country, and even in an admirable little work recently published in Paris, upon orthochromatic photography, the author gives two examples of an extended view with distant mountains and middle-distance town, under what an artist would consider a favourable atmospheric condition, to show how much superior the view is taken upon the orthochromatic plate, because the appearance of haziness is entirely overcome by it, and the town and distant mountains show up in all the distinctness of detail which would pertain to a clear atmosphere.

The best English photographers are working in the true artistic way, and those who are relying upon good composition and light and shadow, with the proper amount of atmosphere, are having the best success, some of those who have relied solely upon alterations of focus to attain their aim, notably Mr. Emerson, having given up in despair.

XANTHUS SMITH.

THE INFLUENCE OF DEVELOPMENT ON GRADATION.

MANY of those photographers who carefully study the journals have been, during the last few years, in a state of considerable doubt and uncertainty as to whether they have any power of controlling and improving the gradation of their negatives by means of suitable treatment in development. That such a power existed *had* been

regarded as a well-established fact, the truth of which was sufficiently confirmed by the opinions expressed on the subject by the best authorities on photographic matters, as well as by the ordinary experience in the dark room; but, in 1890, the publication of Messrs. Hurter & Driffield's paper, with the striking and interesting experiments therein described, showed a strong case against this generally accepted belief, and gave rise to much doubt in the minds of many readers. Dr. P. H. Emerson was so convinced of the truth of the conclusions arrived at by those experimenters that he entirely altered his views in consequence, in regard to the art side of photography; and others, while less hasty in fully accepting the supposed proof that no modification in gradation could result from variation in development, have still felt that the experiments of Messrs. Hurter & Driffield could not be ignored, and that confidence in the older theory was a good deal shaken. As I was one of those who thought so, and having written a short article on the subject in the autumn as a contribution to The British Journal Photographic Almanac while in that rather unsatisfactory state of mind, I decided to undertake a few experiments in order, if possible, to throw some light on the matter; and as the result as regards myself has been to clear away all doubt, an account of my experiments may, perhaps, be interesting to others.

Some of Messrs. Hurter & Driffield's critics have argued that their experiments were unsatisfactory because of the shortness of the range of exposures tested (viz., only those between 10 and 80 C.M.S.), and can scarcely be considered exhaustive. It has also been pointed out that the developers used did not vary sufficiently in constitution, and that considerably greater departure from normal proportions would be made by a practical photographer who wished to greatly change the character of the gradation of a negative in consequence of a known error in exposure. I therefore endeavoured in my experiments to cover the whole range of sensitiveness of the plate, giving exposures varying from those which were only sufficient to produce the smallest appreciable density up to those which approached (or entered) the "period of reversal," and, in developing, I went equally to extremes. Pyro and ammonia was used (except in one experiment), that being the developer which is generally understood to give the greatest amount of control, and, in settling the proportions in which the ingredients were to be mixed, I was guided by the valuable and instructive series of experiments (quite inconsistent with Messrs. Hurter & Driffield's conclusions) which Mr. W. K. Burton described in 1885, choosing those proportions which had given the most and least detail respectively among the mixtures which he used; but I found, in the latter case, that it was necessary to slightly increase the amount of ammonia to suit the plates I was using. These plates were the Ilford ordinary, which I believe are pretty regular in quality and easily obtained. A few preliminary sensitometer experiments gave pretty clear evidence of different action on the part of two developers, and I then proceeded on the lines laid down by Messrs. Hurter & Driffield. My first experiment in that way left no doubt whatever that complete alteration in the character of a negative might be produced by different treatment in development, but, as the two next were more satisfactory in some respects (especially in being much cleaner in the unexposed parts owing to my having backed all plates after the first experiment) I will omit details of the first experiment, and give particulars of the two next. Five exposures in separate patches were made on "plate B," each being ten times the length of the previous one, and varying altogether from 1 C.M.S. to 10,000 C.M.S. The plate was then cut (of course, lengthways) into two pieces, which were soaked a short time in water, and developed separately in solutions mixed in the following proportions:—

No. 1.

Pyrogallol	½ grain.
Sulphite of soda	2 grains.
Bromide of potassium	½ grain.
Ammonia	2 minims.
Water	1 ounce.

No. 2.

Pyrogallol	2 grains.
Sulphite of soda	8 „
Bromide of potassium	2 „
Ammonia	1 minim.
Water	1 ounce.

One strip was developed in No. 1 for two and a half minutes, and the other in No. 2 for ten minutes, but the action being rather slow, the ammonia was then increased to one and a half minims per ounce, and development continued five minutes longer. "Plate C" was exposed in the same manner, divided into halves, and the strips treated as before, except that, in using the No. 2 developer, no addition was made to the ammonia, but the strip was developed for thirty minutes in solution containing one minim per ounce. The results produced were similar in both cases, the strips which had been through similarly constituted developers being very much alike; but the two halves of each plate showed *great* contrast towards each other. The No. 1 developer was clearly superior in the 1 C.M.S. patches, having brought out good, substantial density, and such as would show up well in the print if it formed part of the detail of a negative. When developed with No. 2, these patches were certainly just visible, but so very thin that the amount of deposit there would evidently have *no* printing value, and would be quite useless in a negative. In the 10 C.M.S. patches the densities were much alike in all strips; but, in the results of longer exposures, great differences again became apparent. As developed by No. 1, the densities of the 100, 1000, and 10,000 C.M.S. parts were weak and thin, and hardly appeared to differ when judged by mere inspection, although the photometer showed that density *had* increased with exposure. On the other hand, when developed with No. 2, these patches showed good contrast at each stage, and those representing the longer exposures had great opacity —strikingly different in appearance from corresponding parts of the companion strips. The experiments showed, therefore, that where a negative had received only an instantaneous or very short exposure, in which the light acting on the various parts of the plate had ranged from about 100 C.M.S. in the brightest parts down to some fraction of a C.M.S. in the shadows, that then the No. 1 developer would be much preferable to No. 2, as the more weakly lighted parts would have a reasonable amount of deposit, and the high lights would not be over-dense; so that, if sufficient density were not obtained in developing the plate, a good negative might, at any rate, be made by intensifying. But if the exposure were full, so that *no* part of the plate had received less than, say, 10 C.M.S. of exposure, then it is clear from the above that No. 1 would give an entirely worthless negative, and No. 2 a satisfactory one. It is evident that these results are quite inconsistent with the principles advanced by Messrs. Hurter & Driffield. If the densities resulting from one method of development had been greater *at each step* than the corresponding ones produced by the other, it might have been somewhat difficult to prove that more prolonged development of the weaker strip might not, at a certain stage, have brought all its densities equal to those of the other half; but, where we have some parts denser on one half and some denser on the other, it is clear that no prolongation of development or after treatment by intensification could ever have produced the same range of gradation on both sides. A simple comparison of the strips seems sufficient to prove the case, but photometrical examination still further strengthens it, and is interesting as showing, in figures, how great the difference is. I have examined the strips in a photometer, constructed according to the directions given by Messrs. Hurter & Driffield in their original paper, very slightly modified, and although I have, so far, had but little practice in photometry, I have worked carefully, and believe my figures are fairly accurate. The following table gives the densities found, and the ratios between the densities, in each plate of the parts treated with No. 1, and those treated with No. 2:—

Exposure, C.M.S.	Plate B.			Exposure, C.M.S.	Plate C.		
	Developer No. 1.	Developer No. 2.	Ratio.		Developer No. 1.	Developer No. 2.	Ratio.
1	·29	·09	·31	1	·30	·12	·40
10	·70	·70	1·00	10	·78	·75	·96
100	·95	1·58	1·66	100	1·01	1·41	1·39
1,000	1·05	2·00	1·90	1,000	1·09	1·83	1·68
10,000	1·14	2·19	1·92	10,000	1·19	2·21	1·86

The greater density given by the No. 1 developer, in the case of the 1 C.M.S. exposure is well shown by the table, and 10 C.M.S., in each case, appears as having about equal densities on both halves of the plate; but the great superiority in density brought out by No. 2 for the longer exposures then becomes apparent, and increases at each step till, in the 10,000 C.M.S. patches, differences are shown amounting to a density of 1—that is to say, the strips developed with No. 1 allow *ten times* as much light to pass through, at that part, as do the corresponding strips. I need make no remark as to the "ratio" columns, except to point out that, if

Messrs. Hurter & Driffield's principles applied, the figures in those columns should be *practically identical* for all exposures on the same plate. H. J. CHANNON.

(To be continued.)

ON THE PRODUCTION OF BLACK AND WHITE NEGATIVES BY MEANS OF ARTIFICIAL LIGHT.

IV.

IN a previous article I referred to the influence varying degrees of temperature of the developing solution had upon the plate. A perfect black and white negative previous to intensification should show no reductions on the blacks, but at the same time have a good degree of opacity in the whites. With such a negative, the process of after-intensification offers no trouble, and, provided the plate receive a sufficiency of washing before and after the application of the mercuric chloride solution, the transparent portions will in no way deteriorate.

The knowledge whether or not there has been any reduction in the blacks during development will soon be acquired when the bleaching operation takes place after the application of the chloride of mercury solution. Provided there be no appearance of any bleaching on the clear glass portions of the image, all will go well, but, if after the application of the mercury it is seen that bleaching takes place, then the negative has been over-developed, and a beginner would do well to expose another plate on the same subject, giving less time, and by a judicious use of pyro and bromide force up contrasts without carrying on developments so far. By this means, a knowledge of how far a plate may be developed without causing a reduction in the blacks is arrived at; and once a worker is able regularly to expose and develop in such a manner he becomes master of the entire situation; it takes some practice, and in development a somewhat different method of treatment from the ordinary practice when high lights, middle tints, and on through shadows for details have to be looked for.

It very frequently happens that, no matter how careful a worker may have been to guard against the reduction of those portions of the negative representing the blacks in the picture, that, after completion of the fixing and the plate is taken out into daylight, a very slight reduction will be noticed which was not apparent in the dark room. When such occurs, the plate should be most thoroughly washed, after which an application of a weak solution of iodine and a further thorough wash followed by a very dilute bath of cyanide of potassium will effectually remove the slight reduction; these solutions, however, must be freshly made up, and the greatest precautions taken to avoid staining the plate. When it is seen that there is no deposit on the portions of the negative that ought to be clear glass, the plate receives a very thorough washing, and is then ready for being intensified.

In cases where ordinary negatives embodying high lights, middle tints, and shadows are concerned, the application of a mercuric chloride solution, followed by copious washing and an after-application of a saturated solution of sulphite of soda, or, as some workers advocate, a weak solution of ammonia, will be found as effectual and perhaps as convenient a method to employ as any; but in the class of work we are considering we have no middle tints to look after, but, on the other hand, the great aim is merely to increase to the utmost the opaque portions of the negative; and perhaps there is no better plan to follow or formula to employ than that of cyanide of silver. With such the utmost degree of intensity is usually got. Any one using such for the first time will be struck with the extra amount of density noticeable after the plate has been dried. This will not be so apparent whilst the plate is wet, but is very evident when dried and finished.

As a rule, amateur workers are not conversant with cyanide of silver as an intensifying agent, for the simple reason, doubtless, that the highly poisonous nature of this chemical intimidates many from using such. It is very useful, however, in the class of work we are considering, and with proper care a worker need have little or no scruples in making up a supply and using it.

To make a useful quantity of this intensifier, the following will be found about the right quantities of chemicals to employ:—Dissolve 220 grains nitrate of silver in three ounces of water. In a large jar place twenty-four ounces of water, and with a glass rod dissolve in same by stirring one ounce of cyanide of potassium, when the cyanide is dissolved from the silver solution gradually into the the cyanide solution. Stirring with the glass rod, a white precipitate will be formed, but, with constant stirring, after a time this will be redissolved up, and eventually the solution will become quite clear. It will work best after being a few days old.

The chloride of mercury, or bleaching solution, is made as follows:—In twenty ounces of water dissolve 200 grains bichloride of mercury and 200 grains chloride of ammonium.

The plate, after being most thoroughly washed, is placed in a small quantity of mercury solution, until the bleaching has gone right through the entire film; it is then thoroughly well washed again, and the face of the negative well sponged with a large plug of clean cotton wool, after which the cyanide of silver solution is applied just like applying an ordinary developing solution. The plate will at once assume a jet-black appearance, and in a short time the silver solution will permeate right through to the back of the film. When it is seen that the film is blackened right through to the glass, the negative should, without any further delay, be well washed under the tap for some minutes, and eventually washed in a water bath changed at intervals for, say, an hour or so. If all these manipulations have been carefully performed, and the chemicals properly prepared, the result will be a black and white negative of a class seldom seen by amateurs. The blacks will be represented by what is termed clear glass, and the opaque portions of the negative so dense that no gas flame will be visible when the negative is held at, say, twelve inches from it.

Some workers advocate economy by using these intensifying solutions over and over again; this means, they pour them back into the stock bottles when they have been applied to the plate. I find, however, I invariably get cleaner results by using entirely fresh solutions: so it is just as well to pour the used mercuric and silver solutions down the sink when used, and always employ a clean, fresh supply from the stock bottles.

With a negative having such a wide contrast, a worker will be able to turn out results in the way of printing—either on sensitive plates, such as is useful for lantern slides, either by contact or through the camera—that will astonish those who have never been able to get clean high lights; whilst in platinotype or bromide printing, work will be rendered in a manner hitherto unapproached for pluck and vigour. T. N. ARMSTRONG.

NORMAL AND SOLARISING DENSITIES.

THE intervals of time expressed by the figures 5, 90, 1620, 29,160, &c., given by myself as typical of the relative connexion existing between the exposures necessary to produce, successively, the three most characteristic combinations of two fixed densities under conditions invariable as regards the nature of the subject, the intensity of the light, the sensitiveness of the film, the strength of the developer, and the period of immersion, form a geometrical series, having a common ratio, and exhibit from first to last a uniformly retarded fluxion.

The terms "normal," "neutral," and "reversal," which I carefully selected to designate the three phases of two simultaneously presented extremes of greatest and least contrast, or of transparency and maximum opacity, and two equal opacities, amply convey—to any mathematician at all acquainted with the subject—the fact that the equal opacities are, and must be, mean densities, the three terms alternately implying the idea of combinations of $0+1$, $0{\cdot}5+0{\cdot}5$, and $1+0$ densities, as otherwise the flux and increment could not correspond, as I showed that they did.

Taking two extreme degrees of light and shade in a subject, we observe as one of the leading features of solarisation that, whilst each degree of luminosity in a shorter or longer interval of time affects the film in apparently the same way, and imparts to the two corresponding portions the power successively to acquire mean, greatest mean, and least densities, it is to be specially noted that, although both, so to speak, ascend and descend the same hill, yet is the one ever going up as the other is coming down, and *vice versâ*, each moving simultaneously from base to summit and from summit to base with a constantly retarded velocity, and meeting invariably between these turning points or termini.

Let us regard the gain and loss of density by the two portions of

the plate respectively exposed directly and indirectly—or to the greatest and least light—as the distance swung by a pair of pendulums suspended close together—either side by side, or one in front of the other. Let one oscillation to and fro be taken as equal to a complete cycle of phases. If the angle included between the extremes of position of the shaft were subdivided into any number of equal fractions, representing density, each scalar step, grade, or degree of density would, expressed to the required base, form a series of logarithms corresponding to the periods in which they were described. It would, of course, be essential that arcs of forty-five and ninety degrees should be described in periods with a common ratio, such, for instances, as 5, 90, 1620, 29,160, &c., or as 128, 16,384, 2,097,152, 268,435,456, &c., although x, xn, xn^2, xn^3, or r, r^2, r^3, r^4, &c., are preferable, as of more general application, in which formulæ x is simply the exposure for the phase first found, and n or r the number or ratio by which it must be multiplied or divided in order to produces the succeeding or preceding phase.

In order that the conditions first pointed out by myself—from which much in the way of detail may be elaborated—may be realised, we must be able to see that the swing from 0·0 to 0·5, and from 0·5 to 1·0, of the one pendulum is performed in the period in which the other describes 1·0 to 0·5, and from 0·5 to 1·0. Whether the "swing" is a "whole swing," a "half swing," or a "quarter swing," it will be performed by the one pendulum in precisely the same time as that taken by the other to move the same distance; but, be it noted, one quarter falling density corresponds to one quarter rising density, one half increasing to one half decreasing, and so on. It may not pass the wit of man to devise an irregularly accelerated and retarded velocity by which these points may be enabled to coincide; but at the same time it is evident that, without proof to the contrary, the uniformly retarded velocity proved by myself to determine the extremes and means of density must be accepted as influencing fractions smaller than one-half.

To summarise, then:—The *swing* in density from 0 to 1 of the *indirectly* illuminated portion of the film being strictly isochronous with the *swing* from 1 to 0 of the *directly* exposed part, and the *half swing* from 0 to 0·5 or from 0·6 to 1 being likewise isochronous with the *half swing* from 1 to 0·5 and from 0·5 to 0, it would naturally seem to follow that the quarter swing and other swings describing smaller fractions than I dealt with should obey the same law and be described in proportionate periods, that is, in times whose common ratio corresponds to the common difference of the densities. Without any further data, then, we are in a position to conclude that the time taken by the "solarising" or brightening portion of the film to lose any fraction of mist density will be the exact period required by the darkening part to gain the same amount. Hence, as the one quantity depends upon the other in such a manner that that expressing the time is equally multiplied for equal added or subtracted increments in density, we know that the rate of growth is logarithmic and cannot be otherwise. Knowing this, it is easy to calculate and interpolate the exposures necessary, under similar conditions, to give 0·25 or 0·75, or any fractional part of the unit of opacity, either for the least protected or the most protected part of the film.

My terms, "neutral," "normal," "neutral," and "reversal," taken together with the figures I put forward typically, or, if preferred, with the symbolic expression of the exposures necessary to produce the densities the terms imply, bring out three important facts:—

1. The leading conception that what is true of the "image" of the brightest light is equally true of the "image" of the deepest shadow, and that both alternately decrease, increase, and decrease again in their power to attract the deposit furnished by the developer.

2. That, unless the period required by the one form of image to gain a given increment in density be the time taken by the other to lose the same amount, the phases could not occur in the sequence given by Professor Janssen, nor assume the forms described.

3. Since these selected phases are compounded of two densities, each of which grows at the same rate, and that rate is stated both by figure and formula, it follows that the law is thereby expressed which numerically defines the condition of interdependence of the densities upon the exposures, and of the exposures upon the densities. This law, first given by myself in THE BRITISH JOURNAL OF PHOTOGRAPHY for January 13, 1888, antedates by over two years the publication of any verification or amplification of it.

HUGH BREBNER.

ROUGH PAPER.

[Fillebrook Athenæum Photographic Society.]

CONSIDERING the extent to which rough paper is now being advocated and used for photographic printing, and the undue preference shown to coarse-textured prints by Exhibition Judges, we may, perhaps, profitably devote an evening to a consideration of the principles that should govern its use.

Unfortunately, in every art, and especially in photography, there are many who, seeing a success achieved by a picture in which some new departure is made, cannot appreciate the art qualities that ensure its success, but attribute it to the novel treatment. The inevitable result is that these peculiarities or mannerisms become a craze, and are adopted under all conditions and circumstances without any consideration of suitability.

Some of our prominent workers having printed on rough-surface paper with more or less good effect in special instances, the present craze is "Rough paper," and, preferably, the roughest of the rough, which is frequently used with so little discrimination that, instead of enhancing any artistic merit that the picture may possess, completely obliterates it.

The Judges at some Exhibitions are largely responsible for this state of affairs; for, when it is seen that the principal claim to recognition is the adopting of certain "fads" or eccentricities in general treatment of subject, or coarseness of printing surface, or a combination of both, it must be admitted that, to the ordinary mortal, the temptation is very great to produce a result for the sake of winning a medal that his better taste might condemn. "Cosmos," in his "Jottings" in THE BRITISH JOURNAL OF PHOTOGRAPHY of March 17, in alluding to Judges at Exhibitions, writes: "The worst of it is that people of this kind get so imbued with the idea that their way of making pictures by photography is the right one, that any one who thinks otherwise, and proves the faith that is in him by exhibiting, stands very little chance of an award."

As a striking example of this I may instance an award at our recent Exhibition. An old architectural subject, about 10 × 8, printed on the roughest paper, so that the truth of all straight lines was destroyed, and any detail, which in masses of old stonework would be sufficiently varied and broken, not only lost, but replaced by a regular mechanical series of lights and shades, due to the undulations in the paper, and out of all proportion to the scale of the subject—larger, in fact, than the blocks of stone themselves. While this was medalled, far better photographs of similar subjects, treated more as any artist in monochrome would have rendered them, were passed over, because they were open to the objection of being legitimate photography, sharply focussed, and carefully printed in platinotype. Such awards as this tend to give a fictitious value to rough paper, instead of good technique coupled with artistic merit.

It is frequently contended that rough paper and one or two other kindred crazes are more artistic and *painter-like*, and that photographs other than those that accord with these methods have no claim on the attention of persons of refined and artistic tastes; they are merely photographs, or even "topographical photographs," while the work of the faddists are *pictures*.

The pictorial qualities of a photograph—composition, balance of light and shade, due prominence of foreground, and correct rendering of distance, the whole treatment of subject—are quite independent of any special fad, and are not the sole property of any one school in either photography or painting. On the other hand, *the indiscriminate use of a method of treatment or printing surface, suitable only under special conditions, is certainly not artistic—it is either studied eccentricity or utter want of judgment.*

A rough surface is said to give breadth of effect, which is simply the massing of the lights and shades, and must be obtained by suitable lighting. If this quality is not present in the negative, rough paper cannot confer it.

Every art has its own peculiar character which gives it a special charm, and, if the worker be a master of his craft, he will retain and emphasise that character in expressing his ideas, however much individuality may stamp his works. It would not be considered the highest ideal for an artist in water colours to aim at producing a result that should be mistaken for an oil painting; why, then, should the standard of quality in photography be that our works should look as unlike photographs as possible?

It is quite a new doctrine, that unfortunately seems to be gaining ground, that the legitimate methods of photography are inartistic and incapable of expressing sentiment; that only as we depart from accepted methods are our works to be considered artistic; in brief, that careless technique is essential to art. In painting, a man is judged by the technical quality equally as by the sentiment of his pictures; if either is defective, his work is condemned.

I do not wish to convey the impression of totally condemning rough paper, but only its indiscriminate use. The roughest should only be used for very large work, and then only in special cases. The texture should depend not only on the actual size, but equally on the character of the picture. A bold, simple, or broad effect could be printed with good taste on a far rougher surface than a delicately treated subject, or one in which fineness of detail was more or less essential. The grain should not be obtrusive at the ordinary distance of viewing the picture, otherwise it attracts to itself that attention that should centre on the subject of the picture.

It is very much to be regretted that many whose works show an appreciation of the beautiful in nature should so finish them that, instead of giving pleasure, they only irritate by their coarseness.

Etchings and engravings are invariably on smooth surface paper, and water-colour drawings, excepting those of very large size, on that of fine

grain or moderate texture; but they are not considered inartistic on that account. Those photographers who affect extremes in either roughness of surface, or out-of-focus methods, or misty and gloomy effects, might study with advantage the works of leading etchers, which show that smoothness of surface, fineness of definition, delicacy of treatment, bright and sunny scenes, are not inconsistent with the highest artistic quality.

HENRY W. BENNETT.

AN ATTRACTIVE "OPTIMUS" EXHIBITION.

THERE is at present on exhibition in the premises of Messrs. Perken, Son, & Rayment, 99, Hatton-garden, a large collection of pictures, both direct and enlarged, of a very attractive nature. It is a selection of prints the offspring of the 1892 Optimus One Hundred Guinea Photographic Competition. One of the main conditions of this highly creditable contest was that each negative must be taken by an "Optimus lens."

The resulting prints, several hundred in number, including portraits, landscapes, seascapes, architecture, animal studies, &c., are of very high order of merit from a technical as well as from an artistic standpoint. The sizes varied from 15 × 12 down to quarter-plate. Many display a minuteness of definition that is simply marvellous. Even the 24 × 18 enlargements (also made by "Optimus lenses") from 4¼ × 3¼ negatives are so crisp that they may readily be mistaken for well-defined direct work. We would strongly recommend the "Optimus" firm to enlarge these quarter-plate negatives considerably further, feeling sure the most critical would be amply satisfied with the results. Messrs. Perken, Son, & Rayment must be much gratified at the class of work their prizes have brought together. Among the contributors of prints we notice the names of many of our recognised past masters at the art science.

We understand this firm has already announced its intention to offer another one hundred guinea series of prizes for the best photographs taken with "Optimus lenses" during the present year, the conditions and entry forms of which will be published at the end of April.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 16,—Mr. C. E. Atkins in the chair.

This being a Lantern Night, slides by Messrs. H. E. Davis, Wilkes, Beckett, and a collection, illustrative of South Africa, contributed by the South African Photographic Societies, were shown.

Mr. H. E. Davis showed a very light tripod stand, made by Messrs. Newman & Guardia, and the firm's representative exhibited one of their new-pattern hand cameras.

North Middlesex Photographic Society.—The second of the series of Elementary Technical Classes being given by the above Society was held on Wednesday, the 15th inst., the subject being "Development." Mr. C. BEADLE briefly explained the subject in hand before proceeding to the more practical part, in which he was assisted by Messrs. J. MacIntosh and A. J. Golding. The plates were exposed at a special outing held on Saturday, the 11th inst., each beginner developing his own plates, while the instructor stood by to show and explain as development proceeded. These classes are given, free of charge, to help beginners, and appear to be greatly appreciated, which is very encouraging. The next Technical Class will be held on Wednesday, April 12, the subject being "Toning Gelatino-chloride Paper." The Secretary, Mr. G. Gosling, 13, Lausanne-road, Hornsey, will be pleased to hear from any gentleman wishing to attend.

Harringay Photographic Society.—March 16, Mr. Coghill occupied the chair.—Mr. T. W. A. BALL gave a demonstration of *Retouching*. The demonstrator showed how to reduce a negative with spirit, how to prepare and apply the medium, and he then proceeded to retouch a negative. One new member was elected.

Hackney Photographic Society.—March 14, Mr. E. Puttock presiding.—Members' work was shown from Messrs. Beckett and Dean. Question: "Is it advisable to back all plates taken out?" Reply: "Yes; it is a great advantage, especially when light is strong; in no case could it do harm." Question: "What is the most reliable backing?" Reply: "Caramel and burnt sienna, as per formula given last June." Mr. NUNN mentioned red blotting-paper, and Mr. GOSLINO carbonised manifold paper, as not bad substitutes. Mr. R. BECKETT said that films were better than unbacked plates; but Mr. F. HOUGHTON found no halation on films exposed last week one-sixth of a second. The CHAIRMAN then read a paper by Dr. Paul Jeserich entitled *Detection of Crime by Photography*. Whilst the lecture was being read a series of slides was shown through the Club lantern as alluded to. These were taken from subjects forming criminal cases in Germany. Dr. P. Jeserich treated his subject under the heads of Hairs, Blood, and Forgeries. Hairs, he said, from the same individual were easily recognisable. Human hairs and blood were different from those of other mammals. He instanced cases where his evidence resulted in acquitting some people accused of murder and pointed suspicion at others, to which they ultimately confessed. Forgeries executed in different coloured inks, though the unassisted eye could not detect it, were photographed by *his* process (presumably coloured screens and colour-sensitive plates). They clearly showed the original handwriting faintly, with the additions strongly contrasted. Spectra of blood were shown, which were apparently identical, urging, as a strong point, that no two substances give exactly the same spectra. In a short discussion which followed, Mr. DEAN objected to the too dogmatic way in which the paper was written, claiming that some of Dr. Jeserich's assertions were stronger than the stated facts justified, and that he ought not to assume that human hairs from the same individual have the same size and the same-shaped roots; that a cut hair grows from the middle of the *cut* end; that blood corpuscles from the various orders of the mammalia are *so very* dissimilar from one another in size; that no two spectra are the same. Mr. Dean quoted a reliable authority that the differences between the spectrum of red ink and that of blood, even under very high powers, are undiscernible. Slides from Messrs. Beckett, Hull, Smith, and Salmon were then put on the screen.

Fillebrook Athenæum Photographic Society.—March 20, Mr. H. T. Maltby in the chair.—A discussion on *Rough Paper* was opened by Mr. H. W. BENNETT [see page 186]. Mr. J. W. SPURGEON said that one of the chief characteristics of photography, its ability to render detail, was destroyed if the paper were too coarse for the subject. A style of photograph coming into prominence was the "fuzzy;" but, in his opinion, a sharp picture artistically good was far superior. Mr. CAIRD, speaking as a water-colour worker, said that rough paper was inadmissible for fine work, and most photographs were fine work on account of their small size. In water-colour drawing generally, the whole method of working was broader than in photography; even then very rough paper was only suitable for large and broad effects. Mr. MALTBY considered that taste was shown in choosing a grain to agree with the scale of subject represented. The texture had quite a different object in water-colour drawing from photography, the irregularities of surface allow a play of light and shade, and give transparency to masses of colour, and, by permitting simple washes rather than laboured effects, greater purity of tone results. Next meeting, Monday, April 17. Subject, *What to Photograph*, to be opened by Mr. J. W. Spurgeon.

Putney Photographic Society.—Dr. W. J. Sheppard in the chair.—Mr. Henry Kimber, M.P., was elected a Vice-President, Mr. W. R. Few a member of the Council, and Mr. F. W. Thompson an ordinary member of the Society. Mr. W. E. DEBENHAM gave his lecture and demonstration on *Transparencies by the Carbon Process*, this being one of the papers placed at the disposal of affiliated societies by the Central Committee. Mr. Debenham commenced by fully explaining the theory of the process, illustrating his remarks by diagrams drawn on the blackboard. He claimed that for lantern slides carbon transparencies were unbeaten, as the process gave great range of gradation, clearness in the high lights, and transparency in the shadows, and, further, that any colour could be obtained with absolute certainty; the process was also greatly used in the trade for reproducing negatives for enlargement, photogravure, &c., for which it had been found to be very suitable. The tissue might be prepared by the user without much difficulty, but amateurs would find it more convenient to buy it ready for sensitising, in which state it would keep for a long time. They could readily sensitise it themselves by immersion in a solution of bichromate of potash. This should be done shortly before use, as the tissue will not keep many days when sensitised, even when precautions are taken to store it under the most favourable conditions. Mr. Debenham then proceeded to explain and demonstrate the method in detail, from the preparation of the tissue to the final transparency, giving many valuable hints of a practical nature, which were greatly appreciated by those present, who throughout followed Mr. Debenham's remarks with much interest, and, at his invitation, asked questions as the demonstration proceeded. It is almost needless to say that the whole of the process was brought very fully and clearly before the members, both theoretically and practically, specimen transparencies and reproduced negatives illustrating the lecture were handed round, and the results fully bore out Mr. Debenham's claims for the beauty and utility of the process.

West London Photographic Society.—March 14.—Messrs. HODGES & HORTON read a paper on *The Processes Applicable to Lantern Slides, and Hints on the Management of the Lantern*. Omitting the first part of the subject, as likely to occupy too much time, the authors proceeded to enumerate the optical and other *desiderata* of a good lantern, and, after reviewing the history of lantern illuminants, and dwelling briefly upon the various forms of oil lamps, including the improved lamp of Stock, they proceeded to describe in detail the various types of limelight appliances, including the oxy-spirit, blow-through, mixed jet, and oxy-ether, and to show samples of all but the last in operation. The practical part of the paper was notable for the interesting series of comparisons instituted between discs thrown on the screen from two lanterns placed side by side, employing in succession a four-wick oil lamp of ordinary make, a Stock lamp, an oxy-spirit jet, a blow-through jet, and, lastly, a mixed gas jet. Each illuminant, taken in the order enumerated above, gave a distinct advance in light-giving power as well as in whiteness of the light. At the conclusion an interesting series of slides, belonging to Mr. Le Marchand, made by the albumen process, were shown.

Ashton Photographic Society.—March 16, Annual Meeting, the President (Dr. Hamilton) occupied the chair.—Mr. G. H. DEAN, Honorary Secretary, read the report, which stated that twenty-nine new members had joined the Society during the past year, making the present total 120, or eleven more than last year. The library had been considerably augmented, through the gift of the late Mr. Basil Hall's collection, by his brother, Mr. T. B. Hall. The Council hoped, in the course of a few weeks, to have the books arranged and ready for circulation amongst the members. During the season seven outings were arranged, but, owing to the inclemency of the weather, one was abandoned. Mr. R. T. Marsland, the Treasurer, presented the balance-sheet, showing the income to be 66*l.* 7*s.* 6*d.*, of which 42*l.* 11*s.* 6*d.* had been received in subscriptions, 13*l.* 3*s.* 6*d.* from the sale of tickets, &c., and 9*l.* 7*s.* 6*d.*, the balance brought forward from last year. The expenditure was 50*l.* 15*s.* 4*d.*, leaving a balance to be carried forward of 15*l.* 12*s.* 2*d.* The CHAIRMAN, in moving the adoption of the Secretary and Treasurer's reports, congratulated the Society upon its increased and increasing efficiency. As far as he had been able to judge, the work of the members, photographically, had advanced distinctly, not only in practical detail but in true artistic feeling, without which no photographic society could ever make any real or distinct progress. It was gratifying to him to know that, in their Society, there had been a distinct effort to realise this particular condition. One of their members, to whom they were indebted in many ways, had endeavoured from the beginning to produce real pictures. He referred to Mr. Glazebrook, whose work had received the commendation of Mr. Arthur Severn, a well-known artist, and Mr. John Ruskin, one of the greatest art critics of this century. He (the Chairman) did not mention this with a view only of showing what a good worker Mr. Glazebrook was—although that was an important part of it—but to show that they had realised what artists said photographers were not able to do. He had never heard of any photographic society being honoured by the favourable opinion of two such eminent men. Major Bradley moved a vote of thanks to Dr. Hamilton for the service he had rendered and the great interest he had taken in the work of the Society. Dr. Hamilton was re-elected President, Messrs. J. W. Kenworthy, C. Lord, Thos. Glazebrook, and Major Bradley were elected Vice-Presidents. Dr. HAMILTON moved a vote of thanks to Mr. Dean for his services as Secretary. Unfortunately for the Society, Mr. Dean felt himself compelled through stress of work and through change of residence, which took him further away from the rooms, to resign the office he had held during the last two years. He was sure they all regretted to part with him. Mr. Josiah Matley seconded the motion, which was carried. Mr. Marsland was elected Secretary, and Mr. Walter Leigh Treasurer. Mr. Walter Chadwick was elected Librarian. The following were elected on the Committee:—Messrs. W. C. Brown, T. Chayne, W. Chadwick, W. Greenwood, J. Hutchinson, J. T. Lees, C. E. Redfern, and S. Woolley.

Birmingham Photographic Society.—March 14.—Three sets of slides, lent us by the Liverpool Amateur Photographic Association—entitled (1) *Illustrated Boston*, (2) *In and Around Columbus*, (3) *The White Mountains of New Hampshire*—were shown on the screen and described by Mr. MIDDLETON, with the help of notes which accompanied them. Very interesting they were, showing old and new buildings, landmarks, and busy streets, while the third set were perhaps the more delightful pictorially. Fine mountains, streams, and wooded scenery evidently abound in this charming district. The CHAIRMAN expressed thanks to the Liverpool Amateur Photographic Association.

Liverpool Amateur Photographic Association.—March 16.—Mr. F. HOPE-JONES delivered a lecture on *Eural*, the deserted mansion of the Puleston family on the river Dee, some fifteen miles south of Chester. Photographers are always on the look-out for fresh subjects at which to level their cameras, and this interesting ruin provides picturesque material for them. In addition to this, its historical associations are important, and form an excellent subject for a lantern lecture.

RAPID SOLUTION MAKING.

To the EDITOR.

SIR,—I think it matter for unfeigned regret that Mr. G. W. Webster should have introduced personal feeling into the discussion of a trifling detail of laboratory practice.

I recall with pardonable pride the fact that I have enjoyed the privilege of contributing to the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY for thirty-seven years, from seven pages in a month to a brief paragraph in a week, and I think, Sir, you will bear me out when I say that never until now have I been accused of making use of "covert sneers," or "accusations of making false claims," and I beg to assure you that nothing was further from my mind when writing the letter you did me the honour to publish in your JOURNAL for February 24.

I hope to have the pleasure of meeting Mr. G. W. Webster at the Plymouth meeting of the Photographic Convention, and am therefore specially desirous to avoid saying anything now which might lead to the formation then of a "four-and-twenty feet ring, clear stage, and no favour" in front of the Sir Francis Drake statue on Plymouth Hoe. I beg to assure him that I was perfectly sincere in expressing the opinion that photographers uninstructed in chemical manipulations should feel indebted to the gentlemen named—not specially to Mr. Webster, but to Messrs. Baird and Ayres, who, by the way, do *not* accuse me of sneering.

In his article in the JOURNAL for February 17, Mr. G. W. Webster uses the expression, "In my own case the *invention* was spontaneous." What is this but a claim to having invented an article on sale at Doulton's? Again I say I was equally sincere in feeling "amused" at this claim.

My acquaintance with hyposulphites and their comparative instability dates from 1843, and that knowledge leads me to prefer freshly prepared solutions rather than stale ones laid on in pipes, and after five years' systematic study in a public laboratory, should have found Mr. G. W. Webster's instructions *re* solution-making more acceptable if the accompanying sneer, so far from being "covert," had been less palpable.

I will not trespass on your space to defend "Atticus" (whom I have never had the pleasure of meeting); but as I feel grateful for his suggestion of a calico-covered basket, which I consider preferable to the

lacquerer's "dipping" basket or my own strainer, I cannot refrain from expressing regret that he should have been the subject of such unguarded personality as is contained in the JOURNAL for March 17.—I am, yours, &c., J. MARTIN.

Photographic Works, New Southgate, N.

"ATTICUS'" DEFENCE—RAPID SOLUTION-MAKING.

To the EDITOR.

SIR,—"Atticus is of no account" (so Mr. G. Watmough Webster says in last week's JOURNAL), "but appears to be readily amused." True, "Atticus" is amused at times at the resurrection of old processes and methods, and, though they be reclothed in thick material, the disguise is often not thick enough.

Mr. Webster, however, is very thin-skinned, for even gentlemanly and just criticism produces literary convulsions of a rather inconvenient nature to him; nevertheless, he must not forget that the JOURNAL is the mouthpiece of the profession, and not that of the individual. He charges "Atticus" with untruthfulness; therefore, and not without reason, "Atticus" sharpens his quill to repel and repudiate the charge. "Atticus" is accused of not knowing the difference between a dark room and a laboratory, and that he never uses sulphite in making stock solution of pyro. This is the red herring across the trail, and it must be left to its own natural decomposition; but it is advisable not to go too near during the last stages of decay.

Mr. Webster, at page 100 of the JOURNAL, says, "We all know that great minds think alike. Doubtless, in our case" (*i.e.*, Webster and Ayres) *the invention was original*, whichever claims priority of publication." However, at page 164, Mr. Webster changes front, and says, "This principle of rapid solution" (*i.e.*, the Doulton dipping basket) "is of historical age, and that he used it thirty-five years ago."

Mr. Webster insinuates that "Atticus" must "have a specially original copy of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1893, for it contains statements not to be found in any other copy." The article quoted is "Rapid Solution Making," page 668. The writer says, "His duties consisted in making sundry solutions for stock and otherwise, *i.e.*, pyro, hypo, sulphite, chrome alum," &c. He "sought out the easiest method, and found the Doulton dipping basket a complete success, dissolving the substances named (pyro, hypo, &c.) in a remarkably short time." These are the statements Mr. Webster says that cannot be found in any other copy of this year's ALMANAC. The dissolving of pyrogallic acid in a Doulton dipping basket would certainly prove most expeditious!

Finally, Mr. Webster says (page 164), "It goes without saying that the particular application of the dipping basket is only one of a hundred plans that may be adopted for the same end." This may, or may not, be *tall talk*, but if Mr. Webster will name six practical methods, out of the hundreds he knows of, by which rapid solution can be effected—to meet easily and practically the wants of an every-day photographer—and will supply the information (within a reasonable time) through the pages of the JOURNAL, using cold water in all cases, and not adopting any methods already published in his or his son's articles, "Atticus" will give half a guinea to the funds of the Photographers' Benevolent Association.—I am, yours, &c., ATTICUS.

March 20, 1893.

"CHEAP MOUNTS: A PLEA FOR QUALITY"—THE CAP FITS.

To the EDITOR.

SIR,—In your JOURNAL of the 17th inst. we notice a criticism upon the quality of some mounts just recently circulated. It emanates from a card manufacturer.

There is no doubt in our minds as to the criticisms being intended for our goods, consequently it will be only fair if you will kindly place our reply before your readers, most of whom will have received our samples, and have read the short article referred to.

The mass of buyers with ordinary foresight and sense can only be expected to buy in the market which gives them best value for their money. The selling individuals who have only used proper discretion in pricing their goods, and have had the good fortune after twenty years' sleep (*vide* Rip Van Winkle) to awake to the fact that there is room for other players on the Tom Tiddler's ground of photo-mount makers, cannot be blamed for entering into competition with your irate correspondent, "A Card Manufacturer."

As regards *cheapness*, so often referred to in the article in question, we submit there is no doubt the prices are not extortionate.

There is one serious allegation made, and that is in regard to the durability of, presumably, our mounts, which, if allowed to go uncontradicted, is calculated to do us a great deal of mischief; and as a full answer to this, we are prepared to prove that our "Special Bristol Mount" (the cheapest of those submitted) contains more pure paper than many of the mounts now being offered by other manufacturers.

As regards "A Card Manufacturer's" interests, they are, or should be, mutual with that of the consumer; and assuming your correspondent to be an Englishman, it is time he learned that, by his *gradual* descent in prices, he is helping the foreigner to the whole of a trade that could, and should, be kept in Great Britain, and that there is only one way to regain the photographers' and dealers' confidence, viz., by giving them prices as low as our foreign *confrères* for an article equally as good. This is a Rip Van Winkle's idea of the matter.—We are, yours, &c.,

Pro WILLIS & CO. (LIMITED),
The Long Acre Card Works, London, W.C. F. W. ALLEN.

THE SANDELL PLATES.

To the EDITOR.

SIR,—Needless to say I have read with interest Mr. W. J. Stillman's note on the "Sandell" plates in your last issue, and, with your permission, will endeavour to furnish answers to the pertinent queries contained therein.

The first question, as to whether the absence of halation is due to the thickness of the aggregate coatings, or to the use of emulsions of varying degrees of rapidity? In the case of interiors, it is undoubtedly due to the latter cause, for the triple film, although obstructing a great deal of light, transmits amply sufficient to powerfully react on the most sensitive films if its reflections could pass the lower strata, which is practically impossible.

I may say that before adopting the multiple-film plan, I tried a much thicker film of the rapid emulsion than the combined films furnish, but the results were in no way comparable for the rendering of contrasts. Not only was halation obtainable, but solarisation proved an insperable difficulty, and then the thickness of the film used required an impossible period for fixation.

Secondly, it is not possible that there is any interchange or intermingling of chemical qualities during coating, as will, I think, be understood after the following explanation. The after-coating is only applied when the previous one is perfectly dry, and the bringing into contact of, say, one part of emulsion at 130° Fahr., whose setting point is somewhere between 70° and 80°, with twelve parts of dry emulsion and glass at 60°, will furnish the reason; the setting takes place too rapidly, the absorption of moisture by the dry film or films promoting this. Of course I am assuming that the insoluble nature of the sensitive haloids is understood.

I should mention the fact, well known to emulsion-makers, that the dried emulsion would require a prolonged digestion at 130° to cause a remelting, and I strongly hold the opinion that there can be no migration of silver haloid in a set film.

This, then, will constitute my reply to the third query also.

Proof that the light has effectively penetrated the films in my interiors is furnished by the fact that in almost every case the maximum negative effect is always in the lowest film. Of this result I am assured when I find my window already apparent before development on the surface of the plate as a negative. This, however, disappears soon after development is commenced, a perfect positive taking its place. Then I am sure that solarisation is complete in the upper film (*i.e.*, for the window), partially so in the second film, and at this juncture the third is a *sine-quâ-non*.

Under-exposure of upper film, and under or over-development of lower films, are the only probable causes of failures with these plates. A short or the normal exposure of a single highly sensitive film may be developed by a normal developer; but where strong contrasts are photographed, a weak well-restrained developer should be used until almost sufficient density is obtained in the highest lights, then the shadows which are rendered on the film surface should be brought up by a strong developer. The seeming diffidence of our experts, Sir, in discussing the plates must be my excuse for troubling you to this length.—I am, yours, &c.,

Thornton Heath, March 20, 1893. J. T. SANDELL.

CONTINENTAL POSTAL REGULATIONS AND PHOTOGRAPHIC MATTER.

To the EDITOR.

SIR,—It is to be desired that representations should be made to the Post Office authorities in England with regard to the illiberality of their treatment of photographic matter in transmission to the Continent, as in this respect they are behind most of the European powers. The Italian Post Office permits the transmission of packets of photographic material by sample post, under limits of weight, and with the declaration that the value does not exceed four shillings (five francs), and allows them to pass unopened if inscribed "*tema la luce*" (must not be exposed to the light). If, on the contrary, I order a packet of Solio paper from England, I am told that the end of the packet must be left open, and if it be an order, though ever so small, that it cannot go as a sample but must be sent by parcels post or as a letter. The consequence is that the cost is such as to make the order out of question, and all this little commerce, so convenient here, is forbidden us from England, with the effect of making us dependent on Continental supplies. This is neith

for the good of trade nor the convenience of amateurs, a numerous class nowadays on the Continent, hailing mostly from England and America, and naturally using English material by preference on account of the sizes. A dozen celluloid films, 8 × 10, sent by sample post, would cost about sixpence, but by parcels post about two shillings more. Then the Custom House here always respects the caution not to open in the light, if made intelligible to the officers, and in the Club we have a special label—"entered"—at the Custom House, and which secures any package or sample from being opened. In fact, the Italian Government, poor as it is, consults the convenience of the photographer, both as to security and expense, while the rich English Government does neither. Is there no member of the House of Commons who is an amateur, and would make himself the mouthpiece of the class of travelling photographers, and help to get this abuse corrected? As it now stands, I am often obliged to pay, in order to get some trifling object that I may have immediate need for, several times the value of the article.

What would be the injury to the income of the Post Office if the rules of the Italian Office were adopted, viz., that any article under a kilogramme in weight, and declared of no value, should go by sample post, and, when inscribed by the sending house as sensitive to light, to be allowed to go unopened?—I am, yours, &c., W. J. Stillman.

Rome, March 13.

GLYCERINE.

To the Editor.

Sir,—On starting to read "Beware of Glycerine!" by Mr. Hector Maclean, I expected to find some reference to its nitro compounds. "Citric or other acid" is delightfully vague, and I would remark that it says very little for the permanence of the platinum image if these *supposed* acids were the cause of fading. Was it not due to a mechanical, and not a chemical, action by the image being formed *above* the paper surface?

I have tested my stock of glycerine, but find no trace of acid reaction in a colourless commercial sample. Your correspondent can get a well-known British brand of glycerine for the asking, and it might have saved him from an all-too-contemptuous observation, for I can assure him more than shams are made in Germany, with brains too.—I am, yours, &c.,

March 17, 1893. Arthur Spat.

TESTING THE SPEED OF SENSITIVE FILMS.

To the Editor.

Sir,—Here is a point on which I should be glad to receive instruction. Given two sources of light, the respective actinic powers of which are as 100 to 1, will the effect on a sensitive film be the same from an exposure either of one tenth of a second to the stronger, or of ten seconds to the weaker light, all other surroundings being equal? My notion is that the blow of the one will do more than the push of the other. The behaviour of an exposed film, when acted upon by strong and weak disturbing forces, is perhaps of no scientific value in determing this question; still, it may be worth while to remember that a very fully exposed film will be ruined as a negative by the rapid action of a quick developer, but can be turned to good account by the use of a less vigorous reducing agent.—I am, yours, &c., Angler.

March 18, 1893.

MIXED DEVELOPERS.

To the Editor.

Sir,—I read with much interest your leader on mixed developers. I have lately been using a mixed developer—eikonogen and hydroquinone—with very good results. Having received some metol for trial from Messrs. Fuerst, I found that, with the formula that accompanied it, it was impossible to get sufficient density, though the detail was excellent. I thought I would try it mixed with hydroquinone, and made up some in the following proportions:—

No. 1.

Metol	3½	grammes.
Hydroquinone	1	,,
Sulphate of soda	25	,,
Water	200	,,

No. 2.

Water	50	grammes.
Potassium carbonate	12½	,,

For every sixty grammes of No. 1, I add ten to twelve of No. 2. After mixing No. 1, and letting it stand for a few hours, there is a dense flocculent precipitate, which must be filtered out. The solution then remains quite colourless for several days, and, as a developer, gives abundant detail, and very good density. Perhaps some of your readers who are chemists may be able to explain the nature of the precipitate. All my experiments were made on snap-shot exposures. I may mention that the mount of metol in the developer is more than the amount recommended in the printed directions; but this is not the reason of the improved density, as I tried the stronger solution without hydroquinone, and found it did not give me sufficient density.—I am, yours, &c.,

Morristown Lattin, Naas, March 19, 1893. George Mansfield.

MADDOX FUND.

To the Editor.

Sir,—I have the pleasure to acknowledge the receipt from Dr. A. C. Mercer, of Syracuse, New York, U.S.A., of the sum of 16*l.* 8*s.* 6*d.* for the above Fund, which was closed some time ago. I have placed the money in the hands of Dr. Maddox. The sum is contributed as follows:—

Mr. Ed. Bausch (Bausch and Lomb)	$25
Syracuse Camera Club	$55

I am yours. &c., Andrew Pringle,

Cromwell House, Bexley Heath, S.E. *Hon. Secretary.*

"HONOUR AMONGST PHOTOGRAPHERS."

To the Editor.

Sir,—A paragraph in your issue of the 17th inst., entitled "Trusting to Honour," contains the following sentence: "We should like to see the element of 'honour' entering more largely into competition among professional photographers than this and other recent advertisements would indicate as prevalent." You might, Sir, without doing any one a crying injustice, have applied your remarks to photographic assistants also, for in no case would it have fitted more neatly than between master and man, and in no case does the "element of honour" stand more in need of some revivifying influence. The following is an instance within the writer's experience, and has its bearing upon both parties:—

An assistant accepts the offer of a permanent situation in a provincial town, settles to work, and does his level best through a busy season. A week before Christmas, when work has slackened, and bids fair to remain slack for a period, he receives a week's notice without any previous warning whatever. Upon reminding his employer of the terms upon which he came, he is informed that it is a question of ability, and that complaints have been made of his work—that, in fact, he is generally incapable. Should he proceed against his employer for wrongful dismissal? He knows by this time he has a slippery customer to deal with, and that the chief point in his favour—viz., that no previous complaint has been made—he has but his own bare word to support. He accepts the inevitable, therefore, treating his employer's mean action with the contempt it deserves. The vacancy created by his departure is not again filled until fully *fully three months afterwards.* This latter should be sufficiently significant.

The consequences resultant upon the wrongful dismissal are not at first realised by the assistant. Truly, he is out of work at a slack time, but then he takes the optimistic view that, to a man of ability, all periods are alike. He finds that not only is he out of work in a slack period, but also a period representing the beginning of two or three years' photographic stagnation. He finds his optimistic impression confirmed, in a sense, for many will employ him, but at a wage that every right principle rises against. He can advertise—yes, of course, he can advertise—and in doing so, finds that his modesty is shadowed by the wants of half-a-dozen columns of high-class assistants. He finds that he must increase the size of the adjectives applied to his own abilities, to compensate for the customary *cum-grano-salis* application of the employer—that, in fact, he must lie with the crowd or be ignored as a duffer. Now, strange to say, he considers himself above the crowd in the points of ability and honesty, and is therefore shy of scrambling for his daily bread in competition amongst it. He stands on one side to allow the crowd to pass, but, before doing so, has the last straw of obnoxious conviction forced upon him. Upon stating his requirements to a certain great man, he is met with the calm reply, "My dear sir, you cannot surely expect to obtain such a salary now. *Look at the number of good assistants out of work!*" which is merely the equivalent of saying, "Though not slack ourselves, we must certainly take advantage of the general slackness, and obtain assistance at a cheaper rate than we could do at a busier time." Pure speculation! Miserable money-grabbing! that brings after it a necessary train of evils. So the assistant gasps a little at this new conviction, and then stands aside, mentally putting his foot down in firm resolve to take a position to which his abilities entitle him, or to accept none; to wait for a better time and tide over the present by giving occasional help, though identifying himself with no man's interest. A foolish attitude possibly, but an honest one certainly, not actuated by self-interest only, but with a small amount of thought for his brother-assistant in a like case. Need it be said that this assistant still leads his Bohemian existence?

This case, you will doubtless say, Sir, is ordinary enough to admit of its authenticity being taken for granted. It is not a case towards which the writer desires to call public attention; neither is it one upon which he wishes to base a literary endeavour of the descriptive type; but rather one that he wishes to state as an evil, and suggest a partial remedy thereto. The cause, according to the writer's belief, is the lack of orderly division

amongst photographers, the path from the lowest to the highest being one smooth, gradual ascent, instead of clearly marked steps and landing-places. Employer and assistant lack the distinctive stamp that shall assign to them a definite position upon the photographic scale. It has become a question, not of what a man is, but of what he calls himself, and owing to the absence of honour to which, Sir, you have called attention, each—man to master, master to man—apply a rigid forefinger to their olfactory organs, playfully but sceptically. Each views with suspicion, and is viewed with suspicion again, owing to the "leaven of unrighteousness" that exists among them. The cure can only be in reinstating the worth of man's word, or, failing that, by "separating the sheep from the goats," the latter being the only practicable course. I ask you, Sir, and any of your many readers, what assistant, conscious of the fairness of his intentions, and of the reliance that may be placed upon his abilities, would refuse any test sufficient to ensure him a definite and decided position upon the photographic scale? In former times a man's testimonials seemed all-sufficient, but now, what with bogus testimonials, testimonials written by employers out of pity and knowingly false, added to those firms who refuse testimonials at all times, the written character is looked upon as so much waste paper. Numbers of assistants would raise themselves above the crowd, free from the taint of suspicion with which they are viewed, be they never so clever, were the means but open to them.

Let me suggest a scheme for ameliorating the condition of retouchers. Supposing a negative presenting average difficulties were carefully chosen by, say, the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, and a number of negatives reproduced from it. Supposing the same authority were then to invite any retouchers so minded to acquire one of these reproductions by payment of a certain fee, and guarantee to assign him a distinct position on the list of retouchers according to the work he produces from it—intensification, reduction, and all printing processes being optional. Supposing that this list of retouchers were made containing a certain number of grades, and that each competitor were assigned a position in one or the other by careful comparison with the original print. Supposing such an idea were put into practice, would it meet with approval? To the man who fears a comparative test it would not; but to the genuine assistant it must, because of the secure footing it offers him. Some one asks, "By what means?" When a retoucher is out of work, instead of advertising, he sends up a fee and has his name placed upon the "open list." Any employer wishing for a man of ability sends in a fee and has his name placed upon the "Open List." Every employer wishing for a man of ability sends in a fee and obtains a copy of the "Open List." Selecting what grade or position he pleases, he corresponds with one or another, and is shown the piece of work that secured the position; being satisfied as to ability, the rest is easy.

Such, then, is the rough outline of a plan, the strong point of which is, if once started, it must act and react upon employers and employed—employers taking to it as the best means of obtaining genuine ability; assistants taking to it as a means of proving their genuineness. The greatest fault will be found with it as a species of monopoly, though surely the legitimate worker has a right to a monopoly that will exclude none but fools and rogues.

I fear Sir, that, should you consider this worthy of publication, I shall have already occupied too much space, although I have written but a rough outline of all I would say. The details, however, would present little difficulty should the rough sketch meet with approval, and my apology must lie in the importance of the defence of the honourable portion of a not now too honourable profession.—I am, yours, &c.,

March 21, 1893. N'IMPORTE.

"A HARD CASE."

To the EDITOR.

SIR,—Would you oblige me by giving your opinion on the following. I went apprentice to a photographer on September 10, 1887, and was bound January 9, 1888, and came out of my time January 9, 1892—serving four years' apprenticeship. For three years I took no photographs, then he told me if anybody came while he was out I could try my hand. I did so, and during the last year I took about thirty-five sitters, mostly *cartes*, and one cabinet group of three sitters. Some of the thirty-five I took when he was in; he did the arranging of positions, and I the focussing. I never did a bromide enlargement, and only a few cabinet-size outdoor views. He does not do his own retouching, so I tried it at home on the quiet, and got on fairly well after reading Mr. Redmond Barrett's writings on the subject; toning and printing I had pretty well practiced; very little, indeed, practice at mounting. My principal work was dusting, looking after fires, and filling up picture-frames, and suchlike work. Taking the year all round, he does a good trade and a good deal of picture work.

My wages were 2*s.* 6*d.* for the first year, 3*s.*, 4*s.*, 5*s.* When I came out of my time, he asked me to stay on with him for a year or so, so that he could push me on. I consented to do so, for if I felt so minded to take another place, I could not have done so, owing to my knowing so little. He said he would take another apprentice, and keep me to the business. He said he would give me 10*s.* a week for the first six months, and 12*s.* for the next. I then told him that I could do a little retouching. He said I should try my hand, and, if successful, he would give me a little extra. The first week I got 12*s.*, next 11*s.*, next 10*s.* 6*d.*, next 13*s.*, then 15*s.*; now it has got to 17*s.* a week. He only took an apprentice last week. I only took five sitters during the fifteen months, very little outdoor work—only a few traps and a church. I have never taken a whole-plate or a 12 × 10. I never tried to do a bromide enlargement till last week; in fact, instead of improving myself, I lost what little bit I did learn during the last year of my apprenticeship. Once a couple came to be taken together, and my employer was at the back, and I went into the studio with them and started taking, and he came in and stopped me, and said before them that I had no business starting taking them when he was at home; it was all very well when he was out. Whether right or wrong on my part, he ought not to have spoken to me like that before them, for them to tell it about to people. A few weeks ago I asked him to push me on, as time was getting on, and there was a deal of opposition in our trade, which made it more reason why I should try and learn more. He said he could not see how he could do any different, as nobody came when he was out, and people liked him to take them when he was in. Since asking him I have not taken anybody. He does all the operating himself. This is a large county town, and we have plenty of the working class of people in, but not even them does he let me take.

In fact I am in such a state that if anybody came now and he was out I could not take them, I should feel so strange, as if I never had taken anybody before. Of course I feel thoroughly disheartened, and my time is no pleasant one, as I have no prospect before me. Should you advise me to give it up altogether and turn to some other trade, as I cannot take another situation, as I know so little, not one-quarter as much as I did when I came out of my time, because what little I did learn I have forgotten? His daughter has been away to learn retouching, finishing, &c., and she is coming home in September. Of course he will not want me then. If I took every sitter from now till then, I should only just about feel competent of doing anything like at another place. Sorry I have made my case so long, but it will greatly oblige me by your opinion.—I am, yours, &c. A. E. T.

March 20, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Wanted, first-class enlarging camera, large size, in exchange for Marion's five-guinea embossing press, with four dies, as new.—Address, W. WALKER, Scotholme, Nottingham.

Electric engraving machine, in perfect order, with battery, offered in exchange for 12×10 field camera in good condition.—Address, E. WAITE, 10, Grundy-street, Radcliffe, near Manchester.

Exchange enlarging lantern, nine-inch condensers, with front lens, blow-through jet for limelight, gas bag, pressure boards, &c., for good safety cycle, cushion or pneumatic tyres.—Address, A. COUPE, Photographer, Withington, Manchester.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Robert Jennings, Blackburn.—*Photograph of Edward John Williams.*

William Emmett, Stalybridge.—*Photograph of Lieut.-Colonel Sidebottom, V.D.J.P.*

Underwood & Underwood, Liverpool.—*Fifty-one stereoscopic photographs of various subjects.*

Abraham Flatters, Openshaw.—*Photograph of tranverse sections of the cotton fibre on micrometer scale.*

John Clapperton, Galashiels.—*Photograph of John Dunlop, champion bicycle rider of Scotland, and long distance rider of the world.*

Marshall George Strapps, Wisbech.—*Photograph of carved oak frame representing incidents in the life of the Right Hon. W. E. Gladstone.*

William Wort, Sutton Coldfield.—*One photograph of Frank Howson, professional boxer; Joseph Knowles, trainer; and Arthur Hibberson, assistant trainer.*

H. MACE, A. McCANN, and others.—In our next.

POWDER.—The powder process is fully described at pages 417, 433, and 449 of our volume for 1888.

C. N. FRITH.—Pressure of other engagements prevents us from availing ourselves of the honour. Thanks, nevertheless.

G. H. DUNMORE.—Remit one and sevenpence and three copies of the photograph to our publishers, who will effect the registration for you.

A. Z. (Leeds).—If it is simply a monogram you have on the cards, no licence is needed; but if it is a crest, then a licence will be necessary.

SURGEON-GENERAL COOK.—1. At the office for the sale of Patent Specifications, price 8*d*. 2. Mr. Andrew Pringle's address is Cromwell House, Bexley Heath, S.E.

P. P.—If the prints are made quite dry they will not stick to the burnisher. But it is a good plan to lubricate them with a solution of Castile soap, one or two grains to the ounce of alcohol.

A. R. T.—It is quite true that a patent was applied for for a "Willesden Paper" for photographic pictures. But, so far as we know, it has not been put upon the market. Why we cannot say.

DON.—As the marking can be seen on the plates before they are exposed, it is clear they are not due to carelessness on the part of the user. If the marks are in the film, there is no way of avoiding them when developing.

C. G. ADLETT (Port Elizabeth).—We think the set of three photographs marked "Pluto" entitled to first place; but the superiority over "Coningsby's" is only very slight. We have forwarded the photographs as requested.

CHEMIST.—If you wish to know what the action of light is on silver salts, consult Dr. Eder's *Chemical Effect of the Spectrum*. Your question as to the "action of light on certain substances" is, however, rather ambiguous.

HENRY SUTTON, Geo. Colley, B. B. (Antwerp), F. Johnson, W. H. P., T. H. Faulks, S. H. R. Salmon, H. C. Jennings, W. Guttenberg.—On the abstract subject underlying your various communications, we think it well not to permit any correspondence to be opened in the JOURNAL. But this does not apply to records of actual experiments.

SAMUEL WRIGHT.—In enlarging by daylight no condenser is necessary. Simply direct the negative itself to the sky, or place a piece of white cardboard at an angle of forty-five degrees, so as to reflect light from the sky upon it.

ASSAY.—It is, we believe, illegal to use the current coin of the realm for making chloride of gold. But, for all that, it is often used for the purpose. Those who do so, do not always publish what they have done, we suspect. In employing gold coin, full value in metal is ensured.

E. ARTIS.—1. If you can get the lens to give a sharp image in the centre of the picture while the margins are out of focus, it indicates roundness of field, and that it has been corrected for sitting figures. 2. Either the limelight or oil, it being merely a matter of exposure.

R. D.—Unless the pyro solutions were made up with a preservative, we fear they would be useless for developing purposes. You might, however, try the effect of adding solution of soda sulphite in the proportion of four ounces to the ounce of pyro. Recrystallisation would not, we think, be of much avail.

W. T. SHEPPARD.—Unless an unsuitable pyroxyline was used we cannot say what is wrong. You do not say in what way the collodion is unsatisfactory. We should advise you to get some commercial collodion to compare that of your own make with. Bromo-iodised collodion is quicker than that simply iodised, when iron developer is employed.

W. EMERY.—1. In commencing photo-micrography, you will do well to confine yourself, for a time, to the use of low powers, say, an inch and a half or an inch. When some degree of proficiency is attained with these, the higher powers may be tried. 2. We shall be pleased to give our opinion on the work from time to time. 3. Slow plates to begin with.

J. BLOWER.—The experience is not exceptional. Prints made on rose-tinted paper invariably change when exposed for long to a strong light. The colour is simply discharged by its action. Had the prints been kept in an album or portfolio, they would not have changed in that way. The loss of the pink tint is not necessarily an indication that the photograph is fading.

R. B. J. says that some of his negatives have grown some curious excrescences something like the scales of fishes, and although they can be washed off, they leave a mark. He asks what they are. From the description, there is very little doubt that it is hyposulphite of soda crystallising out of the film. This could only arise from the negatives having received only the most perfunctory of washings.

C. R.—This correspondent says that he sent a negative to a firm for an enlargement, and explained that, although he was an amateur, he was going to supply this picture as a matter of business. He complains that they will not allow him any "trade discount." Why should they? Trade discount, when given, is only allowed to *bonâ-fide* professional photographers, and not to those sailing under false colours.

FRANK OSBORNE writes: "Can you give me any information how I can make a solution of bichromatised bitumen capable of being developed in cold water, or where can I find any instructions on the bichromatised bitumen process?"—We certainly cannot say. We do not know how to make bitumen soluble in water, hot or cold. Has not our correspondent made some mistake in the matter?

B. HERSCHE writes: "I have made up thirty ounces of silver bath—fifty grains to the ounce—and added a few drops of nitric acid. I have only used it three or four times, and it has turned quite brown—nearly black—and it now discolours the paper. Is the bath spoilt, and how?"—The bath is not hurt. If it be shaken up with a little kaolin, and then allowed to stand for a day or so, it will be as bright and colourless as it was at first. The kaolin may be allowed to remain in the bottle.

H. PIQUET.—1. The price you have charged is not only "reasonable" but very low, much less indeed than would have been charged by the majority of photographers. 2. As for the time, it was very short to execute such an order at that season of the year. We should say you will have no difficulty in recovering the amount in the County Court. At the hearing of the case you had better be provided with photographic witnesses of good standing to testify as to the reasonableness of the charges. You will recover their expenses as witnesses.

WILLIAM CONNOR says: "I am trying my hand at enamelling prints. The way I proceed is this. I first French chalk the plates. Then coat them with collodion and allow it to dry. Next place the plates on a levelling stand and pour on a solution of gelatine, and, after this has set and stood a few hours, I take the prints from the washing water and squeegee them down upon it, and I have got excellent results. But now I have got a fresh lot of gelatine, of a whiter kind than I have hitherto used, and this, when poured on the plate, as soon as it begins to set, becomes studded all over with little holes or specks. They don't seem to show much in the prints, but still they are there. Can you tell me the cause and how they may be prevented?"—The cause is an unsuitable gelatine—one that "pits," as many foreign gelatines do. The defect is generally attributed to grease in the gelatine. If a very colourless gelatine must be employed, try one of those specially adapted for dry-plate purposes.

AFFILIATION OF SOCIETIES.—Meeting of delegates at seven p.m., Friday March 24, at 50, Great Russell-street, W.C.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical Meeting, Tuesday, March 28. A demonstration of *Platinotype Printing*, by Mr. F. Hollyer.

AMONG the papers to be read at the Society of Arts after Easter will be one on *The Optical Correction of Photographic Perspective*, by Mr. H. Van der Weyde.

PHOTOGRAPHIC CLUB.—March 29, Last Lantern Meeting of the season. April 5, Adjourned discussion on *The Sandell Plate* and *Toning Chloride Prints*.

A FREE LANTERN LECTURE.—The Harringay Photographic Society will give a lantern lecture to-night (Friday, March 24) at Emmanuel Church, Ducket-road, Harringay, entitled *The Thames from Source to Sea*, at eight o'clock. Admission free; ladies invited.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 30, *The Sandell Plate*, demonstration by S. H. Fry; also *Stripping Gelatine Plates for Collotype Work* demonstration by W. J. Rawlings. April 6. A paper by Mr. G. F. Williams on the *Determination of Plate Speeds*. 13, *The Influence of the Hand Camera*, paper by W. D. Welford. Visitors are welcomed.

CROYDON PHOTOGRAPHIC EXHIBITION.—This Exhibition, which opens on April 5, promises to be most successful. Messrs. B. Gay Wilkinson, T. M. Brownrigg, J. Gale, and John A. Hodges give special lantern displays on the four evenings during which it is open. The demand for the prospectuses has been so great that a reprint has been necessary. Our readers should note that Saturday is the last day to receive notices of entry, which should be sent (no forms necessary) to G. R. White, 55, Albert-road, Croydon.

VANDERWEYDE'S CHICAGO EXHIBITS.—Mr. Vanderweyde is evidently determined not to occupy a secondary position at the "World's Fair." He is sending nearly forty of his choicest works; many of these demonstrate the advantages of his photo-corrector, which he has now brought to a state of perfection or almost so. The *salon* in which they are to be exhibited is richly furnished and complete, including carpet, and, being made portable, is to be packed up here ready to be set up. The most imposing of his pictorial collection is a truly fine work of art, the subject being *Hypatia invoking Apollo*. It is eight feet in height, and, so far as the figure itself is concerned, is quite untouched. In this noble work the artist has, to our thinking, exceeded himself.

A SOCIETY FOR BEVERLEY.—A meeting of amateurs was held last week at the Church Institute for the purpose of considering the desirability of forming an Association for the town and neighbourhood. The Rev. F. J. Hall was voted to the chair. After some discussion, in which it was stated that the number of amateurs locally was about fifty, and that a good organization could be inaugurated, it was unanimously decided to form a Society under the designation of the "Beverley Photographic Society," and it was further agreed that the first field day be on Easter Monday to Bishop Burton. Any pamphlets, samples, society-working rules, &c., will be gladly received by the Hon. Secretaries *pro tem.*, J. J. Morley and A. Pickering.

*** GOOD FRIDAY.—*As Good Friday falls next week, we shall be obliged if our correspondents will note that it will be necessary for us to go to press a day earlier than usual. All communications intended for the next number of the* JOURNAL *should therefore reach us by Tuesday Morning.*

MULTIPLE-COATED FILMS.

It seems more than likely that the subject of multiple-coated films will form matter for interesting discussion for some time to come, since, underlying the fact that such films prove the most effective cure for, or preventive of, halation that has yet been devised, there is the question as to how the effect is produced. Is it the mere extra opacity of the double or triple film that prevents the rays of light penetrating to the glass, and to be thrown back again upon the sensitive layer of gelatine, or do the separate films of varying sensitiveness react in some peculiar way, one upon another, in such a manner as to contribute to, if not altogether to bring about, the result? Such is the question already raised, which will have to be satisfactorily answered.

Double films are by no means a novelty in photography, for if we go back to the very earliest of practical dry-plate processes—the collodio-albumen—we find that that was a double-film process, a preliminary layer of silver iodide in collodion being subsequently coated with iodised albumen, sensitised in a bath of silver nitrate, washed and dried. There is, however, little analogy between the double-coated film of to-day and that of forty years ago. The former consists of two separate layers of sensitive gelatine, each possessing a different degree of sensitiveness, while in the older process the sensitiveness was most probably uniform throughout the whole thickness of the compound film, or as nearly so as is possible with any bath film.

The lower, or collodion film, it is true, was, *per se*, quite insensitive, being prepared in such a manner, with excess of alkaline iodide, that exposure to light before the application of the second or albumen film was said rather to improve the qualities of the plate than otherwise; but, after recoating with iodised albumen, and immersion a second time in the silver bath, the sensitiveness of the iodide of silver in the under layer of collodion was restored, and little difference, we imagine, was to be found in the character of the film at different depths. Even when, later on, bromide was introduced into the second film, it is questionable whether any alteration took place in this respect, for the albumen would more or less sink into the pores of the collodion, and form a practically homogeneous layer instead of being altogether isolated, as in the modern compound films. There is, however, one very noteworthy fact that may be mentioned in connexion with the old collodio-albumenised plates, namely, that, although they were by no means remarkable for opacity, they were wonderfully free from the defect now known as halation.

Some seventeen or eighteen years ago double films cropped up again, this time in a purely scientific rather than a practical form. Captain Abney published the result of a series of experiments of his own, showing that if a sensitive film after exposure were recoated with a second layer of washed collodion emulsion, and then developed, an image would be formed upon both films, that which had not been exposed being affected in some peculiar manner by the chemical action proceeding in the other. The two films in this experiment were even more completely isolated than is the case in the modern multiple film, as, in order to prevent the second layer of emulsion dissolving the film upon which it was poured, as well as to enable the two films to be afterwards separated for examination, an intermediate layer of gum arabic, albumen, or similar substance, was applied in such manner that the two films were actually not even in contact.

It is, perhaps, only right to say that there are those who doubt the accuracy of the observations in connexion with the production of the image on the unexposed film, but from our own trials we think there is little doubt that, under favourable circumstances, it does occur, though there is considerable uncertainty as to what the precise conditions are. We have on many occasions obtained unmistakable evidence of development on the unexposed film, and at other times, under apparently precisely the same circumstances, have altogether failed. So that it may be said there is some doubt as to the possibility of any action taking place between films that are completely isolated—at any rate, in the way of setting up a developing action when there has been no exposure. The reverse effect might possibly occur under precisely similar conditions from easily explainable causes, as we shall point out later; in other words, development might be arrested in one film by that going on in another.

As an outcome of Captain Abney's experiments, it was attempted to utilise the principle of double coating for the purpose of producing composite films combining qualities that could not be obtained in the same emulsion. Thus, it will be remembered, by those of our readers whose acquaintanceship with photography dates back to the period mentioned, that the great difficulty with collodion emulsion workers was to combine extreme sensitiveness with the necessary vigour required in a printing negative. Very sensitive emulsions could be made—not approaching, it is true, the films of to-day—but they were of no practical value, owing to the impossibility of intensifying the images they produced by any known means. On the other hand, it was quite easy to get any desired amount of vigour in an emulsion, but unfortunately only in conjunction with comparative insensitiveness.

Acting on Captain Abney's suggestion, it seemed but natural that, if a plate were coated, first with a slow and vigorous

emulsion and afterwards with one of the rapid and delicate type, the difficulty would be solved, and such in a partial manner proved to be the case; but, owing to the troublesome character of the double-coating process, the matter was never at that time seriously carried out. In more recent years, since the introduction of gelatine emulsions, numerous suggestions have been made, and, we believe, at least one actual commercial attempt to introduce collodio-gelatine plates—that is to say, double films of gelatine and collodion; but, for one reason or another, most probably the extra trouble, the matter has never been followed up.

While the scientific aspect, if we may so term it, of double films has been altogether neglected, the various attempts to utilise the principle practically have hitherto failed, and it is only at the present juncture, when success has been secured in a direction not hitherto looked for, that interest is again aroused. The special claims made for the modern composite films are great latitude of exposure and capability of resisting halation, and both of these seem to be well fulfilled. The former partly covers the ground attempted some fifteen or sixteen years ago, when it was endeavoured to combine rapidity with density, for the result is arrived at by the same means, namely, combining two emulsions of widely different sensitiveness, and so far the *rationale* of the behaviour of the compound film is intelligible.

But it is on the question of halation that discussion will arise. This formed no part of the argument in past years, if for no other reason than that a very large number of collodion films would have to be superimposed before the opacity of even a single gelatine film would be reached, and, indeed, mere opacity was not then looked upon as a cure for the defect. Even now, as shown by Mr. Stillman's article of a fortnight ago, there are those who doubt it, while Mr. Sandell's letter of last week expressly states that mere thickness of film does not prevent halation.

In order to thoroughly ventilate the question, it would be interesting to experiment with films that could be easily separated after development, in order that the action of one upon the other might be carefully studied. For this purpose we would suggest a gelatine film on the top of a collodion film; and, if a triple film be required, let the first, or lowest, be of albumen, sensitised in the silver bath, and thus rendered quite insoluble. Over this might come a collodion emulsion film, as sensitive as can be made, and over that, again, a layer of gelatine emulsion. With such a combination we should have certainly a wide enough variation in sensitiveness, and, for purposes of examination, any of the layers could be easily dissolved off without affecting the others, which is scarcely the case when gelatine lies on gelatine.

The effect of a double film, as now used, must not be confounded with that referred to in connexion with Captain Abney's experiments. There, an exposed film was supposed to transmit some action to an entirely unexposed one during development; in fact, an electro-chemical action was supposed to be set up. In the modern double or triple film each layer receives a certain exposure, which may be sufficient for the more rapid, but not for the others, and amongst them they make a sort of compromise. Whether the rapid film is able to impart extra energy to the slower film in contact with it or not is one of the points to be decided; but we think there can be little doubt as to its power—where reversal occurs—of arresting development in the other film, and it is, possibly, in great measure to this action that the prevention of halation is at least partly due.

LENS FOG.

In a preceding article on this subject we descanted upon some of the most familiar causes of this little-discussed defect, causes that might be described as mechanical. But even that category was not exhausted by us. Let us next refer to a very evil condition of the lens that is sometimes seen in instruments made by opticians in the foremost rank. It is, perhaps, seen most commonly in portrait lenses, but there are some other particular constructions of lenses in which it is often manifest. We refer to the condition of the external margin of the lens. Too frequently this portion of the glass is simply smoothed in the lathe, and the lens is then burnished or screwed into its cell without further treatment. But we aver that there are very few instruments worked with full aperture where this may not on occasion produce fog. When a lens so defective is used in the open air, or even in a well-built studio, if the camera be placed in such a position as to receive a fair share of light from the sky, a portion of that light will strike this part of the lens, and a portion be reflected into the camera and on the plate, and no other result but a veiled image could be expected. Every objective worked with full aperture should have each of its constituent elements carefully blackened at this part to prevent injurious reflection. An asphalt varnish will, perhaps, be as good a medium as anything to use for the purpose, as, when in proper contact with the glass surface, it practically destroys any reflection likely to occur. That a suggestion as to a desirable varnish is not unnecessary is proved by a lens which is before us while writing. It is made by an eminent foreign manufacturer, the posterior combination being of very considerable thickness, and, possibly to lighten the instrument, coned as regards its external figure. If it is placed in the camera without a diaphragm, there is seen such an amount of light dispersed from the inner surface of this cone that it would be utterly impossible to take a good negative with it if a particle of sky light fell upon the instrument. A judiciously applied coating of asphalt varnish would destroy all this danger. But we would further add, that the protection would be more complete if the surface were more roughly polished instead of smoothed, and rendered like the ground glass of the camera.

Another little-observed form of lens fog, which is almost incapable of cure, is that caused by internal reflection from the various faces of the lenses on the plate itself, when a very brightly lighted object is before the camera. Who is there who has not attempted, say, a group of sitters against an only available background, a whitewashed wall, and been disappointed beyond measure at the result? It is true that some of the fogginess produced under the conditions described is due also to the illumination of the bellows of the camera from the brightly lighted plate, but the main portion is to be credited to the lens. For photographing under these conditions there has been suggested as a remedy a preliminary staining of the surface of the plate sufficient to allow the penetration of the image, but insufficient to light up camera and lens with actinic light. Turmeric or logwood solution has, we have been told, been successfully tried. The sensitiveness is diminished, it is true, but the light sent back upon the plate is diminished in greater proportion; and so the evil is abated, if not, as sometimes may prove to be the case, entirely cured. We do not remember ever to have seen this kind of lens fog to have been alluded to, but it very often is produced under ignorance of its true causes. We have often seen another example of lens fog, where the sun strikes the glass surface of the lens itself.

When stopped down and the surfaces quite free from dust, it is possible that no evil may result; but it is not impossible, for the internal surfaces of the lens, their marginal surfaces, and the blacking of the lens tube and shade require to be in a condition perfectly adapted to avoid the kind of reflections we have treated upon.

From all these descriptions of the various kinds of lens fog, there is one obvious moral to be drawn, a large proportion of them are entirely avoidable by properly screening the lens. In drawing attention to this point we are well aware that it is no news at all to many skilled workers, but our readers will bear us out that, whenever a body of photographers meet for outdoor negative-taking, the majority of lenses are not so screened, except perhaps by holding the black cloth, or perhaps a black hat, to shade the objective. And in studio work how many cameras may there not be seen, in the very first class of establishments, with neither screen nor shade beyond the comparatively narrow brass rim provided by the maker. If every lens—studio and field—were shaded off till nothing could be seen from the lens but the particular object or view to be photographed, there would be such an improvement in the vast majority of the negatives taken as to amount almost to a revolution in results.

The "Royal" Photographic Society.—In a long advertisement in a suburban paper, of a local firm of photographers, amongst the list of imperial and royal Exhibitions at which medals have been awarded to them, the Royal Photographic Society of Great Britain is mentioned no less than four times. The parent Society is advancing rapidly now, it is true; but we were unaware that it had obtained a Royal Charter, although we believe it is desirous of possessing one. As the town in which this firm is located possesses an energetic photographic club, which is affiliated with the Photographic Society of Great Britain, and whose President is one of its Council, the advertisement will, no doubt, cause its members some little surprise or amusement.

Simplicity.—In a recent issue of an evening contemporary, which devotes a column to notes and queries, appeared the following:—"Could any reader kindly give me a receipt for the wet-plate or positive process." *Simple?* In due course formulæ are given, over a signature that appears in replies to questions on every conceivable subject. The silver bath is two ounces of nitrate of silver and one drachm of collodion to sixteen ounces of water. Fifty-five grains to the ounce is a little strong for a positive bath, most people would think. The developer contains "galacial" acetic acid. From the wording of the query one is almost led to inquire if the wet-collodion process will in the near future only be associated with glass positives.

Fine Art Exhibition.—An excellent and highly representative Exhibition of paintings, by most of the leading artists, is now open at St. Jude's Schoolroom, Whitechapel. It will well repay a visit to the "far East," as it contains selections from some of the best collections in England. This is the thirteenth show of its kind, and, like all its predecessors, it is highly appreciated by the East-enders, as testified by the number of visitors, the larger majority of whom, it is worthy of remark, are of the working classes, the Exhibition being opened on Sundays. During the few days it was open last year, it was visited by about 80,000 persons. It closes on the 9th prox. Judging from the specimens exhibited in the show-cases of some of the photographers of the neighbourhood, they would do well to visit the Exhibition, and profit from what they will see. The art aspect of photography at the East-end, like that of many other parts, is open to improvement.

The Manchester "Spy" and Photographers.—A few months back we were the first to commend the *Spy* for its action in denouncing the malpractices of "Mons. Sauvy," of Manchester, towards his lady sitters. The *Spy's* success on that occasion, however, seems to have been instrumental in leading to the loss of its editor's head, if we may place any reliance on the following facts, with which we have been furnished. In December last several cases under the Criminal Law Amendment Act were tried against some Bolton tradesmen, and among them was a photographer, in regard to whom the charge was dismissed. Thereupon the *Spy* launched out into a wholesale attack upon the photographer (and photographers in general), with the result that an innocent man has been brought to the verge of ruin by our contemporary's unmerited onslaught. We hear with pleasure that action is to be taken against the *Spy* on account of Mr. Alfred Cowley, of Bolton (the photographer in question), and trust that success will attend any efforts to make good the loss of name and position he appears to have sustained from the *Spy's* cruel and poisonous comments.

The Apprentice System.—In our issue of last week appeared a letter headed "A Hard Case." The case as detailed is but typical of scores of others. We are told, though we hope it is not true, that some photographers, like electrical engineers, make more profit out of their apprentices, "articled pupils," and learners, male and female, than they do out of their legitimate business. With them they usually get a premium for three or four years, and have the whole of the work of the establishment done for nothing, or, as in the case mentioned, at merely nominal wages. Too often the unfortunate apprentice finds, at the end of his time, as the one who writes does, that the whole of his time has been wasted, so far as his knowledge of studio work is concerned—and, indeed, many other branches of the business. A master taking an apprentice is, by law, bound to teach him his trade, and if he does not he is liable to legal proceedings. But, we may ask, what is there now in an ordinary portrait business to demand a heavy premium and several years' services except studio practice, and that, as a rule, is what the pupil gets least of? Plates are now bought ready for the camera. The paper ready-prepared, sometimes even ready-sensitised. The enlarging is often put out to be done, and so, frequently, is the retouching. With these facts before us, and considering the present depressed state of the business, one is naturally led to consider that the masters who take "articled pupils" or apprentices with a premium, and secure their services for a term of years for nothing or for a merely nominal wage, certainly make a better bargain than do the friends of the apprentices.

Studio Portraits with Natural Backgrounds.—Just now professional portraitists seem to be exercising their minds for some novelty to introduce in portraiture to give a fillip to business during the coming season. That something is necessary to stimulate trade there is no question. Now, seeing that there is but little immediate prospect of anything actually new being forthcoming, it may be well to consider whether or not some of the older ideas, that may almost have become forgotten, could not be reintroduced as novelties which, in some cases, they certainly would be at the present time. Here is a suggestion that may be useful to some photographers at seaside places and other pleasure resorts, though less so perhaps to others in the metropolis or other large cities. Many of our older readers will remember a style of portraiture that was, many years ago, introduced by Mr. Edge, whose method of vignetting was incidentally alluded to last week. It was a portrait taken in the studio, but with a background from nature. Not a painted background placed behind the sitter, but a veritable photograph of the scene depicted. As these pictures were first shown there was for a time much conjecture as to how they were produced. This was the way. The portrait was taken in the studio in the ordinary way with a very light, though not white, background. This, if we remember rightly, was shaded off somewhat darker towards the bottom. When the negative was printed an impression was obtained on a lightly tinted ground. Next, the figure was painted over neatly with gamboge. Then this print was exposed behind a negative of some suitable local

landscape view till that was sufficiently printed. In washing out the free silver previous to toning, the pigment was removed. As the paper at the first printing becomes tinted, or toned down, the backgrounds are always subdued and not obtrusive. Further, the landscape negatives, to be suitable, should be kept thin in the development and be taken without strong contrasts of light and shade. It is needless to remind our readers that the lighting of the sitter in the studio should be in accordance with that of the landscape picture which has to form the background. Many visitors to the seaside during their holidays could, no doubt, be induced to sit for their portraits if they could be taken with natural scenery of interest in the locality.

Camera Club Conference.—The 1893 Conference will be held in the Theatre of the Society of Arts on Wednesday and Thursday, April 12 and 13, under the presidency of Captain W. de W. Abney, C.B., D.C.L., R.E., F.R.S. The following is the programme:—Wednesday, April 12, Conference at the Society of Arts, 18, John-street, Adelphi, to be opened by the President at 3 p.m. Papers to be read from 3 p.m. to 6 p.m. in the Theatre. 1. 3 p.m., opening by the President. 2. Mr. William Taylor, *The Establishing of Standards.* 3. About 3.45 p.m., Mr. T. R. Dallmeyer, *Lens Systems.* 4. About 4.45 p.m., Mr. Chapman Jones, *On Certainty in Photography.* 5. About 5.30 p.m., Mr. Leon Vidal, *On the Influence of Photography upon Vision and upon Works of Art, both in respect of form and colour.* 7.30 p.m., Annual Club Dinner for members and friends. Thursday, April 13, 3 p.m., renewal of Conference in the Theatre, Society of Arts. Papers to be read from 3 p.m. to 6 p.m. 1. 3 p.m., Professor E. Mach, *Scientific Applications of Photography.* 2. About 3.30 p.m., Mr. A. W. Clayden, M.A., *The Organization of Meteorological Photography.* 3. About 4 p.m., Mr. Hume Nesbit, *Relations of Art and Photography.* 4. About 4.45 p.m., Mr. Rowland Briant, *Astigmatism and Pictorial Effect in Photography.* 5. About 5.30 p.m., Dr. J. M. Eder, *On the Determination of Focal Points in the Use of Photogrammatrical Apparatus.* Renewal of Conference at 8 p.m. 1. 8 p.m., Mr. H. Van der Weyde, *The Pictorial Modification of Photographic Perspective* (illustrations by the "Photo Corrector," the working of which will be demonstrated). 2. 8.45 p.m., Captain W. de W. Abney, C.B., D.C.L., R.E., F.R.S., *On the Speed of Plates and other Matters.* 3. 9.15 p.m., Mr. H. M. Elder, M.A., *Some Notes on the Effect of Light on Plates.* Friday, April 14, 8 p.m., Exhibition of Lantern Slides in the Theatre. Special tickets are required for this Exhibition. The annual Exhibition of photographs by members will be on view at the Club, Charing Cross-road, after conference week. Admission, on Tuesdays only, from 10 to 12 and 2 to 4, by tickets from members of Club. The Exhibition will continue for about six week. All photographers are cordially invited to take part in the Conference. The meetings at the Society of Arts are open to ladies.

STUDIO-BUILDING.

II.

Before continuing my remarks upon this subject, I should like to ask that any one with whom I am personally unacquainted would not write to me privately for instructions and plans. I do not object to reply when asked for a maker's name and so forth; but it is impossible to write to everybody who may start to correspond with me on this subject. If their wants are sufficiently interesting for the general body of readers of this Journal, I could reply in its pages; but to send one or two plans and particulars of various kinds to a single correspondent, for example, as I was recently asked to do, is not reasonable or right.

Enough, perhaps, having been said upon the shape of the building, a few words may be devoted to its size and proportion. As to the former, the two considerations of *l. s. d.* and surrounding conditions are the chief factors in arriving at a decision, for, within ordinary bounds, the larger a studio is the greater its convenience, and the more complete the control of the lighting. Especially is this so in large groups, as the nearer the group is to the light aperture, if such an expression may be permitted, the more uneven will be the lighting of the individual members composing it. Length of studio is most important for group-taking also, as it is likewise for full-length portraits.

It is always advisable to have a full twenty or twenty-two feet at least between sitter and camera, but this must not by any means be understood as the length the studio should be. At the very lowest estimate, two feet should be allowed for the camera, and another two feet for comfortable working behind it. Double these allowances would not be too much. Then, at the sitter's end, allowance must be made for head-rest (still of occasional use in every studio) and for movable backgrounds. For these purposes four feet is the minimum distance to be reckoned with. We thus arrive at thirty feet as practically the shortest length a studio should possess, if it is to be well adapted for the various purposes a professional portraitist would require it for. A still longer room will naturally offer greater facilities, but when a greater distance than here named is allowed between lens and sitter it will be found that atmospheric fog—unless the air be exceptionally pure, as in some seaside places—will too often be sufficiently manifest to cause a foggy picture. Under all ordinary circumstances, provided the camera is not too near to cause disproportion or distortion, crisper pictures of single subjects are taken when the sitter is near to, rather than far off, the camera. It need not be said, however, that increased distance gives more harmony of proportion as regards hands and limbs.

Breadth of studio, again, is very advisable; when there is room to spare on each side of the sitter, there is so much greater freedom in arranging accessories, and increased command over the light, that it is easy to avoid that tendency to conventional positions, lighting, and management, so fatal to originality and artistic effect of the work produced. Granted the maximum dimensions in length already quoted, I would, if it were in my power, much prefer to increase the breadth than the length.

The next point I have been asked about is the length and thickness of the window bars, the size of the glass, how to glaze, and other similar subjects. Taking the size of the bars first, I should say this is entirely a question for the architect or builder; but, above all, they should be stout enough. A little loss of light from these bars or sashes is of no account whatever in comparison with the danger of leaking and the glass breaking, through the strain on the binding material, be it putty or otherwise, which is certain to be incurred when the bars are too light. It is no unfair estimate to say that nearly one half of the leaky skylights in the country are caused by the frames being too light. Under any circumstances, it will be necessary, for example, to have workmen occasionally on the roof, and, if the bars cannot sustain their weight without a slight bending, it will be found that the next shower, after the glass roof has been so invaded, will discover several leaky spots. The bars can be chamfered off at the inner angles without seriously reducing their stability. I have adopted that plan with advantage, but otherwise have always made a point of having them strong and substantial. One very valuable recommendation as to the shape of bars has been made which, though I have not tried it, I feel sure must be of considerable use as against possible leakage. It is that a deep groove should be cut into the bars for their whole length on each side on their inner surfaces, so as, in the event of water gaining admittance, to lead it away towards the eaves. It will be observed in cases of leakages that the water rarely drops down where it actually enters, it usually "follows" for some distance the angle of glass and bar, and will then, perhaps, travel along the front face of the latter before it falls. This is one cause of the difficulty of localising the exact spot where the leakage exists. It will be judged from this that I have not been without leakages: though certainly they have been few, and would have been fewer still if my instructions had been carried out by the glaziers. At this stage it will be as well to point out a very important matter about arranging the roof. Whether for periodical painting, or for carrying out alterations and reconstructions, the inevitable workman will at times be on the roof, and it will be wise to provide against him and for him. I have experience of the array of ladders and boards slung on the glass, the time wasted, and the

damage done, and for many years past have arranged a method by which this inconvenience could be reduced to a minimum. Each side of my glass roof is provided with a specially constructed ladder for the workmen to use. The roof of my present studio is a wooden ridge, well protected with lead, and upon this ridge the ladders rest, prevented from slipping by a pair of iron hooks, which grip the ridge piece and prevent any danger of slipping. The ladders are always kept on the roof ready for use, and workmen greatly appreciate the safety and convenience of such an arrangement These ladders have long cross pieces at intervals to rest upon the window bars, and prevent swagging and pressing upon the glass; further, they are guarded on the side next the glass, to prevent a careless foot slipping through, by longitudinal laths. My present ladders are nearly worn out through constant service, and I am hoping to be able in the next to introduce still further little improvements.

In addition to these ladders, the skylight bars have permanently let into them, and projecting some distance, strong thick screws, for the purpose of supporting the long planks which the British workman generally finds it necessary to employ when he is on a roof. This prevents the surreptitious use of a nail or two, which he is to apt to insert in the woodwork to aid in securing his paraphernalia, with the inevitable consequence of starting a leak. One other point as to workmen on the roof. The studio I built before my present one was on a lofty building overlooking a large yard, over which I had no rights or easements of any kind. I could not build even a projecting spout, nor put out a window. In consequence, to obtain the effect of side light, I made the wall of the studio on that side only four feet above the floor, and then the glass roof shot up sheer and steep till the ridge was over twenty feet high. It was difficult to get workmen to venture on to it, and when they were there I was so uneasy as to their safety, that eventually I got the builder to erect a kind of iron bar fencing the whole length of the roof against a possible accidental fall, and, further, encroached upon the glass by fixing a narrow wooden pathway for the workmen to pass along, taking care to line the glass for a few inches above it with narrow wooden strips, to avoid breakage by an inadvertent footstep. When this was done my mind was at ease, and I found no difficulty in getting workmen upon the steep roof.

At the risk of unduly lengthening my paper, I will here narrate a personal experience. A plumber and glazier had undertaken the job of putting up the fence, and, when completed, I went upon the roof to examine and test it. I was leaning against it; if it had given way, I should have known nothing about it, for the drop would have been fifty feet on to the flags, and the workman said, "You had better not lean against it, sir, it might give way!" He had actually made this safety fence of narrow thin iron gas piping, further weakened by cutting the threads for the screws which joined the sections. I was horrified at the risk I had been in, and, I need not say, greatly incensed at the way the work had been executed. Of course, all this had to be taken down, and a solid iron rod put in its place. It is so entirely possible that others might meet with a similar experience, that it will not be thought a needless encumbrance to have narrated this occurrence.

G. Watmough Webster, F.C.S.

THE INFLUENCE OF DEVELOPMENT ON GRADATION.*

My next experiment was principally directed to finding how gradation was affected by length of time in development, and again I found reason to believe that the conclusions of Messrs. Hurter & Driffield did not apply under the altered and extended conditions under which I was working. A half-plate (plate D) was given the same series of exposures as before, except that the last was increased to 100,000 C.M.S., as I wished to have an example of reversal; this 100,000 C.M.S. patch was very distinctly darkened before development. The plate was cut into six pieces, marked with consecutive numbers, and four of them were developed together in the No. 2 developer for varying lengths of time. The 100,000 C.M.S. patch appeared before any other, and kept the lead for some time. The other two pieces were treated with developer No. 1. The following table will give the details of the experiment and the resulting densities:—

PLATE D.

		Developer No. 2.				Developer No. 1.		
	Number of strip.	1.	2.	3.	4.	5.	6.	Strip 5 × 1·4.
	Time of Development.	4 mins.	10 mins.	20 mins.	50 mins.	2 mins.	4 mins.	
Exposure.	C.M.S.							
	1	·00	·00	·06	·43	·22	·30	·31
	10	·00	·06	·58	1·44	·57	·87	·80
	100	·06	·35	1·54	2·59	·86	1·19	1·20
	1,000	·12	·71	2·08	3·07	·97	1·30	1·36
	100,000	·19	·76	1·66	2·37	·90	1·20	1·26

The different action of the two developers is again very strikingly apparent; a comparison of strip 3 with strips 5 and 6 shows that very strongly. In regard to the length of time of development, Messrs. Hurter & Driffield's experiments led them to the conclusion that the ratios between the densities, produced by varying exposures, were always constant, and that the only difference in result to be expected from a long time of development over a shorter one was, that all densities would be increased, but that the increase would always be in the same proportion all through the scale, so that the ratios would still remain unchanged. Now, in the case of strips 5 and 6, where the alterations in time and density are within comparatively narrow limits, that rule proves fairly correct; by multiplying the smaller densities by 1·4 (as I have shown in the last column) we obtain figures nearly corresponding to those of strip 6. But the strips developed with solution No. 2 certainly show no evidence of their being subject to such a rule. In every case, an alteration in the time of development has led to a complete change in gradation, and, so far as any theory can be formed from a single experiment, this one appears to show that the parts which have received the fullest exposure are the first to develop and the first to flag. They have a long lead at first, and are always more and more nearly overtaken by parts less exposed as development proceeds. I mentioned that the 100,000 C.M.S. patch appeared before any other and kept the lead for some time; this is quite in accordance with general opinions, as it has often been noted that, when negatives are reproduced by the reverse action of light, a *positive* appears at the first stage of development, which is afterwards overpowered by the superior density of the less exposed parts. The figures are quite in accordance with that fact, and show that, up to the time of ten minutes of development, no reversal had taken place. If a negative, therefore, had received so long an exposure (on an "Ilford Ordinary" plate) that it amounted in some parts to as much as 100,000 C.M.S., it appears that the picture might still be saved and all reversal avoided by treating the plate with developer No. 2 and stopping the action after ten minutes. It is true that the result would be very thin, but still a fair negative might probably be made from it by intensification. By comparing this with some of the previous results, some idea may be formed of the great range of exposures from which it may be possible, by proper treatment, to produce passable negatives. If we suppose a subject to be chosen in which the intensities of the light vary as much as 1 : 1000 between the brightest and darkest parts, and consider firstly such an exposure to be made on it as would give a range equal to ·1 to 100 C.M.S. by means of rather prolonged treatment with the No. 1 developer, there is little doubt a fairly good negative might be made from it on an "Ilford Ordinary." The tables I have given show some considerable density on the 1 C.M.S. line, and, in another experiment, an exposure of ·1 C.M.S. has produced quite distinct though thin deposit; so that in such a negative we need have absolutely bare glass nowhere, and every variation in intensity of light through the picture would be represented by *some* difference in gradation in the density of the negative. Now, if that exposure had been increased *a thousandfold*, we should then have only reached a range of exposures of from 100 to 100,000 C.M.S., and it has, I think, been shown that even then the case would not be hopeless. And this is taking it for granted that the presence of either bare glass or solarisation on any part of a negative would be a fatal defect, which is not the general opinion of photographers. Of course the possibility of obtaining the ideal "perfect negative," which has all the "values" correctly represented, would not exist in these extreme

* Concluded from page 185.

cases. Messrs. Hurter & Driffield have shown how such negatives may be made, and the principles they advance on the subject are no doubt generally correct, although I think they will have to be modified by the conditions that the developer must be normal in constitution, and the time of development regulated; but whether the same end may be reached by other means, whether the necessary "period of correct exposure" would be shifted in position under altered conditions such as those I have described, or whether it would exist at all, would require much more elaborate experiments than mine to discover. It is interesting to note how, in the last table, the density of the 100,000 C.M.S. gradually falls behind the others. It is first in strip 2, between 100 and 1000 C.M.S. in the next, and considerably less than the 100 C.M.S. patch in the strip 4 column.

The following table will give the details of another experiment in which I endeavoured to test the action of different *species* of developers. The proportions given of the ingredients represent grains per fluid ounce (minims of ammonia), and, except as regards strips 1 and 6, I think they are in about ordinary working proportions. Sodic sulphite was employed in all the solutions, but, as it was unlikely to affect gradation it has been unnecessary to give the amount used in each case.

PLATE E.

Number of Strip.		1.	2.	3.	4.	5.	6.
Developer.		Pyrogallol ..... 1 grain Potass bromide ..... 1 " Ammonia 2	Eikonogen ..... 5 Potass carbonate 12	Amidol ..... 3 Sodic sulphite ... 30	Hydroquinone ... 2 Potass carbonate 12	Pyrogallol ..... 1 Potass bromide... 1 Ammonia 2	Pyrogallol ..... 2 Potass bromide... 3 Ammonia 1
Time of Development.		5 Minutes.	8 Minutes.	4 Minutes.	10 Minutes.	6 Minutes.	30 Minutes.
Exposure.	C.M.S.						
	·1	·01	·02	·01	·02	·01	·00
	·25	·03	·07	·08	·07	·03	·00
	1	·24	·42	·47	·31	·32	·03
	10	·93	1·74	1·75	1·37	1·51	·44
	100	1·33	2·66	2·75	2·22	2·42	1·12
	1,000	1·48	2·86	3·04	2·55	2·84	1·63
	100,000	1·45	2·25	2·35	1·91	2·52	1·62

A comparison of strips 1, 5, and 6 will show, once more, that very great alteration in gradation results from altering the constitution of the pyro developer; but in regard to the four *species* of developers, when used in normal working proportions (as in strips 2 to 5), I do not find so much variety in the ratios as I should have expected. These densities may be compared more conveniently by examining their ratios when compared with a standard exposure. I have therefore taken 10 C.M.S., which is a fairly regular exposure, and now give the ratios of other densities when those of 10 C.M.S. are made equal to 1, omitting, however, the results of shorter exposures than 1 C.M.S., as the accuracy of such small figures cannot be depended on.

Number of Strip.		1.	2.	3.	4.	5.	6.
Exposure.	C.M.S.						
	1	·26	·24	·27	·23	·21	·07
	10	1·00	1·00	1·00	1·00	1·00	1·00
	100	1·43	1·53	1·57	1·62	1·60	2·55
	1,000	1·59	1·64	1·74	1·86	1·88	3·70
	100,000	1·56	1·29	1·34	1·39	1·67	3·68

The range of exposures used by Messrs. Hurter & Driffield would be covered by the difference between the 10 and 100 C.M.S. lines, and the ratios between these in regard to strips 2 to 5 certainly vary very little, not more than in similar experiments described by those gentlemen; and even on the 1000 C.M.S. line the variation is not great, although eikonogen is found (as it was also by Messrs. Hurter & Driffield themselves) to give less density than other developers. The phenomenon of reversal, however, seems to be much influenced by the species of developer used, being far less strongly marked when pyro has been employed; but perhaps it is the alkali used which has the principal influence in that matter. In strips 1 and 6, it will be noticed, the density of the 100,000 C.M.S. patch is practically the same as that of the 1000 C.M.S. I do not think, however (taking the experiment with plate D into consideration), that this absence of reversal is altogether owing to the composition of the developers. It is probably mainly due to the fact that the action was not carried so far in developing those strips as in the other cases, so that, in consequence, the less exposed part only just reached the same density as the 100,000 C.M.S. patch; more prolonged development might probably have given the former a considerable advantage. Apart from reversal, this experiment shows little difference in the actions of the various kinds of developers, but I doubt whether other experiments may not give very different results. The experience of Messrs. Hurter & Driffield with para-amidophenol may, very possibly, be repeated in other cases, and what has been found to apply to that one developer, prove to be true of all. That is, that the special action of a developer may be found to depend very much on the quality of the plate, so that, while two species may give very similar gradations for equal series of exposures on some makes, they may yet prove to be very different in their effects when other plates are used. In using eikonogen in the autumn, on a different quality of plate, it certainly seemed to me to have an advantage over pyro and amidol for short exposures, which is not shown in this experiment with the "Ilford Ordinary."

On the whole, I think the experiment shows that development is, unfortunately, not so simple a matter as Messrs. Hurter & Driffield's experiments gave good reason for believing. Considering that there are now so many varieties of developers, every one of which may be greatly modified by altering the proportions of its ingredients as well as by various additions or omissions, and considering also how great is the difference between various qualities of dry plates, it would have been very satisfactory to have found that, after all, there was a simple rule which applied to every case. But, as that now appears to be more than doubtful, we have scarcely any scientific guidance to fall back upon, and development is likely to remain a mere rule-of-thumb matter, but it is much to be desired that those photographers who have time on their hands will devote some part of it to an attempt to add something to the small knowledge we now possess of the action of developers.

I ought to mention, perhaps, that I have in all cases used the expression "density" in the sense adopted by Messrs. Hurter & Driffield, viz., as representing the logarithm of the reciprocal of the transparency. A density of 1 stands, therefore, for a transparency of $\frac{1}{10}$; a density of 2 for a transparency of $\frac{1}{100}$, &c. It is the ratios between such logarithms, and not those between the transparencies themselves, which, if Messrs. Hurter & Driffield's original principles, as described in the paper on *Photo-chemical Investigations*, were correct, *should be* unalterable (after exposure), and not at all dependent on the method of development employed.

H. J. CHANNON.

FURTHER NOTES ON GUAIACOL AND ALLIED PHENOLOID COMPOUNDS AS DEVELOPERS FOR GELATINE DRY PLATES.

[Photographic Society of Great Britain.]

IN May, 1890, I brought to the notice of the Photographic Society of Great Britain, that guaiacol, or methyl-catechol, possessed fair powers of developing dry plates. It cannot be recommended as a practical developer, on account of its very strong smell, and its slow and weak action as compared with the ordinary developers. It has, however, recently been found useful by R. E. Liesegang as a developer for bromide paper prints.

In a very interesting paper published in the *Bulletin de la Société Française de Photographie*, vol. xxxvii. p. 310, Messrs. A. and L. Lumière, of Lyons, have given some results of their investigations into the relations between the chemical constitution of a large number of reduciug agents, and their action on silver bromide altered by light, and have found that in various bodies belonging to the aromatic series of benzene derivatives, to which most of the ordinary organic dry-plate developers belong, certain conditions must be fulfilled in order that they may possess the power of developing a latent image on silver bromide.

The principal of these conditions are:—

(*a*). In order that a substance of the aromatic series may act as a developer of the latent image, it is necessary that the benzene nucleus should contain at least two hydroxyl groups OH or two amidogen groups NH_2, or even one hydroxyl and one amidogen. The power of developing also holds good when the molecule contains a larger number of groups OH or NH_2.

(*b*). Substitutions which may be effected in the group OH or in the group NH_2 destroy developing power in all cases in which at least two of these groups do not remain intact in the molecule.

Now guaiacol ($C_6H_4<^{OCH_3}_{OH}$) presents a substitution in one of two hydroxyls, and although Messrs. Lumière's first experience as to its developing power agreed perfectly with my own, the fact that it is a developer seemed to them opposed to the principle laid down in (*b*). They remark, however, that the guaiacol of commerce is not a perfectly defined product, and contains, besides methyl pyrocatechin, a number of other substances, among which may be some diatomic phenols to which the developing properties may be due, and that the question is one for further inquiry.

Is Guaiacol a Developing Agent?

In a more recent communication to the Photographic Society of France, Messrs. Lumière announce that they have been able to prove that pure guaiacol is not a developing agent, and that the developing powers shown by certain samples are due to impurities. I have not yet had an opportunity of seeing their paper, nor am I a sufficiently good chemist to carry out an investigation on the lines they have laid down in their first paper, even if I had the leisure to do so; but I have again tried my first sample of guaiacol, together with a fresher and apparently purer one, and have also made some experiments with creosote and creosol, which should have been made earlier, and find that there is every probability of Messrs. Lumière's statement being correct as regards guaiacol. Creosote and creosol have both shown developing powers, and even carbolic acid itself, when oxidised, shows this power, though it does not do so when pure.

The guaiacol used in my first trials in 1890 is now quite brown and oxidised. It is labelled "*guaiacol puriss*," and was obtained from Dr. Schuchardt, of Görlitz; but he prepares a still purer product, which I have not tried. It would be impossible to obtain here an absolutely pure sample, but a fresher and perfectly colourless sample which came from the same source as the first, and is nominally of the same quality, but has been with me for about a year unopened, has also been tried and found to be a very much weaker developer than the first sample was and now is. Whereas the brown oxidised guaiacol with potash will develop a well-exposed plate with fair rapidity and moderate intensity, the colourless sample will, under the same conditions, only give a very weak but well-detailed image, even after a very prolonged development. From this it appears highly probable that an absolutely pure sample would not develop at all, and it is possible that the slight developing action observed may be due to the oxidising action of the air during the prolonged development, as seems to be also the case with carbolic acid. It may be noted also that when first tried the now oxidised sample of guaiacol showed a slight green tint with alkalies, and it now gives quite a dark green solution, while the solution of the fresher sample in alkalies is almost colourless, and shows no trace of green oxidation.

In these last experiments the guaiacol has been dissolved in caustic potash solution, about 1 c.c. of guaiacol to 5 c.c. of a 10 per cent. solution of the potash, and the clear solution diluted to about 35 c.c. It was noticed that the old guaiacol was not so readily soluble as the new.

Guaiac Resin.

If the developing power shown by guaiacol be not due to oxidation products, but to some impurity, it becomes interesting to know what that impurity is, because it may possibly be a powerful and effective developer in itself, as it must presumably only be present in very small quantity in the purified samples of guaiacol I have tried. The nature of this impurity will no doubt depend on the method of preparation of the guaiacol, as to which I have no information. As this substance forms the principal constituent of beechwood creosote, and may be obtained by fractional distillation from it, the guaiacol of commerce is probably obtained in this manner, but it may also be produced by the dry distillation of guaiac resin, and by other chemical methods.

As regards guaiac resin, I find that a solution of it in aqueous caustic potash solution is only a very feeble developer of silver bromide in gelatine dry plates; the developing agent in commercial guaiacol would therefore not appear to be one of the constituents of guaiac resin in its ordinary state, and we may look for it with better chance of success in creosote, some samples of which have been found to possess much stronger developing powers than guaiacol.

By destructive distillation guaiac resin yields guaiacene (C_8H_8O), guaiacol ($C_7H_8O_2$), creosol ($C_8H_{10}O_2$), and pyroguaiacin ($C_{39}H_{44}O_6$). If the latter product fulfils Messrs. Lumière's conditions, it might be worth examination.

Creosol a Developer.

Creosol is a colourless oily liquid, with a strong aromatic odour, not so pleasant as guaiacol. It is not more soluble in water than creosote, but mixes in all proportions with alcohol, ether, glacial acetic acid, and alkaline leys. The sample I have is, however, of a brownish tinge, and is not so soluble in alkaline solutions as guaiacol. A developer was made up as follows:—

Creosol	1 c.c.
Solution of caustic potash, 10 per cent	7 c.c.
Water, to	30 c.c.

The solution of the oil was not complete, a well-exposed plate took a long time to develop, but seemed to give fair density, which went off somewhat in fixing. With carbonates of soda and of lithia it only gave very weak images. It should be noted that, as in the case of guaiacol, the specimen of creosol I have used is not pure, and the experiment should be repeated with the pure product, which is unobtainable here.

Creosote also has the Power of Development.

Creosote from wood tar is a very complex mixture of phenoloid compounds, varying in character and quantity according to the method of distillation employed. In Thorpe's *Dictionary of Applied Chemistry*, Mr. B. Nickels gives the following list:—

Monohydric phenols: Phenol, paracresol, xylenol or phloral.

Methylic ethers of dihydric phenols: Guaiacol, creosol, homocreosol, cœrulignol.

Methylic ethers of trihydric phenols: Dimethyl-pyrogallate, dimethyl-methyl-pyrogallate, dimethyl-propyl-pyrogallate, and methyl-pyrogallate.

The principal constituents are, however, guaiacol and creosol, the former predominating in Rhenish beechwood creosote, while creosol forms the chief constituent of creosote from Stockholm tar.

Of two samples of creosote, one "beech-tar" creosote of German origin and the other ordinary creosote, probably English, obtained from a local druggist, I find that both have the power of developing a gelatine dry plate when mixed with alkali; but, while with the former the images obtained have been weak, those obtained with the latter show a good printing density, and are of a good brownish colour, free from stain or fog. The developer was made up as follows:—

Creosote (English)	1 c.c.
Solution of caustic potash, ten per cent.	5 c.c.
Water, to	35 c.c.

With ammonia the German creosote was only slightly soluble and developed a very weak image.

The English creosote had quite a different smell from the German, and more tarry. Both were only slightly yellowish in colour.

It is difficult to ascertain what is the cause of the great difference in the developing powers of these two samples of creosote; but further investigation may lead to its discovery and the isolation of the substance which produces it. In any case the developing powers of creosote seem to be worth further inquiry, though it is not likely to come into use as a developing agent in ordinary practice.

Old Carbolic Acid has Developing Powers.

I have also found that some very old carbolic acid (Calvert's No. 2) which has been kept here for some years, and become brown and oxidised, possesses distinctly marked developing powers when mixed with potash. The colourless crystals of unoxidised carbolic acid of the same manufacture have almost no such power, though after prolonged development in contact with the air a feeble image becomes visible. In this case the developing power is probably due to the formation of hydroquinone and pyrocatechin under the oxidising influence of the air.

Electrolysis of the Developers.

I have tried some of these developers by the electrolytic method, noticed in a recent paper on the amidol developer, published in the December number of the *Journal of the Photographic Society of India*.

A solution of

Guaiacol (colourless)	5 c.c.
Caustic potash solution at 10 per cent.	30 c.c.
Water, to	120 c.c.

was electrolysed in a voltameter with platinum electrodes about one inch apart, using four gravity cells giving a current of ·18 ampère with a pressure of about 4·2 volts. At first the current through the voltameter was about 7 milliampères with a pressure of 1·3 volt, but it ran down steadily, and after thirty minutes was only 2·3 milliampères, with a pressure of ·8 volt. Hydrogen was given off in a frothy form, at first fairly briskly, the yield being about ·4 c.c. in five minutes, ·6 c.c. in ten minutes, 1·0 c.c. in twenty minutes, and 1·3 c.c. in thirty minutes. The anode became coated with a brown resinous

substance, which stopped the current. This substance was only partially soluble in alcohol with a maroon-brown colour, and was very similar to a deposit formed by treating English creosote with baryta water. The same coating of the anode was noticed with silver electrodes, and the current was almost stopped, although the coating was very thin. The colour of the solution after electrolysis was a light maroon-brown with greenish reflections. The developing power of the solution was not found to be improved much by electrolysis, though the formation of the image seemed to be somewhat accelerated.

A solution of the old discoloured guaiacol with carbonate of potash electrolysed under the same conditions gave similar results as to the yield of hydrogen, though the current through the voltameter at starting was about 6·5 milliampères with a pressure of 1·8 volt, and after forty minutes was 4·25 milliampères with a pressure of 1·4 volt, which is very much higher than in the first experiment. The yield of hydrogen was about ·3 c.c. in five minutes, ·6 in ten minutes, 1·0 in twenty minutes, and 1·9 in forty minutes. The solution, to start with, was a very dark green colour, which became paler in the hydrogen tube and still darker in the oxygen tube. The solution generally also darkened. The anode had a reddish-brown deposit upon it. The developing power of the solution after electrolysis was not tried till next day, and was found to have decreased considerably.

Carbolic acid solutions electrolysed gave somewhat similar results as to the coating of the anode with resinous matter, and the consequent stoppage of the current.

A solution of :—

Old carbolic acid	8 c.c.
Caustic potash solution, ten per cent.	32 „
Water, to	120 „

was electrolysed with three dry cells giving a current of six ampères with a pressure of 3·75 volts. The evolution of hydrogen was very brisk, and some oxygen or other gas was given off at the anode. The yield of hydrogen was 1 c.c. in five minutes; 1·9 c.c. in ten minutes; 2·6 c.c. in twenty minutes, the yield of gas from the anode in the same time being ·5 c.c. The current through the voltameter at starting was six milliampères with a pressure of 2·75 volts, and in twenty minutes was six milliampères with a pressure of 1·5 volts. The solution in the hydrogen tube became lighter in colour, while that in the oxygen tube darkened. The electrolysed solution seemed to have considerably increased developing powers, but this is uncertain, as it was tried under different conditions to the unelectrolysed solution.

A similar trial of fresh carbolic acid and potash in the same proportions, using platinum electrodes and four gravity cells, was made. The current through the voltameter at starting was 5·75 milliampères, with a pressure of 1·3 volts. This pressure remained almost constant for thirty minutes, but at the end of that time the current was only 3·5 milliampères. The yield of hydrogen was ·5 c.c. in five minutes; ·9 c.c. in ten minutes; 1·3 c.c. in twenty minutes; 1·8 c.c. in thirty minutes, and ·8 c.c. of gas was given off into the oxygen tube. The solution in the hydrogen tube remained colourless, that in the oxygen tube took a bluish dirty violet colour, and the solution generally had a turbid greenish tint. In a V voltameter with silver electrodes, the anode became coated at once with a brown varnish-like substance, and the current from six dry cells (about eight volts) barely passed through. The solution after electrolysis had no apparent developing power.

I have not yet been able to complete these electrolytic observations, or to try creosote and creosol in that way.

With the exception, perhaps, of creosote, none of the substances experimented on appear likely to be of any practical use as developers, but I have thought that the fact of their having developing powers might be worth recording, and a further investigation of the substances which cause impure samples of non-developing phenoloid compounds to exhibit developing powers may have useful results.

Addendum.

Since the above was written, the mail has just brought the *Moniteur de la Photographie* of December 1, containing Messrs. Lumière's last paper, in which they show that guaiacol, after thorough purification, no longer reduces haloid salts of silver after exposure to light, and therefore is not a developer. They made a search for the substance which communicates its developing power to guaiacol, but without the slightest success; the ammoniacal liquor in which the crude guaiacol was first washed develops an image, but all efforts to isolate and analyse the active agent failed, probably because it was only present in very minute proportions in the ammoniacal liquid. They remark that of some substances a very small quantity is sufficient to bring about the reduction of silver bromide. For instance, a photographic plate may be developed with an alkaline solution of para-amidophenol at one-ten-thousandth or less than two grains to a quart.

As noted in my paper, my later experiments with guaiacol tend to confirm Messrs. Lumière's conclusion that it is not a developer. Messrs. Lumière do not seem to have observed with the pure product any trace of an image which could be attributed, as I have thought possible, to oxidation products. Consequently the faint images I have observed with my purer sample of guaiacol, and with clear crystals of carbolic acid, are probably due to oxidation products or other impurities present in my samples, and not generated during development. The question is a complicated one, and would require much closer investigation than I am able to give it.

In connexion with the foregoing, Colonel Waterhouse has the following on the above subject in the *Journal of the Photographic Society of India*:—

Guaiacol, Phlorol, and Cresols.

Since my last note, in the January number, was written I have tried two fresh samples of guaiacol, one of them purified from potash and the other an ordinary sample of English origin, obtained locally, which seems to be very pure, judging from its freedom from colour when mixed with potash and the slowness with which it develops. Both these samples have, however, undoubted developing powers, and it seems difficult to obtain a sample of perfect purity and without any developing power, unless one prepares it for oneself, as Messrs. Lumière have done. It is an operation requiring more care and time than I can give it at present.

I have also tried some other derivatives of creosote, among them crésol, para-cresol, and phlorol, and find that, mixed with potash, they are all capable of developing an image on a dry plate, though not practical developers. Phlorol seems the most active, but cresol develops without difficulty, while para-cresol only gave a very weak image in two days. The solution of the latter in caustic potash has a strong orange colour, which deepens by exposure to the air. It remains to be seen if this strongly coloured solution may be turned to useful account in conjunction with other developers. In this case also it is probable that the developing power may be due to impurities or oxidation products formed during the progress of development.

As it seemed possible that the impurity which confers on these phenols the property of developing might be pyro-catechin, or some homologous substance, an experiment was tried to ascertain how small a quantity would suffice to bring out an image. It was found that a solution of one-fifty-thousandth of pyro-catechin in a one per cent. solution of caustic potash (or about one grain of pyro-catechin in five pints of a five-grain solution of potash) was sufficient to develop a distinct but very weak image. It is possible that even a smaller quantity would suffice, and under these circumstances it may readily be understood how enormously difficult it is to obtain these complex derivatives of wood-tar and creosote absolutely pure and free from substances which have developing power.

Colonel J. Waterhouse, I.S.C.

ENLARGEMENTS PRINTED ON PREPARED CANVAS.

In the "Answers to Correspondents," on page 95, two alternative methods of making enlargements on prepared canvas are mentioned as being suitable because they give permanent results—"carbon transfers" and "dusting-on." Both are bichromate processes, and both, although the colouring materials are permanent enough for this purpose of being printed without the canvas being removed from the stretcher, and for painting upon in oil colours after having been printed, are about the most unsuitable that could be recommended.

The carbon print must be made and developed on another (the flexible) support, and transferred to the oil-painted canvas, adopting suitable means to secure it thereon. I have tried to, and succeeded in, squeegeeing the carbon tissue when printed direct on to the canvas, and developing it there, but it will be seen at once that the risk run of spoiling the prepared canvas by the hot water is so great that it is not a desirable way to work, nor would any artist of note risk the destruction of his after-work on such a ground if he knew of it. The coloured gelatine of more or less thickness is also so antagonistic to the oil surface that, even when properly fixed, it is, so to speak, always struggling to remove itself. So opposite are the two bodies that a coating of gelatine, glue, or size, is used to prevent the preparation sinking into and spoiling the appearance of the back of the canvas, and this is sometimes done so maladroitly that pictures, especially if they are of considerable age and kept for a lengthened period in a damp place, will frequently scale off in large blisters as thick as egg-shells. This takes place where the sizing which the canvas generally undergoes is,

as previously mentioned, too thickly coated or the sizing too strong. The size first swells from the absorbed damp; then, after a time, decomposes, giving forth vapours, and the paint and canvas part company, entailing, where the picture is a valuable one, no end of care, time, and trouble in putting a new canvas on the back of the old and rotted one, or otherwise removing the canvas, thread by thread and fibre by fibre, from the scale of paint and picture, and cementing that down on a new canvas. Such a thing can be done, but never without injury to the picture. Where a gelatine film of appreciable thickness is interposed between the prepared ground and the oil colours which compose the picture—say, portrait—there the elements of destruction are laid. I have seen such an example, even with a silver enlargement, where gelatine in excess had been used; the entire picture reticulated, so that, on looking through it in sunlight, it seemed as if pierced with a fine network just like a Meissenbach of transparent cracks, which they were. This was one of the present President of the Edinburgh Society's works, which he will remember, for he condemned it at once as unfit to leave his establishment, asking my opinion of the probable cause of so unusual an appearance, and had another executed in its stead. A well-known master, the late Norman Macbeth, R.S.A., a frequent contributor to these columns, Sir George Watson Gordon, P.R.S.A., as well as others who could be named, would never allow their cloths to be sized at all, but primed on the cloth direct, almost forcing the first coat through to attach the paint and canvas thoroughly together, just as plaster is forced through lathing and riveted, as they call it. So much for the association of the gelatino-carbon image with the oil-painted portrait enlargement. How this is, or may be, produced need not be noticed here.

The dusting-on process is one that is based on a very different principle, the bichromatised colloid body being so treated that it becomes hygroscopic, and in printing from a negative a negative is the result, from a positive or transparency a positive. The print is produced by action of the humid atmosphere upon the insolated surface, and brushing over it a colour which sticks to the slightly tacky surface. For this purpose very finely levigated black lead is probably the best. Gas black, or lamp black, also do well. Ivory black is recommended, but has not been so successful in my hands. There are also many of the other colours in powder which can be chosen if black is too strong in tint for the painter's scheme. The specifically lighter they are, the better will they take on the tacky surface of the colloid composition. One great objection to the working out of this process with any large size of plate and canvas is the difficulty in our climate and in most work places of keeping the air sufficiently dry and at an even equable temperature and degree of humidity during the process of brushing on the powder. Even in breathing upon it to confer the requisite degree of humidity, there is the great probability if the subject is large, say up to life size—of making one place more tacky than another, and so causing a heavy, blurred, smeary image, which no after-working seems able to clear This, which annoying in large subjects, is quite unfelt on small sizes, where the aid of a friendly open fire assists in securing images fine enough for enamels, of which I have made several examples on opal glass as well as on the orthodox enamel plaque. The image, when finished from the enlargement, after washing, drying, &c., is too delicate to stand rough work with the painter's brush, and must be floated over with a coat of thin varnish, the thinner the better. All this trouble and care must be taken to produce an image which, in addition to its colloid nature, although that is hardened by exposure to light in conjunction with a bichromate, yet even that which is hardest, and also that which has not been so affected, must retain, even when washed free of all surplus bichromate, and such sugar, or honey, or glycerine, or other hygroscopical addition, acted upon by acid, alum, &c., a most undesirable quality as an intermediary between two surfaces of oil paint, the canvas ground, and the artist's colours.

The same remarks apply to another medium which is often used for cheap enlargements in oil, "collodion transparencies" transferred to the canvas, and for that class of work they should be more strongly emphasised.

Remains now the printing of the image on the prepared canvas ground itself, without an intermediary, or only that with which the artist paints, which will allow intermixture and penetration so that the material of which it is formed becomes one with the colours and the ground, and that is our old and safe friend, nitrate of silver, which, in spite of all that may be said as to permanency, is, in the method to be described, most permanent, one proof of which may be quoted.

I was shown a short time ago by one of our best artists one of several such prints on canvas that had been done by myself considerably over twenty years ago, which had been knocking about the studio for all that time. It was a figure subject, copied from one of his own designs, on 26×15 stretcher, and there was no sign of change or fading whatever; the whole thing was so vigorous that I was amazed it did not tempt the artist to begin and finish it, and said so; but he said, "I have already painted half a dozen of them, and am tired of it, even though I have been asked to finish it. I'll rather paint a new subject on the same canvas;" and, on again calling at a later date, it had been painted out and was ready for the new subject.

To begin with the prepared canvas itself: do not, as is the usual photographic habit, purchase the lowest priced, "made-in-Germany" kind of material at so many or so few pence each, or shillings a dozen, stretchers included, kind of thing; for, if that class of stuff is made use of for this purpose, it is almost certain to prove a failure. Rather use, although it costs more, that material made by such old-established London houses as Charles Roberson, Winsor & Newton, Newman, Lechertier, Barbe, & Cie., and people of that stamp, who have a reputation to lose. If the buyer has a choice, take the oldest in stock. Prepared canvas is like collodion and wine—time ripens and improves it; and, in selecting it, see that it is sound and somewhat elastic, and without that habit, which some over-sized rolls have of cracking when handled, bent, or folded. Age also seems to abolish some of the bad habits of the newer or more youthful material, habits not suited to the best qualities of photographic printing, for which proceed as follows:—Take the strained canvas, wash it over with a cloth (flannel by preference) and water, using a little dry, washed whiting along with it to remove any surface impurity, finger marks, or grease, which often occur to sully the surface: wash clean with water, after this, and while the painted surface is still damp rub over and into it, with a small bit of cloth rather than a brush, or pad of cotton, a sponge kept for the purpose does well enough, the salting solution, which is made up of half a pint of tepid water, 40 grains of common salt, to which add 10 drops of acetic acid and 5 grains of previously melted gelatine. When this is dried, which can be done in front of a fire, take a 30 to 40 grain solution of ammonia nitrate of silver, the method of making which is, or should be, well known, and with a bit of Canton flannel, or a fine sponge does as well, having marked with a pencil round the negative or negatives, say of the head and hands, the position they are to occupy in the picture, those places only need to be salted and silvered, rub lightly over with the ammonia nitrate in all directions, and dry at once in front of an open fine. Go over the same places a second time, dry as before, and the canvas is ready for printing. It is well to have a board the thickness of the stretcher and slightly less than the inside size, to keep the canvas level, and, having arranged this where the canvas can lie flat, place the negatives in their proper place with any little thing to weight them, on two sides only, there is need for nothing more in the way of pressure. The printing is very rapid, as silver printing goes, and may be fairly well judged by the colouration of the parts outside the negative or through the broad crosses, which should be scratched through the film to the glass. These also assist the registration when examining the print, which can easily be done by holding the edge of the negative with one hand and raising it slightly with the other. When sufficiently printed, wash with water run on from the tap until the surplus free silver is removed; do not tone, as there is no need for that, and fix with hyposulphite of soda poured on and kept in motion till fixation. This can be determined by the simple test of rubbing with the finger, when, if not fixed, the silver remains fast; but, if sufficiently so, then the silver will rub off easily under the finger. All that remains is to run the tap for a few minutes, for, the surface being impervious, there is nothing to retain any trace of hypo, the infinitesimal quantity of gelatine not being able to retain any of the fixing salt. The finished proof may be dried either in the air or in front of the fire, and is then ready for the artist. I have said nothing of the placing of the figure in the proper place, or of the sketching in with a crayon the outline of the figure where the negative is not made sufficiently large for this purpose, but will say a few words on the subject if that be needed. W. H. Davies.

PHOTOGRAPHIC INDUSTRIES—MESSRS. MORGAN & KIDD'S WORKS AT RICHMOND.

That the present popularity of the gelatino-bromide process for enlargements is due to the efforts of Messrs. Morgan & Kidd, of Richmond, more perhaps than to those of any other firm, will be easily recognised when it is understood that it is now some twelve or thirteen years since those gentlemen began to practise and exploit this system of photographic reproduction. The artistic beauties and technical excellencies of the bromide work which they themselves turn out to such a great extent, conjoined to the admittedly high qualities of the now universally known bromide paper of their own preparation, entitle them not only to recognition as among the earliest pioneers of the process, but also to the thanks

photographers generally for having been the means of firmly establishing an enlarging method which, on æsthetic grounds and on the score of permanence of results, has long since achieved a most favourable place in public estimation.

The growing use of gelatino-chloride paper may possibly tell adversely on bromide paper for contact work in small sizes, but for enlargements we have yet to make the acquaintance of the process which will displace gelatino-bromide, or even challenge its pride of position. This reflection was forcibly borne in upon us on the occasion of a recent visit to Messrs. Morgan & Kidd's works at Richmond, when we were favoured with the opportunity of making a rapid inspection of many of the departments in active operation. In what may be termed the exhibition gallery hang many charming bromide enlargements on paper and opal, both plain and coloured, which exhibit the capabilities of the process to perfection, while, before our departure we were shown some pictures over eight feet by four feet, intended for the Chicago Exhibition, and betraying a delicacy of gradation, wealth of detail, and harmony of effect such as one would expect to find in the very smallest work.

Numerous rooms are set apart for making enlargements, and in one of these, Mr. Kidd, who kindly piloted us through the intricacies of these many-roomed works, allowed an assistant to make a 23 × 17 enlargement for us "while we waited," and the vignetting of the picture and the masking off of portions of it during exposure by the deft use of a large card with an aperture in it, was in itself a capital object-lesson in a valuable item of photographic practice. It was also interesting to observe how the picture was developed in a very shallow glass-bottomed dish with a quantity of solution which scarcely looked enough to cover a half-plate print, let alone one the size under treatment. Needless to say that the dish was not merely rocked, but kept in rapid motion from side to side, so as to ensure the even flow of the developer. Iron still reigns paramount at Richmond, by the way. We notice that fixing of the prints is allowed to proceed in subdued light, that after washing they are well sponged down on an upright sheet of glass, and that they are cleared with acetic acid. For enlarging purposes daylight (with external reflectors) is used; in dark weather and at night the electric light is available.

A system of rapid contact printing, which we saw in progress, struck us as being very ingenious, and it will be of interest to the many thousands of readers of our Almanac, as the picture of the German Emperor given with the volume for 1892 was printed in this manner. The negative in a movable frame is fixed in an opening in the wall, behind which is a Welsbach light. The frame carrying the large sheet of bromide paper, upon which a number of exposures is made, is placed in position, the negative by a simple movement brought into contact, the exposure given, then the negative thrown out of contact, the frame carrying the paper moved, the negative again brought into contact, and the succeeding exposure given. At the time of our visit a large number of prints from one of Mr. Kidd's negatives of Durham Cathedral were being made.

Each batch of bromide paper that is made is subjected to test exposures under a graduated screen, and a trial picture is taken by exposure to a test negative having the widest range of tint. One room is set apart for the examination of the coated paper before packing; another for a critical review of prints before they are sent out. We saw the operation of packing the paper in the now familiar tubes, the making of frames for the finished enlargements, gilding, moulding, &c. (here a department of considerable extent and importance in itself), and were permitted to have a view of the large staff of lady and gentlemen artists at work on bromide paper and opal and carbon pictures.

Time did not allow of our making a detailed inspection of all the departments at Richmond, but we were fortunate enough in passing a considerable portion of our stay in the rooms devoted to the latest addition to their business which Messrs. Morgan & Kidd have made. This is the photo-mechanical and collotype department. Of the latter process a number of most charming specimens in various coloured inks, hang in an annexe of what we have called the Exhibition Gallery, which certainly take rank among the finest examples of this now favourite process of reproduction. In the collotype section, rooms are devoted to the coating, sensitising, and drying of the plates, the details of the process employed being given in a short paper by Messrs. Morgan & Kidd which we published a few weeks ago on the occasion of the demonstration given to the members of the Richmond Camera Club. Both hand and steam power are employed for the printing, the former for very small work. The collotype machines used are those of Messrs. Schmeira, of Leipzig, and work up to the largest sizes ordinarily available. Examples of Messrs. Morgan & Kidd's collotype work appear in the *Yachtsman*, *Knowledge*, and other publications; and while we were at Richmond we were shown, among other specimens, reproductions of corals for a work on the subject being prepared under the superintendence of Dr. Gunther, of the British Museum. Our last Almanac, as our readers know, also contains an example of the process, which has been highly eulogised.

As occasion requires the electric light is availed of for enlarging and illuminating purposes throughout the establishment. The non-actinic light employed in the enlarging rooms is of a most agreeable nature, oiled orange paper screening the lamps. Some of the developing trays in occasional use are of such enormous size that they can only be actuated on a species of ball-and-socket arrangement placed on the floor to support them. The ordinary water used at the works is drawn direct from the adjacent Thames, and passes through a huge carbon filtering apparatus much resembling a gasometer on legs. Asked how much paper was coated per diem, Mr. Kidd, in preference to committing himself to any arithmetical statement, smilingly said that the daily quantity would last almost any photographer a lifetime.

The premises cover a large area of ground, including, as they do, departments, in addition to those mentioned, for carbon printing, the coating and drying of the bromide paper, plate-making, &c. The number of rooms occupied defied our own attempts at counting, and Mr. Kidd's memory. But we did learn that the firm employs over a hundred persons (with the precise number of which, in contradistinction to the rooms, Mr. Kidd humorously said every Saturday made him acquainted), and in concluding these brief notes of a highly interesting visit we cannot more fitly do so than with congratulations to employers and *employés* at the good and cordial inter-relations which we did not fail to observe exist at Messrs. Morgan & Kidd's works at Richmond.

VARIOUS METHODS OF ADDING CLOUDS TO LANDSCAPES.

There has been so much said and written on this subject that one might think that everybody knew everything about it, and that the reiteration of the oft-told tale was but so much wasted time and paper. Notwithstanding this, a large percentage of those who practise photography for amusement consider it either a too troublesome a process to adopt, or do not feel themselves sufficiently expert to risk spoiling a print that is good in all other respects by an addition of which they feel somewhat doubtful of properly performing.

I am induced to make these remarks having occasionally met most painstaking and apt amateurs who would not hesitate to spend money and trouble over their hobby, and yet who make their prints with quite blank skies, or not more than slightly tinted, just sufficient to tone down the glaring whiteness of the paper. This, then, is my excuse for recapitulating the well-worn topic of how to put clouds to landscapes. The methods of performing this really simple process are somewhat varied, and most of them capable of producing satisfactory work when properly handled. The busy photographer will undoubtedly give the preference to that plan which is most easy to do and gives a minimum of waste. In the first place, a few words about taking a cloud negative will not be out of place.

We must not start with the idea of a cloud negative being necessarily that which will print an excellent study *by itself*, as many excellent pictures, from this point of view, are utterly unsuitable for adding to landscapes. The most useful in this connexion would probably make very poor, flat pictures by themselves. *Imprimis*, find your clouds by selecting some elevated or other position where there are no obstacles in the foreground or middle distance to interfere with a clear and unobstructed view of the horizon. The effect of perspective must be considered in clouds as much as in landscapes, and those taken with a *level* camera are generally the best and most effective. A little tipping of the instrument is of no consequence; but clouds, like the earth beneath them, are subject to the same laws of perspective, although these laws may be violated with less chance of attracting attention. It is preferable to set about copying them on a right principle.

The seaside offers the very best opportunities for good cloud studies, but it will be observed clouds formed over the sea are somewhat different in character to those over the land, especially as they approach the horizon. The photographer should have both kinds at hand. With regard to the position, one looking west affords most opportunity for effect, especially if we are desirous of moonlight or sunset effects. Of course, clouds may be found at all points of the compass, and those formed in the north-east or south-east are often very beautiful. A morning sunrise is not so good for our purpose as an evening sunset, owing to a greater proportion of vapour and haze than later on in the day, it being almost impossible to get sufficient

contrast in clouds if any haziness intervenes, a very little destroying the delicate nuances of shading that add so much to the cloud beauty. This fact makes cloud photography in towns difficult, for there is generally enough smoke to obliterate all clouds for some degrees above the horizon, if nothing else interferes in the form of chimneys and buildings. Clouds on the zenith are absolutely useless for any photographic purpose, always looking mappy and out of perspective when added to a landscape. This difficulty, no doubt, deters many from trying to make cloud negatives. Patience and opportunity are undoubtedly required, and a little disappointment must not be minded. Generally speaking, stormy weather provides the greatest variety of forms, and quiet after the storm is usually best of all.

Very fine cumulus clouds may be secured in settled summer weather, but the spring months generally afford opportunities for cloud work that should not be neglected. Some think a mackerel sky good for printing in; but, as this pattern of cloud depends for its effectiveness on the contrast of pearly white with deep blue, it is somewhat disappointing in the negative. Of all patterns of clouds, a rather dark one, with a bright edge, is most useful for combination printing, especially if there is only a small space to fill.

Our station being selected, its aspect carefully noted, there is no alternative but to wait for the clouds to arrange themselves to suit the fancy of the photographer. A finder in the camera is very useful. Unfortunately, a day when the most effective grouping occurs is often objectionable on account of wind or showers, and the elevated position selected adds to the discomfort. Bearing this in mind, a light, flimsy outfit is less suitable than a heavier and more substantial one. A good waterproof cover for the apparatus will often come in useful. It sometimes happens that the shutter of the dark slide has to remain open for some time longer than ordinary in order to make the exposure at exactly the right time. Extra precaution must be taken to prevent access of light to the plate in the interim. A cord tied to the camera screw, and pulled down firmly to the ground immediately beneath by means of a peg, a stone, or a loop in which the foot can be placed, will add considerably to the rigidity.

Any good, clear-working plate can be satisfactorily used, and should be backed. Excessive rapidity is a drawback. A plate such as the Ilford ordinary is quick enough with an exposure of half a second, and with a stop about *f*-64 for the time. No part of the limb of the sun should be visible in the negative if the clouds passing the sun are to be taken, or a dense patch of light will result, quite spoiling the effect.

The quality of negative required is a *clear*, *thin* one, showing good contrasts, and plenty of detail, with little density. The exposure and development must be calculated for this effect. Any lens giving a flat field and good definition is suitable. Very rapid exposures are not required, as a rule, although now and again an instantaneous one may be necessary; but better results for our purpose are obtained by longer exposures, the development being calculated accordingly. There are so many opportunities of taking clouds when they are nearly motionless, that such times should be selected for taking them. Owing to their distance, a slight movement in the masses of vapour is not noticeable on the negative with the short exposure required.

As to development, any of the usual kinds will answer. Such combination that would be used to render white drapery will make good clouds. Hydroquinone answers very well, but most of mine I have developed with pyro-ammonia well restrained. I would suggest that the kind of development to which the photographer is most used is best. Knowing what he wants, he sets about getting it as with any other sort of negative, and as far as I know there is no particular treatment required. A clear, thin negative is to be tried for, so thin that the prints over which it may be laid are distinguishable through all but the very densest portions. In a good diffused light (direct sunshine must always be avoided) a cloud negative should be sufficiently printed in ten minutes or less. The effect of using a too dense negative is to get a patchy effect, the dark clouds coming too dark for the landscape, and the light ones deficient in detail. If the printing is continued to get out detail, the whole thing will look heavy and bad, and the picture will lack atmosphere and become worthless; on the other hand, a clear, thin negative will enhance the atmospheric effect.

One great difficulty in using unsuitable cloud negatives is to so mask the picture that the junction between the two is unobservable. It is almost impossible to do this without either letting the clouds encroach on the distance of the landscape and get muddled up with it, or show a clear white space between the two, either of which is fatal to artistic effect. If the printing is properly managed with suitable negatives, if even two or three are used, the closest scrutiny should fail to discover the junction of them with the landscape, or any signs of double printing whatever.

EDWARD DUNMORE.

(To be concluded.)

ON THE APPLICATION OF PHOTOGRAPHY TO SEISMOLOGY AND VOLCANIC PHENOMENA.

THERE is scarcely a branch of art or science that does not at the present day call in the aid of photography, either directly or indirectly, and seismology is no exception. It may, therefore, not be out of place, in the case of a journal particularly devoted to this subject, to enumerate and briefly describe the various applications of photography that have actually been made, or that are suggested, in connexion with earthquake and volcanic phenomena.

EFFECTS OF EARTHQUAKES.

First, of course, we have the common application of photography to record the effects of earthquakes and of volcanic eruptions. The value of photographs of this kind cannot be over-estimated, but it will not be fully appreciated till considerable time has elapsed, and until future seismologists want to compare the effects of earthquakes and eruptions of their time with those of the present time. We can imagine of what value they will become if we think what we would give for an accurate set of photographs of the effects of any historical earthquake or eruption, say, of the last century. Undoubtedly, a hundred or two years hence, it will be of the greatest importance to geologists to be able to compare the condition, for example, of Bandai-san with its condition within a few days of the eruption that blew its upper half into the air nearly five years ago. The more rapid changes in the interior of the craters of active volcanoes can also thus be noted with advantage. Even such secular movements as the gradual rising or depressing of coasts may also, perhaps, be recorded more definitely than they have been heretofore.

There is one thing that should be emphasised here, and that is the importance of preserving systematically all photographs of the kind mentioned, printed by some permanent process. In cases where the photograph is of such general interest that the outside public may be looked upon for the purchase of anything over about fifty copies, the collotype process is, at the time of writing, to be recommended; in other cases the platinotype, in spite of its present comparative expensiveness, on account of the recent great rise in the price of platinum. Up to the present time, so far as the writer knows, such photographs as are of particular seismic interest are to be found scattered through various publications, but have not been systematically brought together in any single collection.

CURVATURE OF THE SIDES OF VOLCANOES.

Professor John Milne has used photography in determining the curvature of the sides of volcanoes.

That is to say, the inclination and curvature were measured from photographs at the time in existence. In using photographs for this purpose it is necessary to be sure that the swing back of the camera was vertical at the time the photograph was taken, otherwise the measurements will not accord with the truth. Now, although photographers have been pretty well drilled into appreciating the necessity of having the swing back of the camera vertical in the case of buildings, there are few that appreciate the necessity in cases where the subject contains no right lines, and the greater number of photographers "tip" the camera without bringing the swing back to the vertical again in photographing a high mountain. This is, indeed, one of the reasons for the commonly unsatisfactory rendering of mountains by photography. The effect of tipping back the camera without readjusting the swing back is to give an effect in the photograph as if the mountain were leaning away from the camera to just the amount that the ground glass leans back. In other words, the slope of the mountain is reduced, and the mountain is dwarfed. There may also be slight errors due to refraction.

COPYING SEISMOGRAPHIC RECORDS.

We next come to another set of uses of photography that need little more than enumeration. Thus the record of an earthquake, by nearly every seismograph, is scratched on smoked glass, the smoke film being afterwards fixed with common photographic varnish. It goes without saying that photography is the best way of obtaining copies of such records. The blue process is most commonly used, although, in the case of the small diagrams given by bracket and duplex pendulum seismographs, more delicate processes have a decided advantage. Except for want of permanency, albumenised paper is to be preferred to anything else.

It scarcely needs to be stated that photography has been useful in producing illustrations of seismological instruments, also, in a number of matters of detail such, for example, as the production of scales, with finer division than any that were readily procurable machine divided.

PROFESSOR W. K. BURTON.

(To be continued.)

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The second public exhibition of photographs by members and others of the above Society was opened on the 22nd inst. by the Mayor of Leicester (Alderman Underwood), in the Co-operative Hall, the latter a handsome apartment, no doubt admirably adapted for functions of a political or theological tendency, but leaving much to be desired when the object in view is to display to the best advantage a collection of pictures. However, arrived at length, mentally recalling a couplet well known on the Tyne-side—

"Stairs, stairs,
Who climbs them, *swears!*"

at the *locale* selected, we are able to chronicle a distinct success for the Leicester Society, and to congratulate them on a small but very creditable and interesting exhibition.

Some sixteen members sent in frames, and others were contributed by workers in various parts of the county. Dealing first with the work of the members, it is clear that the chief honours fall easily to the President (Mr. Porritt) and Mr. G. Bankart, both in reference to the artistic selection of the subject and careful, tasteful, technical handling of the negative. Mr. Porritt shows various enlargements, all excellent and pleasing, *Old Cottages at Knighton*, perhaps, taking the palm. The President's smaller work is also very good—No. 7, *Roman Bridge*, a difficult subject well rendered; No. 17, *Roman Baths;* and some charming studies in Derby and Wales, all worthy of particular notice.

Mr. Bankart's work is so well known and so good as hardly to call for further criticism. He contributes eighteen views—carbon prints—all, with one exception, rather cold in tone. It is a question whether a rigid adherence to one tone, say, engraving black or Indian ink, is desirable; we think not, and fancy that several of these fine pictures, notably the pure landscapes, would have looked better in sepia or brown. Mr. Bankart's carbon prints are, in quality and finish, up to anything we have seen in this beautiful process. Mr. Frank Brown shows several enlargements, all in his best style. Mr. F. G. Pierpoint also contributes three enlargements, all showing a considerable amount of work, but effective and pleasing, *Haddon Hall* making a striking picture. Mr. Pickering (the Hon. Secretary) is represented by a few architectural studies, all of good quality. Messrs. Seville & Co. exhibit, with other work, a very good enlargement in bromide, *Now for a Sail—Yarmouth Beach*, a familar and artistic subject. Mr. J. H. Seddon shows promise of better things to come in *Views in and around Knighton*. Other exhibits by members are contributed. Messrs. S. P. Baker, Cowdell, Robt. Frost, F. Jolliffe, S. S. Partridge, J. Toone (whose landscape work is the better), G. E. Woodcock, and A. W. Wilson. Mr. T. Scotton also proved a tower of strength to the home side by his collection of fine enlargements and architectural subjects, *Lincoln* and *Peterborough Cathedrals* being particularly deserving of praise. The exhibits loaned, and most of them shown at other exhibitions, comprise work by Bernard Alfieri—*The Grey Dawn, Sunset, Against the Sky*, &c.; examples by Mr. S. Francis Clarke; some half dozen charming studies by Mrs. Clarke; medal pictures by A. R. Dresser; studies and enlargements by the Autotype Company and G. W. Wilson & Co., the latter's exhibit including also work by F. M. Sutcliffe, the ever-welcome *Water Rats* and *A Stern Reality;* and Chas. Reid. Mr. J. Pike, of Leicester, sends six frames; Mr. Martin J. Harding, of Shrewsbury, some fine "bits" and snap-shot pictures, these latter very good indeed; Mr. Isaac Slater, of Llandudno, six landscapes, which for detail, selection and perfect tone are very hard to beat; and Mr. R. Keene, of Derby, a series of his well-known views.

Lantern slides by the President (Mr. Bankart), Mr. Wilson, Mr. Pickering, and others, were shown on the screen at intervals during the evenings; vocal and instrumental music also diversifying the proceedings.

It should be mentioned that the Hon. Secretary (Mr. Pickering), immediately after the opening ceremony, became the happy recipient, at the hands of the Mayor, on behalf of the members, of an optical lantern by Archer & Co.; this lantern was used for the projections, and is evidently a very fine instrument. It only remains to be said that the exhibits were well arranged, that a neat little catalogue was issued, and that the public attendance was everything to be desired.

Our Editorial Table.

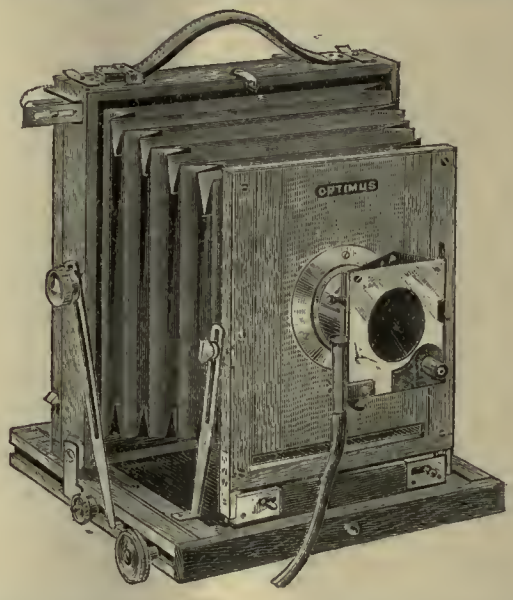
Stereographs.

By Horatio N. King.

Mr. King has sent us some choice stereographs, both ancient and modern. Those of the former class are views on paper of the Burnham Beeches, from collodion negatives, taken by him, in company of the late Frederick Scott Archer, over forty years since. The negatives from which these were printed must be in a state of good preservation, showing, as they do, no evidence of having faded. The others are transparencies on glass, forming views respectively in Windsor Castle, Haddon Hall, and Hampton Court Palace. These are backed by a matt varnish having an exceedingly fine grain.

Optimus Spirit-level.

Messrs. Perken, Son, & Rayment are introducing a small spirit-level for attaching to the side of the camera, and capable of being



used either laterally or horizontally, as indicated in the cut, the level itself folding back to the side of the camera, and being observable when in that position. It should prove a useful little adjunct.

PATENTS COMPLETED.

Improvements in the Manufacture of Pyroxyline Solutions and Compounds for Varnishes and Coatings.

(Communicated by Frederick Crane, Bloomfield, New Jersey, United States of America.)

No. 6542. Joseph Sinclair Fairfax, 433, Strand, London. *February* 18, 1893.

This invention, as communicated to me by my foreign correspondent, relates to improvements in the manufacture of pyroxyline solutions and compounds thereof for various useful purposes; and it refers to solutions and compounds of a similar nature to those employed in my application No. 6543 of even date herewith.

The pyroxyline, or nitro-cellulose, used in the manufacture of these compounds is of the kind or grade known as soluble pyroxyline, and is obtained by subjecting vegetable fibre to the action of nitric acid, or of nitric and sulphuric acids, in a manner well known.

The solutions and compounds referred to are in a liquid, or semi-liquid, condition at the time of their use or application as varnishes or coatings, and which eventually become set and hard. The invention consists in the employment of certain known fluids which have been discovered to possess the property of dissolving pyroxyline at ordinary temperatures, and which also impart to the pyroxyline solution or compound made by their aid certain peculiar and desirable properties. For many purposes for which pyroxyline compounds are used, and particularly where such compounds are used in the form of thin solutions for lacquers or varnishes—or in the form of heavier solutions to be evaporated down to a solid film—it has been found especially desirable to use a solvent for the pyroxyline which would volatilise with considerable rapidity, and at the same time would not absorb water or moisture from the atmosphere to any appreciable extent. So far as hitherto known, no one solvent for pyroxyline combined both these properties of quick drying and non-affinity for water, and it has been customary to use a compound solvent therefor. By this is meant a solvent consisting of several distinct substances artificially united for the purpose of producing the kind of solvent required, and this compound solvent would consist—in part at least—of liquids having an affinity for water; as, for example, methyl alcohol and acetone. The compound solvent would also partly consist of non-hygroscopic liquids (not having an affinity for water), such as amyl acetate and benzine, the two classes of solvents being mingled in such proportions as would be necessary—in each case—to produce a solvent sufficiently non-hygroscopic for the use for which the pyroxyline compound was required.

Now, it has been discovered, and communicated to me by my foreign correspondent, that the substance commonly known to the trade as acetone oil, when purified as hereinafter mentioned, is not only a powerful solvent of pyroxyline, but dries with considerable rapidity: that it is practically non-hygroscopic, and can be used either alone or in combination with some miscible and cheaper liquid (such as benzine) as a solvent for pyroxyline in all pyroxyline compounds where heretofore it has been necessary to use compound solvents.

This acetone oil is composed mainly of what are known as volatile ketones, boiling below 140° C. These ketones may be obtained by the destructive distillation of metallic acetates. While a chemically pure and dry acetate should yield a pure acetone with simultaneous formation of the corresponding carbonates, the crude or commercial acetate will yield a distillate containing in addition to acetone and water these higher ketones along with certain acetates and other decomposition products.

The acetone and water having been eliminated by the usual processes of fractionation and absorption with dehydrating agents, there remains an oil, which my foreign correspondent informs me has valuable properties.

For some uses, however, it is not necessary to remove the acetone, for it is a solvent of pyroxyline, and, where a non-hygroscopic liquid is not required, it is not injurious to the compound, even if present in considerable proportions, while, if a practically non-hygroscopic solvent is desired, a small proportion of acetone is rendered innoxious by the presence of these non-hygroscopic higher boiling ketones.

When the acetone oil has been purified, as above stated, by removing the excess of acetone and water, the volatile ketones remaining are but slightly absorbent of water—that is, are practically non-hygroscopic—and are miscible in large proportions with petroleum and mineral naphthas, and many of the other liquids useful in pyroxyline solutions or compounds.

It is to be understood that I do not confine myself to any particular source for, or process of, obtaining this mixture. For example, the acetates of calcium, barium, strontium, lead, and probably others, when destructively distilled, all decompose with the formation of ketones as an invariable feature; and therefore I desire to avail myself of any of the acetates as a source of the said ketone oil mixture. In applying the invention I may employ these ketones alone, or with other miscible harmonious liquids in compounds of pyroxyline. Nor do I intend to confine myself strictly to the boiling point mentioned, but merely give the boiling point of 140° C. as one at which the most valuable of these products will have come over in fractionation.

Having thus outlined the invention, I will now proceed to specify some of the mixtures and uses to which the same may be applied. For pyroxyline compounds to be used as lacquers or varnishes where it is essential that the film or coating remaining after the solvent has evaporated should be adhesive, tough, hard, smooth, free from cloudiness, and especially where quick-drying qualities are essential, the following formulas have been found useful:—

15 gallons methyl alcohol or acetone.
50 gallons petroleum naphtha.
35 gallons volatile ketones or acetone oil.
25 pounds soluble pyroxyline;

Or for a solution required to be still more non-hygroscopic:—

50 gallons volatile ketones or acetone oil.
50 gallons petroleum naphtha.
25 pounds soluble pyroxyline.

It will be understood that the consistency of these solutions may be varied by using more or less pyroxyline, but the above will dry at ordinary temperatures, and will produce a varnish film having the desirable qualities above mentioned, and that other substances may be combined with the above to meet special requirements.

Claims:—1. The combination of acetone oil with pyroxyline, substantially as and for the purpose hereinbefore described. 2. The combination of purified acetone oil or higher ketones with pyroxyline to form a practically non-hygroscopic quick-drying solution, substantially as and for the purpose hereinbefore described. 3. The combination of acetone oil, or of higher ketones, with pyroxyline and miscible harmonious liquids, substantially as and for the purpose hereinbefore described. 4. The combination of acetone oil, or of higher ketones, with pyroxyline and miscible harmonious liquids, substantially as and in the proportions hereinbefore described and specified.

Improvements in and relating to Automatic Photographing Apparatus.

No. 3014. Hector Joseph Bonaventure Thiroux, Boulevard Henri IV., Paris, France.—*February* 16, 1893.

This invention relates to photographing apparatus intended, on the receipt of the desired coin, to automatically expose a sensitive plate, and thereafter develop and produce a permanent photograph thereon, and deliver the same to the purchaser.

In the improved apparatus, the necessary baths into which the plate is dipped after exposure are arranged in a straight line, and the plate is carried, while in each bath, by a pivoted carrier, operated by a rack movement on, or controlled by, a carriage moving along over said series of baths.

Each carrier, on lifting the plate from the respective bath, holds the same under a rose, while the carriage automatically opens a cock by which water is supplied from a reservoir to flow over the plate; the plate is then transferred to the next carrier and immersed in the next bath. When any person desires to be photographed, that person stands in front of the machine and draws out a handle, which carries back the carriage to its commencing position, lifting the cover from in front of the dark chamber, and so exposing a sensitive plate in the camera by a lever action operated by the carriage. On dropping the requisite coin into the slot, the lens is uncovered, and at the proper time again covered. The carriage, having been as aforesaid drawn back by hand, on release of the handle moves gradually forward under influence of a weight, and under control of a suitable speed governor, so that the exposed plate, dropping into the first carrier, is dipped in the first bath, and undergoes the successive operations necessary for producing a finished photograph by being transferred from carrier to carrier and bath to bath, as before mentioned, until the carriage arrives at the end of its course, when the speed governor and carrier operating racks are thrown out of gear, so as not to operate when the handle is again drawn out. In connexion with this apparatus I employ an electric incandescent light, of sufficient power for illumination of the person photographed just at the time of exposure, causing the mechanism to close and interrupt the circuit exactly at the correct moments, so that the electric supply may not be wasted. I also employ a small continuous electric light upon the machine sufficient to enable the instructions, &c., to be read.

A further improvement consists in an electric heating device to dry the photographic plates previous to delivery. This device is also intermittent, being supplied with current at the time only at which the plate to be dried is passing adjacent to it. It consists of a fabric of wire warp—for instance, copper, platinum, or other convenient metal—to be heated by passage of the current, and a weft of asbestos fibre.

Improvements in Photographic Cameras.

No. 5744. Walter Palmer, Westfield, Reading, Berks.—*February* 25, 1893.

My invention relates more especially to the photographic cameras known as "hand" cameras, and has for its object to reduce the size of the camera and to enable the focussing to be very rapidly effected.

According to my invention I employ a frame or part known as the front of the camera (to which is attached the lens and shutter of the camera), a central frame or part, and a frame or part known as the back of the camera (which is arranged for the holding of the negative picture). These frames or parts may be of any convenient shape. They are connected together from points within or without their sides by a system of lazy tongs, which may be applied to either two or more sides of the camera.

The lazy tongs start from one point of attachment on any one side of the back or front, crossing the central frame in one point within or without that side, and ending in one point on the corresponding part of the front or back.

The systems of lazy tongs are in planes either parallel or at right or other angles to each other, and the centres or points of attachment on which the parts work are fixed on the front central frame and back respectively, thus ensuring a rigid and parallel backward and forward movement of the front and back, the central frame being at the same time maintained at the proper distance between the front and back, no matter what may be the amount of expansion of the lazy tongs.

The movement of the lazy tongs also enables me to arrange a convenient focus indicator.

Within or without or both within and without the lazy tongs is a non-actinic casing or covering, capable of expanding or contracting with the movement of the front and back.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

March 23,—Mr. A. Haddon in the chair.

Angle of View.

Mr. Haddon (having temporarily vacated the chair for the purpose) said that Mr. Everitt stated that some years back the late J. H. Dallmeyer, in a pamphlet, had given exactly the same rule for calculating the angle of view included on a plate as he (Mr. Haddon) had done in his Almanac article. He (Mr. Haddon) would like to say that he was ignorant of that fact. Criticising Mr. Everitt's remark that artists sometimes placed the point of sight outside the picture itself, and the same gentleman's rule for finding the angle included by measuring the distance from the point of sight to the furthest point of the plate, Mr. Haddon asked, "If the rule were carried to an extreme, and applied to only a small part of the picture, would it be right to say that, in the latter case, the angle included was as great as in that of the former?"

Mr. P. Everitt, in quoting Mr. Haddon's rule, said its mistake was in taking the long side of the plate instead of the diagonal, and quoted Professor W. K Burton and Dr. Eder as supporting his (Mr. Everitt's) views.

It was understood that the subject would be further discussed at a future meeting.

The Association's Technical Lectures.—II. Cameras, Dark Slides, and Tripods.

Mr. Edgar Clifton delivered the second of the series of technical lectures already announced. In it he showed the development of cameras in use at the present time, describing the simple form of box camera used by Niépce in 1818; the collapsible camera; the telescopic camera of metal, suggested by Grubb, and which Mr. Clifton was of opinion might be serviceable for large sizes now. The first bellows-body cameras were made on the concertina principle. Having shown that the Kinnear camera, introduced in 1853, had been perpetuated in the conical-bellows cameras now in present use, Mr. Clifton exhibited a modern camera of that form, also one of square form, and dilated upon their respective advantages and disadvantages from a practical point of view. Latimer Clark's stereoscopic camera was shown and described, and the lecture concluded with an examination of dark slides, ancient and modern, as well as the various types of tripods.

A discussion followed, the lecturer being thanked.

The lectures, with the discussions upon them, will be ultimately published in book form, hence the brevity of our report.

Affiliation of Photographic Societies.—Meeting of Delegates, March 24, Mr. Edgar Clifton (Photographic Club) in the chair.—The Secretary announced that, since the last meeting of delegates, seventeen more societies had been admitted, bringing the total to forty-six in all. The sub-committee which had carried out the technical lectures on photogravure presented their report, in which they expressed an opinion that their success yields great encouragement towards undertaking something on similar lines in the future, and that they were very greatly indebted to Mr. Herbert Denison, and to Mr. Horace Wilmer, for their assistance. On the proposal of Mr. F. A. Bridge (Photographic Club), seconded by Mr. Beckett (Hackney Photographic Society), the report was adopted. The Chairman said that, owing to the lamented death of Mr. William Bedford, it would be necessary to appoint a fresh chairman, and on the proposal of Mr. P. Everitt (London and Provincial Photographic Association), seconded by Mr. A. Mackie (Photographic Society of Great Britain), Mr. Andrew Pringle was unanimously appointed. Mr. Everitt remarked that, up to the present, they had not received a balance-sheet, and he was of opinion that a regular date should be fixed upon which the annual balance-sheet should be presented, and he would propose that the Treasurer be requested to furnish a balance-sheet to date, and that such balance-sheet be presented at the next meeting of delegates. After some discussion it was seconded by Mr. Mackie and carried. The appointment of an independent Treasurer was raised, but at the suggestion of Mr. Bridge this was deferred until the balance-sheet should be in the hands of the delegates. The question of the organization of the Technical Albums was raised, and the Secretary was instructed to communicate again with the Secretaries of the Societies in the matter. A lengthy discussion ensued on the advisability of the Affiliation inviting a conference of Judges to consider exhibition rules, and it was finally decided that this should be done, and a sub-committee was appointed to arrange preliminaries, the sub-committee to consist of Mr. Beckett and Mr. Mackie, together with the Chairman, Mr. Andrew Pringle, with power to add to their number.

City and Guilds of London Institute.—March 22.—A paper was read by Mr. Staynes on *Pinhole Photography*. A special prize is being offered by Mr. Staynes for this class of work at the forthcoming competition of the Society.

North London Photographic Society.—March 21, Mr. Oakley in the chair.—A Special Lantern entertainment was given in the reading-room at Canonbury Tower, when there was a large attendance of the members of the Canonbury Constitutional Club as visitors. About 300 slides were shown, which, with few exceptions, were of excellent quality. A selection from the Leeds set was also shown, and some slides kindly lent by Messrs. H. M. Hastings and Guardia were much admired. The next meeting will be on April 11 instead of Easter Tuesday.

Harringay Photographic Society.—March 24.—A Lantern Lecture, entitled *The Thames from Source to Sea*, was given by the President of the Society (Mr. Dudley Towers), and a collection was taken for the liquidation of the debt on Emmanuel Church.

Hackney Photographic Society.—March 21, 1893, Mr. R. Beckett presiding.—Question: "Can any member give his experience of the Zoka hand camera?" Reply: "Good, as a low-priced camera." Question: "What lens is best for landscape work?" Reply: "Rapid rectilinear, or single landscape, if it will work at *f*-11." Mr. R. Beckett recommended having a lens that will cover a size larger than the plate, so that it will cover when the lens is raised. Mr. S. Herbert Fry then gave his demonstration of the Sandell plate. A question was asked, "If any special precautions were to be taken, such as against the light," &c. Reply: "No." A print was handed round—the subject showed the bright sun in one corner, boy on bicycle, rails against the sky in the background; there was no halation.

Putney Photographic Society.—The Members' Annual Lantern Slide Competition was held at the Society's rooms, Charlwood-road, on Monday, the 20th inst., Dr. W. J. Sheppard in the chair. Mr. A. Horsley Hinton officiated as Judge. There were two classes, viz., (*a*) Landscape and Seascape and (*b*) Figure Studies, Street Scenes, Portraiture, &c. The Society's bronze medal was given as first and a certificate as second prize in each class. The slides, in sets of six, having been passed through the lantern by Mr. Ovey, Mr. Horsley Hinton awarded the prizes as follows:—Class A, first prize, Mr. H. Faulkner; second, Mr. A. E. Smith. Class B, first prize, Mr. W. F. Gorin; second, Mr. W. Martin, jun. Having the power under the rules to award a silver instead of a bronze medal to the best set should it merit that distinction, Mr. Horsley Hinton stated that he had no hesitation in giving the silver medal to Mr. Faulkner for his excellent set of landscapes.

Richmond Camera Club.—March 20, Mr. G. W. Ramsay in the chair.—Mr. J. R. Gotz gave an able and interesting demonstration of the treatment of the different varieties of gelatino-chloride, and colloido-chloride papers of the well-known Obernetter make. Having shortly traced the history of chloride papers from their first introduction by the late Mr. Obernetter in 1867, Mr. Gotz described the different makes of Obernetter paper now in use, and showed finished prints upon each of them. He then proceeded to tone a number of prints in different toning baths, such as "aurol" (consisting of gold, sulphocyanide of ammonium, and chloride of strontium), the phosphate of gold bath, "Platinol," and others. Very beautiful results were obtained, especially with the matt-surfaced paper toned with aurol. He then developed some lightly printed pictures on colloido-chloride paper, our old friend pyro being the agent, and toned and fixed some in a combined, and others in separate, baths. Printed-out transparencies on glass and celluloid, and opals were also shown, the same emulsion being used as for the papers; and specimens were toned with gold and platinum. Mr. Gotz also showed and explained his changing box for cut films, an admirably designed piece of apparatus capable of holding three dozen films.

South London Photographic Society.—March 20, the President (Mr. F. W. Edwards) in the chair.—A considerable number of prints for the "Winter Work" Competition were handed in for adjudication. Mr. Bainbridge Lyon was declared to have secured the first place with his picture entitled *Roydon*. Mr. W. E. Harman's two farmyard studies, and Mr. E. J. Lester's snow-covered trees came next in merit in the order mentioned. The judging was done by the President, assisted by Mr. H. G. Banks and the Secretary. Mr. Ransom exhibited a hand camera called "The Queen," the invention of a South London resident, Miss Nellie Crouch.

Brixton and Clapham Camera Club.—March 21, Annual General Meeting, Dr. J. Reynolds, F.R.G.S. (President) in the chair.—The statement of accounts showed that for the year's working the income slightly exceeded the expenditure, notwithstanding the fact that considerable additions had been made to the apparatus and general stock. The new officers are as follows:—*President:* Dr. J. Reynolds, F.R.G.S.—*Vice-Presidents:* Messrs. J. W. Coade, F. Goldby, and W. H. Harrison.—*Committee:* Messrs. Bartrop, Butler, Dockree, Edwards, Kent, and Levett.—*Hon. Treasurer and Curator:* Mr. R. G. F. Kidson, 37, Villa-road, Brixton, S.W.—*Hon. Secretary:* Mr. B. E. Pinder, 7, Macdowall-road, Camberwell, S.E.

Tooting Camera Club.—March 22, Annual General Meeting, the President in the chair.—The Hon. Secretary read his report, and submitted Treasurer's balance-sheet for the past year, showing a balance in hand of 3*l*. The following officers were unanimously re-elected: *President:* Mr. A. H. Anderson.—*Vice-President:* Mr. J. H. Beckett.—*Committee:* Messrs. H. Berger, G. H. Dollery, W. Irwin, and R. Simmons.—*Hon. Treasurer:* Mr. C. D'E. Stowell.—*Hon. Secretary:* Mr. J. F. Child.

Croydon Camera Club.—March 22, the President (Mr. H. Maclean, F.G.S.) in the chair.—A large number of members' slides were passed through the lantern for selection to show at the Exhibition which opens on April 5. So numerous were the slides that, after nearly three hours, the further completion of the task was adjourned to March 29. The slides submitted were limited to such as would illustrate the following subjects:—"A Trip on the Continent," "In and About Croydon," "Holidays by the Sea," and "Rural Surrey," which will be respectively the titles of the sets shown by the members on the four evenings of the Exhibition, in addition to those of Messrs. Gale, Wilkinson, Brownrigg, and Hodges. Messrs. Ryan and Hereford were elected members.

Ashton-under-Lyne Photographic Society.—March 20.—Mr. L. E. Morgan, of Messrs. Fuerst Brothers, London, gave a demonstration of *Amidol Developer*. Mr. Morgan said that amidol was a new developer of one solution, and was very useful for the tourist. He also showed its working by developing a half-plate negative, a bromide print, and also a lantern slide exposed in the room. One of the members brought a quarter-plate negative he had exposed during the day, which Mr. Morgan developed very successfully.

March 23.—Mr. J. T. Lees gave a lecture on *Photographic Optics*. He explained the different forms of lenses by means of a large number of diagrams, also the use of the stop, and why and when it ought to be used. His lecture was very instructive, and of great benefit to the members present.

Glasgow Photographic Association.—March 23, Mr. William Lang, jun., F.C.S., President, in the chair.—The lecturer was Mr. J. Buchanan, who gave a very interesting and graphic account of his personal experiences of Chili and Chilian civil war. Gold mining and prospecting in the Andes were fully described, as was also the nitrate industry. The lecture was illustrated with a large series of slides from photographs taken by the lecturer, some showing the bombardment of the towns by the fleet; others, gold mining and nitrate operations on the Andes, at a height of 10,000 feet above sea level. At the close, Mr. Buchanan was awarded a vote of thanks.

Photographic Society of Japan.—February 3.—Dallmeyer's new "telephotographic" lens was shown and explained by Mr. W. K. Burton. The lens consisted of a Dallmeyer patent portrait lens, with a back attachment in the form of a diverging lens of short focus. The lens gives an image many times larger than can be got by an ordinary lens, with the same extension of the camera; moreover, by making certain adjustments, the focal length of the combination can be changed at will, so that, within very wide limits, any size of image that was desired could be obtained. For example, a photograph of Ueno, from Kaga Yashiki, had been taken on a 12×10 plate, with a single rapid rectilinear lens of sixteen-inch focus, and a photograph had been made with the new "tele" lens, adjusted so as to have the same back focus. The photograph taken with the rapid symmetrical lens showed half of the race-course with the hill behind; but the whole of the grand stand could not find room on the plate with the "tele" lens. Mr. Burton had been successful from his very first experiment, but had to admit that he had found some difficulty in making the adjustment for correcting spherical aberration when the focus of the lens was changed. This difficulty he had no doubt, however, he could overcome. It was necessary to ensure absolute steadiness of the camera, as the slightest motion resulted in lack of definition. The lens shown was mounted

n aluminium, and was ext ordinarily light. Negatives taken on the 'Sandell" plate were shown, an l an explanation of the plates was given. The plate was coated with several films of the emulsion, one over the other. Next the glass was a film of very slow emulsion ; on the surface, one of the highest sensitiveness. It seemed impossible to get halation with this plate. The explanation of this lay in the fact that a very slow emulsion transmits red light only, so that no actinic light can reach the back of the glass to be reflected therefrom. Further than this, if under-exposure were avoided, it was not of much consequence how long an exposure was given. If the upper film were ever so much over-exposed—even solarised—it was only necessary to continue development till an image was developed in the film below. The fog of the upper, over-exposed film could be removed by a reducer.

FORTHCOMING EXHIBITIONS.

April 5-8 ..... *Croydon Camera Club, Braithwaite Hall, Wellesley-road, Croydon. Hon. Secretary, G. R. White, 55, Albert-road, Croydon.

,, 10-29 ..... *Crystal Palace. The Executive, Crystal Palace, S.E.

,, 12-15 ..... *Bolton Photographic Society. Hon. Secretary, J. E. Austwick, 10, Rushton-street, Bolton.

,, 17-29 ..... *Photographic Society of Philadelphia. Hon. Secretary, R. S. Redfield, 1601, Callowhill-street, Philadelphia, U.S.A.

May 4-6 ..... *Forfarshire Photographic Association. Hon. Secretary, W. J. Anckorn, West Port, Arbroath, N.B.

* Signifies that there are open classes.

Correspondence.

RAPID SOLUTION MAKING.

To the EDITOR.

SIR,—In response to the challenge of "Atticus," I herewith send you the required list in a sealed envelope, merely premising, firstly, that, before opening and publishing it, you satisfy yourself that the money will be forthcoming if the adjudication be against that correspondent; and, secondly, that "Atticus" consents to your adjudication being final.

With regard to such other part of his letter not thus touched upon, I can only say his quotations are mainly incorrect or garbled, and his statements mainly incorrect. The original article referred to, and the letter of "Atticus," are all published, and any one sufficiently interested to refer to them can see that. I am stating pure facts. "Atticus" refers to "gentlemanly and just criticism." I think the space of the JOURNAL would be less wasted if he confined his remarks to subjects he was familiar with.

As to Messrs. Martin, I at once accept their disclaimer as intending a covert sneer, but I must say that I think any ordinary reader would see it as I did; but, if the paragraph quoted from their first letter on the subject had used the words of this last, "photographers uninstructed in chemical manipulations," no objection would have been raised.

I regret that Messrs. Martin still persist in accusing me of making a false claim in the same breath that disclaims any such act. They say, quoting me, "What is this but a claim to having invented an article on sale at Doulton's?" I reply I made no such claim, for, if I did, it would be false; the words I use bear no such interpretation.

I do not think it is worth more discussion, and I can sincerely say I hope to be able to have a friendly hand-shake with Mr. Martin at the Plymouth Convention.—I am, yours, &c., G. WATMOUGH WEBSTER.

March 27, 1893.

[The sealed envelope referred to by Mr. Webster is in our possession, and we shall be glad to hear from "Atticus" as to his willingness to accept our adjudication as final.—ED.]

MASKING NEGATIVES.

To the EDITOR.

SIR,—I see in your article in THE BRITISH JOURNAL OF PHOTOGRAPHY of to-day's date on "Composition Printing" the plan of painting over the part to be masked with gamboge or some other non-actinic colour is attributed to Mr. Edge. I may say the device was my own, introduced at the time I was manager for Mr. Edge, and which I have found a plan of great value many times since, and for many other purposes than that of adding natural backgrounds to portraits.—I am, yours, &c.,

27, *Glenthorn-road, W., March* 24, 1893. EDWARD DUNMORE.

INTENSIFICATION.

To the EDITOR.

SIR,—Mr. T. N. Armstrong always writes with such a completeness of knowledge, and out of such a fulness of experience, that whatever he propounds is of interest, and whenever he recommends a departure from the ordinary, one is ready to believe that he has found some good reason for such departure. May I therefore, as one who has used the cyanide of silver process of intensification for, say, some years, ask whether the formula given by him has any advantages over the ordinary formula as originally given by Dr. Monckhoven, and known by his name? The formula is simplicity itself, being just.

No. 1.

Bichloride of mercury ..... 10 grains.
Bromide of potassium ..... 10 ,,
To each ounce of water.

No. 2.

Nitrate of silver ..... 10 grains.
Cyanide of potassium ..... 10 ,,
To each ounce of water.

which at least is easier to recollect than Mr. Armstrong's arrangement.

Further, I would ask intending users to pause before they throw away their used solutions. They are not the cheapest solutions that photographers use, and I, for one, have never found the least detriment to result from using them over and over again *ad libitum*, and almost *ad infinitum*. If my experience has been unusual, I should be glad of correction by others who have also fairly used the process.—I am, yours, &c., W. BISHOP.

25th March, 1893.

ANOTHER "HARD CASE."

To the EDITOR.

SIR,—Could you inform me when the Photographers' Assistants' Union is going to think about business? Although long talked of, nothing seems to move, and I think, as every other assistant I meet thinks, it is high time we had some Union, considering the way employers are imposing on us. I have a wife and four children to keep, and the highest wages I can now obtain is 25*s.* per week (which is next door to starvation), although I have been an operator these last fifteen years. I have just been compelled to give up a situation at above wages because, not being able to afford to ride, I had to walk sixteen miles per day, and work from 9 a.m. till 7 p.m. with nothing inside me but a few slices of bread and butter every day. Myself, wife, and children are in nothing but rags, and we have to all live in one room. I cannot put it down to depression of trade (although I know trade is bad enough), for the last man I worked for, whose takings averaged about 40*l.* per week, only paid me 25*s.* per week to do about three people's work, but thought nothing of squandering away 6*l.* to 7*l.* per week in cigars, cabs, and champagne nearly every week. A friendly hint in your paper would do much towards some sort of Union amongst assistants, and would secure you our most hearty thanks.—I am, yours, &c., SWEATED.

March 27, 1893.

REDUCING ACTION OF HYPO ON AMIDOL-DEVELOPED PRINTS.

To the Editor.

SIR,—I had a curious experience a few days ago which I have not seen previously mentioned, *i.e.*, the reducing power of a hypo bath in which bromide prints developed with amidol have been fixed.

I developed four bromide prints with amidol and fixed them in a freshly made hypo bath. On the following day I developed another print with amidol, and as I had not time to mix a fresh fixing bath I used the one of the day before. I left the print in the bath rather longer than usual (about half an hour) and was astonished to find that the image had almost entirely disappeared. I tried another print afterwards as an experiment, and the same reduction took place. The bath was certainly not fit to have used a second time, being discoloured through insufficient washing of one of the prints fixed the previous day, which had probably carried a good deal of the amidol developer into it. I should like to know if this reducing action has already been noticed.—I am, yours, &c.,

18, *Hough-green, Chester, March* 27, 1893. J. N. HIONETT.

MIXED DEVELOPERS.

To the EDITOR.

SIR,—In reference to your remarks on the above, I may mention that I find metol a very useful addition to pyro developer in certain cases. If the detail hangs back after the full quantity of soda is added, I find a small quantity of a two-grain solution of metol is wonderfully active in bringing it out.—I am, yours, &c., CLIFFORD E. F. NASH.

Cheltenham, March 27, 1893.

A PAIR OF COMPLAINTS.

To the EDITOR

SIR,—From an advertisement in your paper I forwarded on approval a camera and three slides to a photographer in a small town on the borders of Wales. The camera and slides were quite new, and I sent them on

just as they came from the makers in a wooden box by parcel post. After a good deal of delay and writing several times, I hear from the photographer that the camera is in a "swollen" condition (note it was perfect and just as it left the maker's), and that he would not pay return postage; so I sent stamps for it to be returned. Not contented with this, he actually keeps the wooden box camera was sent in, and returns it and the slides simply wrapped up in paper without any protection, and the consequence is it arrives in a damaged condition, and will cost probably 10*s.* to 20*s.* to repair. Truly a mean act, and a specimen of what the borders of "gallant little Wales" can do.

I should also like to say a word as to my experience of how some of the "cash with order" firms treat their customers. Say a varied order amounting to 2*l.* or 3*l.* is given and cash sent. From this will be deducted 3*s.* to 5*s.* for box and packing, when the box often consists of a frail piece of cardboard, or at best an old grocer's box, probable value 3*d.*; and goods accordingly are kept back, thus adding ten to fifteen per cent. to the price of the articles. Often, again, goods ordered are not in stock, and you are kept weeks and sometimes months waiting without any compensation; and should you mildly suggest that having paid the money you expect the goods in a reasonable time, you are told it would be simply impossible to keep everything catalogued in stock, &c., &c. Should firms insist upon "cash with order," they should be in a position to supply the same or refund money by return.—I am, yours, &c.,

Finnart House, Ballantrae, Ayrshire, March 25, 1893. JOHN POWER.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

H. PICKERING.—Received; thanks. We had already arranged to be represented.

C. GARDNER.—The collotype process is not patented. The patent for the Woodburytype process has expired.

J. C. W.—If you have not registered the copyright, there is no redress. Treatment such as you detail is by no means unusual by the illustrated papers.

A. WHITE.—Send a sketch or rough plan of the proposed studio and the surrounding buildings. On the other matter, refer to the local regulations as to buildings.

S. W.—A lens with an an aperture of *f*-6 will do admirably for a hand camera, but we doubt whether any lens of this aperture, of four-inch focus, will cover with fine definition to the edge of a quarter-plate.

H. THORNE.—Quite true. It is illegal to copy a bank note by photography or any other means, even if the size be different from that of the original. Probably, if the size was an inch or so less, no notice would be taken; still the illegality is the same.

W. WILLOUGHBY.—Burton's work on *Photo-mechanical Printing*, published by Messrs. Marion, Soho-square, deals fully with collotype. Numerous articles on the subject have also from time to time appeared in this JOURNAL, which should be of assistance to you.

SODA.—1. See reply to H. Mace. 2. In the same way as albumen prints are burnished if they are made perfectly dry. 3. Not if you can get practical lessons from a competent teacher. 4. It depends upon the result required. The majority of sitters are not satisfied with prints from negatives that have not been retouched.

H. MACE.—Without knowing the form of the studio, it is difficult to advise as to the area of glass that should be employed; but, if it be of the usual ridge roof form of the dimensions stated, then the glass, starting, say, four feet six inches from the background end, may extend for ten or eleven feet at the side and top. If you send us a sketch of the studio, we shall be able to advise you more definitely.

STUDIOS.—Several correspondents have written of late, asking advice as to glazing studios—the amount of glass, its position, &c. If these communications had been accompanied by a rough sketch of the structure, and its aspect, we should have been enabled to advise more definitely. The amount of glass in a studio should be dependent upon its size, its aspect, and the purpose for which it is required.

T. BIGGS.—We cannot advise you authoritatively. The case had better be submitted to a respectable patent agent. This much, however, we can tell you, if you have made, and publicly used, or sold the apparatus prior to the date of the patent, and can prove that you have done so, you can go on making it without let or hindrance. If the patentee, under these conditions, takes proceedings, he is sure to be defeated.

A. MCCANN.—Mildew stains can be removed from engravings by "cleaning or restoring" them. The usual method is to treat the engraving with a solution of hypochlorite of lime, to which an acid, such as oxalic, has been added, and then well wash with water to remove the bleaching agent. If the engravings are valuable ones, this kind of work had better be intrusted to experienced hands, or good prints may be ruined.

PERCIVAL & CO.—The so-called "gold bronze" on the tissues does not seem to us to contain any gold at all; at any rate, it all disappeared when touched by nitric acid. As gold is quite unaffected by this acid, you may draw your own conclusions. We do not think, however, it will prove injurious to the photograph, more especially as the ink upon which the bronze is dusted and the paper intervene between the bronze and the picture.

E. G.—If the prints turn yellow in the fixing bath, it shows that the solution is out of order. "Two ounces of hypo to the sheet" is no criterion as to the strength of the solution used. That should be four ounces of hyposulphite of soda to the pint of water, and should be made fresh for each batch of prints If this strength be employed, and the hypo is good, there should be no yellowness in the prints, provided the time of immersion is sufficient.

C. WADE.—From what you say of the camera, we think it wants thoroughly scraping and re-French polishing. If you are not up to this work, and do not have it done for you, we should say the best thing would be to obtain one or other of the commercial furniture polishes, and use it according to the directions supplied with it, taking care, first of all, that all dirt is carefully removed with soap and water. If this be not done, the dirt will show more prominently than it did before.

RECEIVED.—W. Coles, and others.

FALLOWFIELD'S "REMEMBRANCER."—The last issue of Mr. Fallowfield's list has been received. It contains particulars of a wide range of bargains and novelties.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Fixtures: April 3, Excursion to Ely Cathedral, starting from Liverpool-street Station at a quarter to nine. 5, Annual Meeting. 17, Lantern Evening, *North Wales*, Mr. John A. Hodges.

PHOTOGRAPHIC CLUB.—April 5, *The "Sandell" Plate*, and adjourned discussion on *Toning and Fixing Baths for Gelatino-chloride Paper*. 12, Members' Open Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—April 6, a Paper by Mr. G. F. Williams on *Determination of the Speed of Plates*. 13, Paper by Mr. W. D. Welford, *The Influence of the Hand Camera*. Visitors are welcomed.

FORFARSHIRE INTERNATIONAL PHOTOGRAPHIC EXHIBITION.—The Committee of this Exhibition ask us to say that the 3rd of April is the last day for receiving entry forms from intending exhibitors, and exhibitors requiring forms must apply at once.

NATIONAL PHOTOGRAPHIC EXHIBITION.—Owing to the Easter holidays intervening, it has been decided to extend the time for receiving entry forms to Wednesday, April 5, 1893, and it is hoped that exhibits may be delivered at the Crystal Palace not later than that date.

KODAK CONCERT.—The Kodak Dramatic and Musical Club gave an entertainment to their fellow workers and friends in the "Mona Hotel" on Thursday, last week. The room was crowded, and the programme very attractive. Much credit devolved alike upon those who managed and those who took part in the proceedings.

WE understand that Mr. W. J. Belton, the well-known photographer of 26, St. Paul's-crescent, Camden-square, has been appointed by the Paget Prize Plate Company to demonstrate their printing-out opals and lantern slides before the photographic societies. Secretaries desirous of arranging a demonstration should apply to the Paget Prize Plate Company, Watford, N.W.

DR. ANDRESEN'S PHOTOGRAPHIC DEVELOPERS AND CHEMICALS.—We are informed that Messrs. Sharp & Hitchmough (of Liverpool), Messrs. James Woolley, Sons, & Co. (of Manchester), and Messrs. Mawson & Swan (of Newcastle-on-Tyne), have been appointed wholesale agents for Dr. Andresen's preparations in those towns and their surrounding districts respectively.

THE "SHASIN SOWA."—We have received a set of the *Shasin Sowa*, a monthly journal that has been running for over a year. Anglicised, the *Shashin Showa* is "Photographic Chat," and it is published (at Tokyo) in Japanese. Mr. W. K. Burton is an occasional contributor, and his articles are (fortunately) printed in English, otherwise it would have been difficult for us to decide as to the precise character of our young contemporary.

PHOTOGRAPHIC COMPETITION AT THE WELSH NATIONAL EISTEDDFOD.—At this Eisteddfod, which takes place at Pontypridd in August next, the following photographic competition will take place:—For set of not less than six or more than twelve photographs, illustrating the coal industry from the cutting to the shipment; prize 5*l.* For set of not less than six photographs illustrating the industries of Wales; prize 5*l.* For set of six instantaneous photographs of a football match, illustrating various phases of the game; prize 2*l.* For landscape photograph; prize 1*l.* For architectural photograph; prize 1*l.* Adjudicators:—Messrs. T. Forrest, B. Thomas, and Lawrence. Photographs to be sent to the General Secretary, National Eisteddfod of Wales, Pontypridd.

*** *Several answers to correspondents are unavoidably held over till next week.*

COMBINING ENLARGEMENTS FROM DIFFERENT NEGATIVES.

If an enlargement from two or more negatives were required to be made on bromide paper, so as to form one picture, there are many who would not know how to proceed in order to obtain a successful result. We have, indeed, known professional enlargers to decline to undertake this class of work. Yet, the matter is easy enough, provided the system of protecting the first exposed image with a non-actinic pigment, while the second is being impressed as described a fortnight ago, in connexion with combination printing, be adapted to the circumstances. Of course, as the image after the first exposure has been made is not visible to the eye, the procedure has to be somewhat modified. By way of illustration of the method, let us take two negatives similar to those cited in the article referred to, namely, a group of several persons, and it is desired to introduce a figure or two that is in one negative into an enlargement from the other. The latter being the principal subject, we will term this the first, and the other the second negative.

In the first instance, make a print from each of the negatives, and cut out such portions of that from the second one as are to appear in the enlargement, and stick them in position on the print from the other. This picture is to serve as a guide for arrangement in making the enlargement. Then stop out with black varnish all portions of the second negative, except those utilised in the guide print. In place of stopping out with black varnish, a paper mask cut out from a print may be fixed on the negative; but, by whichever plan the blocking out is done, it must be complete, as any light that would pass through it would destroy brilliancy. Now take the two negatives together with the guide print into the enlarging room, and put the masked negative into the enlarging camera or lantern. Project the image on to a piece of white paper, fixed on the easel, of the same size as the enlarged picture is to be, and arrange it in the position it is to occupy in the finished picture, as guided by the small print, and focus. Cap the lens, and substitute a piece of bromide paper for that focussed upon, then make the exposure, giving such time as this negative may require. It will be obvious that, if the paper were developed at once, the figure would be obtained on a perfectly plain white ground.

It is now necessary to protect this already impressed image while the exposure to the primary negative is being made. Cover the lens with a piece of orange glass; that will allow of the optical image still being seen, while the light will have no action whatever on the paper. Now, without disturbing anything, neatly paint over the image with a non-actinic pigment. With prints on albumen paper, almost any water colour can be employed; not so, however, with gelatine paper, owing to the coating being more absorbent of water, so that a permanent stain of the pigment might be produced. The best pigment to use is powdered gamboge—to be obtained from all druggists—mixed with alcohol, as then the gelatinous coating of the paper is not moistened with water at all, and the risk of staining from the colour is thereby avoided. As, however, the gamboge is difficult to see in the feeble orange light, it is advisable to mix some other pigment with it so as to make the brushwork more easily distinguishable. A little finely powdered ivory black answers admirably, and the resinous character of the gamboge serves as a sufficient adhesive to fix it temporarily to the paper. The pigment will dry in a few minutes, though it is not at all necessary to wait for that.

When the first exposure has been properly protected, the negative is removed, the paper being left undisturbed; the other, the principal, negative is now put into the enlarging apparatus, the yellow glass still being kept on the lens, and adjusted so that the enlarged image from it will occupy its right position as regards that already impressed on the sensitive paper. The small print must here be brought into requisition as a guide once more. It is at this stage of the work that the advantage of strengthening the colouring power of the gamboge in the yellow light, with the little black, will be most appreciated. After the right position of the principal negative is obtained the image is focussed, the yellow glass still being retained on the lens. When all is ready, the second exposure is made, of course, in accordance with the density of this negative, and quite regardless of what the previous one may have required.

The doubly exposed paper is now taken to the dark room, and the pigment removed with a soft sponge or pledget of cotton wool moistened with spirit. It is then ready for developing and fixing in the ordinary way. There is, however, a little precaution to be taken. The spirit, when the pigment is applied, has a slightly hardening action on the coating of some gelatine papers, so that they become rather less readily absorbent of water. Therefore, it is a good plan to allow the paper to soak for a rather longer time than usual in the water before the developing solution is applied. This prevents any unequal action of the developer on the two exposures.

In the foregoing it has been assumed that the proportions of the images in the two originals are identical, but it often happens that they are widely different. Hence they have to be brought into unison by the greater or less amplification of the one than the other. This often necessitates the paper being removed from the easel and replaced between the two

exposures. Therefore an accurate system of registration is imperative. Want of space necessitates this portion of the subject being deferred till some future occasion.

WASHING THICKLY COATED FILMS.

The tendency during recent years in the preparation of gelatino-bromide plates has been in the direction of thicker films than were in vogue in the earlier days, that is to say, films of greater robustness, both in the matter of silver and of gelatine. Films composed of a more than ordinarily thick layer of gelatine, containing a comparatively small proportion of silver—making up in thickness, in fact, what they lacked in richness—had been tried, as had also the reverse conditions, a maximum of silver salts in conjunction with a minimum of gelatine; but, while the former were usually found to be slow in action and deficient in range of gradation, the latter were wanting in delicacy, and too often wanting in keeping quality.

Perhaps, however, the greatest difference to be found between the two classes of plates was in their physical character, more especially in their behaviour under the action of developing, fixing, and washing. With the earlier workers in gelatine plates the great difficulty experienced was in conjunction with the length of time occupied, as compared with collodion, in development, and, subsequently, in fixing and washing. It was soon found that this difficulty increased in proportion to the comparative richness of the emulsion in gelatine, and that, if the same quantity of silver bromide were spread upon the plate with less gelatine, the result was an image of equal or greater vigour, and capable of passing through the various operations in a far shorter time. The difference, in fact, in the behaviour of different makes and batches of the earlier plates was very puzzling, if not misleading, and slowness of development was frequently set down erroneously to want of exposure, and *vice versâ*.

For many years past, the necessity has been recognised of a fairly robust film of gelatine, if the plate is to possess the intrinsic qualities now considered desirable, and also the capability of withstanding ordinary wear and tear both before and after exposure and development. But still more recently several of the leading makers have put on the market special plates, bearing films of more than ordinary richness both in silver and in gelatine, and the present season sees the introduction of two, and even three, films, coated one on top of the other. The advantages claimed for such special films are sufficiently obvious, and need not be discussed here, our object being rather to consider what have been put forward as their disadvantages, or as objections to their use.

These objections—if they can be so called—centre, as we have suggested, in the length of time the various solutions take in acting upon the thick layer of gelatine. It stands to reason that, if a careless operator, accustomed to the use of thin films, or those weak in gelatine, gets hold of one of the thicker ones, and tries to treat it in the same way, failure will be the inevitable result; but he can scarcely blame any one but himself, as the instructions issued with such plates invariably draw attention to the necessity for increased care, especially in the matter of washing. But, on the other hand, the most careful worker may find the extra time occupied in fixing and washing too great a tax upon him for ordinary work, in which case the remedy is, we think, very simple, namely, to reserve the specially coated plates for the particular purpose for which they are intended, and for all ordinary work to use ordinary films. In thus acting, he will be only following the dictates of common sense; for, clearly, it must be an unnecessary outlay, both in money and time, to employ say, a triple-coated film—necessarily an expensive article—where a single one would answer every purpose as well or better. Let special films, in fact, be reserved for their special work.

Where, however, abnormally thick gelatine films are employed, it will be as well always to bear the fact in mind and to act accordingly. In the first place we have to deal with the development, which, like the various other operations, takes place more slowly than with a comparatively thinner film. Except, however, in the matter of a slightly increased difficulty in judging density, no trouble will be experienced here. There are possibly still some operators who adhere to the old-fashioned plan of soaking the film in water before applying the developer, but a very short experience with the thickly coated films will suffice to cause them to relinquish that system for reasons already sufficiently obvious.

The first portion of the manipulations in which unsuspected trouble may lurk is the washing after development and before fixing. In the ordinary course of work perhaps too little care is generally given at this stage, though with plates of normal character the result is not very serious. The necessity for washing at this stage arises from two causes: to stop development, and, which may appear to amount to the same thing, though it really does not, to remove the developing solution from the pores of the gelatine. The first result is arrived at, for all practical purposes, by rinsing the solution from the surface, after which very little further action will occur; but the application of a very weak solution of bromide will effectually arrest all further action. But if the plate—we are speaking now of one of the thick films—after but a brief rinse, be passed into the fixing bath, with its pores still impregnated with developer, another action altogether is set up. The hypo commences to dissolve the silver bromide, with the result that there are present side by side on the film, not only a soluble salt of silver, but also a reducing agent in the form of the unremoved developer, and until that developer is exhausted it will go on reducing the dissolved silver, and so cause fog or veil.

This is no imaginary picture, but actually what does occur, as may be proved in five minutes by actual trial. Where ordinary care—the ordinary care bestowed upon a normal plate—is given to one of the double-coated and no more, the result as regards veil is not great, but it is sufficient to take away from the negative that sparkle and purity of colour that belongs to a perfect image. The result does not take the form of a stain that may be removed by means of the alum bath, but consists of reduced silver of precisely the same nature as the image, and can only be removed by similar means—in other words, by reducing solutions.

Very many operators are in the habit of examining their negatives by daylight before fixing, a practice which has been over and over again condemned, but still prevails. With the thick films of to-day there is more than ever reason why the negative should be completely fixed before it sees daylight, owing to the greater difficulty of eliminating the developing solution, which, under the renewed action of light, must inevitably veil the plate.

The question of the possibility of preventive measures may be considered, although, in similar matters, we are always in favour of letting matters take their proper course with correct

treatment—that is to say, with fair washing, and plenty of it. The alum bath, either plain or acidified, may be applied after development; but it is, in our opinion, objectionable, for the same reason already referred to, the difficulty of removing it before fixing; for, as has frequently been pointed out, the application of a solution of alum to a film containing hypo, or *vice versâ*, is highly injurious instead of beneficial. But if a solution of metabisulphite of potash, or, what is nearly equivalent to it, a solution of sulphite of soda, acidified with citric acid, be applied to the film, it may be passed into the fixing bath almost immediately without danger, while the action of the developer will be completely arrested, as well as its staining power destroyed.

So far as the subsequent action is concerned of the fixing agent and alum, if used, and their removal, there is, we fear, nothing but patience and care. To facilitate the fixing operation itself, the bath must be of good strength, and the temperature kept up to 60°, or even higher. The practice of throwing a few handfuls of hypo into a quantity of cold water, to make an ice-cold solution for immediate use, will certainly not work satisfactorily with thick films. The temperature must be kept up, and, to ensure perfect fixation, a second bath should be used, and plenty of time given after fixing is apparently complete. After that, very thorough washing in a changing stream of water is the only means by which the stability of the negatives can be ensured.

A Large Photographic Society.—We learn that the Photographic Society of Vienna has a membership of over 500. With one exception, we in this country have no society with such a membership.

Platinum or Platinum-toned Prints.—At the last meeting of the Photographic Society of Great Britain the Chairman (Mr. John Spiller) stated that a solution of cyanide of potassium formed a test for ascertaining whether a print be in pure platinum or is a silver print toned by the agency of that metal. In the latter case, the silver forming part of the image is attacked by the cyanide, while the print in pure platinum is unaltered.

Meeting of Exhibition Judges.—The Affiliation Committee of the Photographic Society of Great Britain and the allied Societies are, we understand, taking steps to call a meeting of Exhibition Judges with a view of arriving at rules for their guidance. It will have been observed that Mr. Andrew Pringle has been appointed Chairman of the Committee, as a successor to the late lamented Mr. Bedford. The choice of Mr. Pringle could not well have been bettered.

Gaiacol (or Guyacol).—As bearing upon Colonel Waterhouse's recent experiments with gaiacol, Messrs. A. Béhal and E. Choay's remarks on the subject may be of interest. They find that the guyacols of commerce are essentially variable products, their boiling points ranging from 200° to 215°. None of them contain more than fifty per cent. of definite guyacol, the rest consisting chiefly of cresylol and cresol. Pure guyacol is a white, crystalline solid, fusible at 28·5° and boiling at 205·1°.

The Central Photographic Club.—We understand that the Committee of the Club, as the result of several meetings, have formulated a set of rules for the government of the Club, and have also come to a decision as to the financial basis upon which it will be carried on. A recommendation as to suitable premises has also been arrived at. In addition to the foregoing, several other matters of importance will be laid before a meeting of intending members and others interested in the Club, to be held at the Memorial Hall, Farringdon-street, on Monday evening, April 17, at eight o'clock.

Hyposulphite of Ammonium.—At a recent meeting of the Société Française de Photographie M. Labarre detailed the results of some experiments with hyposulphite of ammonium as a fixing agent. He recommended it for paper prints in preference to hypo, used at the same strength. It is more easily eliminated from the print, while it keeps better, and, if any deposit forms, filtration suffices to leave the efficacy of the solution unimpaired. These characteristics, as well as the ready solubility of the salt, its colourlessness, &c., confirm the results of the German experimentalist's conclusions which we quoted a few weeks back. The salt at present is very costly, but M. Labarre promises to give a method of preparation on an industrial scale.

"The First Photograph."—According to a daily contemporary, an interesting object for exhibition at the World's Fair at Chicago has just been dispatched to America. It is the first sun picture of the human countenance ever taken, and it has been lent by Sir William Herschel to the University of the City of New York, and will form a part of their exhibit. This Daguerreotype of his sister was taken by Professor Draper, of the New York University, on the roof of one of its buildings, and early in 1840 was sent as a present from that gentleman to the late Sir John Herschel, by whose family it has been preserved to the present time in exactly the same state as that in which it was sent to England. The loan of this interesting photograph has been made by Sir William Herschell at the request of the Rev. Henry M. MacCracken, Chancellor of the University, transmitted through the American Minister in London. The lady of which it is a portrait still lives, at the age of eighty-seven, and a recent portrait of her will be exhibited side by side with the picture mentioned above.

NATURALISTIC PHOTOGRAPHY.

[Photographic Society of Great Britain.]

Two years ago I withdrew my book, *Naturalistic Photography*, and I owe you some explanation for so doing. My researches into the subject of vision and perspective drawing were mainly responsible for that act, and if you will bear with me for a little I will endeavour to explain my position. When I first took up photography I was told by the whole photographic world (including optical experts)—told by all, without exception, that if the photographic observer closed one eye, and placed the other eye at the focal distance of the lens used in taking the photograph under observation, he would see the picture "true to nature." I felt all along that such was *not* the case, and maintained the "sharp" or any other photograph, when viewed under such conditions, was not true to nature—to nature as the *two eyes* see it, and hence arose a long and inky warfare.

Gentlemen, it was in this as in many other disputes—we were both right and we were both wrong.

The opticians were right from the mathematical standpoint, and I was right from the physiological and psychological standpoints, and so it was evident there were two truths to nature—the perspective or mathematical truth and the psychological or visual truth. After many practical experiments I found the closest truth to nature IN PHOTOGRAPHY (*from the physiological point of view*) was to be obtained by throwing the background of the picture out of focus to an extent which did not produce *destruction* of structure—that was my limit; the principal object of the picture being either sharp or just out of the "sharp." This convention I termed the naturalistic method of focussing, and pointed out it had no connexion with a general *soft sharpness* such as that produced by Mrs. Cameron's badly corrected "Jamin," or by pinholes, or by throwing the *whole* of the picture out of focus—practices all inferior from the naturalistic standpoint, in my opinion, to my method—which is a deliberate and conscious act to be modified according to circumstances, and no hap-hazard "dodge" like the "soft sharpness" or "bastard naturalism," as my friend, Mr. Balfour, calls the more mechanical "soft-sharp" method.

This naturalistic method I practised and advocated, and found later on, by further research, that it was justified by physiology. Well, gentlemen, all this led to a great storm in a teacup, and disputes arose as to how we did see with two eyes, and what was really *truth to Nature* from the visual standpoint. In the course of this

argument, I was pleased to find a broad-minded optician taking an interest in these matters. I refer to my friend Mr. Dallmeyer, whose acquaintance I did not make till after the publication of my book, and whose knowledge in practical optics has enabled him to make a lens of my conception (*i.e.*, the tele-photo lens), a lens which, to my mind, is the most powerful tool yet put into the hands of the decorative photographer, but still a lens that, I hope, is only a step to a better.

Well, gentlemen, all this argument—though warm at times—did good, and set many thinking, and at last I was lucky enough to drop upon the key to the solution, which key I published in April, 1890, in a number of *Photography*. It was a short paper, entitled, "A Note on Naturalistic Focussing." My friend Mr. Goodall, who has always been interested in the practice of photography, was told by me of this little research, and immediately he took it up enthusiastically, and suggested some new proofs and experiments, and together we published the results in a pamphlet, entitled, *Perspective Drawing and Vision*, a pamphlet that created another storm in the teacup, but a pamphlet whose propositions, I venture to say, still remain unshaken, though the Royal Astronomer at Sydney was invited to a public argument in the *Photographic News*—a challenge still open to him, or any other person of physiological or psychological training; and here I may say Dr. Griffiths and Mr. Sutcliffe were the only two photographers who were acute enough to see and acknowledge in public the force of the pamphlet.

Well, gentlemen, from this pamphlet it was self-evident to me that there is no *absolute* truth to Nature from the visual standpoint, for, as each man's sight is different, the only absolute truth to Nature for each man is his own view of her (though certain broad features remain true to all). On the other hand, from the mathematical standpoint, or perspective drawing standpoint, there is an absolute standard, such as the sharp photograph taken with rectilinear, and otherwise duly corrected, lenses.

Now, gentlemen, I will quote you a paragraph from a text-book on psychology, published only last year, a passage which shows how this view is now so far accepted that it has entered psychological text-books for students. The quotation is:—

"Almost all the VISIBLE shapes of things are what we call perspective *distortions*. Square table tops constantly present two acute and two obtuse angles, circles drawn on our wall-papers show like ellipses, &c., and the transitions from one to another of these altering forms are infinite and continual."

That, gentlemen, is the position. Whence it is evident that NO photograph gives things as we *see them* with our two eyes, though some photographs give results NEARER to what we see than others, and those are the naturalistic photographs.

The next question I put to myself was, "How true must the photograph be so that it may be considered naturalistic?" And this gave me much trouble, but at last I think I can offer the solution, which is, it must be true in fundamentals to the point of *illusion*. Thus a man's boots must not be twice as big as his head, and so on with everything.

So, gentlemen, what I advocate is, truth to the point of illusion (for I am not considering to-night scientific photographs, but decorative or pictorial photographs); and I may now say the methods of practice I advised in *Naturalistic Photography* I still advise, and the artists I held up for admiration in that work I still hold up as the best exemplars of their various crafts, but my art philosophy is different, as I shall show you to-night; and, lastly, I do not consider photography an *art*, but regard it as a mechanical (I say *mechanical* advisedly) process, whose results are sometimes more beautiful than art, but are never art, just as Nature is often more beautiful than art—just as the beautiful Japanese *lilium auratum* surpasses the painted lily—yet is the real lily not art but Nature. So the photograph is not art, but a mechanically recorded reflection of Nature. To state this matter more clearly, I have adopted a genealogical form of presentation.

NATURE.

(The fountain-head of sensuous impressions, but not necessarily of *ideas*.)

One | branch.

PHOTOGRAPHY.

(A cross between *Nature* and a *machine*.)

Two | branches.

Realism.
(The sharp photograph — wherein sentiment, illusion, and decoration are disregarded; merely a register of bald facts mathematically true.)

Naturalism.
(The more or less correct reflection of Nature, wherein truth of sentiment, illusion of truth (so far as possible), and decoration are of first importance.)

From which it is self-evident that I believe there is no true realism nor naturalism in the arts proper, but only in *photography*; for TRUE realism and naturalism are *impersonal*—the results of a mechanical process, which photography logically is—because, under the same *physical* conditions, the same *results* will always follow. Place the camera under certain physical conditions, and the same results will always follow, which is *not* the case with art, which is *personal;* indeed, the personal element in real art is paramount and all-pervading. Thus, art is a cross between *man* and Nature, or:—

ART.

(Cross between man and Nature—no machine intervening.)

Two | branches.

Impressionism.
(Which is a purely *personal* vision of Nature as thus: an impressionist may paint *sharply*, or may paint colours wrongly from defect of vision—as does Monet.)

Idealism.
(Cases in which the imagination is used; that is, the combining of several ideals into one harmonious whole. The idealist may transcend *known* Nature, and so the vase is produced.)

In brief, what I submit is, that all *artists* (who do not use photography, and such are bastards) are either impressionists or idealists, and that logically they *cannot* be either realists or naturalists, for they can never be truly *impersonal*. M. Zola *calls* himself a "naturalist," but he is not, as Mr. Thomas Hardy has pointed out; were I to classify him, it would be as a morbid impressionist. On the other hand, M. Viaud, a far more sensitive artist, has been called a "naturalist;" he has publicly denied it, calling himself an "idealist," which he is not—he is an impressionist; morbid, too, in his way. On the other hand, Theocritus I should call a sane impressionist, and Milton an idealist—or, to put it into paint, Mr. Whistler is a sane impressionist, and Rossetti an idealist. And there can be insane impressionists and idealists, as lunacy students know, as well as mediocre, mattoid impressionists, as was the late Richard Jefferies in literature, and (say) Prout in paint.

But still there is a link binding Nature, art, and photography together—a touch of kinship—and that is, *decoration*. The artist admires Nature when she "sings in harmony," *i.e.*, is *decorative;* he admires the photograph when it "sings in harmony," *i.e.*, is *decorative;* and he admires works of art when they "sing in harmony," *i.e.*, are *decorative*. Thus photographs must be *decorative* to appeal to artists, but that does not make them *art* any more than Nature is art when she is decorative. In a word, art is the personal expression of a personal vision of Nature or ideal. A decorative photograph is a mechanical reflection of Nature when she "sings in tune," the good photographer requiring to know when Nature does "sing in tune." In a word, he must have true perception of the beautiful to succeed, after that he is merely the starter of a machine.

If you will allow me to digress for a moment, let me here make a reservation. It is that it matters not, for *merely* decorative purposes, what lens be used, or how it be used; what exposure be given, or how it be given; what developer be used, or how it be used; what printing method be adopted, or how it be handled, *provided* always the result be *decorative*, for no photograph can be said to have any "art qualities" (this does not allow it can be art) without being first of all decorative—a harmonious whole. That is the first quality which differentiates the few photographs from the thousand. But there are higher qualities—degrees of interest and distinction, as it were—and to possess these it must be illusively true, and fine in its *natural* sentiment, as well as decorative; in a word, "naturalistic." And even Mr. Whistler (a far greater artist than philosopher) gives himself away upon this very point in what I, years ago, called his brilliant but illogical "Ten o'clock," though such an acute critic as Mr. Henley has called this lecture the greatest art writing of the century, which I submit it is not. In this "Ten o'clock," Mr. Whistler advocates throughout his work art, for art's sake (*i.e.*, pure decoration), as the be-all and end-all of art. But I submit that he gives his case away when he writes:—"*As did her high-priest Rembrandt, when he saw* NOBLE DIGNITY *in the Jews' quarter of Amsterdam.*" Or—"To the day when she dipped the Spaniard's brush in light and air, and made his people . . . . STAND UPON THEIR LEGS, that all nobility and sweetness, *and tenderness and magnificence should be theirs by right.*"

Gentlemen, "noble dignity," "tenderness," &c., have *nothing* necessarily to do with decoration, but they are the ALL-ESSENTIAL qualities for fineness of sentiment in the pictures cited.

It was on this very point that our greatest poet, Mr. Swinburne fell foul of Mr. Whistler and got worsted. I venture to think had Mr. Swinburne merely quoted these and similar passages his position would have been invulnerable, but he must "write." Indeed, truth

of sentiment and fineness of sentiment are distinctly advocated as virtues in these passages, and as I have always claimed them to be, and so what becomes of *l'art pour l'art* theory and the nonsense that "subject" has nothing to do with it. I have always maintained "subject" is as necessary as decoration for the perfect work, and I still maintain it; but the incompetent misunderstand "subject"—confounding it with "story-telling."

What is wanted in naturalism is a decorative illusion of Nature, a decoration embodying some fine and true *natural* sentiment, the decoration without the sentiment (not sentimentality) is a mere sensuous patchwork of colour, the sentiment without the decoration is mere "literature in the flat," and the truthful illusion without either sentiment or decoration is a mere statement of fact, which explains why Mr. Whistler's masterly "Carlyle" must always be of more *interest* than (say) a "still-life" picture by the same hand.

This may be a fitting place to insert a warning against an error born of misunderstanding. It has been said many times that, by-and-by, photographers will do works of art when they get "soul" into their photographs; this and all sorts of pretentious rubbish has been written by third-rate painters and second-rate photographers. Gentlemen, the photograph that is fine in sentiment and decoration and true to illusion can never be *improved upon* any more than can the statue of the Venus of Melos. A perfect work is good for all time, as Mr. Whistler has said. Means are now at the command of photographers to produce the perfect black and white photographic work, though in future increased *facilities* for producing such work may be found by inventors.

P. H. Emerson, B.A., M.B. (Cantab.)

(To be concluded.)

ON THINGS IN GENERAL.

One of the events of the month must be considered Mr. Taylor's paper on *Spirit Photography*. What were the results, and how obtained? That is the question, and the reply has not yet been given. It was amusing to see the truly logical reply of the veteran fencer to Mr. Downey, who thrust at him straight, "Does Mr. Taylor think there were such things as spirit photographs?" "The question is outside the subject," was the ready reply. Here was an exact parallel to the once famous, or notorious, lecturer who roamed the country under the name of Parallax, delivering a course of three lectures proving, or to prove, that the world was not a globe, but a flat surface. Wonderfully ingenious were his arguments, and relentless the logic with which he was usually able to demolish the opponents who disputed with him in the public discussion that followed each lecture. The usual taunt cast at him by the overthrown logicians was, "Oh, you don't believe the earth is flat, after all!' Mr. Taylor's reply was on all fours with his.

Another paper on a perennially interesting topic that was bound to attract attention, if only from the personality of the writer, was that of Dr. Emerson on "Naturalistic Photography"—almost the same old story and stale arguments, the trite aphorisms that are always used to adorn the subject, all the more interesting as being from the mouth of a recusant teacher. This time, however, Dr. Emerson has soared to a height of repudiation that the most rampant of photographic detractors has not attained. Not content with denying all claims to fine art, he will not admit photography to be even an art. Now, on the point of fine-art photography, as those (if any) who give my lucubrations any thought will be aware, I have consistently held that it is not only an art but a fine art—one, it is true, with an extremely limited range, but still a fine art. I never have seen a satisfactory reply to two queries I make. If there is no fine art in photography, how is it that it is possible to produce by photography a scene, a view, or a representation (I will not use the word "picture" for fear of offence) that no artist can tell by simple inspection whether it is an engraving in one class, or a sepia or monochrome painting in another? Secondly, if a painter of repute took pains to learn photography, would, or would not, some of his results be more artistic than those of the photographer with no art education? If the reply be in the affirmative, would not the cause of the difference, the art feeling of the painter put into his photographic work, be rendered evident to those who looked at the photographs? Dr. Emerson argued that sharp photographs were not true to nature; but, using his words exactly in the sense he uses them, it is very certain that many a painting of acknowledged excellence is not true to nature, and indeed is further from it than most photographs. Bearing on this topic, Mr. H. W. Bennett's paper in last week's Journal may be read with considerable interest, and I may be forgiven for quoting from it. "The indiscriminate use of a method of treatment or printing surface, suitable only under special conditions is certainly not artistic—it is either studied eccentricity or want of judgment." Then, again, "etchings or engravings are invariably on smooth surface paper, and water-colour drawings (excepting those of very large size) on that of fine grain or moderate texture; but they are not considered inartistic on that account. Those photographers who affect extremes in either roughness of surface, or out-of-focus methods, or misty, gloomy effects, might study with advantage the works of leading etchers, which show that smoothness of surface, fineness of definition, delicacy of treatment, bright and sunny scenes are not inconsistent with the highest artistic quality."
