THE Hon. Secretary of the Hackney Photographic Society writes: "I have to ask if you will be good enough to correct an error made in your issue of two weeks ago in one of our reports. Mr. Sodeau was made to say that, as 'caramel is slow in drying, he would advise a piece of slightly greased paper to be applied to the back of plate before applying the backing.' This is wrong. It should have been 'to apply the backing first and the greased paper after.'"

ASHTON-UNDER-LYNE PHOTOGRAPHIC SOCIETY.—October 11, *Demonstration on Lantern-slide Making*, by Mr. J. T. Lees. Members are requested to bring negatives in printing frames. Chairman, Dr. Hamilton. 18 and 19, Instructions will be given to beginners in *Lantern Slide-making in the Dark Room* by several members. 25, Lantern Exhibition of members' slides, each member to be limited to twenty slides. Chairman, Mr. William Greenwood; Delineator, Mr. Jos. Hutchinson.

WE have received the prospectus of the Borough Polytechnic Institute, together with the programme of the winter session of the Photographic School held in connexion therewith. The lecturer in photography is Mr. A. W. Dollond and the instructor in retouching Mr. George Elliott. The syllabus comprises Photographic Technology and Practice. The lectures will be illustrated by experiments and demonstrations, and will be given on Friday evenings from eight to nine. The course commences on October 6, and is continued until the last week in April.

CROYDON CAMERA CLUB.—October 18, Lantern Night, exhibition of Mathew's hand lantern. November 1, *Various Methods of Making Lantern Slides*, illustrated with slides on the screen, by J. H. Gear. 15, *National Prize Slides*. 29, *Modern Developers*, by Mr. Leblanc. Meetings begin at eight. Members should bring examples of work. Council Meetings October 11 and 25, and November 8 and 22. Tickets for the Pall Mall Exhibition are now obtainable of Hon. Secretary at half price.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Congress of the Photographic Society of Great Britain and affiliated societies will be held on October 10, 11, and 12. The meetings, a programme of which we have already published, will be held as follows:—Tuesday, October 10, eight p.m., at the Gallery, 5A, Pall Mall East. Wednesday, October 11, three p.m. and eight p.m., at the Theatre, Society of Arts, John-street, Adelphi. Thursday, October 12, three p.m., at the Theatre, Society of Arts, John-street, Adelphi; eight p.m., Special Lantern Night (admission by ticket only), at the Gallery, 5A, Pall Mall East.

AMATEUR PHOTOGRAPHIC ASSOCIATION FOR GREAT YARMOUTH. — At a meeting held at the Two Bears Hotel, Southtown, Great Yarmouth, on Tuesday, September 26, it was proposed and seconded that a club be formed for the study of photography, which was carried unanimously. It was further resolved that the club be called "The Great Yarmouth Amateur Photographic Association," and that only those who practise photography be eligible for membership. Subscription 5*s.* per annum, payable on election. The first meeting of the Association will be held on Tuesday, October 10, at eight p.m. sharp, at the Two Bears Hotel, when the subject of *Negative-making* will be fully discussed, and applications for membership considered.

"THE PROUD TURK."—It appears from a letter we have received from Mr J. S. Bergheim, the producer of the picture, that we were wrong in stating that it is made upon a textile fabric, as it is in reality a glass positive or transparency backed with blotting-paper of the nature and colour described. It follows, of course, as Mr. Bergheim says, that there is no colour from coolest green to warmest red that he cannot give the same picture by changing the backing. "The model," he observes, "is not a Mahomedan, but a Viennese who has never been to the East. I am gratified to know that the treatment has led your critic to believe my model was, in fact, what I wished the picture to represent." We, too, are gratified to find that the once much-used process of photo-crayon, so called, of the late Oliver Sarony, which has been so often described and recommended in these pages, is not quite dead, but has such an able exponent as Mr. Bergheim.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 9	Camera Club	Charing Cross-road, W.C.
,, 9	Darlington	Trevelyan Hotel, Darlington.
,, 9	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 9	Lantern Society	20, Hanover-square.
,, 9	Norfolk and Norwich	Bell Hotel, Norwich.
,, 9	North Middlesex	Jubilee House, Hornsey-road, N.
,, 9	Putney	Boys' Gymnasium, Charlwood-road.
,, 9	Richmond	Greyhound Hotel.
,, 10	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 10	Derby	Smith's Restaurant, Victoria-st.
,, 10	Great Britain	50, Great Russell-st. Bloomsbury.
,, 10	Hackney	206, Mare-street, Hackney.
,, 10	Manchester Amateur	Lecture Hall, Athenæum.
,, 10	Newcastle-on-Tyne & N. Counties	Central Exchange Art Gallery.
,, 10	Paisley	9, Gauze-street, Paisley.
,, 10	Rochester	Mathematical School, Rochester.
,, 10	Stockton	Mason's Court, High-street.
,, 11	Ipswich	Art Gallery, Ipswich.
,, 11	Leicester and Leicestershire	Mayor's Parlour, Old Town Hall.
,, 11	Leytonstone	The Assembly Rooms, High-road.
,, 11	Munster (Annual)	School of Art, Nelson-place, Cork.
,, 11	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 11	Southport	The Studio, 15, Cambridge-arcade.
,, 11	Stockport	Mechanics' Institute, Stockport.

,, 13	Maidstone	"The Palace," Maidstone.
,, 13	West London	Chiswick School of Art, Chiswick.
,, 14	Hull	71 Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 28,—Mr. T. Bolas in the chair.

Messrs. J. E. and R. A. Hodd were elected members of the Association.

Mr. F. E. Ives, who was present, was welcomed to the meeting by the Chairman.

A question from the box asked how the enormous amount of dust resulting from the use of a flash lamp for interior work could be obviated?

Mr. W. E. DEBENHAM replied that Schirm, with his ribbon lamp, used a tube immediately above the ribbon. Magnesium deposited very slowly when diluted with air, but when concentrated deposits very rapidly. The object should be to keep it undiluted with air as much as possible.

The CHAIRMAN stated that Mr. Warnerke had described a magnesium lamp which required a chimney.

Mr. Haddon gave a lecture on preparing plaques for vitro-enamelling [see page 643] which was accompanied by a practical demonstration of all points except the firing, which was highly appreciated, being made exceedingly plain to those present.

The CHAIRMAN said it was always interesting to follow a workman like Mr. Haddon. It was a treat to listen to him, and note the careful and thoughtful way in which he had gone to work.

In reply to a question by Mr. R. L. Kidd, Mr. HADDON said fusion usually took about one and a half minutes.

Mr. P. EVERITT suggested that Mr. Haddon should undertake to give practical instruction in the subject to those desiring it.

Mr. J. S. TEAPE had recently attempted the preparation of plaques according to Mr. Haddon's instructions, and showed several results.

After a short discussion, a cordial vote of thanks was passed to Mr. Haddon for the paper and demonstration.

Northern Photographic and Scientific Association.—Ordinary Meeting, September 28, the President (Mr. Robins) in the chair.—The following alterations in the constitution of the executive were made, namely, Mr. Coghill resigned the Vice-Presidency, and was elected Secretary; Mr. Murrow resigned the Secretaryship, and was elected Treasurer; and Mr. Beagley resigned the Treasurership, and was elected Vice-President. Mr. COGHILL then explained the making of lantern slides by the wet-collodion process, and was assisted in the practical portion by Mr. Simmons. The greatest interest was taken throughout the whole proceedings, and the PRESIDENT, after thanking these gentlemen on behalf of the meeting for their services, said he was authorised to state that those members who wished to co-operate for the purpose of obtaining chemicals, &c., at a low rate and of uniform quality, might send in their names at once. He also requested those who wished to join the beginners' class to send in their names at their earliest convenience. The address of the new Secretary, Mr. D. P. Coghill, is 252, Whiteman-road Hornsey, N.

Hackney Photographic Society.—September 26, Mr. Puttock presiding.—Members' work was shown by Mr. BENTLY, and asked members' opinions as regards exposures. These seemed fairly correct, but pictures could be greatly

improved by better lighting and a little fuller development. Question was asked whether any member had had any experience with toning Nikko paper with hypo and alum. Mr. SMITH said he had used the bath and found it much easier to work after a few prints had been toned. Mr. ROBERTS had used it for an hour and a half, and found no difference in tone. Mr. MAGNUS showed a print with a red stain, and asked for a reason. Mr. BECKETT, jun., said that its appearance seemed to be due to contamination with other chemicals. Mr. Beckett then gave a paper upon *Bromide Enlargement by Artificial Light*, which was appreciated very much by the members. He dealt with the various lenses, lights, &c., which might be used in the process, and described the whole procedure in a very lucid manner. With regard to negatives which were a very important thing to bring about good results, he advocated a negative of medium density with a slightly yellow stain as producing good results. Thin negatives gave fair results, whilst ghosts were useless. A demonstration was given by Mr. Beckett, jun., in which amidol was used as a developer, and some splendid results were obtained. There were numerous advantages given in favour of enlargements, amongst them being alteration of character of prints, which was sometimes needed, and larger pictures showing to more advantage than small prints. A vote of thanks to the lecturer and demonstrator brought the evening to a close.

West London Photographic Society.—The following are extracts from the Annual Report for 1892–3:—"The membership has increased, by the absorption of the Chiswick Camera Club and partly by the accession of new members, and it now stands at seventy-three as compared with sixty at this time last year. This result appears in the face of several resignations. A change in the Hon. Secretaryship has occurred, owing to the resignation of Mr. Lionel Bennett, whose services, always performed with hearty good will, had earned him a well-deserved popularity. It was with universal regret, therefore, that the news of Mr. Bennett's enforced resignation was received. His place has been filled by the promotion of the Assistant Hon. Secretary, Mr. Rogers, whose place in turn has been taken by Mr. Stein. The work of the last Session comprised eight papers, of which four were technical and practical, two descriptive (with lantern slides), and two dealing with the artistic side of photography. In addition, there were three evenings devoted to the Society's business, one Lantern Evening, and thirteen Technical Social Evenings. The Annual Dinner took place on May 9, and wound up the Session. The outdoor meetings were arranged in districts nearer to headquarters than last year, with a view to increasing the attendance, but this device has apparently made no noticeable improvement, the attendances remaining practically as before. The Fourth Annual Exhibition was held on January 10 and 11, 1893, at the Chiswick School of Arts, with very gratifying results. The number of pictures was 171 against 135 for 1892, and the number of slides was 128 against 76. The Judges' report, which has already been in your hands, speaks for the high standard of the exhibits, and it is hoped that the forthcoming Exhibition may show a still further advance in the quality as well as in the number of pictures. The Society sent a collective exhibition to the Crystal Palace Photographic Exhibition, and was fortunate in obtaining the Silver Challenge Cup against several strong competitors. The Cup will be on view at the Annual General Meeting. The Society decided to embark upon a Photographic Record of Objects of Historical and Archæological Interest within a radius of five miles from headquarters, and Mr. Whitear was appointed to organize the work. According to information he has laid before the Council, it appears that up to the present the interest shown in the matter is confined to very few members, and the Council hope that further attention will be given to this useful branch of work. Through the good offices of Mr. Winter the Society has become possessed of a dark-room sink and fittings, and the President has promised a set of dishes for use with the same."

Richmond Camera Club.—Extract from the report from the year ending August 31, 1893:—"The Club, which is steadily increasing, now numbers about fifty members. Three members have resigned during the year, and eighteen new members have been admitted. His Highness the Duke of Teck, G.C.B., graciously consented, in March last, to become Patron of the Club. During the winter session weekly meetings were held. There was a good average attendance, and the programme comprised a series of practical and instructive papers and demonstrations by members of the Club and friends, who kindly gave their services. In the summer meetings were held monthly, and were better attended than the weekly meetings of previous years; but the monthly excursions, which were also arranged, commanded only a very meagre attendance. The use which has been made of the Club library fully justifies its existence, but there is need of a larger assortment of books, and the Committee hope that members will supply them. The *conversazione*, given at the Theatre Royal on January 9, was very successful. The entertainment consisted of an exhibition of lantern slides, with musical interludes, and a show of members' work. Light refreshments were provided. Five hundred invitations were issued, and the room was well filled. The arrangements, including the catering by Mr. Mouflet, were very satisfactory. An exhibition of slides and pictures was also arranged in conjunction with the Lower Thames Valley Branch of the Selborne Society, at Matson House, Richmond, on January 25 and 26, and was well attended. The press notices of both entertainments were very eulogistic."

Bath Photographic Society.—The last of the summer outings took place on Wednesday week to Claverton. The sun shone forth in all its splendour for an hour or so after the start was made and some excellent pictures were secured. But those who did not avail themselves of the first opportunity soon found a change was taking place, and rain fell heavily, therefore the further progress through Warleigh had to be abandoned. For the information of tourist photographers it may be mentioned that the avenue from the top of North-road, entrance gate and lodge at the Manor, Claverton Church, the terrace and steps and the old cottages, were among the subjects photographed. At the first indoor meeting of the winter session, October 25, a discussion will take place on the most suitable method of mounting and framing photographs.

Liverpool Amateur Photographic Association.—September 28, Mr. Paul Lange in the chair.—The business included the election of four new members. Messrs. C. A. Rawcliffe, E. C. Lowe, John H. Burns, and R. F. Soper. The event of the evening was a lantern lecture by Mr. JOSEPH EARP, *A Holiday in Normandy*, illustrated by 160 slides from negatives taken by the lecturer and Mr. J. W. Swinden, both members of the Association. The excellence of the slides, and the really original description, enlivened by flashes of quaint humour, altogether made a most enjoyable evening, which was highly appreciated by a large gathering of members.

Nelson Camera Club, Nelson, New Zealand.—The Fifth Annual Meeting was held on June 21, 1893.—The report showed that the finances were in a satisfactory condition, and that the membership had increased to nine honorary and forty-two ordinary members. The usual monthly meetings have been fairly attended, and the monthly competitions have always been an interesting item in the proceedings. The Annual Exhibition was held on January 26, 27, and 28, 1893, and was in every way a success. Between 500 and 600 pictures were on view, and crowded rooms testified to the public appreciation of these exhibitions. A special interest attaches to this one, as it was the first held in New Zealand in which *three* Clubs took part, the Dunedin and Auckland Societies both sending fine collections of pictures to represent them. Lantern-slide Exhibitions were given each evening, and, as usual, proved very attractive. A marked improvement was visible in the work shown in this branch of photography, some of the Auckland Club's slides being specially good. Flashlight photographs of the audience were taken each evening and exhibited on the screen during the following one. Mr. J. R. Sigley was the lanternist. The general opinion of press and public seemed to be, "Not quite so large a show as usual, but better quality." In November, 1892, an exhibit of fifty frames was sent to the Dunedin Photographic Society's Exhibition, and in March, 1893, 108 prints and 108 lantern slides were sent to the Auckland Photographic Club's Exhibition; in both instances favourable comment was given to the work of the Club. It is to be hoped that the Wellington and Christchurch Clubs will combine those of Auckland, Dunedin, and Nelson in their Exhibitions for the coming year, as these friendly interchanges of work will, doubtless, be of great good to the cause of photography in New Zealand. The following officers were re-elected for Session 1893–4:—*President:* Mr. C. Y. Fell.—*Committee:* Messrs. H. Brusewitz, R. Jackson, A. Pitt.—*Hon. Secretary:* Mr. A. H. Patterson.

FORTHCOMING EXHIBITIONS.

1893.		
October 6–Nov. 15 ...		*Photographic Society of Great Britain, 5A, Pall Mall East, S.W. Assistant Secretary, R. Child-Bayley, 50, Great Russell-street, W.C.

Correspondence.

ON PHOTOGRAPHIC PERSPECTIVE.

To the EDITOR.

SIR,—I adhere implicitly to all I have said, and I further say that, granted a dog kennel, for simplicity sake, square, box-shaped, and six feet each way, and, also, a square house (with flat roof), sixty feet each way, the kennel to be six feet distant and the house sixty, then, under no position conceivable, will the lines of the house photograph and the kennel photograph (the position of lenses being unchanged) coincide if superposed. If Mr. Debenham disputes this, will he please state accurately a case with a position of these erections where he believes the photographs would coincide, and then I will demonstrate where the error is. I criticise not his argument, but his opponent's version of it.

As to distortion, it is a question needless to discuss where disproportion ends and distortion begins. My remarks did not apply to anything either Mr. Debenham or any one in particular had written; they were intended to apply to the topic generally.—I am, yours, &c.,

FREE LANCE.

ALPHA PAPER.

To the EDITOR.

SIR,—You publish a letter in this week's JOURNAL relating to an enlargement on Alpha paper by Mr. Howson, which has induced me to write to you upon the use of this paper for enlarging purposes. I have, during the past eighteen months, made a number of enlarged prints on Alpha paper, which have proved very satisfactory to my friends and myself. The coldness of ordinary bromide enlargements is, to me, tiresome and depressing, and, judging from the number of workers who resort to uranium and other doubtfully permanent methods of toning, the feeling is somewhat general. The use of Alpha paper (which, I believe, is coated with a washed gelatino-chloride emulsion) offers a simple method of obtaining either warm or cold-toned enlargements. Its greatest drawback is its slowness. To those who are blessed with the use of the electric light I do not suppose this is a matter of very great moment, but an attempt to enlarge by means of an ordinary oil lantern is disastrous. The only remaining method—daylight enlarging—is, to my mind, by far the best; of course, the exposure is necessarily a long one. I have found that, with the enlarging camera pointing to the sky (north), using stop *f*-10, enlarging from quarter-plate (ordinary class negative), to 10 × 8 on a bright summer day, the exposure needed is fifteen to twenty minutes. I always aim at obtaining a red-brown image by development, from which, by toning, I can get any colour down to blue. I use the Ilford hydroquinone developer, as I find the acid bath, after ferrous oxalate, an abominable nuisance and a powerful reducer of the warm image.

Like most other amateurs, I like to do most of my enlarging in the winter, and, strange as it may seem, I find Alpha paper most suitable for that purpose. First, I may mention that I always aim at getting rather thin negatives for enlarging; I think I may say it is an absolute necessity for Alpha enlarging in the winter. Like most others, I have my business to attend to during the day, so, before leaving home in the morning, I erect my enlarging camera, and, having placed the paper in position, I leave it exposing for the whole day, using a small stop, say *f*-45, and if the day is fairly bright I find, on developing at night, a properly exposed enlargement. The paper has great latitude. I have, on one or two occasions, been unable to develop the same night, and the paper has been exposed two whole winter days, and still a good print has resulted; in fact, with some negatives, such a prolonged exposure is a necessity. Of course this, to a certain extent, is all guesswork, but I have arranged a small table (compiled from Dr. Scott's Light Table), by which I can gauge, to almost a certainty, the amount of exposure the paper needs or has received. This table I will forward if you think fit. I invariably fix and partly wash Alpha prints before toning. I do not much care for the toning bath published by the Ilford Company, it is so apt to tone too purple; but of course this is merely a matter of taste, and will, no doubt, prove a great attraction to some workers. I generally use an old Solio combined bath. With this I get nice sepia and brown tones, and the alum hardens the film. I feel sure that, if the Ilford Company could, or would, increase the sensitiveness of the paper, there would be a huge quantity used by amateurs. There is one point in relation to the packing of Alpha and also bromide paper to which I should like to call attention. The method of selling cut pieces is a good one so far as small sizes is concerned, but, when we get to 10 × 8, and over, I do not think it is a blessing. We do not always want to make a dozen 12 × 10 enlargements; but, if we buy a packet of that size, what must be done? We may wish to enlarge to 15 × 12, but that means another packet of paper. I think if these papers were sent out in two whole-sheet tubes, in the same manner as P. O. P., it would be a matter of great convenience for the would-be enlargers whose pockets will not stretch all at once to the price of a ten-feet roll. By this means any size enlargement may be made up to 24 × 17 (or whatever may be the size of the whole sheet) without a big preliminary outlay. I also think it would conduce to the increased sale of the paper.—I am, yours, &c.,

W. RIDLER.

13, *Brunswick-street, West Gorton, Manchester, September* 29, 1893.

PHOTO-MICROGRAPHY.

To the EDITOR.

SIR,—Mr. Ives's tiger seems to be gradually shrinking from his original handsome dimensions. We have now got to this from Mr. Ives: "Some achromatic objectives will certainly give better results with yellow light than any apochromatics will with the ordinary white light and ordinary gelatino-bromide plates." This is a new importation into the discussion, and, further, I very seriously question the accuracy of the statement. I have not made any special experiments to determine the point, but I have a strong impression that my apochromatics give better results on ordinary plates than any achromatics I have tried on colour-correct plates. I find the spherical aberration better corrected and the fields flatter with the apochromatics than with the achromatics, but I have not had the advantage of using the American achromatics referred to by Mr. Ives, my tests having been confined to a few of the best kinds of British and Continental objectives.

I do not propose to continue this controversy, which must be aimless, till I have seen the productions of Mr. Ives, on which he bases part of his argument. I consulted one of the references given by Mr. Ives in a former letter to you, the only reference on which I could easily lay hands, the *Photographic Times*, April 25, 1890. Finding that the productions by Mr. Ives there criticised were: Flea × 36, proboscis × 60, sting of Bee × 70, diatoms × 130, and sections of wood, I was not tempted to pursue my inquiry into Mr. Ives's achievements.

Several British and foreign microscopists have privately expressed to me a hope that Mr. Ives may be induced to give us the chance of seeing his productions with achromatic glasses, that we may compare them with results obtained with apochromatics. Personally, I should much like to see them, so that I may get to the bottom of the question, for I am quite open to conviction; it must be well worth a sheet of paper and fivepence in stamps to enlighten a whole hemisphere. Till I do see the photographs in question I can say no more.—I am, yours, &c.,

ANDREW PRINGLE.

"WARMING STUDIOS."

To the EDITOR.

SIR,—Under the above heading, you inserted some years ago, in THE JOURNAL, a note from me strongly recommending "George's Calorigen." I have had nineteen years' experience of them, and at present have four in use. Your correspondent in last week's number is wrong in one or two points. The agents are Messrs. Farwig & Co., 4, Upper Thames-street, London, E.C., and I have one put in an ordinary fireplace, the grate having been taken out. It has been in use for over eighteen years with perfect success. I advise your correspondent to apply to Messrs. Farwig for one of their descriptive papers about the stove. I enclose my card.—I am, yours, &c.,

L. M.

October 3, 1893.

THE UNILUX.

To the EDITOR.

SIR,—We notice in your description or reference to our new Patent Unilux Lantern, now on view at the Photographic Exhibition in Pall Mall, that you say "the light is directed on the screen by a rectangular prism or mirror placed at the *outer* end of each object-glass, in manner like to the lanterns of Beechy or Keevil.

Please allow us to correct this, as ours is different, and we think new.

In our lantern the *prism* is placed *inside* the object-glass, as it were, is *between* the two combination lenses of the objectives, and fills up the whole space between them. You can easily get at the prism for examination by unscrewing the cap, when the prism will be drawn out.

We shall esteem it a favour if you will kindly mention this alteration in your next, and oblige.— We are, yours, &c.,

ARCHER & SONS.

43 *to* 49, *Lord-street, Liverpool, October* 2, 1893.

GELATINO-CHLORIDE MOUNTANT.

To the EDITOR.

SIR,—A good deal has, from time to time, been written on the subject of mounting gelatino-chloride prints. The use of various mountants, the backing of the prints with some waterproof paper, the pasting of the prints around their edges only, and various other devices, have been in turn suggested, whereas, as a matter of fact, these prints are no more difficult to mount than are those on albumenised or any other paper.

With your permission, I submit to the reader of THE BRITISH JOURNAL OF PHOTOGRAPHY a mountant for gelatino-chloride prints, which leaves nothing to be desired. The formula is :—

Gum	2 ounces.
Glycerine	½ ounce.
Methylated spirit	1½ ,,
Distilled water to	8 ounces.

Dissolve the gum in 4 ounces of the water (cold), then add the glycerine, and lastly, gradually and with constantly stirring, the spirit, making the whole up to 8 ounces with water if necessary.

Gum arabic being at the present time very dear, its place may advantageously be taken by either Senegal or Ghatti gum, this last being very good for the purpose, and only about a shilling a pound or less.

The advantages of this mountant are as follows :—1. It keeps indefinitely. 2. It is always ready to use at a moment's notice. 3. It can be brushed *all over* the back of the print. 4. It does not cockle the mount. 5. It does not injure the print. 6. It is easy to use, cleanly in use, and dries quickly.

I enclose for your acceptance and inspection a print mounted with some of this solution, which has been made some five or six years, and I have prints by me mounted the same length of time which do not show any signs of deterioration.

Should any of the mountant accidentally get on to the gelatine surface of the print, either from the brush or the fingers, it may be rubbed off, *before quite dry*, with a clean cloth, without any mark being noticeable.—I am, yours, &c.,

J. H. BALDOCK, F.C.S.

St. Leonard's-road, Croydon, September 30, 1893.

HACKNEY, SOUTH LONDON AND LEYTONSTONE EXHIBITIONS.

To the EDITOR.

SIR,—To meet the convenience of exhibitors wishing to compete at our respective Exhibitions, arrangements have been made whereby the exhibits will be transferred at the close of each Exhibition on to the next Exhibition, saving the large expense of carriage (*i.e.*, they will be sent from Hackney to South London and from thence to Leytonstone) upon payment of 1*s.* 6*d.* for every three frames and 6*d.* for each set of lantern slides in addition to the entry fees to the Secretaries of the last two Exhibitions, by whom they will be received and carriage paid.

W. FENTON-JONES, Hon. Sec. Hackney Photographic Society.
CHAS. H. OAKDEN, Hon. Sec. South London Photographic Society.
ALBERT E. BAILEY, Hon. Sec. Leytonstone Camera Club.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED :

Abraham Flatters, Openshaw.—*Sixteen photographs of sections of Cotton.*
Jabez Greenwood, Carlisle.—*One photograph of Coniebrough Castle.*
George Watmough Webster, Chester.—*One photograph of Rev. Canon Acheson.*

J. BISHOP & CO.—Price-list received.

GELATINE.—Take a negative of the plaster cast on an ordinary gelatine dry plate.

E. MILLHOUSE.—The spot on the negative has not been caused by the lens, but by a drop of ammonia.

E. D.—1. There is a varnish consisting of celluloid dissolved in amyl acetate which will answer for the purpose. 2. Unable to account for it.

COLLOTYPE.—There is, we believe, a class for collotype at the Polytechnic Institute, 309, Regent-street. Write to Mr. E. H. Farmer at that address.

EXPERIMENTALIST.—Surfaced paper, suitable for collotype printing, may now be had from most of the houses that supply enamelled paper for lithography.

JAMES LETT, JUN. (Harrisburg, Pa.).—No articles on lens-making have recently appeared in our pages. There is a series running through the *English Mechanic* just now.

J. H. P.—Both the selecting and the judging have this year given rise to an unusual amount of dissatisfaction. Your figures are admirable, although we should have preferred them with fewer accessories.

LIVERPOOL.—The cause of the majority of the stains produced in intensifying negatives is incomplete washing between the different operations. There is no doubt whatever that it is the cause of them in the negative sent.

R. O. S.—If you are in any doubt as to whether the mounts cause the fading of the pictures, why not test them by the method described in an article a few weeks ago. It would be much better to do so than write asking if a certain maker's mounts always cause prints to fade.

F. G. S.—The only difficulty in copying maps is to get the lines clear. As the time of exposure is no object, use the slow plates supplied for photo-mechanical work. Avoid rapid plates under any conditions. It is needless to say that a non-distorting lens must be employed.

R. LODER.—If the negatives are so thin that they will only yield grey and flat prints in platinotype, try printing them on gelatino-bromide paper. By this means you will, doubtless, be able to get vigorous prints, and, with a little experience, of a tone very similar to those of platinotype.

NOTTE.—Pyroxyline suitable for the purpose may be obtained of Messrs. Hopkin & Williams, Hatton Garden, E.C.

W. H. HORTINOTON.—We should think that, in addition to the lights in the hall, arrangements would have to be made whereby extra lights of, say, eight to ten thousand candle power would have to be directed on to the platform; in that case, on the data you give, an exposure of about two seconds would probably suffice.

C. A. S.—To make a solution of indiarubber, get some of what is known as masticated rubber, and dissolve it in benzol to the consistence desired. The easiest way to get a solution of rubber is to take the solution as sold at the indiarubber shops, and dilute that with benzol. This is much less trouble than dissolving the rubber in the first instance.

T. MALONY.—In all probability, and from what you say we have very little doubt about it, the transfer ink is at fault. It should not be used as received from the warehouse, but thinned down, and this has not been done sufficiently. Try the effect of further dilution with an equal bulk of turpentine, and do not print the transfer so deep.

"STOBARS" would be much obliged if any of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY could tell her the best amateur club to belong to, where the photographs are criticised, and exhibitions with prizes held now and again.—See the Society pages of our ALMANAC. Possibly the Postal Photographic Society would meet the first requirement of our correspondent.

C. C.—As the mounts are lettered with bronze powder, it is more than probable that it is the cause of the spots on the pictures. Should they be the source of the evil, you have no remedy against the one who supplied the mounts, as you say you contracted for bronze lettering, and bronze powder, it is well known to all photographers, is liable to have an injurious action on the silver image.

M. H.—Unless you are going to work with the camera near the Franco-German frontier, a passport is not necessary, and, even if you are going to, a passport will not give any advantages, except, if you get into trouble, it will be of assistance in helping you out of it. Our advice is, when travelling anywhere on the Continent, to be provided with a passport, even in countries where one is not required.

R. A. H.—As a rule, what are termed "Ordinary" plates are not rapid enough for hand-camera work, with the lens with which the majority of them are fitted, except in an unusually good light. At this time of the year, in the streets of London, rapid plates must be employed, also a lens of large angular aperture. With a lens *f*-11 and the plates mentioned good-quality negatives must be expected with a hand camera.

W. SYMONDS.—In order to obtain deep, rich, purple-black tones, the paper must be rich in silver, and what is of equal, if not greater, importance is, that the negative must be of a strong and vigorous character, that is dense in the lights and very clear in the shadows. With these conditions fulfilled, if the print be somewhat over-printed, no difficulty will be experienced in obtaining rich deep tones with any of the recognised toning baths.

A. X. Z.—Makes a general complaint of the cutting of dry plates. He says: "Sometimes in the same packet one or two may be too large to go into the rabbet of the dark slide, while others will be so small that they cannot be retained in it; and the nuisance is still greater when a changing box is used." This complaint used to be common enough at one time, but now it is one we seldom hear of. Makers are now particularly careful in this matter. We think our correspondent's experience is somewhat exceptional.

T. BURGEN.—From the description, the camera is evidently a very old one, made for the Daguerreotype process. The lens, being by Voigtlander, is probably a very good one, but it is more than likely that it does not work to focus, that is, the optical and chemical foci are not coincident. However, it is none the worse for that, if the necessary alteration be made after the image has been focussed optically. It is very doubtful if the camera and slide are sufficiently light-tight for the modern dry plates.

ROBIN asks if plates, orthochromatised according to a formula in the ALMANAC and used with a yellow screen, are supposed to give true colour values because he has found that they render the yellows perfectly white and the blues nearly black? He says: "The effect produced is too great. The plates are too orthochromatic." This is precisely the effect that will be obtained by using too deep a yellow screen. This has been pointed out many times in these columns during the past few years. In the choice of a colour screen regard must be paid to the subject and the method by which the plates are prepared. In working orthochromatic photography, three or four screens, of different depths, should be at hand, to be employed as occasion may require. Our correspondent should repeat his experiments, with the same plates, on the same subject, but using a much lighter yellow screen. It will be a good object lesson.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1745. Vol. XL.—OCTOBER 13, 1893.

We are now engaged in the compilation of the Almanac for 1894, and will welcome short articles on practical topics from those who have formerly contributed the results of their experiments and experiences in photography to its pages. This invitation we also extend to the younger readers of The British Journal of Photography and its Almanac.

In order to avert the chance of our having to omit any articles from the Almanac on account of their lateness of arrival, we would suggest that intending contributors send us the copy of their articles at the earliest possible moment.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, if they have not already done so, will oblige us by at once forwarding lists of officers and other details for inclusion in the directory of Photographic Societies, in order that the list may be made complete.

The Publishers desire us to inform intending advertisers that copy for their advertisements cannot be received after Monday, October 16, on which date they intend closing up the announcement pages of the Almanac.

PHOTO-CRAYON.

The fact that there is a photographic printing process capable of proving such a "sell" as did that by which Mr. J. S. Bergheim's medalled picture, *The Proud Turk*, was produced, is warrant sufficient for giving some account of its history, capabilities, and *modus operandi*.

In 1869 the photographic world had its interest roused by an announcement that the then well-known photographer, the late Oliver Sarony, of Scarborough, was about to introduce quite a novelty in portraiture, one by which excellent and wonderful effects could be obtained by a minimum of trouble and expense; not only so, but that portraits which might fairly lay claim to be artistic could by its agency be produced by photographers devoid of art culture. In due course specimens were shown to the public, and were everywhere greatly admired. They were vignettes of 15 × 12 inches in dimensions, were delicate in gradation, and surrounded or partially so by crayon hatchings, which merged from the figure into the coarse drawing-paper on which they appeared to be produced. In brief, there was a singular charm about these photo-crayons, as they were designated, and, as the process had been patented, many photographers obtained licences for making them, in most instances to their financial advantage.

These pictures were nothing but enlargements produced by the wet-collodion process on plates of glass. They were, of course, transparencies, but so thin and delicate were they that the half tints could scarcely be seen until the glass had been dried and a sheet of paper brought in close contact with the image, which then appeared as if it were on the material placed behind it. In truth, so deceptive were they in this respect, that the most minute examination failed in establishing the fact that the image was not on the drawing-paper employed as the backing. If what we have now to say aids in resuscitating this process, improved as it may be by greater knowledge than prevailed a quarter of a century since, we feel sure that it will conduce to the pleasure of many, and possibly to the profit of not a few.

We have said that the photo-crayon of the past epoch was an enlargement. It was made by placing an ordinary *carte* negative in a lantern, and projecting the head and shoulders upon a large plate of collodionised glass. The exposure was brief, a strip of magnesium ribbon being usually employed as the source of illumination, although any other light might be used. The glass was prepared by coating it with bromo-iodised collodion, and, after allowing it to set, laying it face upwards in a flat dish containing a solution of nitrate of silver of about the strength of thirty-five grains to the ounce of water. While this was becoming sensitised, which occupied two or three minutes, and a cover placed over the dish, the portrait was being adjusted and focussed on a plate similar to the one which was to bear the picture, but faced with white paper. This was supported in a vertical position, a simple easel, in our own case, sufficing for this purpose.

The lens is covered with a cap in which is fitted a disc of yellow glass, the sensitive plate made to take the place of the paper-covered one, and any final adjustment effected by the yellow cap, the removal of which permits of the exposure being made, which, with a single strip of magnesium, requires thirty seconds more or less. But, during exposure, it must be vignetted by the interposition, immediately in front of the sensitive plate, of a large sheet of cardboard, having in it an aperture about the size of the head and shoulders of the enlargement; and this must be kept gently moving all the time in order that the vignette shall have a very soft margin.

The image is developed by—

Pyrogallic acid	2	grains.
Citric acid	2½	„
Water	2	ounces.

This ought to be poured on in such a way as not to wash off the solution of nitrate of silver with which the surface is still covered. If it does not flow smoothly, the addition of a few drops of alcohol will impart this needed property. The development will proceed slowly, but on no account must it be allowed to proceed beyond the formation of an exceedingly thin image. Those who try this process for the first time invari-

ably make the mistake of carrying the development too far, producing a heavy, black-looking picture. It is fixed in hypo-sulphite of soda, washed and dried.

The image is examined by pressing the film side against a white sheet of paper. The margins and high lights ought to be quite white, or as white as permitted by the interposition of clean glass. If there is any degradation of tone, it indicates fog, which with such a developer ought not to be present. This fog may be prevented by using an older or riper collodion, or by adding to it a few drops of tincture of iodine. This, in almost every instance, will ensure the absence of fog. Should the half-tones be heavy and smudgy, over-development and possibly over-exposure are indicated.

It is in the mounting that the effect which gave the special name to the process is produced. Instead of backing with plain paper, Sarony employed drawing-paper on which had been printed by lithography peculiar, sketchy, crayon-like lines which, intermingled with and extended beyond the soft outlines of the vignette, gave it the appearance of freedom and artistic effect. In many instances, the photographer produced these hatchings himself by a blacklead pencil; but, in any case, it was impossible to say by examination that they were not highly finished and artistic crayon portraits executed by skilled artists. They created a *furore*, and the journals and societies of that period devoted much attention to the process.

Why, then, did they fail to secure lasting recognition? The public had not in those days been educated to relish black tones, preferring those of warm tint; and the fatal mistake was made of toning them with bichloride of mercury, followed by hyposulphite of soda; and, while by these agents the most beautiful tones were obtained, the photograph itself faded to an unpleasant light yellow colour, but as the crayon hatchings still maintained their original darkness, the ultimate effect was most incongruous. Hence the decadence of the photo-crayon.

Tastes have changed since the days when the photo-crayon reigned with such supremacy, and we know that, if untampered with in the way indicated, there is no reason why it should not be permanent. Again, the backing of the transparency may be of any material and of any colour. If one of dark colour be selected for the sake of a special effect, touches of high lights may be put in by the crayon or otherwise.

There is a question of optics involved in this process, into which we cannot now enter, beyond saying this, that it is not only necessary, while there is the closest possible mechanical contact of the backing paper with the transparency—which, by the way, must have been varnished—that they should not be placed in optical contact, else will the whole effect be lost. A film of atmospheric air must intervene.

We own our indebtedness to Mr. Bergheim for affording us an opportunity of directing attention to a nearly forgotten but excellent process.

SUPPLEMENTARY EXPOSURES.

Our article in last week's issue on *Reflected Light in the Camera*, has drawn forth two communications from correspondents who seem to be of opinion that the presence of a small amount of extraneous light is not altogether disadvantageous, inasmuch as it plays the same part as the supplementary exposures that were at one time recommended for the purpose of shortening the time of pose in portraiture. One of our correspondents also alludes to the remarks of Professor George W. Hough, reported in the same issue, which go to show that supplemental exposures, under certain conditions, increase the rapidity of a plate some five times.

Looking back to the days when such supplementary or auxiliary exposures were, if not fashionable, at least seriously looked upon and carefully tested, it is very doubtful whether any real benefit can be said to have been derived from them. There were instances, undoubtedly, where a close examination of a negative that had been subjected to this treatment exhibited, perhaps, faint traces of detail in the deeper shadows that did not exist in the corresponding plate similarly treated, except for the auxiliary lighting; but, in all such instances, it was claimed by the opponents of the system that the advantage was more apparent than real, that the additional detail was of no practical or printing value.

This was in the days of wet collodion, when the supplemental lighting was performed in a variety of fanciful ways, such as exposing the plate to the feeble light reflected from black velvet or to that transmitted through a coloured translucent screen. Some, again, coloured the interior of the camera, so that it might reflect light of a feebly actinic character, which acted simultaneously with the camera exposure proper, while others applied a certain amount of what was termed "judicious fogging" by directly exposing the plate to the action of a feeble artificial light. In one and all of these methods the result was practically the same, namely, the production of a slight veil over the whole of the plate.

But the supporters of the supplemental lighting theory claim something more for the system than a mere general veil. That, we can well understand, can be applied in a variety of ways, by staining the negative film, by the application of a matt varnish, or by printing through tissue paper and similar media. But none of these are capable of doing more than, perhaps, slightly alter the ratio of gradation and prolong the time required in printing, while the true supplementary lighting is claimed to bring out more detail.

Some years after the first agitation in favour of supplementary lighting, the question was studied by Messrs. W. K. Burton and W. E. Debenham amongst others, and this time in connexion with gelatine plates and the sensitometer. The fanciful and uncertain methods of lighting by means of coloured glasses and reflected rays were relinquished in favour of direct exposure for a determined period to feeble artificial light. By careful and repeated trials the minimum time was ascertained in which a visible fogging of the film could be produced by exposing it at a distance of several feet from an ordinary candle; and, this period having been found, it was easy to graduate the preliminary exposures in such a manner as to bring about the supposed action of light that precedes the formation of a visible image.

The theory of the supporters of this system—and it is a reasonable one—is that the light must act upon the plate or film for a certain time, in order to, so to say, overcome its *vis inertiæ* before it can produce a developable impression; and that the function of the supplemental exposure is to just overcome that *vis inertiæ*, and leave the film in a condition to form a developable image, with the briefest possible exposure in the camera. The theory, we repeat, is reasonable enough, and is in accordance with what actually occurs when a sensitive surface is exposed to light, since, unless the latter be very powerful, an appreciable time elapses before any palpable effect is produced.

Working upon this theory, Messrs. Burton and Debenham, in the experiments we have referred to, showed that, when

carefully and judiciously applied, the auxiliary exposure did undoubtedly conduce to the production of an increase of sensitiveness to the extent, if we remember rightly, of two or three numbers of the sensitometer. But they also showed most conclusively that it ended there, and was of no practical value in camera exposures.

Some fifteen or sixteen years ago the preliminary sunning of albumenised paper in order to hasten its printing power was recommended in America; in other words, the application of the system of auxiliary lighting to the formation of a visible image, as distinguished from a developable one, was made. Here it is possible to follow more closely and accurately the working of the system, for with the comparatively slow-printing surface the paper may be exposed for a very considerable time to a weak light without the production of any visible change. If, we will say, a piece of albumen or gelatino-chloride paper be exposed to feeble diffused light for a period of one minute without any visible change, and two or three seconds later a change becomes visible, it is impossible to believe that that capacity for change has sprung suddenly into existence. It is most certainly the result of some invisible change produced by the first sixty seconds of the light's action, a preliminary change that must precede the formation of a visible impression.

If we ascertain the period which is required under certain conditions of light to set up the first sign of a visible change, and then expose a piece of paper for three-fourths or seven-eighths of that time, a portion of it being protected by an opaque mask, we may expect that paper to be in a condition to form a visible image more rapidly on one portion than on the other, and such in practice proves to be the case. If a piece of paper so partially exposed be placed behind a negative, and re-exposed for a few seconds in a good light, the image will, in all probability, make itself visible on the exposed portion before it does on the other. But—and here comes the practical point—the difference is so slight, and the second portion of the image follows the other so quickly, that, before the printing can be said to be fairly started, any distinction between the two portions is completely lost.

The experiment may be instructively varied by exposing a piece of paper under a star, or other shaped mask, in the feeble light of an ordinary room for a period short of that found to be necessary to produce a visible impression. If, now, the mask be removed, and the exposure continued, we ought presently to see an image of the mask in white upon a faintly tinted ground; but, as in the previous case, the very greatest care and the closest observation are needful, and even then it is very often much a case of individual eyesight. We have often, when trying this experiment, found perhaps one individual claim to be able to recognise an image that was invisible to ourselves and others. A graduated sensitometer screen forms perhaps a better mask for use in such trials as these than one of opaque paper.

The result of a series of experiments of this kind, if carefully conducted and closely studied, will be to convince the inquirer that, although there may be an apparent advantage in the preliminary or supplemental exposure, it is so slight in comparison with the total result as to be practically inappreciable. In fact, in order to secure any apparent benefit at all, the auxiliary exposure must be of the very shortest, otherwise the general action or fog will be sufficient to hide any partial action that might otherwise be there.

Turning back, then, to the suggestion that reflected light in the camera can be of any practical use in shortening exposures, we most strongly deny it. In fact, as we have endeavoured to show, the evidence is all against the practical utility of auxiliary lighting in any form, but especially with gelatine plates. All who have had practical experience in rapid work are well aware that better results are obtainable by careful and prolonged development than by rapid forcing. Every plate has, more or less, an inherent tendency to fog, which is only brought into stronger prominence by increasing the energy of the developer whenever it may lie dormant for a long time under a weaker solution, and so permit of the gradual development of the feeblest impressions of the lens. By purposely exposing the films to light, however feeble the inherent tendency, it only heightened, and the prospects of success from protracted development correspondingly decreased.

How slight an auxiliary exposure is necessary is shown by the figures quoted by Professor Hough in his article in last issue. Plates that were exposed for only two seconds to the red glass window of the dark room were said to be increased in *apparent* sensitiveness five times; that is to say, the sensitiveness by the sensitometer showed five times greater, though, as Messrs. Burton and Debenham showed years ago, such readings are utterly fallacious. If, however, the "red window" is anything like those in ordinary use, the result should set us thinking on the subject of the importance of shading our negatives during development.

As a practical test of the value of preliminary lighting for shortening the camera exposure, a plate was placed in the dark slide and the shutter partly drawn, when it was exposed for a fraction of a second to the light of a common Swedish paraffin match at the distance of about eight feet. The exposure made in the camera, as usual, was purposely curtailed, and the development was conducted on the slow-and-sure principle, with the view of getting out as much as was possible from both portions of the plate. So far from the preliminary exposure proving beneficial, it was, in every case where an ordinary plate was used, the reverse. At no stage of the development did the supplementary exposure place that portion of the plate in front of the other; on the contrary, very early in its progress the image became veiled, and long before the unassisted half was completed the remainder of the plate was hopelessly fogged.

The experiment was repeated several times with slight variations of the exposures, both supplemental and in the camera, but with practically the same result, except when a double-coated film was used, and then a novel feature of the multiple-coating principle made itself apparent, inasmuch as in this case the supplementally lighted portion of the plate began to show its image several seconds before the other; but after a very short time all difference between the two portions disappeared, and at the finish there was no distinction whatever, the remarkable point being that the fog that accompanied preliminary exposure in the other cases was entirely absent from the double-coated film.

PHOTOGRAPHING HIGHLY POLISHED SURFACES.

Reverting to the previous article (see page 618, *ante*), we shall here describe some of the methods or dodges frequently resorted to by those who make a feature of the above class of work, premising, however, that what was said a fortnight ago with re-

gard to the method of illuminating the objects to be copied will be borne in mind.

Taking first by way of example a silver or gold vase of the usual hypo—highly burnished in parts, and in others frosted. One very excellent way of dulling the surface for photographic purposes is to take a lump of tolerably firm putty and lightly dab over the burnished portions with that. This, if carefully done, will not be at all perceptible in the photographs. After the negative is secured the putty can be cleaned off with a plate-brush, whiting, and benzol. Another method is to place a piece of ice in the vessel, this by cooling the metal quickly causes moisture to condense upon it and thus dull the surface without at all interfering with the finest detail in the chasing or engraving. To be successful with this plan, one or two precautions have to be taken. The ice should not be put into the vase until everything is arranged and the plate is ready for exposure, and it should be taken out directly after it is made, the reason for this being that the moisture will continue to condense on the cold metal and soon run down as tears, which would be reproduced in the photograph. If a second negative has to be made, then the ice can be replaced. If the atmosphere is very dry, it may be requisite to sprinkle the floor of the studio with water to provide the necessary moisture. Another point in connexion with this system is that the temperature of the room must be tolerably warm, for, if it be very cold, the condensation will be correspondingly slow, if at all.

Silversmiths, and others, who make a practice of having their goods photographed, generally have the negative taken before the things are finally polished. This materially aids the work of the photographer.

By taking advantage of the condensation of moisture the copying of china and glass articles can be greatly facilitated, and the same applies to jewellery; but it is obvious that ice cannot always be used in the manner just described. However, the difficulty may be got over in another way. The articles may be kept for some time previously in a cold place. Then, when they are brought into a warm atmosphere, moisture will condense upon the surface as dew, as is frequently noticed when cold tumblers or wine glasses are taken into a warm room where the air is moist. In the case of small articles they may be cooled by putting them for an hour or so in a refrigerator, or, if that is not at hand, a packing-case with a few pieces of ice at bottom will answer the purpose quite well.

Furniture should always be, and usually is, photographed before it is polished. The best start for our present purpose is when it is finally glass-papered ready for the polish. In this condition the surface is quite dull, though it does not show the grain of the wood; but this is fully developed by slightly oiling it, as the polisher does before commencing his labours.

Some persons are much surprised at the excellence of the photographs of machinery usually to be seen at most industrial exhibitions, and often wonder how they are done. The matter is very simple. The machines are painted over with flatting colour, of a slate hue, before the negatives are taken, as the lettering for the maker's name frequently is painted in black. In photographing machinery in factories this dodge should always be resorted to, otherwise it is next to impossible to clearly delineate many of the bright parts under some conditions of lighting. If the flatting be done with a mixture of turpentine, white lead, and lamp-black, the colour can be quickly cleaned off with a piece of "cotton waste" charged with benzoline. It is often important that the name of the maker of machine be conspicuously shown; a little chalk, if it be in an ill-lighted portion, rubbed over the letters, is all that is necessary to obtain this end. Distemper has sometimes been recommended for coating machinery prior to photographing it, but flatting is far preferable, as it "takes" better on the metal, which is always more or less greasy and repellent of water, while with benzoline it is quite as, if not more, quickly removed than distemper would be.

Among the many odd jobs a photographer is often called upon to do is to take a photograph of a grave or tombstone, when, of course, the inscription is one of the important features. This is not always an easy thing to do, particularly when the stone is of some coloured granite and the lettering is gilded. The best thing, under these circumstances, is to make a paste of whiting in water, and with it fill up the cut-in letters, using a palette knife for the purpose. It is easily done, and readily brushed out when the negative is obtained, and in no way injures the gold.

Recipients of medals who make use of them for business purposes frequently require them photographed, and, when they get the pictures, are sometimes disappointed with the result, owing to its not being equal to those frequently to be seen in the possession of numismatists and others. The reason for this will be obvious when it is mentioned that the photographs issued in the numismatic publications are not taken from the originals at all, but from casts of them made in plaster of Paris; and, to aid the photographer, the plaster is slightly tinted with a dark pigment, such as umber, for example, to take off the excessive whiteness. Most of the medals utilised for advertising purposes are reproduced by electrotyping, and, when this is the case, there will be no difficulty in obtaining plaster casts from the original moulds from which the electrotypes are made. When gold, silver, and bronze medals are to appear in the same picture, the plaster of Paris should be tinted according to the metal; for the silver a very slight tint, for the gold a shade or two darker, while for the bronze it may be somewhat deeply coloured. In illuminating the cast a strong side light should be used, as mentioned in the former article, so as to bring out the relief in the strongest manner possible.

It often happens in the case of presentation articles, such as clocks, inkstands, and the like, that the inscription is on a separate plate affixed to the article, and it is important that it should be distinctly rendered. When this is the case, the plate should be removed and taken to a copper-plate printer, who will ink it in—that is, fill up the letters with printer's ink, leaving the surface perfectly clean. By this means the lettering will be obtained perfectly clear and distinct in the negative. After a satisfactory negative has been obtained the ink can be cleaned out with either turpentine or benzine.

Photography on Mount Ararat.—Our readers may remember the details of a hoax, which was accepted as truth by many of our newspapers, some little while ago, to the effect that the remains of the Ark had been sighted and photographed; but at last it would appear a view of the mountain itself has been secured by the aid of the camera. Mr. H. F. B. Fynch, with his brother and a French guide, are credibly reported as having, after seven and a half hours' climb, succeeded in ascending Mount Ararat on the 19th ult. He has promised interesting information upon his return to England, and he states that he has taken some photographs.

Grinding and Polishing Lenses.—The usual explanation of the preliminary process of grinding lenses is that a series of "scratches" are produced by the abrading material, but Lord Rayleigh showed that this is an error. The normal process is the production of isolated detached pits, not scratches. The glass gives way under the emery, and at the same time the latter suffers abrasion from the glass. Our readers will be surprised to learn that an image seen through glass which has been finely ground, but not polished, has perfect definition. His Lordship stated that a glass lens finely ground gives very good definition, but there is a great loss of light by irregular reflection, and it is to avoid this that a lens is polished. He believed the process of polishing was not continuous with that of grinding, and that it consisted of the removal of a molecular layer from the glass surface. Grinding is easy and rapid, polishing tedious and difficult. By various interesting methods he measured the thickness removed, and found that, when a thickness equal to two and a half wave-lengths of sodium light was removed, the polish was sufficiently good. Four wave-lengths removed gave a perfect polish.

The Action of Light on Dyed Fabrics.—Among the singular results observed in connexion with the fugitiveness of eosine colours may be mentioned the fact, stated by the Committee lately referred to, that when there is added to an eosine dye such a colour as methyleosin, a particular phase of fugitiveness is destroyed. It does not prevent the fading as a whole, but, when the colour has faded to the "pale-faded tint," no further alteration occurs. That the conclusions of this Committee, however, must not be taken to be paralleled by pigments of similar origin is evident from the fact that they say "the number of very fast reds is extremely limited, but it includes both natural and artificial dyes, namely, madder, cochineal, alizarine," &c. Now, it is well known to artists and to the manufacturers of carbon tissue that cochineal pigments—crimson lake, for example—are, in the highest degree, fugitive, and the substitution of alizarine reds for cochineal reds marked a distinct advance in the permanency of the general colour of purple-hued carbon prints.

British Association Memoranda.—The photography of interference and diffraction phenomena has been rendered easy of accomplishment by a new and simple apparatus devised and exhibited by Mr. Croft. No bench is used, and the various pieces of apparatus are mounted on the usual stands employed for holding lenses, &c. One of these contained a thin aluminium plate with a needle hole, or the slit of a spectroscope, on which the light of a lamp was focussed by means of a lens. The eyepiece of a Beck microscope was used for observing, and was placed about two feet from the slit or point, the object being introduced between. The stands are to be adjusted in such a manner that the light proceeds straight into this eyepiece. The whole special apparatus required need not entail an expenditure of more than a few shillings. It is suitable for showing or photographing the usual diffraction phenomena, and of Fresnel's bi-prism, sharp edges, perforated zinc, &c. Mr. Croft proved the value of this simple apparatus by exhibiting a series of curious phenomena, including an example of the bright central spot in the shadow of a small opaque spot (shot) photographed by its aid.

Lord Rayleigh's Substitute for Telescope Object Glasses.—Considerable interest continues to be exhibited in this suggestion (explained in these columns a few weeks ago). Letters over the signature of "H. F. Newall," and "Robert S. Ball," have appeared in response in the columns of *Nature*. The latter says, "Accepting what Lord Rayleigh says as to the present possibilities in the preparation of plates, I fail to see where any considerable saving is to be effected in the cost of the apparatus, as he appears to suggest." Also, "It is certainly easier to test the qualities of an objective corrected for visual than for photographic rays (if I may still use language which Lord Rayleigh has pointed out as incorrect). On this account it would, therefore, be desirable to have plates such as he refers to rendered available for astronomers engaged in photographic work." Professor Newall does not speak so strongly as Sir Robert Ball, but dwells on the advantages of violet refractors (*i.e.*, refractors corrected so that the minimum focus is for violet light). He sums up by saying that still greater advantages would accrue if a means of avoiding the difficulties of supporting, adjusting, and maintaining a mirror could be devised.

THE PHOTOGRAPHIC SALON.

The Photographic Exhibition known as "The Photographic Salon" was opened to the public, at the Dudley Gallery, on Monday last. The circumstances surrounding its inception were of such a remarkable piquant character that it is only the bare fact to say that its opening has been awaited with great curiosity. The popular belief, not altogether unsupported by weighty evidence, is that the Salon has been started in opposition to the old-established Exhibition of the Photographic Society of Great Britain, and, despite all the sophistry and special pleading that may be adduced to prop up the somewhat thin contention that it is intended to supplement rather than to rival the display in Pall Mall, we believe that it could only be with difficulty that an impartial judge would lean to the former view. There is, of course, the odd plea that the Salon affords scope for the Exhibition of purely "art" photographs which the older Exhibition does not; but the irony of fate opportunely intervenes to demolish any such fantastic theory, for at Pall Mall just now there may be seen on the walls medalled exhibits as strange, as bizarre, and as wishy-washy as the most conscientious Salonist could possibly desire. If, then, the Photographic Society has proved itself willing to recognise the special variety of photographic production which it is the aim of the Salon to nurture and encourage, the *raison-d'être* of the latter institution inevitably rests on the most slender support, and the continuance of a second Exhibition, either in a rival or supplementary capacity, is out of the question.

There are nearly 300 pictures on the walls at the Dudley Gallery, over 480 having been rejected by the committee of selection. The 300 exhibits are the work of about 110 persons, nearly half of whom, singular to tell, are also exhibitors at Pall Mall. These figures indicate that there is not, after all, a very large number of people anxious to demonstrate the necessity of a second Exhibition, otherwise it is difficult to account for such an even-handed support of the two. It would probably be near the mark to assume that, except in the cases of about half-a-dozen gentlemen whose names the reader can supply for himself, nobody cares two straws for the Salon as such, save and except that it gives him an additional opportunity of challenging a verdict upon his powers from the critical public; and a cheap opportunity, to boot, as the Salon does not charge for wall space.

Coming, however, to the Exhibition itself, we must admit that the promoters have done remarkably well, and have succeeded in getting together what is, on the whole, an undoubtedly fine collection of pictures, judiciously chosen and well hung. Indeed, we go further, and say that, in the department of portrait work, there is on view a number of examples we have never seen excelled, and the merit of which is a revelation. Of what are known as composition subjects and figure studies there are some capital examples, and in the way of land and seascapes some really good efforts. But not all the pictures are of the fuzzy kind; far from it, thank Heavens! A good proportion of them would delight the soul of even a photographic optician. With some, however, there is a strong need of what the Marchioness described to Dick Swiveller as "make-believe" before you can be tolerably sure that the producers of such low-toned, depressing, blurry libels on Nature are not having a game with you. For the rest, the appearance of the Exhibition is decidedly agreeable, warm and sepia tones abounding, rough papers and fabrics being plentiful, and, with few exceptions, great taste being shown in the framing. The catalogue does not vouchsafe any particulars as to the printing methods employed but most of the pictures are priced, and for eight of his characteristic views Mr. Davison asks the modest sum of forty guineas, which, area for area, is less than half what Mr. H. P. Robinson wants. On the whole, we should prefer Mr. Robinson's.

We have already made the acquaintance of many of the pictures at other Exhibitions, although their inclusion here is probably due to a lack of omniscience, such as even committees of selection may be expected to suffer from.

Songerie (No. 11), by M. Hector Colard, is the first noticeable frame; it is that of a well-posed female figure in classical robes; the face is half in shadow, and the deep sepia tone helps the effect, which is most artistic. Mr. Calland has *An Orchard in June* (No. 14), in which he is uncommonly successful with his fruit-blossoms. Such subjects are generally disappointing. In *A Still Delight steals o'er the Earth* (No. 16) Mr. J. B. B. Wellington has a richly toned study of a bland landscape with the rays of an evening sun striking athwart it; there is depth, sparkle, and crispness in the treatment of the work, which is probably as good as anything Mr. Wellington has done. *Only a Fisher-boy* (No. 19) is the name Mr. Sutcliffe gives to a jolly laughing lad, the best of the artist's exhibits, unforced and natural. Mr. Lewis Cohen, in *A Sultry Day* (No. 21), successfully shows us a rider on horseback pausing at a pool amid umbrageous surroundings, and Mrs. Francis Clarke, in *A Study* (No. 25), has a good old man's head. This kind of thing is getting a little overdone, since everybody has found out what capital subjects old men's heads make. A word of praise is distinctly due to Mr. F. W. Gauntlett for *We Parted in Anger my Love and I* (No. 27*), as it tells a story which is easily understood. Have we not all had sweethearts, and have we not al quarrelled with them? Two young people have evidently just had a tiff, and are going their several ways half regretfully, a rustic bridge separating them. There are not many touches of nature in this austere Salon, and this is one of them. Mr. Henry Van der Weyde shows several of his familiar studies, such as *Cardinal Manning* (No. 31), *Hypatia* (Nos. 32 and 33), *A Study* (No. 34) of a pretty lady looking up at a caged bird, and a costume portrait of the handsome *Lady Helen Vincent* (No. 35).

Homeless (No. 36) is a woman's head with a sorrowful expression It is a warm-toned picture, and its producer, Mr. G. M. Wane, is to be congratulated on a sound piece of work. Mr. F. Hollyer, in *Millicent and Daniel* (No. 37), has a charming unforced study of a girl with a dog. *The Foster Mother* (No. 42), a young girl caressing a lamb, by Mr. T. C. Hepworth, is exceedingly good, but the lady's foot looks uncommonly big. This is the kind of thing Mr. Van der Weyde would probably consider as coming within the scope of his photo corrector. Mr. H. P. Robinson has seven large pictures in his best style. In *Preparing for Shrimping* (No. 54) the figures are happily disposed, and the lighting is good; in *Stormy Sunset* (No. 56) the artist successfully quits his favourite pastorals for striking cloud effects. In *Coming Boats* (No. 61) a woman is looking out to sea, while there is a boat with a man in it in the foreground, the effect with the sea and clouds being bold and striking. *Morning Mist* (No. 64) is a sunrise picture with sheep in the landscape, and *Declining Day* (No. 71), another exceedingly fine evening effect. Perhaps the most striking of Mr. Robinson's pictures is *Wild Weather* (No. 67), a woman on the seashore battling against a strong wind. The veteran's hand has not lost its cunning. Mr. Shapoor N. Bhedwar sends two pictures, one *In commune*, a weird portrait of probably a Fakir, and another, *The Voice of Silence*, a blind Fakir apparently in the act of blessing his daughter. The latter is an extremely powerful study.

Two companion studies by Dr. Hugo Henneberg, *Midsummer* (No. 62) and *An Evening in Autumn* (No. 68), catch the eye by reason of a certain charm of naturalness, the former in particular, with a lady in summer attire admirably assisting the effect aimed at in the view.

Nos. 73, 74, and 81 are delightful little Italian bits by Mr. J. A. Sinclair in his own bright, incisive style, and close by them are six exquisite views by Colonel Gale, of which *A Roadside Pond* (No. 79) is a simple theme handled with masterly effect. *The Dreamy Milldam* (No. 82), with a man pursuing the gentle art thereat, and the groups of cattle in *After a Summer Shower* (No. 83) are also choice examples of Gale's style. It is always a pleasure to contemplate work like this. Hard by is *Toccata* (No. 85), by Mr. Maskell, in quite another vein. Perhaps Colonel Gale has spoiled us, but when we were contemplating Mr. Maskell's picture we were induced to say, with the man in Mr. W. S. Gilbert's ballad, that "we know it's very clever, but we do not understand it." It is a landscape with a melancholy tint, and it is out of focus, with the high lights looking as if they were put in. *A Fair Wind* (No. 87), a tiny yacht study by Tom Bright, is capital; but *On the Danube* (No. 90) is an ordinary river view, out of focus, dirty, yellowy-brown in tone, and by Herr Watzek. Is it supposed to be after an old master, or is it a "gosk?' Dr. P. H. Emerson shows a soft and pleasing *Portrait of a Lady* (No. 92); Mr. T. Manley (No. 93), a delightful study of child life in *It takes such a Lot of Thinking over;* and Mr. Lintott, a miniature view, *Off Greenwich;* and (Nos. 95–104) Count Gloeden, some more of his nude *Figure Studies*, perfect in modelling and lighting, although not perhaps always so in the grouping.

Mr. Ralph Robinson has ten exhibits, in which, however, he hardly does himself justice; certainly they do not come up to his Camera Club work of last year. Probably the best are, *Cooling Stream* (No. 112), some cattle in a stream; and *A One-sided Chat* (No. 127), a lady talking to a dog, the expression on the animal's face being cleverly secured. Mr. J. Craig Annan is also a generous exhibitor. In his *Fishers' Wives* (No. 117) several women are busy at work, while a lout of a man looks on with his hands in his pockets. One feels inclined to cuff him. *The Beach, Zandvoort* (No. 119), a long narrow view of the seashore, with numerous Dutch fisherwomen crowding round a fishing boat, is one of the best of Mr. Annan's exhibits, *the* best being probably *A Utrecht Pastoral*, a flock of sheep passing up an avenue of leafless trees. There is not much in the subject, but it is handled with rare skill, the winter chill being cleverly suggested, and the whole effect being most realistic. This must rank as one of the best landscapes in the room. Mr. Bernard Alfieri has two realistic studies of *A Winter Landscape* (Mo. 125), and *Silver Birches* (No. 126), as well as a large water piece with a mouldering *Derelict* (No. 129), enveloped in gloom and dismalness. *Wind* (No. 130), is another of Mr. Alfieri's, the play of the reeds and rushes being highly suggestive of atmospheric disturbance. A fine *Head of a Painter* (No. 132), by A. Buschbek; a richly toned farm scene, by Dr. Julius Strakosch, *Children Playing* (No. 138); a clever *Twilight* (No. 142), a sombre scene of craft on a river (query the Yare near Yarmouth Bridge), by Mr. Arthur Golding, all deserve mention and notice. Mr. J. S. Bergheim is represented by twelve pictures, chiefly large portrait studies, designed to suggest various effects and schools of painting. They include *Gipsy Queen* (No. 143), a portrait full of force; *Gazalleh* (No. 144), a charmingly soft engraving-like female head; *Sybil* (No. 147); *Beatrice* (No. 148); *Helen* (149); *Listening to the Voices* (153), a simple study of a girl seated at a window in a very natural, unconstrained, listening attitude; *La Juive* No. 154), and *Penserosa* (No. 155), a lightly draped lady, designedly taken considerably out of focus, so as to avoid a too realistic sharpness. Space will only permit us to speak in general terms of Mr. Bergheim's exhibits, many of which, aside of what they aim to be, are undoubtedly very fine from an ordinary photographic point of view. Good portrait work is shown by Mrs. Myers, although, in a *Portrait of Mr. Gladstone* (No. 165), as well as in her *Boy's Head* (No. 1), she makes her high lights uncommonly prominent. Mr. Karl Greger is successful with large work, and we like two Burnham Views (Nos. 165 and 184) by Mr. A. Horsley Hinton, as they are plucky and striking, but we altogether fail to appreciate others of Mr. Hinton's landscapes here; they have far too much "breadth" for such unregenerate mappists as ourselves. Mr. W. Crooke's portraits, *Miss Gratton* (No. 160); *Professor Blakie* (No. 178); and *David Bispham, Esq., as Comte de Neven*, are strikingly good, particularly the latter, which is got up to resemble a fine steel engraving. Two night views of *The Thames Embankment* (No. 192), and *The Eiffel Tower* (No. 193), by Mr. G. Loppe, show the lamps and lights, and are clever *sui generis*. We leave them to take a prolonged plunge into a bath of "pinhole," "astigmatic," "broad" and "diffused" effects by Messrs. Charles Moss, Rowland Briant, and others, to emerge for a moment at an ably treated view of *Carthagena* (No. 206), by Mr. A. E. Oakes. Then comes Mr. George Davison with fourteen studies mostly printed on fabric. Of these *Dedham Pool* (No. (213), and *A Seashore Pasture* (No. 223), arrest our fancy, as, while undeniably "broad" in treatment, they do not appear deficient in some kind of definition. Most of the others show the master of selection and composition, and exhibit Mr. Dawson at his best, or worst, as the reader

pleases; one picture, *The Hedger* (No. 235), being honourably entitled to receive the entire contents of a confectioner's shop for "breadth of effect."

Mr. Thomas Manly's *Naughty Bow-wow* (No. 219) is an amusing dog and child piece, and skilful withal, and the same exhibitor has other work of a like kind (Nos. 225 and 232). Mr. Henry E. Davis shows three small views shrouded in an intolerable deal of frame, *Fretful Spring* (No. 239) a realistic little bit; *Breaking Storm—Moonlight* (No. 240) and *Bisham* (No. 241) the last a delicate little river view which would bear enlargement. Mr. F. Hollyer's portraits, *Walter Crane, Esq.* (No. 258), *The White Frock* (No. 260) being the full-length portrait of a lady; *Rev. Stopford Brooke* (No. 263), *Albert Moore* (No. 277) are just what Mr. Hollyer has long accustomed us to. In *H. E. Davis, Esq.* (No. 277) the characteristic expression and attitude of the original are well secured, and the portrait is a highly successful one. Mr. H. H. Hay Cameron's portrait of *Master Harry Hetherington* (No. 262) shows the young gentleman's arm at right angles with his head, but Mr. Cameron succeeds better with *Henry Irving as Beckett; Mrs. H. E. Hoare*, a graceful piece of work, and *Master Wellesley*, a softly, harmoniously lighted portrait. *Sweet Kitty* (No. 271), by Mr. Arthur Burchett, is the picture of a smiling girl in a delightfully natural and easy attitude, and Mr. W. A Cadby's portrait of a girl in *Setting Sunlight* (No. 267) has some daring but striking effects of lighting. Lastly, the effect of Mr. Rowland Briant's *Mellow Mists of Autumn* (No. 272) is decidedly more convincing than that of this gentleman's other contributions to the Exhibition. We have only space now to add that in addition to those named excellent work is shown by Rev. F. C. Lambert; Miss Farnworth, Baron Rothschild, Messrs. R. Keene, C. Patterson, T. M. Brownrigg, A. R. Dresser, Viscount Maitland, Messrs. Seyton Scott, W. Thomas, H. Tolley, Major Nott, Messrs. Clarence Moore, F. H. Evans, B. Gay Wilkinson, H. W. Bennett, and others.

The Exhibition remains open till November 11, and is well worth visiting, as it contains something to suit all photographic tastes. But take it all in all, the Salon does not differ in essence from a really good Photographic Society's Exhibition except in its surrounding circumstances and its possession of perhaps a larger percentage of pictures having a "more subtly suggestive style of treatment," which is Salonic for badly focussed photographs. *Ainsi soit-il!*

JOTTINGS.

I AM sad at heart! The most unhelpable individual is the man who won't help himself, and nothing is more galling to one than to find that one's outlay of time and trouble on behalf of a friend who needed assistance has been rendered nugatory by a mixture of stupidity and wilful blindness. Throughout all its recent troubles I have been doing battle for the Photographic Society of Great Britain, denouncing its enemies, exposing their tricks and manners, indicating the traps and difficulties before it, solely with the object of helping the old Society to profit by my warnings and emerge from its crisis triumphant and successful. The Society's Exhibition is the very pivot of its existence, and, if that goes wrong, the Society's prestige is seriously shaken. This year, in the face of determined opposition, it behoved the Society to put its best foot forward and have an Exhibition which should be worthy of the occasion and of itself. But what do we find? Certain trifling improvements in the direction of sumptuary detail, selection of apparatus, &c.; but, for the rest, failure and *fiasco*. The Exhibition, designed to be small and good, is successful in the first regard alone; and as for the judging——!!!!!! The notes of exclamation must supply what my language cannot possibly convey, for, like the habitually profane waggoner, the tail-board of whose waggon gave way at the top of a steep hill, thus releasing a heap of potatoes which rolled away down the hill, "I ain't ekal to it!" Then, on top of the Society's humiliation, I am told that the Salon Exhibition is an extremely good one. Credit where credit is due, of course, but for the sake of the old Society, which is just now suffering from its own blunders, I am sad at heart. So, strike the banjo's sweet and tuneful string, and let me soothe my wounded feelings with a little music!

Rumour says that a new photographic paper is shortly to appear and rumour also says that it will eclipse anything of the kind now in existence, that it will have a lot of money behind it, that it will, in a special sense, take art photography under its wing, that it will, in short, play up Ancient Nicholas, and break things. The names associated with the enterprise are not unknown to the photographic eye, and are witnesses to the ingenious manner in which the gentle art of advertisement can be practised upon an unsuspecting public under all sorts of innocent but impenetrable disguises. I wish the new venture (if it appears) all the success it may deserve, but in the present state of the photographic trade, coupled with the fact that the journalistic ground is said to be already fully covered, I am not very sanguine of its chances of setting the Thames on fire.

Are outings a failure, and is the excursion played out? I notice in one or two annual reports of the Photographic Societies lately published that a falling off in the attendance of members on the occasion of the Societies' outings is recorded. As the weather during the past summer was above reproach, the explanation cannot take the old familiar shape, so I suppose that the outing fever is on the wane. This is rather a pity, inasmuch as to those who do not care for the violent delights of cycling there are few more enjoyable ways of passing a Saturday afternoon than with a camera amid beautiful natural surroundings. Have all the show-places near the large towns been exhausted by the older photographers, and are there no young ones to take their places? The reply to the last part of the question would seem to be in the negative. I fancy, too, that just now the growth of Photographic Societies is not so rapid as it was three or four years ago. I don't know whether such small facts as these can be taken as an indication of a lull in the spread of amateur photography, but they are certainly significant of possible changes coming over the spirit of our dreams.

May I ask whether it is the function of Judges at photographic exhibitions, when sending in a report, to append criticisms of the pictures they have judged, giving, by implication, their reasons why awards have been bestowed or withheld; if so, I would recommend such Judges to be quite sure their reasons will stand the microscope of common sense before making them public. Personally, I agree with you in your remark of September 29, "that a wise Judge always withholds his reasons." On this showing, the Judges of the Falmouth Exhibition, whose report on the Exhibition is published in your pages of September 22, run the risk of being called the reverse of wise. Of one exhibit, to which they gave a bronze medal, they say the pictures "are cleverly told stories, *but are somewhat too suggestive of the shop show-frame.*" To stigmatise work as of the shop-show-frame kind, and give it a medal, is rather contradictory, isn't it? Again, to say of an *At Home Portrait* that "it should have stopped there" is very unjudicial, and savours of the partisan. Then Mr. F. W. Edwards' interiors of Westminster Abbey are called "perfect work, printed in a most unpleasant colour." Is this loose writing, or do the Judges know what they mean? I don't. They first call a thing perfect, and then proceed to discount its perfection, which, to say the least of it, is a nonsensical proceeding. On the whole, the judging at Falmouth seems to have been about as funny as that at Pall Mall. Where, oh, where was my old friend Mr. William Brooks?

How many more times, I wonder, are we to have the suggestion that boxes of plates and packets of sensitive paper should have the date of manufacture stamped on them, so that the photographer might know whether he was buying old or new material? Your correspondent who wrote the other day, and those who write so glibly on the subject, cannot be aware of the difficulties surrounding it. The principal one is the old one of supply and demand. If a manufacturer knew that for certain brands and sizes of his goods there was a constant and steady demand, which obviated the necessity of the distributor holding them in stock beyond a given length of time, the thing would be simple enough; but this is a state of affairs never, under any circumstances, likely to happen. A dealer is largely at the mercy of the capricious laws I have named. An article may go

off with a rush, or it may hang fire, there is no telling. Hence there is only one thing that will prevent sensitive preparations from remaining in stock—say, for more than three months—and that is the willingness of manufacturers to take them back and cast them into the waste tub, which is an idea altogether too Utopian for further reflection.

I do not know whether the Kew Lens Testing System is much availed of by opticians, but I have often thought that an institution which could officially certify as to the good qualities of photographic preparations generally would "fill a long-felt want," and be exceedingly useful to producer and consumer alike. Selecting one instance out of many that occur to me, what trouble, loss, and vexation are caused to the poor photographer by his mounts, the quality of which he always has to take on trust, only too often to find that they develop all sorts of ruinous markings on his prints. Could the manufacturer sell the photographer his parcel of mounts with an expert's guarantee of their purity, much loss and acrimony would be spared all parties. Here is an opening for a clever chemist to start in business as an expert in the analysis of photographic preparations Don't all speak at once! COSMOS.

MATT EFFECTS ON ALBUMENISED PAPER.

ALTHOUGH for the production of matt-surfaced pictures, which are now becoming very popular, there are plenty of specially prepared papers, it may occur to others, as it did to me recently, that none of them are at hand or readily available when wanted. Under such circumstances, the method I adopted may prove equally useful to others. The plan is not my own, but was introduced upwards of twenty years ago, by whom I really forget, but I know that I tried it when it was first proposed, and got some results that satisfied me very well in days when everything must have the albumen gloss. The method consists in printing on the reverse side of the paper. Well, not that only, because, if any of my readers try it on ready-sensitised paper they will be disappointed. The paper must be *sensitised* on the reverse side—that is, it must be floated with the albumen surface uppermost. If this be not attended to, there will be no picture at all, or very little on the surface at least, although a strong image will be formed in the body of the paper.

The sensitising solution is prepared in the ordinary way, though, if strong, black tones are required, to resemble platinotype, it is desirable to use a rather stronger bath than usual (certainly not less than sixty grains to the ounce), and to have it neutral, or it may be slightly alkaline; the paper must be floated for a longer period than in the ordinary way, as the solution has to penetrate through to the albumen, and draw the soluble chlorides to the opposite surface. The albumen is coagulated in the same manner as if it had been in contact with the solution, showing that the latter must penetrate completely.

The printing goes on about as quickly as under ordinary circumstances; if anything, perhaps, a little more slowly, and should be carried to a good depth, as it comes down more in the toning and fixing than when on the proper surface of the paper. The washing, toning, and fixing are conducted just as usual, and for platinotype tones I use either carbonate or phosphate of soda. Better still, perhaps, for that colour would be the old lime toning bath.

Prints made in this manner, if the tone is good, are difficult to distinguish from platinotypes, especially when got up on "plate-sunk" mounts.

Another useful application of the method of sensitising from the back of the paper is in the production of paper negatives. It very often occurs that a negative has to be reproduced, and a very simple way of doing it is to make an albumen print, and from that a paper negative, the only difficulty being in getting sufficient density and contrast for printing purposes when the image is wholly in the albumen. By sensitising from the back this difficulty disappears.

For this last purpose gelatino-chloride paper may be used, for, although it might be supposed the image would be confined to the emulsion surface, it will be found that, if the reverse side of the paper be put next the negative, there will be little or no image on either surface, but a very strong one between the two. W. LINDSAY.

GELATINO-CHLORIDE PAPERS.

[Brixton and Clapham Camera Club.]

IN 1865 Wharton Simpson devised a process of silver printing in which the sensitive salts were held in suspension by collodion, and the process was called "Simpsontype." For some reason or the other this process died out in favour of albumenised paper; but in 1882 Captain Abney suggested a chloro-citrate or citro-chloride emulsion, which contained chloride of silver and citrate of silver emulsified in gelatine. This was the first mention of a gelatino-chloride printing paper (Woodbury).

In 1885 J. B. Obernetter, of Munich, introduced, commercially, a gelatine emulsion paper, and was followed, in 1886, by Liesegang, of Düsseldorf; but it was not till 1890 that the manufacture of gelatino-chloride papers was commenced, commercially, in England.

Gelatino-chloride emulsion paper is a paper coated with an insoluble film of gelatine and either sulphate of baryta, chalk, &c., the purpose of this film being to prevent the subsequent coating of emulsion of sensitive salts from sinking into the pores of the paper, and thus forming a white or coloured impermeable support for the sensitive emulsion (Woodbury).

It will keep for months under proper conditions. I have obtained first-class results on paper two years old (specimen). It can be obtained cut to sizes or in sheets for cutting. Great care must be taken to handle the sensitised surface as little as possible.

It will suit almost all kinds of negatives—a thin negative in a weak light, or a piece of tissue paper pasted over the printing frame, or a piece of ground glass laid over the frame. The paper is able to give good prints from such weak negatives better than can be obtained by any other means, and also weak negatives can be made to give good prints by printing under green glass (signal green, procurable at Defries', in Houndsditch), for the emulsion contains silver chloride and silver citrate. The action of the light upon chloride of silver is almost entirely confined to the ultra-violet rays, while the citrate of silver is altered by the blue rays and some distance into the green, which have hardly an effect upon the silver chloride. The silver chloride gives more gradation than the citrate; so, by printing through green glass, we prevent the action of light upon the chloride, and confine it almost entirely to the citrate, which gives much greater contrasts.

For dense negatives, print as quickly as possible, exposed to direct rays of sun; the blank whites can be softened down afterwards by exposing to the action of the light after removal of print from printing frame. Some strongly recommend varnishing negatives for use with gelatino-chloride paper, as it contains so much free nitrate of silver, and, therefore, very liable to silver-stain the negative. I am glad to say I have found no such necessity.

The paper is more sensitive than albumenised paper, and care should be taken to examine prints (whilst printing) in a weak subdued light. Print much darker than is required for the finished print, especially if to be toned with platinum, for great loss takes place in all after-operations; but, if the combined bath (toning and fixing) is used, it is not necessary to print so dark—no rule can be laid down; each operator will be able, by experience, to gauge, tone, &c., for himself.

After removal from frame, and if about to tone, be sure and give the prints a good washing, running water preferred, to remove all free silver tested by looking through some of the last washing water placed in any glass vessel, all the milkiness disappeared, all is well for next part. Some place salt in final washing water, but I have never found any such necessity. If the combined toning and fixing bath is to be used, no preliminary washing is required. After last washing, transfer print to solution of chrome alum, one ounce to ten ounces of water, for three or four minutes; remove and wash well again. To ensure even toning, do not buy cheap gold chloride; get the best, and make up into solution, fifteen grains to fifteen drachms water—equals one grain to the drachm.

TONING FORMULÆ.

A.

Sulphocyanide of ammonium	1 drachm.
Gold	2½ grains.
Water (distilled).....	5½ ounces.

B.

Soda acetate	88 grains.
Gold.....	2½ ,,
Water	5½ ounces.

For use, 3⅓ B to 1 part A.

ALL TONES FROM FOX-RED BROWN, TO BLUE BLACK.

Soda phosphate	20 grains.	Will not keep.
Gold	1 grain.	
Water	12 ounces.	

Gives purplish tones.

Carbonate lime	38 grains.	Extravagant, keeps fairly.
Gold	7½ „	
Water	10 ounces.	

Gives purple tones.

Soda acetate	1 ounce.	Keeps well.
Water	20 ounces.	
Soda bicarbonate	40 grains.	
Gold	15 „	

Gives rich purple-black tones.

To make this bath, dissolve the the soda in 18 ounces water, gold in 2 ounces water; mix, stand for 6 hours. For use take 1 ounce of solution to 10 ounces of water; after use filter and use to dilute next bath when required.

SEPIA TONES.

A.

Sulphocyanide of ammonium	1 ounce.
Sat. Sol. Carb. Amm	15 to 20 drops.
Water	50 ounces.

B.

Gold	1 grain.
Water	20 ounces.

Mix together until red colour disappears, then ready, not before; tone to deep purple, wash well, immerse in hypo. Result:—rich sepia black, suitable for rough or matt surface.

BLACK TONES.

Eastman's Formula.

Acetate of soda	30 grains.
Gold	1 grain.
Water	4 ounces.

Immerse, print, and tone just to a chestnut brown, remove at once, and immerse in combined toning and fixing bath, and allow to remain with rocking, till desired tone is reached. Without rocking gives grey tones.

COMBINED TONING.

Fixing Bath (Eastman's).

A.

Hypo	1 ounce.
Alum (potash)	¼ „
Soda sulphate	¼ „
H_2O	10 ounces.

B.

Gold	2 grains.
Lead acet.	8 „
H_2O	1 ounce.

For use, take two ounces of A to two drachms of B, mix. Allow to clear if necessary before use.

PLATINUM TONING.

Eastman's.

Potass chloroplatinite	5 grains.
Citric acid	40 „
Salt (common)	40 „
Water	20 ounces.

Welford's Bath.

Gold	4 grains.
Soda bicarbonate	90 „
Water	6 ounces.

Make when wanted. Over-toning is impossible. Easy to make.

All toning baths to work A 1 must be sufficiently saturated with chloride of silver, obtained by placing strip of unused paper in bottle containing toning solution.

TUNGSTATE-PHOSPHATE.

Ammonium sulphocyanide	140 grains.
Sodium phosphate	140 „
Sodium tungstate	100 „
Water	24 ounces.

When dissolved put scraps of untoned paper (a weak fixing bath is advisable for this bath), 10 per cent. only, into bottle, filter, and add 15 grains gold dissolved in 4 ounces water.

ORDINARY FIXING BATH.

Hypo, 2 ounces, to water, 10 ounces. Prints appear darker dry than wet.

After fixing wash well. I have found three-quarters of an hour ample. If for glazed surface, pass prints through alum solution again then wash finally; matt surface do not need second lot of alum; for glazed prints absolutely clean glass is necessary, and not too heavily squeegeed.

For matt surface clean ground glass or celluloid is necessary; if glass is preferred, a focussing screen is recommended, the grain being so fine. Ordinary ground glass is of not much use, too coarse, and gives shiny specks on dry prints.

Let all squeegeed prints get bone dry before stripping. I have never found the necessity of waxing glass surface before squeegeeing, as is recommended by some. Should any shiny specks show in finished print, caused through the print not having come into contact with ground glass or celluloid, the same can be removed by gently rubbing with a little fine pumice powder. Trim in ordinary way.

MOUNTING.

If for matt surface, ordinary stiff starch paste, removing all traces of brush marks which may show through finished and mounted print with fine pumice.

For glazed prints: Whilst drying on plate glass, paste with mountant a piece of waterproof backing paper; allow both to dry, then trim and paste (whilst on glass) on to the mount, allow to get bone dry, then detach; or, whilst print is drying on glass, paste a piece of stout cartridge paper (smooth) on to the print, when both are dry strip from glass and paste on mount with gelatine mountant, as follows:—

Gelatine	2 ounces.
Water	2 „
Alcohol	4 „
Glycerine	½ ounce.

Made thus: Soak gelatine in water for five or six hours, dissolve by gentle heat, then add glycerine, and lastly the alcohol in small quantities, stirring.

Or mount glazed prints by means of cut out mount, just touching edges of print with adhesive, lay down on card, pasting cut-out mount into card.

Paper used in manufacture of chloride papers is generally Baryta paper or Kreidé (German chalk, Woodbury). I have tried the following makes and found all thoroughly satisfactory; Aristotype (Liesegang), Cellerotype, Obernetter (Gotz), can be had either glossy or matt, Eastman's Solio.

I now purpose giving you a list of defects met with, and their causes, which are soon got over by perseverance, care, and cleanliness.

Degradation and Darkening of High Lights.—Examining prints whilst printing in too strong light.

Uneven Tones. — Paper damp, printing in damp atmosphere, acetate bath being acid.

Yellow Prints.—Exhausted bath, bath too warm, excess of sulphocyanide.

Greenish Half-tones.—Too long washing after fixing.

Loss of tone in Fixing Bath.—Insufficent printing and toning, hypo bath too strong.

Red Stains on Toned Prints.—Traces of hypo on fingers or in dishes, touched print before toning.

Rosy tints in Half-tones.—Weak gold bath.

Last advice, to get satisfactory prints is to exercise care, strict cleanliness in all manipulations, and do not spare the alum washings between each operation.

E. DOCKREE.

TO-NIGHT (Friday, October 13) the Central Photographic Club will have a smoking concert by way of housewarming at its rooms, Coleman's Hotel (late Ashley's), Henrietta-street and Maiden-lane, Covent Garden, W.C. Visitors will be welcomed.

THE HACKNEY EXHIBITION.—This Exhibition will be opened by Sir Charles Russell at Morley Hall, Triangle, Hackney, on Tuesday next, October 17. The awards will be presented by Captain Abney on the following day. Pictures will be exhibited by, amongst others, Messrs. Warneuke, Thomas Fall, Marshall Wane, F. W. Edwards, Birt Acres, J. B. B. Wellington, Dresser, Brooker, Gottlieb, Elliott, Mrs. Catherine Weed Barnes Ward, &c., &c.; and in the apparatus section there will be exhibits by Messrs. Marion, Wray, Watson, Platt & Witte, Powell, Hannam, Park, Fuerst, Doublet, Morris, Rawlings, &c. There will be concerts and lantern displays at intervals, orchestra, organ, &c.

THE ROCKET PLATE.

Under this name a new plate has been introduced by Messrs. Elliott & Son, Barnet, who claim for it the proud position of being the fastest plate made. The cut here shown is a reproduction from a negative obtained

by its agency in the middle of September last, and will show its great sensitiveness. The stop was *f*-11, and the indicated exposure a six-hundredth of a second. The plate gives a soft image, and will stand considerable forcing in development, while the grain is so fine that it bears enlarging to many diameters. Some other prints submitted show horses in the act of jumping fences.

A PORTABLE STAND.

In this stand three things will be observed from an inspection of the cut. First it packs up in a small space, being, in fact, of walking-stick form; secondly, it is extensible, as the legs can draw out; while, thirdly, the legs are permanently attached to the triangle or top, which is so constructed as to fold when being packed up, as shown in the figure on the top right-hand corner of the drawing. Some degree of ingenuity has been displayed in its entire construction, and there seems nothing to prevent it from being quite rigid when opened for use. Messrs. George Houghton & Son are the makers of this handy and portable camera stand.

Our Editorial Table.

The Art of Projection and Complete Magic Lantern Manual.

By An Expert. London: E. A. Beckett, Kingsland-road, N.E.

In this Manual we have a very complete account of the various inventions, discoveries, and manufactures of Mr. W. C. Hughes, the well-known lantern-maker of Brewster House, Kingsland, N.E.

In the course of his brief historical *résumé* we are glad to find that "Expert" gives credit to Marcy, of Philadelphia, for effecting the revolution in mineral oil lamps, which he undoubtedly did. Several pages are devoted to the construction, fitting up, and working of the Pamphengos, both singly and in pairs. Biunial lanterns, triple lanterns, and oxyhydrogen lime jets receive a considerable degree of attention; while the directions for registering effect slides are very full and complete. Gas cylinders and bags, pressure gauges, ether saturators, opaque and transparent screens, reading lamps and desks, all find a place. The application of the electric light to the lantern; the higher departments of projection, such as by the polariscope and microscope, not to speak of the preparation of slides by photography, are all highly suggestive to the student of the lantern. In the account of Mr. Hughes's mammoth Aphengescope for Prince Town College, New York, it is stated that "there is a loss of *eighty per cent.* of the light by reflection." When we consider that the loss of light by reflection from a well-polished silvered-glass mirror has been estimated at only five per cent., it is possible that there may be some mistake in the figures, unless the object from which the light is reflected on to the screen is a very absorbent one. The book throughout is well illustrated with diagrams.

Pictorial Effect in Photography.

By H. P. Robinson. London: Piper & Carter.

The fact of this work having gone through several editions (this is the fourth) shows the extent to which it is appreciated by those who take more than a merely technical interest in photography. It is the first work that was devoted to the art aspects of the art science, and it has taken its place as one of our classics. Since the work was first written (in 1868, if we mistake not) much has happened in pictorial photography. "Two events are" (we quote from the preface to this last edition), "however, of chiefest importance—the introduction of very sensitive dry plates, and the almost universal employment of mat papers of different kinds and various degrees of surface, from smooth to very rough." Mr. Robinson, in a few supplementary essays, brings his original teachings up to date, and amplifies subjects referred to in the body of the work. We confine ourselves at present to merely enumerating these essays, which are—"In Search of the Picturesque," "The Enjoyment of Photography," "Wind," "The Qualifications of a Portrait Photographer," "Without a Camera," "So Natural!" "The Use of Nature and Idealism in Art," "Originality." As all interested in this department of photography will be certain to procure copies of the work for themselves, we refrain from either describing or quoting. We may, however, observe that in the main work certain illustrations which have long done duty have been superseded by others. No one can read the work without being, if not instructed, at least much interested.

News and Notes.

The address of Miss Eardley, formerly of Dalston, is desired by Mr. R. Stewart, Photographer, Elgin, N.B.

London and Provincial Photographic Association.—On Thursday, October 19, Mr. T. C. Hepworth will show his slides.

South London Photographic Society.—October 16, Members' Lantern Night. Testing slides previous to being sent in for exhibition.

Central Photographic Club.—October 20, Open Night; experiments, results, &c. 27, Carbon Demonstration by Messrs. Elliot & Son.

The Judges at the South London Photographic Society's Exhibition will be Messrs. F. P. Cembrano, jun., W. E. Debenham, and Leon Warnerke.

Croydon Microscopical and Natural History Club Soirée.—The twenty-fourth Annual *Soirée* will be held on Wednesday, November 22 next

Widnes Photographic Society.—October 25, Open Meeting. November 8, *Flashlight Photography*, by Mr. W. Priestnall. 22, Open Meeting. December 6, *Chemistry of Photography*, by Mr. H. Wareing.

Mr. E. M. Nelson writes that the formulæ given by Dr. Piffard, in the course of his paper on *A Suggested Improvement in the Correction of Lenses for Photo-micrography*, &c. (page 641), should be "$R. - p = \frac{2n \times \sin u}{\lambda}$," and "$R. - p = \frac{2\ N.A.}{\lambda}$" respectively, and not as stated by Dr. Piffard.

MESSRS. NEWMAN & GUARDIA announce that they have opened new premises comprising offices, show-rooms, stores, dark room, &c., at 92, Shaftesbury avenue, London, W. This change has considerably increased the space available at their factory, which, for the present, remains in Farringdon-road. But they are also making arrangements for removing their plant and machinery to larger premises as soon as possible.

LEYTONSTONE CAMERA CLUB.—October 14, Inauguration of the New Hall and Studio.—There will be a cold collation served at half-past six, followed by the opening address by the President. The remainder of the evening will be devoted to music, and it is particularly requested that all members with vocal ability will assist in the success of the evening. 18, Demonstration of the Simplicity of Dr. M. Andresen's *Developing, Fixing, and Tone-fixing Cartridges*, by Mr. Eugene A. Leblanc. Chair taken at eight o'clock.

MR. W. J. STILLMAN writes: "In my reply to Mr. Blair, as printed in the JOURNAL of September 29, there are two misprints, which make nonsense of the sentences in which they occur. I am made to say, in the end of the first paragraph, 'as I did the other dry plates for glass,' &c., where I wrote 'for years;' and in the third paragraph, 'What have you and your fellow professionals attributed,' &c., where I wrote 'contributed.' I take the opportunity of saying 'Amen,' with all my force, to the note of Mr. Debenham in the same issue of the JOURNAL with mine.

THE second Annual Exhibition and Competition of the Leytonstone Camera Club will be held at the Masonic Hall, High-road, Leytonstone, on Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday, November 20, 21, 22, 23, 24, 25, 1893. The Veronese Band, under the direction of Signor Constantine Baga, has been engaged, and will play each afternoon and evening. There will be lectures, demonstrations, lantern displays, and other entertainments at intervals during each evening. The Judges are Messrs. F. P. Cembrano, jun.; Colonel J. Gale; Andrew Pringle; and twenty medals are offered for competition. Extra entry forms and all further information can be obtained from Albert E. Bailey, Hon. Secretary, Rose-bank, South-west-road, Leytonstone.

PATENTS COMPLETED.

IMPROVED MEANS FOR REGULATING THE RAYS OF LIGHT PASSING THROUGH PHOTOGRAPHIC LENSES.

No. 13,373.—JAMES WILLIAM FAWCETT, "Berthanga," 15, Argyle-street, St. Kilda, near Melbourne, Colony of Victoria.—*August 26*, 1893.

WITH the means at present in use for regulating the rays of light passing through photographic lenses, it has been usual to make the apertures in the stops and shutters in a line or concentric with the optic centres of said lenses. With this construction, however, the major portion of the rays of light pass on to the sensitive plate from the sky or upper portion of the landscape, whilst only a small portion pass from the foreground, the effect upon such plate being unequal, so that it has been found to be impossible under ordinary conditions to correctly photograph clouds and other aerial effects at the same time as the foreground or main part of the land or seascape.

Now the object of this invention is chiefly to enable these results to be obtained, and partly to impart a stereoscopic effect to the photograph.

It consists in arranging the apertures in the diaphragms, stops, and shutters of photographic lenses so that their larger area is below the optic centre of the lens, thereby allowing a greater proportion of light to pass from the foreground on to the sensitive plate than from the sky, thus tending to equalise the effect upon the plate, as will be well understood by photographers.

According to my invention, I make the lens aperture of triangular or approximately triangular shape, with the base arranged horizontally, and I cut a similarly shaped opening in a horizontally sliding plate or shutter, which may be actuated by hand or by any other convenient means.

By forming the aperture in the horizontally sliding plate or shutter, as just described, and by sliding it horizontally, a stereoscopic effect is given to the finished photograph by reason of the light being allowed to enter first at one bottom corner, then gradually being allowed to pass through the whole of the lens aperture, and finally through a small opening at the opposite bottom corner, thus as it were to a certain extent photographing the object from two different points of view, and so producing the desired effect.

In order to reduce the size of this lens aperture, a plate having a triangular or approximately triangular hole or notch cut in its lower end, may be arranged to slide vertically through a slot in the brass mount of the lens in the same way as the ordinary stops, said plate being capable of adjustment to any required position so as to cut off more or less of the upper part of the lens aperture.

I prefer to make the lens aperture in the form either of an equilateral, or else of an acute-angled isosceles triangle, and arrange it so that two-thirds of its height is below the optic centre.

The principle of construction above described can be applied to detachable instantaneous, or other shutters, such as are usually fitted upon the forward part of the lens.

IMPROVEMENTS IN ACHROMATIC DISPERSING LENSES.

No. 10,000. PAUL RUDOLPH, Carl-Zeiss-strasse, Jena, Grand Duchy of Saxe-Weimar, German Empire, and CARL ZEISS, of the same place.—*September 9*, 1893.

IN optical systems (such, for instance, as the Galilean telescope, and the so-called tele-objective which has of late been used for photographic purposes) which contain, besides the achromatic objective, and distinct therefrom, an achromatic dispersing lens of a shorter focal distance than the objective, the dispersing lens has hitherto always been achromatised in the same way as an objective consisting of single lenses cemented to each other is achromatised in order to correct the spherical aberration at the same time with the dispersion of colours. Analogously the main lens (which in this case is negative) of dispersing lenses of this kind, has been made of crown glass of low refractive power, and the correcting lens to be cemented to it (which in this case is positive) has been made of flint glass of considerably greater refractive power. This difference or graduation of the refractive power is actually as necessary and indispensable in a dispersing lens as it is in a collecting lens, if the dispersing lens is to be not only chromatically but also spherically corrected, and consists at the same time of single lenses cemented to each other; for it is only through the surplus or excess of refractive power of the positive constituent or element over that of the negative constituent or element that the inner surfaces of a dispersing lens obtain a spherical aberration contrary to and compensating for that of the outer surfaces.

In combinations of lenses of the class described it is not advisable, however, as we have found by theoretical and practical experience, for obtaining a good total effect of the combination as a whole, to correct the diapersing lens by itself or separately with regard to spherical aberration as has heretofore been done either intentionally or otherwise.

If, as is the case with the aforesaid combinations of lenses, the focal distance of the dispersing lens be considerably smaller than that of the objective belonging to it, and if the distance of the said dispersing lens from the objective be at least equal to its focal distance, its spherical aberration can always be easily neutralised or prevented from injuring the total effect by intentionally leaving a small amount of uncorrected spherical aberration on the part of the objective. In the usual arrangement for correcting these systems the surplus of the refractive power of the positive element of the dispersing lens invariably involves an objectionable increase in the degree of curvature of its outer surfaces, which is necessary in order to obtain a given focal distance. Moreover, this surplus of refractive power causes at the cemented inner surfaces of the lens (which have a comparatively great degree of curvature) effects of aberration which render it difficult to obtain an accurate adjustment of the total effect of the combination, especially outside the axis.

These considerations have led the inventor to the discovery of means for effecting the achromatisation of such optical systems by an arrangement different from, or contrary to, that heretofore employed, namely, an arrangement in which no compensation or great reduction of the spherical aberration is connected with the achromatisation of the dispersing lens, but this lens, although perfectly achromatised, retains, as regards spherical aberration, the character of a simple uncorrected dispersing lens.

This result is obtained by forming the positive part of the cemented system of flint glass having a refractive power equal to, or only slightly greater or less than, the refractive power of the negative part, but having a relative dispersion of colours presenting a sufficient surplus over that of the negative part to admit of the achromatisation, whilst retaining convenient degrees of curvature of the surfaces of the two parts.

The chief advantages accruing from the employment of achromatic dispersing lenses of this novel description in the optical combinations or systems hereinbefore referred to are as follows, viz.:—(1) for any required focal distance a considerably smaller degree of curvature of the outer lens surfaces is obtained than is required with the arrangement heretofore employed, and this degree of curvature is enabled to be even further reduced in case of need; (2) the positive spherical aberration (being of the same nature as that of a single convex lens) which takes place at the inner cemented surfaces of the lens can be reduced or transformed into a negative spherical aberration (which is of the same nature as that of a single dispersing lens).

The first-named advantage is made evident by the following comparison:—

In all achromatic dispersing lenses heretofore employed the refractive index n D of the crown glass is between 1·51 and 1·52, the refractive index of the flint glass n^1 D is between 1·60 and 1·63. The surplus $(n^1 - n)$ in the refractive index of the positive element over that of the negative element is consequently between 0·08 and 0·12. Under these circumstances, complete achromatisation —if the most favourable kinds of glass as regards dispersion of colours are selected—requires a total degree of curvature K of the outer surfaces of the

lens (K = algebraic sum of the reciprocals of the radii of curvature of both surfaces) at least equal to 2·4 times the reciprocal of the focal distance $\left(\frac{1}{f}\right)$ of the lens, viz. :—

$$K = 2{\cdot}4 \times \frac{1}{f}.$$

But if the aforesaid surplus or difference $n^1 - n$ is reduced to a smaller amount, say 0·03 for example, at the same time retaining as great a difference as possible in the relative dispersion of the two parts (from which follows indirectly that the cemented lens, in the practically applicable forms, retains a spherical aberration of the same nature as that of a concave lens) complete achromatism can be obtained with the following kinds of glass, viz. :—

Crown : n D = 1·574 ; n F − n C = 0·01005.

Flint : n^1 D = 1·603 ; n^1 F − n^1 C = 0·01576 with a degree of curvature of the outer surfaces.

$$K = 1{\cdot}9 \times \frac{1}{f}.$$

If $n^1 - n = 0$ be taken, the required degree of curvature is reduced to—

$$K = 1{\cdot}67 \times \frac{1}{f}.$$

Again, if $n^1 < n$ be taken (for which the kinds of glass available leave ample margin without the complete achromatisation of the lenses being affected) the proportion of $K\frac{1}{f}$ may be reduced as may be required so that the external form of the dispersing lens may be brought near to the plano-plate or to the watch-glass shape without the radii of curvature of the inner surfaces (if a triple cemented lens is admissible) becoming excessively small in comparison to the focal distance.

The following kinds of glass :—

Crown : n D = 1·6112 n F − n C = 0·01068

Flint : n^1 D = 1·5366 n^1 F − n^1 C = 0·01102

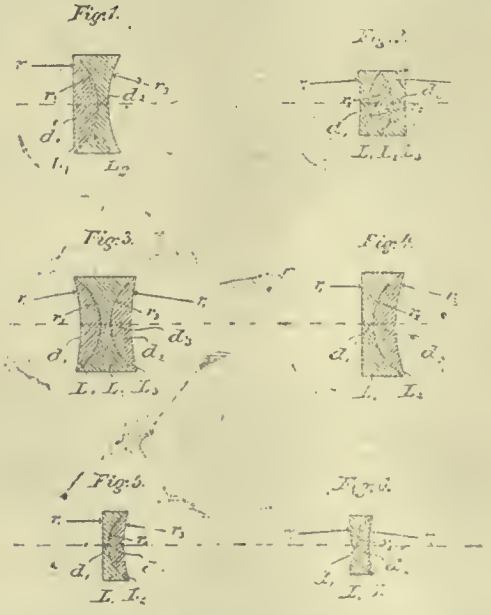
give for instance,

$$K = 0{\cdot}34 \times \frac{1}{f},$$

while the radius of the inner cemented surfaces of a symmetrical triple lens of these kinds of glass with the flint glass situated inside is

$$r = 0{\cdot}094\, f.$$

As regards the second advantage mentioned, namely the reduction of the spherical aberration at the inner cemented surfaces of the dispersing lenses, or the transformation or conversion of the character of this aberration, it is evident that in the same degree as the indices of refraction n^1 and n approach conformity, the effect of refraction of the inner cemented surface or surfaces, and in connexion therewith the spherical aberration, ceases more and more, that is to say, greater degrees of curvature of these surfaces can be selected without causing irregularities in the correction. If $n^1 = n$ be taken, the cemented achromatic dispersing lens considered apart from the achromatism acts as a simple dispersing lens. Of special practical importance, however, is the power of employing (in dispersing lenses of the kind in question) a positive element (flint glass) whose refractive index is smaller than the refractive index of the negative element (crown glass), and thereby obtaining, in addition to the aforesaid great reduction of the degree of the outer curvature, a conversion of the character of the spherical aberration of the inner surfaces being a different effect to that obtained with the constructions heretofore employed for achromatic dispersing lenses. This conversion is extremely advantageous in the lens combinations now under consideration (Galilean telescopes, tele



objectives, and the like), for obtaining correcting effects outside the axis through the dispersing lens which cannot be obtained with the ordinary composition of the latter.

According to the special requirements of the purpose for which it is to be employed, the new dispersing lens is composed of two or three single lenses cemented together, the said lenses being composed of two, or in some cases three different kinds of glass, and may be constructed either as a symmetrical or as an unsymmetrical lens.

The selection of the several separate elements of the combination must (if the best effect possible is to be obtained) be governed by the construction of the objective with which they are to be combined, taking especially into consideration its aperture and its spherical correction.

In order to more clearly explain the practical effects of the invention, we will now proceed to describe, by way of example, several types of lenses suitable for different constructions of objectives, and for various purposes of application, the said lenses being represented in section in figs. 1 to 6 of the annexed drawing. The signs or letters of reference in the formulæ hereinafter given, correspond with those marked on the figures, and the kinds of glass are determined by the indices of refraction n D n C and n F for the Fraunhofer lines D, C, and F.

All the figures given refer to an undetermined focal length which is regarded as the unit of length. The radii of thickness and diameter which are required for a lens of a given or determined focal length f are then obtained in inches or millimetres by multiplying the figures given in the formula by the number f expressed in inches or millimetres.

(1) Unsymmetrical double achromatic dispersing lens for Galilean telescopes with achromatic objectives of ordinary construction represented by fig. 1 for the focal distance of 50 mm. The part L is composed of flint glass, and the part L_2 of crown glass.

The following formulæ correspond with a focal distance of 1·0 referred to a focal distance of +1 of the objective lens, this factor, −1·0, being omitted from the formulæ.

Radii.	Thickness of Lenses.	Diameter of Lenses.
$r_1 = 0$	$d_1 = 0{\cdot}151$	0·54
$r_2 = 0{\cdot}3303$	$d_2 = 0{\cdot}063$	
$r_3 = +0{\cdot}6126$		

Kinds of Glass employed.

	n D	n C	n F
Flint L_1 =	1·61201	1·60729	1·62383
Crown L_2 =	1·61230	1·60912	1·61990

Degree of the Outer Curvature.

$$K = 1{\cdot}63 \times \frac{1}{f}$$

2. Symmetrical triple achromatic dispersing lenses for Galilean telescopes with objectives of relatively large aperture. Focal distance of −1·0 :

(*a*) Flint glass L_2 (fig. 2) between two glass lenses L_1 and L_3 for the focal distance of 50 mm.

Radii.	Thickness of Lenses.	Diameter of Lenses.
$r_1 = -1{\cdot}8753$	$d_1 = d_3 = 0{\cdot}055$	0·36
$r_2 = +0{\cdot}2816$	$d_2 = 0{\cdot}137$	
$r_3 = -0{\cdot}2816$		
$r_4 = +1{\cdot}8753$		

Kinds of Glass.

	n D	n C	n F
Crown : $L_1 = L_3$	1·57276	1·57017	1·57891
Flint : L_2 =	1·52294	1·51094	1·53022

Degree of the Outer Curvature.

$$K = 1{\cdot}17 \times \frac{1}{f}$$

(*b*) Crown glass L_2 between two flint glasses L_1 and L_3 represented by fig. 3 for the focal distance of 50 mm.

Radii.	Thickness of Lenses.	Diameter of Lenses.
$r_1 = -1{\cdot}0247$	$d_1 = d_3 = 0{\cdot}117$	0·53
$r = -0{\cdot}3233$	$d_2 = 0{\cdot}052$	
$r_3 = +0{\cdot}3233$		
$r_4 = +1{\cdot}0247$		

Kinds of Glass.

	n D	n C	n F
Flint : $L_1 = L_3$ =	1·53486	1·53169	1·54257
Crown L_2 =	1·52094	1·51871	1·52617

Degree of the Outer Curvature.

$$K = 2{\cdot}0 \times \frac{1}{f}$$

3. Double negative lenses of various focal distances for a photographic combination, and which may be employed with any photographic objective, but are especially adapted for use with an achromatic objective of three cemented lenses of which the elements of construction are for the focal distance of 1·0, as calculated for the focal length of the positive lens employed.

Radii.	Thickness of Lenses.	Diameter of Lenses.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

October 10,—Ordinary Meeting.,—The President (Captain W. de W. Abney C.B., in the chair).—The attendance, which was a large one, included several ladies.

Captain Hills and Mr. Grenville were elected members.

The medals awarded to them by the Judges of the Exhibition were presented by the President to Mr. Calby, Mr. J. A. Sinclair, and Mr. Charles Moss; the other medal winners were absent.

Photograph of Large Hailstones.

A photograph of hailstones, natural size, taken during a thunderstorm at Richmond, Yorkshire, on July 18 last, by Mr. Metcalfe, of that town, was passed round. The hailstones were, if anything, larger than hen's eggs.

President's Annual Address.

The President, in the course of his annual address, said the session just opening marked a new era in the history of the Society. As they were aware, a Photographic Congress was to be held on the two following days. There was an annual Photographic Convention held in different localities, and the Camera Club also held an Annual Conference, but the Photographic Congress was a combined movement of Societies affiliated to the Parent Society, which would have the effect of binding them to that Society. Referring to the opening of the Photographic Salon, he said he thought it a natural outcome of photographic art, and that there was ample room for two exhibitions. They (the Society) should make their standard as high as possible. A healthy rivalry was to be wished for. He wished good luck to their rivals and good luck to themselves. Touching on the affiliated Societies, he said he was pleased to find the movement successful, although at first he opposed it. There were forty-seven Societies now affiliated. He hoped soon the Society would be in new premises. For legal purposes the incorporation of the Society was to be desired, but he thought a Royal Charter unattainable. Having reviewed recent advances in heliochromy, Lippmann's "interference" photography, photographic optics, and MM. Lumière's experiments in printing with salts of manganese, cobalt, and cerium, the President concluded by remarking that he was glad to see collodion looking up once more. Any one who had worked with collodion still loved it. There was something in the very smell of the ether that was attractive.

A vote of thanks to the President for his address was moved by Mr. W. S. Bird, seconded by Mr. W. England, and carried unanimously.

Professor Marshall Ward, who was to have read a paper, being unable to attend on account of illness, the remainder of the evening was devoted to an exhibition of the lantern stereoscope.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

October 5.—Mr. Thomas Bedding in the chair.

Mr. A. Buchanan was unanimously elected a member.

Relative Quantities of Sulphurous Acid present in Potassium Metabisulphite and Sodium Sulphite.

Mr. A. Haddon observed that at a previous meeting Mr. B. J. Edwards had stated that potassium metabisulphite contained seven times as much sulphurous acid as sodium sulphite. This was wrong, as would be demonstrated by the following. The chemical formula for potassium metabisulphite was $K_2S_2O_5$, and, by ascertaining its molecular weight, the percentage of sulphurous acid contained in it could also be arrived at, thus:—

$$\left.\begin{array}{l}2K\,(39)=78\\1O\,(16)=16\\2S\,(32)=64\\4O\,(16)=64\end{array}\right\}=128\text{ weight of sulphurous acid.}$$

Molecular weight = 222

therefore the percentage of sulphurous acid = 57·6.

Treating sodium sulphite in the same way, the formula for which is $Na_2SO_3 + 7\,H_2O1$,

$$\left.\begin{array}{lll}2Na & (23) = & 46\\1O & (16) = & 16\\1S & (32) = & 32\\2O & (16) = & 32\\H & = & 14\\7O & (16) = & 112\end{array}\right\}\text{sulphurous acid} = 64.$$

Molecular weight = 252

and the percentage of sulphurous acid present = 25·4,

from which it would be seen that, instead of seven times, potassium metabisulphite contained a little more than twice the weight of sulphurous acid than sodium sulphite. Mr. Haddon also pointed out that, in buying the latter salt, one paid for more than half its weight of water.

Vitro-enamelling.

The following question from the box was read: "Does the powder, or the substitution process give the better result for making photographic enamels?"

Mr. Haddon said that a variety of tone could be obtained by the dusting-on process. The substitution process gave black tones.

Mr. J. S. Teape said that the substitution process allowed no retouching, the actual image having to be fixed as produced. The dusting-on process allowed artistic retouching, and an increase of brilliancy.

Mr. Haddon said retouching was possible with the substitution process, using vitrifiable powders ground up in oil of lavender, and refiring. In reply to another question, Mr. Haddon said that, in his experiments, he used a Fletcher gas muffle, which took a plaque a little larger than those he had made, viz., two inches square. Such a muffle cost between 2*l.* 10*s.* and 3*l.*

Lantern Society.—October 9, first meeting of the Session.—The Hon. Secretary announced the reduction of the subscription and the accession of ten new members. Mr. C. S. Scott showed his new lantern-slide printing-frame, an ingenious arrangement for printing slides by contact, and adapted for use with the new printing-out lantern plates. The set of slides being sent to America by the Society were then shown on the screen. Members subsequently inspected the new lantern purchased by the Society, which is fitted with one of Mr. E. M. Nelson's double-crown condensers, the front lens of which, on being reversed, enables parallel rays to be obtained, and a nine-inch Wray projection lens. The performance of the lantern left nothing to be desired, both as regards definition and entire absence of colours in the image. The lantern is adapted for scientific work as well as for the ordinary work of showing slides.

Northern Photographic and Scientific Association.—September 28.—The subject was the *Preparation of Lantern Slides by the Wet Collodion Process*, by Mr. P. D. COGHILL. The lecturer described in detail the various stages in the manipulation of the slides from the albumenising of the glass to the finished pictures, each step being minutely gone into, and the various formulæ for developing, clearing, toning, &c., given. Mr. Coghill also illustrated his lecture by preparing a lantern slide from a negative and finishing it off.

OCTOBER 5.—A lecture was given by Professor J. MACFAYDEAN, Dean of the Royal Veterinary College and Lecturer on Pathology and Bacteriology at that Institution, on the subject of *Pathogenic Germs and Disease*, Mr. J. G. Robins (President of the Society) occupying the chair. The lecturer said that bacteria were, in reality, minute vegetable life, and were the most common of all forms of life, abounding in enormous quantities. A great number were non-pathogenic, or incapable of producing disease, but others were of a pathogenic or disease-producing kind, and with these he proposed to deal. The lecturer then proceeded to describe the germs of anthrax, glanders, tetanus, tuberculosis, diphtheria, cholera, &c., photographs of the various bacilli being thrown upon the screen by the aid of the lantern.

Hackney Photographic Society.—October 3, Mr. R. Beckett in the chair.—Members' work was shown by Messrs. Barnes, Hudson, and Puttock. The following questions were asked:—"What exposure was necessary for printing in clouds on a lantern plate, nominal exposure for a negative being forty seconds?" Presuming the density of the negative to be the same as that which is to be printed from, it would require about fifteen to twenty seconds' exposure. Mr. S. J. Beckett used the cover glass to put the clouds upon. Mr. Fenton-Jones used a printing frame, shading portion upon which the landscape would come with a book. A similar question was asked as above for printing on clouds on bromide paper, the exposure would be about a quarter to half of what the negative would require. Mr. S. J. BECKETT asked the best way to remove amidol stain from lantern slide? Several members stated it could not be removed. As a trial, nitrate of soda was suggested. Mr. GRANT asked the reason of black spots upon a negative developed with pyro and soda? Mr. BECKETT stated it looked like an old plate. Mr. SMITH asked "whether any shorter exposure was required for bromide paper, developed with Dresser's formula?" Opinions seemed to be that it should be the same, only a weaker developer would take longer to obtain the same degree of density. With amidol, according to the strength of developer, so you can make it a quick or slow developer, density being obtainable with either. Mr. E. J. WALL then proceeded with a very instructive paper upon lenses, and dealt very largely with the subject, giving the various kinds, their uses, manufacture, faults, &c., illustrated with designs in coloured chalks. A vote of thanks to Mr. Wall for his paper concluded the evening.

Brixton and Clapham Camera Club.—October 3, Dr. J. Reynolds, F.R.G.S. (President), in the chair.—Four new members were elected, two of them being ladies. At the conclusion of the ordinary business, Mr. E. Dockree, one of the members, read a paper upon *Gelatino-Chloride Papers* [see p. 656]. Later in the evening the club decided to purchase an enlarging camera and it is expected that sufficient funds will be forthcoming to enable the Club to purchase the apparatus at an early date. Next meeting October 17, paper by Dr. Reynolds on *Diazotype Printing, i.e.*, printing in aniline dyes.

South London Photographic Society.—October 2, Mr. Maurice Howell (Vice-President) in the chair.—At the conclusion of the formal business, Mr. E. J. Lester gave an instructive and interesting address on *Outdoor Portraiture*. In his opening remarks he stated that the beginners' instruction books always made a point of advising photographic novices to leave portraiture severely alone until they had mastered, to some extent, the art of taking views. However good this advice might be, it was in nine cases out of ten wholly ignored, and the beginner, as a rule, commenced his photographic career by *attempting* to get pictures of his admiring relatives and friends. The speaker would, therefore, endeavour to show how portraiture might be undertaken out of doors with results that very often could hardly be distinguished from studio work. The background was the first obstacle to be overcome, when a large vignetted head was the desideratum. He found that a clean blanket, stretched across a line, and fastened with pegs, acted as the best medium in this respect. He always selected the wall of the house from the other side of which the sun was shining, and then fixed his background at an angle; the person whose head was to be taken was seated (and this was most important, as in this class of work long exposure was necessary, and, if the subject was made to stand, the head would be almost certain to move), and a side face arranged for, the tip of the nose was focussed, and the exposure made with an ordinary plate (about four seconds in a fairly strong light) at *f*-11, which stop will be most useful. All darkness which would otherwise be noticeable under the chin and at one side of the face was thus got rid of, and a nice shade on one side of the face substituted, which gave the finished print the appearance of studio work. If the eyebrows of the sitter were very prominent, the face should be slightly raised, and the camera tilted on a parallel with it. Heliotrope was the best colour for ladies to be photographed in. If a sitter was fair, light clothes should be worn, but, if dark-complexioned, the operator should see that only black, or very dark blue, clothes were put on. With regard to developing, he was in favour of pyro-soda. As to a background for a group, he advised his hearers not to attempt to improvise one, or it was almost certain to end in failure, and, if they must have an artificial background, they would have to get one made specially.

Croydon Microscopical and Natural History Club (Photographic Section), October 5, Mr. K. McKean chairman.—Mr. J. H. BALDOCK read a short paper on the treatment of "Nikko" paper, and demonstrated the process of development with the ferrous oxalate, Thomas's hydroquinone, amidol and metol developers, the two latter giving softer blacks than the former. The after treatment, in order to obtain a warm colour by means of uranium toning, was also shown. Mr. SPARROW then gave an account of his experiences with mezzotype, a rough printing-out silver paper, and exhibited a number of prints.

Croydon Camera Club.—The winter meetings were successfully inaugurated on October 4, when a large gathering assembled to hear the PRESIDENT (Mr. H. Maclean, F.G.S., give an address on *Photographic Novelties*. Multiple-coated films, lenses, developers, exposure meters, printing frames, "Nikko," and other things which were more or less new, formed the burden of a discourse which seemed to be very acceptable. Much discussion ensued. Amongst many points raised may be mentioned: Mr. PIERCE advocated metol for intensifying negatives; Mr. WHITE and others considered exposure meters "worse than useless, being misleading;" Mr. WRATTEN did not think any conclusion as to the amount of silver in a dry plate could be drawn by the quantity of pyro recommended by makers as most suitable for its development. Mr. George Carden showed a very complete series of about forty whole-plate prints of "Condemned Croydon." A large portrait of Mr. H. E. Neeves (a deceased member) was presented to the Club by Messrs. Isaac & Sladden. Messrs. Bowen, Miles, and Burrough were elected members.

Birkenhead Photographic Association.—October 3, Dr. W. H. Hunt in the chair.—The result of the Annual Outdoor Competition was announced as follows:—Silver medal, Mr. W. H. Davies (a new member); bronze medal, Mr. W. T. Briggs. The business of the evening was an excellent lecture by Mr. A. W. BEER (an ex-President of the Society), entitled *A Glimpse of Brittany and the Bretons*, which proved a most enjoyable and instructive entertainment. Mr. Beer's slides are almost all reductions from 10×8 negatives, and are, consequently, very perfect in their detail. His subjects are principally architectural, about thirty slides being devoted to Mont St. Michael alone. The PRESIDENT announced that the Society's ordinary meetings would be held on the first Tuesday in each month in future.

Birmingham Photographic Society.—October 3, Mr. J. T. Mousley in the chair. About fourty-five members present.—Mr. SMITH, of the Platinotype Company gave a practical demonstration of the working of the process in all its branches. Mr. Smith developed prints on the hot bath, cold bath, and for sepia tones, which latter were especially admired. Prints made on various textile fabrics were also developed, and some marvellously beautiful finished results were shown, all present agreeing that this was a remarkable application of the process. Mr. Smith also showed the working of the special printing lamp, a proof being ready for development in ten seconds. The lecturer having kindly answered numerous questions, a hearty vote of thanks was accorded to him and to his firm.

Leeds Photographic Society.—October 5, Mr. Godfrey Bingley in the chair.—After the ordinary business was concluded Mr. HERBERT DENISON read a paper on *Photogravure*. In a very lucid manner he described the whole process, from negative to the finished print. He passed round to the members negatives, tissues, and copper plates in the various stages of manipulation, and showed that this very beautiful and permanent process was within the reach of all. Mr. Bownes, one of the members who have taken up this process, also showed some very pretty pictures, also Mr. Ramsden showed one produced thirty-five years ago. Discussion followed, and questions were asked regarding cost, &c., which Mr. Denison answered. A hearty vote of thanks was given to Mr. Denison at the close.

Sheffield Photographic Society.—The Annual Meeting of the above Society was held at the Masonic Hall on Tuesday evening, Mr. B. J. Taylor in the chair.—After the election of two new members, the Treasurer presented his statement of accounts, which showed a very considerable balance in hand, and was considered satisfactory and duly passed. The Secretary gave a general report of the proceedings for the year, showing in detail the work which had been done each month. The excursions, although not numerous, had been well attended, and resulted in good work being done, especially the one to York. The Society was never in a more flourishing condition, and the proceedings were characterised by an amiable tone throughout, each member being anxious to promote the general good of the Society. The Secretary also announced several important fixtures for the ensuing year. The officers for the coming year were elected as follows:—*President:* Mr. Ernest Beck.—*Vice-Presidents:* Messrs. B. J. Taylor, Bradley Nowill, and George Bromley *Council*:—Messrs. J. Smith, W. T. Furness, T. G. Hibbert, T. Firth, and D. C. Brooks.—*Reporter:* Mr. E. H. Pearce.—*Treasurer:* Mr. W. M. Toplis.—*Secretary:* Mr. T. Camp.

Widnes Photographic Society.—September 27, Mr. V. C. Driffield presiding.—Mr. George Rae gave a limelight exhibition of a number of his slides, which were afterwards placed on the table for inspection and criticism. Mr. J. Neuburn brought a number of P.O.P. prints, and other members brought negatives, which were handed round and commented on. The meeting assumed a conversational tone, and topics of interest were discussed. Two new members were elected.

FORTHCOMING EXHIBITIONS.

Correspondence.

ALPHA PAPER.

To the EDITOR.

SIR,—It is with pleasure that I notice in your valuable paper a correspondence on "Alpha Paper." I think to users of this paper some practical information on the methods of working it will be of service to many.

Your correspondent (Mr. Ridler) seems to have been very successful in his work, whereas I, along with many others, have had just the contrary result. My first attempt at enlarging to whole-plate from quarter-plate with Alpha paper, using *f*-24 stop, giving eight minutes' exposure in bright light, developing with the Universal developer, and toning with Ilford's combined bath, proved successful with five papers in getting nice brown tints; but, alas! since then, no matter what exposure I give, I have been unable to obtain such results. I have written the makers, enclosing at the same time two prints, and they kindly replied, stating "over-exposure," although these two prints had only received seven minutes' exposure, about the same light as the others, same stop, &c. The prints came up after development nice red-brown cast, but as soon as soon as they were immersed in the toning bath they turned all colours but the right one.

I have tried again, this time using their advertised Alpha paper developer; but, alas! even with a good image after development, the picture left the paper after being in the toning bath about ten minutes.

Under such circumstances, I think those of our photographic friends who are successful users of this paper might let us poor benighted creatures into the secret of working this paper to a successful issue, and I am sure, amateurs, we should be very thankful for such information.

I like the paper, and, if I could only work it satisfactorily, I should use such in preference to bromide, which gives very cold tones.

I hope some of your readers who are users of this class of paper will not be afraid to divulge their system of working, as I think we should be glad to be of service to any friends who are trying to become thoroughly acquainted with this class of work for their own personal pleasure, not seeking to injure in the least their professional brother's position in a legitimate trade.—I am, yours, &c., G. H. STANSFIELD.

40, *Mountain-road, Bradford, October* 8, 1893.

ENLARGING FOR AMATEURS.

To the EDITOR.

SIR,—Mr. Ridler, in your last issue, hits the nail on the head. He has placed his finger, with unerring accuracy, on the sore point of enlargements by amateurs.

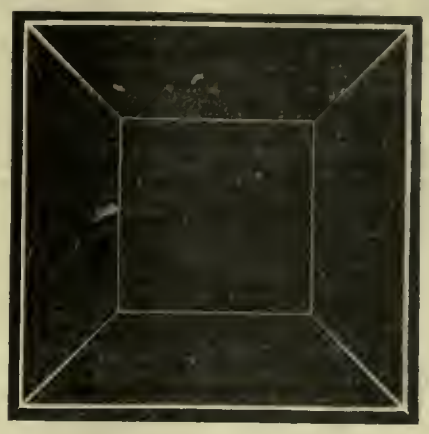
Why, Sir, we do not all possess rent-rolls of thousands a year coming to us through no fault of our own and at no expense to ourselves, so it can't be expected that our laudable desires to enlarge to all sorts of odd sizes can be gratified, unless his suggestion, and a reasonable one too, is acceded to. His suggestion of putting bromide paper up in two-sheet tubes is eminently practical, and should have been anticipated by the manufacturers.—I am, yours, &c., S. WILFRED BENSEN.

4, *Pembroke-villas, Richmond, Surrey, October* 9, 1893.

PERSPECTIVE.

To the EDITOR.

SIR,—In reply to the challenge of "Free Lance," let the accompanying diagram represent a shed with open end. The lines of the outer square are the bounding lines of the inside at the near end, which is in a plane sixty feet distant from the eye (or lens), and the inner square is the far end, which is at a distance of 120 feet, the shed having a depth of sixty feet. The eye is supposed to be at half the height of the shed, and



opposite the centre. The lines at the far end, representing equal magnitudes with those at the near end, and being at double the distance from the eye, they will—being in a plane parallel with those of the near end—come out as of half the length of these latter's, and form a square concentric with the outer square, and of half its linear measurement. The diagonals are the vanishing lines, whose positions are fixed by those of the squares.

Now, let the diagram represent the interior of a box, having linear dimensions one-tenth of those of the shed, and at one-tenth of its distance, *i.e.*, the front in a plane six feet from the eye, and the back twelve feet. The inner square will again be concentric with the outer square, and of half the linear dimensions, and the diagonals must connect their angles as before.

An interior is selected for simplicity of demonstration, but the same rules will apply to exteriors, and, indeed, the sides of the shed and box might stand for the exteriors of adjacent sheds and boxes.—I am, yours, &c., W. E. DENENHAM.

THE SALON.

To the EDITOR.

SIR,—In the preface to the catalogue of the Photographic Salon it is said, "That photographers do not use their process to the best artistic advantages may be true; but, if so, the fault is with the worker, not the method. . . . Perhaps the greatest curse of photography in the sense now under consideration is the fatal ease with which indifferent work may be produced by its means."

Accepting this as a truism, it gave me great pleasure to find that, in an Exhibition mainly promoted by our leading amateurs, no less than 145 of the frames hung are contributed by the much-abused class to which I belong.—I am, yours, &c., A PROFESSIONAL.

London, W., October 9, 1893.

MR. PRINGLE AND MR. IVES.

To the EDITOR.

SIR,—I am sure there is nothing in any of my letters to justify Mr. Pringle in saying, "Mr. Ives' tiger seems to be gradually shrinking," &c. My statements have been perfectly consistent from first to last, and the last claim I made is the strongest of all.

It is unfortunate that I have not got my references by me, because I am sure that I could readily furnish conclusive proofs of everything I have asserted; but the facts are so obvious, and have already been recognised by so many, that I do not feel justified in importing my library for the sake of obtaining these refereuces. Nor do I know how Mr. Pringle would undertake, with fivepence for postage, to fetch a lot of negatives which are now in a Safe Deposit in Philadelphia, and cannot be removed by any one at present in America.

For the present I am content to have called attention to facts which others may readily prove for themselves.—Yours, &c., F. E. IVES.

Charing Cross-road, London, W.C., October 8, 1895.

GAS COMPRESSORS.

To the EDITOR.

SIR,—In your LANTERN SUPPLEMENT to last week's issue of THE BRITISH JOURNAL OF PHOTOGRAPHY, there is a paragraph, in which such a serious charge is made against gas compressors that I cannot allow it to pass unanswered. Your contributor, "Radiant," states that "in the rooms of a well-known photographic society . . . . a *twelve feet* bottle of oxygen was found to contain *seventeen feet*."

If we are to read this statement in the light of the context, it means that a cylinder calculated to be filled to a pressure of 120 atmospheres actually contained 170 atmospheres.

There is no reason to assume that the cylinder was charged by a Brin Company, and, if the facts were as stated, there is every reason to conclude that it was not; but many of your readers will probably infer that we were responsible for it.

Your contributor states that . . . . "for the credit of the gas compressor, he is certain such a thing does not often happen, but it is neither impossible nor unknown."

As a matter, not of credit, but of justice to the Brin Companies, I beg to say that such experience, as far as they are concerned, *is* impossible. Our compressors are fitted with what are technically known as "dead weight" safety valves, which blow off at five atmospheres above the filling pressure, and there are other minor safeguards as well. I can therefore confidently assert that no negligence on the part of a workman, or inaccuracy of pressure gauges can bring about the overcharging of our cylinders, and no one would, I am certain, venture to attribute over-pressure to *deliberate intention*.

I feel sure you will admit the gravity of your contributor's statement from the gas compressor's point of view, and oblige me by inserting this reply—I am, yours, &c., KEN. S. MURRAY, *Manager*.

Brins Oxygen Company, Limited.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED :—

Thomas Pringle, Edinburgh.—*One photograph of Queen Mary's Chair.*

Wm. Vick, Ipswich.—*Six photographs of Helmingham Hall Suffolk, showing Queen Elizabeth's Room, Drawing-room, Dining-hall, and the Library.*

Miss Sarah Angelina Acland, Oxford.—*Two photographs of Mr. John Ruskin; one photograph of Mr. Ruskin and Sir Henry Wentworth Acland, Bart., K.C.B.; one photograph of Mr. Ruskin, Sir Henry Wentworth Acland, and Mrs. Arthur Severn.*

PERPLEXED.—We have forwarded your letter.

H. A. A. (Basingstoke).—We know nothing of the firm named.

ALBERT LEVY (Paris).—Thanks for your interesting communication.

FELIX ST. CLAIR.—Rochelle salts are the double tartrate of sodium and potassium.

E. J. S.—Thanks; letter next week. We shall be pleased to have the article referred to.

F. B.—Sorry we cannot open our columns to a discussion on the Sunday opening of museums.

R. R. W.—In our volumes for 1891 and 1892 are numerous articles on toning bromide prints, to which we refer you.

H. JANCOWSKI.—The case is a bad one, but of course we cannot make public the man's alleged faults. We can only advise a legal remedy.

J. E. G.—The picture is extremely good. The stains are difficult to account for. Hypo, before toning, might perhaps cause them.

H. DEAN.—You evidently require some elementary instruction in gelatine emulsion-making. Consult an article on the subject in the ALMANAC for 1891.

R. CLEMENTS.—The engraving being copyright, it will be illegal to copy it, notwithstanding that it is not your intention to sell copies, but only to show them in the reception-room. A penalty is incurred by every copy produced, whether offered for sale or not.

S. F. J.—We are not at all surprised at your want of success. Although chrome alum will cause gelatine to become insoluble in warm water, it will still be softened by it; and, with a prolonged action of hot water, it will be rendered very soft and tender.

G. ARCHER.—The carbon print has the appearance of having dust enclosed between the image and the transfer paper. Probably the picture, after it was developed, was allowed to dry in some place where dust settled upon it, and that was not removed before the transfer paper was applied.

S. A. E.—You are certainly entitled to a week's salary in lieu of notice, or a month's if you are a monthly servant. Trade being exceptionally bad does not entitle an employer to discharge an *employé* without a proper notice. You can certainly recover what is due through the County Court.

DERBY.—The cause of the milky appearance of the solution of oxalate of potash is lime in the water used. The opalescence of the finished slide proceeds from the same cause—lime in the washing water. This, however, is readily removed by immersing the plate in very dilute hydrochloric acid.

N. W.—So far as we know, the friends of the lady cannot compel you to destroy the negative; but, as you obtained it surreptitiously, when the lady was in *déshabillé* in her own garden, by pointing the camera over the wall, it would be most ungentlemanly, not to say disreputable, not to accede to the lady's wish.

V. B.—It is very unfair for the paper to pirate your photographs, but we do not see how you can move in the matter, as you have no copyright in them, even though they were duly registered at Stationers' Hall. The reason there is no copyright is that the photographs were taken by an *employé*, who is the author of the work, and registered in your name, who had nothing to do with taking the views.

S. PRICE asks for a good medium with which to black the inside of a wooden camera, that will not rub off when the camera is dusted with a damp cloth. One of the best things for the purpose is lamp-black mixed with brown, hard varnish, thinned with methylated spirit. The proper portions can only be ascertained by trial—applying a little of the mixture to a board and letting it dry. It is advisable to use as much varnish as possible, but not sufficient to cause the work to dry glossy.

T. GILES.—The only way to obtain methylated spirit of the old kind—that is, free from the mineral naphthas—is to obtain the necessary permit from the Excise authorities. Without that, none of the vendors of the spirit will supply it. Any that may be obtained at the oilshops would assuredly contain the objectionable matter. Indeed, no other is allowed to be sold by them. When the requisite permit is obtained from the Excise, the spirit must be purchased from a methylator, not from the oilman.

Z. Y. X.—The plant for working the Woodburytype process is somewhat costly. The printing presses are not expensive, but the hydraulic press is, and so are the steel plates, if the size be large. Then there is a powerful rolling press required in preparing the paper and the polished plates to be used with it, unless the paper can be purchased ready for use, which we believe is not the case in this country. The cost of the necessary appliances for working Collotype will be far less, and this process, we imagine, will answer your purpose best if the prints are wanted as book illustrations.

T. A. B. says: "I have recently had supplied to me a lot of photographic mounts that are lettered in ordinary black ink. When the prints are burnished the letters become smeared over the mount, and, when they are rolled, the ink comes off on to the roller, and so soils the next mount that is rolled. Can anything be done to prevent this, as the thing is a great nuisance?"—This is not an uncommon experience with freshly printed cards. The ink is not dry. The only thing is to wait until it is. The drying may be accelerated by spreading the cards out in a warm and dry place.

F. CROFT says: "I often see it mentioned that more vigorous prints, and more permanent ones, may be obtained by printing from strong negatives on highly sensitised paper. Will you please tell me where this kind of paper is to be obtained? I have inquired at several shops, and am told they only keep one kind."—We imagine that, if our correspondent requires this sort of paper, he will have to sensitise it for himself, unless he requires it in sufficiently large quantities to make it worth while for the manufacturer to prepare it specially to his order. It should be borne in mind that, to obtain the full advantage of this kind of paper, it should be strongly salted, as well as being sensitised on a strong silver solution.

S. BENYON writes as follows: "Are the dark rooms, so obligingly supplied in some hotels, to be relied upon? I ask the question because on a recent holiday I availed myself of several of them for changing plates, and I found that all the plates I changed at two places fogged badly on development, evidently light fog, while all the others—the same brand and, in one case, from the same dozen—were perfectly right. It is very kind to provide tourists with dark rooms, but it is just the reverse if they are not safe to use."—Whenever we use a strange dark room, we always make it a rule—and most others do the same—not to expose the plates to the source of illumination more than can possibly be avoided. Following this course, personally we have nothing of which to complain.

A. A. A. says: "I was apprenticed two years ago for four years, at a small progressive salary, and a premium of 30*l.* was paid by my friends. There is another apprentice besides myself, and between us we do all the work—what little there is—that is, the printing, mounting, and spotting, and keeping show-case clean. Neither of us has received any instruction in the studio, as the principal takes what sitters there are, and they do not average one a day. It seems to me that when we are out of our time, and that will be in less than a year with my fellow-apprentice, we shall know very little of the business, except the printing. Ought we not to be instructed in studio work, which is the most important thing to learn?"—Certainly you ought. It is the old tale with apprentices. But a master can be compelled to teach an apprentice the whole of his trade. Those who paid the premium had better consult a solicitor on the matter. It is a great pity that friends should apprentice youths in establishments where such a limited business is done. What really practical experience can they acquire, particularly when there are two or three apprentices at a time?

*** Several articles, letters, answers to correspondents, &c., are held over till next week.

JOURNAL OF PHOTOGRAPHY.

No. 1746. Vol. XL.—OCTOBER 20, 1893.

EQUABLE TEMPERATURE.

The time of year is approaching when, as a matter of course, the photographer expects the various solutions he employs to have an average temperature much lower than in summer. To very many this variation, though it is felt to be the cause of some difference in working, is commonly disregarded, as "things come all right in the end." It is our purpose to endeavour to show that to attain, with the least expenditure of time and material, uniform and good results, it is most important to deal with temperature, and the temperature of solutions, in the dark room and laboratory.

These remarks will be less applicable to large establishments, where every convenience exists for keeping the premises at a fairly even temperature the year throughout, as they will be to those who may start a day's work with "everything cold;" although it may be said that, even here, there is room for improvement. We know of cases where the night temperature is considered of more importance than the day; and the difference in the mere question of comfort in handling bottles of solution—in the one case almost freezing, and in the other at as comfortable a temperature as in summer—has a strong bearing upon the chance of successful results.

Let us follow the various processes as they would occur in every-day working at times when low temperatures might be expected to prevail. First, there would be stock solutions of sulphite of soda, hydroquinone, &c., to be overhauled. It may be at once said that those who base their working on saturated solutions—made by keeping a surplus of crystals always in their bottle—will, when an equable temperature does not prevail, be wofully at fault in their formulæ in winter weather. Thus, hydroquinone crystals may be expected to be found shooting through the liquid, from the bottom of the bottle to the stopper, as the cold will have diminished the solvent power of the water; while sulphite of soda and other salts may be expected to form a solid crystalline mass at the bottom of the bottle, which will be exceedingly difficult of removal, so much so, that too often the bottle gets broken in the endeavour to disintegrate the mass. This argument alone, by the bye, is a strong one against the saturated solution principle altogether. It is often adopted in the endeavour to save trouble, but this is not achieved in the long run. A mark on a bottle to show a certain measure of liquid, and a definite weight of crystals put in, is simple and reliable. The effect of low temperatures on sulphite of soda solutions is very quickly seen, and, indeed, when the dark room is not kept heated, a twenty per cent. strength is the maximum permissible. Thirty or forty per cent. is often spoken of, but even where the temperature does not get low our advice is, a maximum of twenty-five per cent.

The solutions in good order, the next process to claim attention will be the development of exposed plates. We hold here very strong opinions upon the value of equable temperatures. One well-known successful photographer is reported to state that he places a number of negatives in the developing solution, leaves them exposed to its action five minutes, washes and fixes, and gives no more thought to the development. He is certainly an exception to a vast majority. Most photographers closely examine the negative as the image first appears, and then use accelerator or restrainer, or leave the solution unaltered, according to the indications of the first stages of the image production. We think the decision what to do with the solution is rather a matter of experience combined with the length of time the image takes in appearing and growing than an actual judgment formed upon the particular gradation of a negative under scrutiny. If this be so, the temperature of the developer is a matter of paramount importance. A plate placed in a developer at 40° will take a very considerably longer time for the image to appear, and due density to be reached, than would be the case with a developer at, say, 65°. These are ranges of temperature commonly experienced at this time of the year. Then, again, the mere loss of time, when many plates are to be developed, is a matter for consideration, either for amateur or professional. It may be said that to endeavour to work at a uniform temperature would entail too much trouble in practice; but we have recently seen in a large studio a plan carried out that is simplicity itself, and we here refer to it, not necessarily as possessing any novelty, but merely to show how simple it is to carry out what we have said we look upon as a matter of prime importance. At this time of the year, as the water is delivered from the main, its temperature is often not far from 40°. What we saw was a youth pouring boiling water into a large jug of water taken from the main, till it reached a temperature—as ascertained by a thermometer—of 70°. This was kept in the dark room while development proceeded and the various stock solutions were reduced to the requisite strength by dilution from this "warm water." We were informed that, all the winter through, the temperature of the developer rarely varied more than three or four degrees at the outside, and we could readily believe, as we were informed, that it greatly increased the certainty of good results. The plan was simple, feasible, and, there can be but little doubt, utilitarian. The capabilities of usefulness in the simple use of hot water are by no means exhausted, and at a future time we propose to continue our consideration of an important and neglected aspect of manipulation.

MATT-SURFACE PRINTS ON ORDINARY PAPER.

NOTWITHSTANDING the great variety of choice that at present offers in the way of printing methods, there always seems to be room for anything that is new, or, if not new, at least out of the common routine. Witness, for instance, the revival, in the present Exhibition of the Photographic Society, of the old and almost forgotten photo-crayon process. It is difficult to decide what is, at the present day, the "prevailing fashion" in photographic printing; for, while one section of the community pays most attention to platinotype and matt bromide effects, there are others who incline rather to the enamelled or glazed finish and style, others who keep the happy mean represented by the newer kinds of gelatino-chloride or albumen papers. There can, however, be but one opinion as to the rapidly growing popularity of matt effects both for large and small work.

Comparatively few of the modern producers of matt prints, whether on platinotype, bromide, or chloride papers, are at all familiar with the charming results obtained on the plain papers of forty years ago or thereabouts, some of which were produced by development, others by the alternative process of "printing out." As a rule, the productions of the present day partake of the general character of platinotype, that is to say, they are of the cool grey or neutral black tone, with here and there a departure in the direction of sepia or brown, although the latter tints are seldom or never equal to those obtained in days gone by. But the rich purple-black tones and velvety softness of the old plain paper prints are almost unknown now, although, when seen, they never fail to attract the attention of even the most ardent admirers of the more modern style.

And yet such tones are by no means impossible of attainment with some of the matt printing-out papers at present in use, although perhaps a departure from the usual course of procedure is needful in order to get them; with the development papers they appear to be wholly unattainable, unless it be by means of some more or less roundabout method of toning, certainly not by development proper.

To produce them, with paper of home preparation is, however, one of the easiest things in the world to any one who will take the trouble to depart from the strictly beaten track and, at any rate, partly prepare his paper instead of purchasing it ready for use in the printing frame. One such method was alluded to in our issue of last week, although the results thus obtained are, perhaps, not equal to those derived from a specially prepared paper.

The first *desideratum* is, of course, a suitable paper, which should be not only even in texture, but free from any impurities likely to act injuriously in connexion with the salts employed in sensitising. When a specially prepared paper for photographic purposes is available, the difficulty, of course, disappears, and it only remains to select a sample the texture of which best suits the size and character of the pictures to be produced. If such paper can be obtained in the salted state—and we believe some of the dealers still keep it in that condition—so much the better, as not only will at least one operation be saved, but it may be accepted as granted that the surface has been properly sized.

Starting with an unsized paper, it will be necessary to ascertain by experiment, first of all, whether the preliminary sizing has been performed. We do not here allude to the sizing which necessarily takes place in the process of manufacture, but to a special process, that with most samples of paper is necessary, in order to keep the sensitive salts, as far as possible, on the surface, and so conduce to brilliancy of image. This is more particularly necessary for small work, exhibiting fine detail and gradation, which would be utterly ruined or lost in the sunken-in appearance resulting from an unsized or imperfectly sized paper. In this respect, the process referred to last week is scarcely adapted to small work, although it answers very well for large bold effects.

The materials usually employed for this purpose consist generally of arrowroot, gelatine, and sometimes we have used gum tragacanth with advantage, the first and last being preferable for purple tones, while gelatine answers best for brown tints. The latter is applied in the liquid state, by floating the paper for a sufficient period to allow the solution to penetrate the surface uniformly without sinking too deep, and the strength will be regulated by the texture and hardness or absorptive character of the paper. The point to be aimed at is to close the pores of the paper without imparting any perceptible gloss to the surface.

Arrowroot and gum tragacanth require different treatment on their application, and considerably more care. The former is made into a stiff smooth paste by boiling, and must be entirely freed from lumps and allowed to cool. The latter is allowed to swell in cold water until it assumes the form of a thick paste, which must also be rubbed perfectly smooth. To apply either of these to the paper, it is spread upon a smooth surface, preferably of glass, and the size is then rubbed on well with a soft turkey sponge, using only sufficient force to cause it to spread evenly, and the treatment must be continued until a perfectly even appearance results, and the paper lies uniformly limp and flat upon the support. It is then hung up and allowed to become thoroughly dry.

Some operators combine the sizing and salting operations in one by dissolving the salts in the size, but this method is scarcely to be recommended except in very skilful hands. The danger arising from the uneven spreading of the salted size would obviously be much greater than when it is unsalted, while, in the case of gelatine, the risk of the salting penetrating into the paper instead of remaining on the surface would also be increased. When, however, a hard and even layer of size has been applied, it is comparatively easy to add an equally uniform coating of salt by floating the paper for a short time on a solution of suitable strength.

The salting solution consists mainly of one or other of the soluble chlorides, bromides, or iodides, according to whether the paper is intended for development or for printing out; but other ingredients of an organic character are often added, with a view of influencing the tone or brilliancy of the resulting prints. Thus citric, tartaric, acetic, lactic, and malic acids, or their salts, are frequently used in combination with the chlorides for printing-out paper, but for those intended for development the utility of such additions is not so obvious, sufficient variety of effect being produced by modifying the combinations and proportions of the haloid salts.

If gelatine forms the basis of the size, the salting solution for printing-out papers may consist of chloride alone, the gelatine producing a sufficiently organic reaction to give vigour to the image, but with arrowroot it will be preferable to combine the chloride with one or other of the organic salts. For a plain salting solution nothing succeeds better than a ten or twelve-grain solution of chloride of ammonium. Chloride of barium is used by some on account of the less hygroscopic character of the barium salts, which conduce to the keeping qualities of the paper both after salting and sensitising, though it is more difficult to obtain purple tones when the barium salt is employed.

Of the different organic salts of silver, the citrate seems to combine best with the chloride; hence, where an organic salting bath is required, we prefer to use a mixture of chloride of ammonium and citrate of potash, in the proportions of eight grains of the former and ten of the latter to the ounce of water.

The prepared (sized) paper is floated for a couple of minutes on the salting solution, or a measured quantity may be poured on to it and spread evenly by means of a small piece of sponge or a flat camel's-hair brush; but the floating method is to be preferred, as giving an even coating without allowing the solution to penetrate too deeply into the paper. When floated sufficiently, the sheet is drawn over the edge of the dish on a clean glass rod to remove the superfluous solution, and hung up to dry in a warm room. The more rapidly the drying is effected, the more will the salting be confined to the surface.

A method of combined sizing and salting may be mentioned which gives excellent results as regards both tone and brilliancy, the image showing little tendency to sink into the paper if the various floating operations be too prolonged. The sizing mixture consists of a solution of bleached lac in borax, one hundred grains of the former being boiled with twenty grains of the latter in an ounce of water, until completely dissolved. The solution is set on one side for some days, until it deposits an opaque sediment and becomes clear and bright. It is then decanted or filtered, and ten grains of chloride of ammonium added, when it is ready for use. This solution may be applied freely to the paper by means of a brush, and allowed to soak in until the paper becomes quite limp, when the surplus is drained off. When dry, the surface becomes insoluble, and the sensitising solution shows little tendency to sink deeply. The tone produced by the borax is a pleasing purple black. We have not used this method of sizing for development paper, but have no doubt it would answer.

White and Silvered Reflectors.—Opinions appear somewhat divided amongst those who produce enlargements by daylight, as to whether looking-glass or white reflectors are better, that is, if one may judge from what one sees in every-day practice. Some use the one and some the other, and they each, doubtless, think it the better. We refer to this topic here, in reply to a correspondent, instead of in the usual column, because the query put is not an uncommon one. Now, each kind of reflector may be the better under certain conditions of the light. For example, with a clear, blue, cloudless sky, if a silvered glass be employed, very little light of value will be reflected, and the image will appear lacking in illumination; but, if a sheet of white paper be laid over it, the aspect is entirely changed. The image is at once more brilliantly lighted, and the exposure correspondingly curtailed. Under these conditions the white reflector is the better. On the other hand, if the sky be covered with bright, fleecy clouds, then will the better light be obtained with the looking-glass, because it reflects them direct on to the negative. Therefore it will be seen that both sorts of reflectors are the better under different circumstances, and for this reason silvered glass is preferable as a fixture, because it can at any time be covered up with a sheet of white paper or cardboard. Thus the advantage of either kind can be secured at will.

Clouds in Lantern Slides.—*Apropos* of the advent of the lantern season, and a question asked at a recent meeting of one of the Metropolitan Societies as to the relative exposure for printing in clouds with a negative of given density, when one of the members suggested that the better way was to print the clouds on a separate glass, we would here remark that that is the system we have generally advocated; in fact, it is the one usually adopted by the best workers when clouds are utilised from a second negative. The advantages of this method of procedure are manifest, for it requires very great judgment to correctly time the exposures of the two negatives so that the images develop in unison with each other. Many slides are lost through the clouds not being dark enough, or being too heavy for the landscape; more generally the latter. When both images are on the same plate, there is no way of getting the clouds and landscape in perfect accord if the two negatives, as is often the case, are of a different character. When, however, they are printed on separate plates, one being the cover glass, there is no difficulty in the way, as the development of each plate can be modified according to circumstances. Furthermore, any slight outline from unskilful masking is less conspicuous when the picture is on two plates than when it is on one. As we have said before, much trouble may be saved by printing the clouds on the cover glass instead of on the same plate as the landscape.

Reversing Mirrors.—It will be remembered that a few weeks back attention was directed to the subject of reversing mirrors, and to the fact that they should always be left perfectly free in their settings. Since then we have been shown a mirror that had been condemned as worthless because, so it was asserted, it was impossible to produce a sharp negative with it. A casual examination sufficed to show why this might be the case, and it was this: The glass was about six inches by four, and was set in a brass mount, the flanges of which were secured by metal screws, which clamped it tightly. These screws we loosened, so that the glass could be shaken about freely in the mount. A negative was now taken, and it proved to be perfectly sharp. The fine definition of the lens was not impaired in the slightest degree. This mirror was fixed, as the majority are, in front of the lens, but we could not help, as we have done before, doubting if this is the best position for it to occupy. So far as results are concerned, it matters not whether it is placed before or behind the lens. For several reasons, the latter would appear to be the preferable position. Inside the camera it is less exposed to atmospheric influences, there it is better protected from mechanical injury than it is when fixed in front of the lens. Furthermore, the mirror fittings are liable to obstruct the light, or cast a shadow on the object to be copied when, as is often the case, it is very close to the camera. We are quite aware that mirrors are fitted in that way, but it is not general, in this country at least.

Piracy.—Scarcely a week passes but that we have complaints from photographers, more especially those in provincial towns, of the piracy of their work by some of the illustrated press. It is pretty evident that some, not all, consider a photograph common property, and treat it accordingly, whether it be copyright or not, and that, too, without any acknowledgment to the artist. Often the reproduction is slightly altered, as by the introduction of a figure or so, but this does not evade the copyright. There is no question that, when a copyright photograph is pirated by any of these papers, very heavy penalties could be obtained. Why then, it may be asked, are they not enforced? There are, we suspect, more than one reason. Many photographers, in a small way of business, do not care to risk the heavy law expenses sure to be incurred in attacking a wealthy paper, who would defend the action at any cost. One of the objects of the National Association of Professional Photographers, by the bye, was to have been the protection of copyrights, but we have never heard of a single instance of their moving in the matter, and some flagrant cases of piracy must have come under their notice. Some photographers do not think it worth while making their work copyright until they find it has been reproduced; then, of course, there is no remedy, yet they complain all the same. We imagine that the majority of photographers whose works have been pirated would have had no objection to their reproduction if their permission had been asked, and an acknowledgment given in the paper of the authorship thereof. The reproduction of the photographs in an illustrated periodical we imagine does not injure the sale of the original. Still the copyright is the property of the photographer, and it ought to be respected. Some day, perhaps, an illustrated paper may be mulcted in heavy penalties for piracy of a "common photograph."

Outdoor Meetings.—The summer season may now be considered at an end, and many of the Societies will be issuing their annual reports. Some have already done so. It will be interesting to note this year what will be said with reference to the periodical outings arranged by the different Metropolitan ones. The two or three whose report has been published contain the almost stereotyped sentence to the effect that the attendance at the outdoor meetings has been very meagre notwithstanding that previously existing arrangements had been modified, &c. Not infrequently a rider has hitherto been added, that unpropitious weather has probably been the reason. No such idea can possibly be entertained this year; for never before have we been favoured with such a summer for outdoor photography. Why, then, the spare attendances? One reason we know which has tended to it is that meetings have been arranged in districts where good subjects were known to exist, but when the members arrived there was no one to point out in which direction they lay. Hence strangers to the neighbourhood often returned home without seeing anything worth photographing, while they had been within a short distance of most charming subjects for the camera. Another reason, and perhaps a stronger one, is that many people who are particular in the choice of subjects do not care to go with a large party. They prefer to go alone or in company with one or two others at times, and to places, more convenient to themselves than those arranged by the Society of which they are members. Seeing that, so far as the London district is concerned, outdoor meetings are practically a failure, would it not be well for some of the Societies to consider whether they should not be abolished? Ostensible meetings that do not come off do not add to the status of any Society, photographic or otherwise.

PHOTOGRAPHY IN NATURAL COLOURS—*UN FAIT ACCOMPLI.*

On Wednesday evening, October 11, the first business of the Photographic Congress then assembled at the Society of Arts was to hear an account from Mr. Leon Warnerke of the results in colour photography obtained by M. Lumière. There was a very large attendance, and Captain W. de W. Abney, C.B., F.R.S., was in the chair.

Mr. Warnerke read a paper descriptive of the modifications on Lippmann's plan of preparing the sensitive plate arrived at by M. Lumière. This has already been given in the pages of The British Journal of Photography (see page 325, May 26, 1893); and to that article, as well as to others in our volume for 1891, we may refer the reader who may desire to be placed in possession of the working details of the method employed by M. Lumière.

By the kindness of Mr. Warnerke, we have had an opportunity of privately inspecting the photographs. At the meeting referred to he would not let them go out of his hands, as they are regarded as too valuable to be risked. A large number of learned societies are waiting their turn to have them before them. The pictures are about two and a half inches by one and a half inches, and are mounted under common glass prisms and backed up with opaque material such as paper. When viewed in the ordinary way, they appear something like an ordinary lantern slide would against an opaque material. Held at their proper angle, however, they are seen in the full beauty of their natural colours. On Wednesday night, Mr. Warnerke said that, for viewing them, the best plan was to have sky light reflected, or, when lamps were in use, to have the light reflected from the shade or glass. For projection, a very powerful light was required. Looking at these pictures was like looking upon nature on a bright summer day, and they must all feel that they were in the presence of one of the greatest inventions of the nineteenth century.

We have said that we had an opportunity of examining the specimens privately. They have a certain metallic-like lustre, but are notably true and realistic in most of the colours. One of them, the first in the order of success, was a photograph of a chromolithograph of a French soldier. This had an exposure of an hour. It would be absurd to talk of fidelity to the original in the absence of the latter or any means of telling what it was like; but, knowing what chromos generally are, we risk the assumption that it was extremely good. The gems of the collection are, however, four views from nature. In these the blue of the sky, the play of sunlight on the green trees, the marigolds on grass beds, the red tiles of a house roof, zinc roofing, gravel paths—and, in fine, what we term the *tout ensemble* of the colour effect are truly remarkable. The exposures given to these five range from 40 minutes down to 4 minutes, the last being an indoor picture representing a *savant* seated at his table, upon which are his microscope, bottles of chemicals, &c. The flesh tints of the gentleman's face and hands are rather too pinky, but the copper sulphate in a bottle, the yellow mount of the microscope, some fluorescein and other chemicals are perfectly reproduced.

These pictures were projected on the lantern screen at the Society of Arts, and called forth great applause. For ourselves, we can say that on the screen nothing was lost in the way of colour effect. The images were necessarily very small on account of a somewhat rough-and-ready projection system employed. This apparently consisted of the passage of a beam of light from an arc lamp through a lens on to the picture, the prism mount of which reflected the light on to another lens which transmitted the image to the screen. After some of the pictures had been shown a second time, a discussion took place.

Mr. J. Spiller said that for the first time they had had a satisfactory demonstration of photography in natural colours, and they ought to congratulate MM. Lippmann and Lumière, who had brought it to this state of perfection. He would also like to thank Mr. Warnerke, who had anxiously looked after the interests of the Society in the matter, and had succeeded in getting the loan of the pictures for exhibition. Nothing that had been done before approached what they had seen that night.

The President (Captain Abney) said that what they had seen that night was very remarkable; but it did not give him the idea that we had yet achieved photography in natural colours, as natural colours were pigments, so that we were as far off as ever we were. Here they had photographs which gave approximately the colour of nature seen by reflected light; for, looking at it at one angle, the true interference phenomenon was seen. If we were going to take photographs by this means, we should have to take the precaution of having the light falling on them from one particular direction. Still this did not make it the less wonderful. He had, himself, experimented with the process, and had produced results superior to anything of Lippmann's he had seen. In taking spectrum photographs, it was quite possible to get blue at the red end, and red for blue. There was one weak part in the pictures shown, and that was, the reds were not as good as they ought to have been; that was because the plate was sensitised to correspond with the colour wished to be reproduced. To get interference by photography, they must develop for it, as, with a red light and a plate not sensitive to it, one could not get the interference which was necessary. The next step to be made would be to get a pure red which was necessary to give the finishing touch to the process, and, for that, what was wanted was something to enable us to photograph the red end of the spectrum in a satisfactory manner. There was a pure bromide process extant, which might be utilised for the purpose because it was more sensitive to the red than to other parts of the spectrum. He congratulated Messrs. Lippmann and Lumière for taking such photographs as they had seen, in a reasonable time, for four minutes was not a long time.

AMERICAN NOTES AND NEWS.

Frederick Hart Wilson.—It could not possibly fail of being a severe blow to Dr. Edward L. Wilson when he lost his son, a young man of talent and promise, who had in some measure been educated to succeed him in conducting *Wilson's Photographic Magazine* (*née* the *Philadelphia Photographer*). Born in 1864, he showed an early taste for naturalist studies, on which was soon grafted a training in science, literature, and art. After leaving college, where he graduated with honours, he initiated a literary career by becoming a reporter on the daily press, subsequently studying art in Paris and New York. He

contributed to several periodicals, illustrating many of his articles by his own sketches, which were mainly of a humorous or satirical nature. One of his best articles was the paper he wrote for the St. Louis Convention in competition for the $100 prize offered, and from which we hope to give copious extracts on an early occasion. His health gave way after having undertaken the editorship of *Ohio in Art*, and on August 8 he died at Hygiene, Colorado, whither he had gone for recuperation. Our sincere sympathies are tendered to his sorrowing father and friends.

The Hand Camera of the Future.—It is the opinion of Mr. C. Ashley Snow (in *Wilson's Magazine*) that the hand camera of the future has yet to be evolved. It will work at about *f*-8. It will be provided with a finder giving a view as large as the plate used; and it will, by a reflecting mirror, present the view rightly, instead of upside down, as now. The lens will be so attached as to be easily removed for the substitution of others often more suitable for the kind of work in hand. The shutter will be wholly under control, and the focussing device respond to any demands made upon it. There will be an iris diaphragm, and a ball-and-socket joint to the tripod head. There should be a swing back and a side swing. These conditions are Mr. Snow's. Let us see to what extent English manufacturers have anticipated then. Almost all hand cameras of any pretensions have lenses working at *f*-8, and some exceed this considerably in rapidity. We have, on more than one occasion, described hand cameras, made and sold in England, in which the finder is identical in size with the sensitive plate. Nay, some eight or nine years since, this was a feature in cameras made by at least one maker in New York, and this, too, by means of a reflecting mirror, presented the view rightly instead of upside down. A camera having this peculiarity was patented in England, so long ago as August 20, 1861, hence this feature has long since been recognised. The substitution of one lens for another is already effected in many of our best hand cameras. The shutters *are* under control, and we already have iris diaphragms to our lenses. Concerning the ball-and-socket joint to the tripod head, what has a tripod to do with a "hand camera," the species now spoken of? True, a tripod is a delightful, if not a necessary, adjunct to a hand camera, and we would never think of going on a photographic outing without one; but the instrument becomes not a "hand," but a *stand* camera, when it has to invoke the friendly aid of a tripod. Besides, ball-and-socket heads are made and sold every day in London. So Mr. Snow's desiderated hand camera of the future *has* already been evolved, and is the camera of the present—that is, for those who prefer it to the simpler kinds equally easy of access, a fact, of which he will become aware if he will brave the fancied terrors of the Atlantic, and favour the Mother Country with a visit. All the same, Mr. Snow's prospectus is a good one, and, to render it absolutely perfect, his camera of the future only requires to be made binocular. Then it would, indeed, be the hand camera *par excellence*.

The American Photographic Press and the World's Fair Congress.—The *Photographic Beacon* administers a mild castigation to its New York brother, the *Times*, for a statement or prophecy it was unwise enough to make a few weeks since to the effect that "the *Photographic Times* is the *only* photographic magazine that will give a complete report of all the most important papers read" at the World's Fair Congress of Photographers, and asks: "How does he know? He was not there, and the editors of several of the other magazines were." We ourselves were, and still are, unaware of any private understanding with the Directors of this Congress in virtue of which such a statement could have been made. It is the case, however, that on the day on which we read this in the *Times* we were in receipt of a first consignment of the papers referred to, which had been kindly printed specially for the press with the view of giving them the greatest publicity possible; and, the *Photographic Times'* prediction notwithstanding, it is only fair to ourselves and to the Congress to say that we can point to our pages of the past few weeks in corroboration of the fact that we, at any rate, have given a complete report of the most important papers read. It is not safe to prophesy unless one knows.

Another New Flashlight. — We learn from the *Beacon* that, in course of a meeting of the Chicago Camera Club, an adjournment was made to the studio to witness a new system of flashlighting a sitter. The Williams system consists of a frame supporting thirty-six small gas jets in four rows of nine each. Immediately behind each burner is a small cup, into which are placed a few grains of magnesium powder, and the cups are attached to rods connected together, so that, by the turning of a crank, they are simultaneously emptied over the flames from the jets, giving a brilliant mass of light spread over a comparatively large surface. A negative of a lady was taken by this agency, and that it was successful was proved by a slide made from it being projected on the screen a little later on in the evening.

How Massey Photographed at the World's Fair.—It puzzles us somewhat to know precisely by what means Mr. W. E. H. Massey managed to snatch, under the very eyes of the *vigilantes* of the Chicago Exhibition, such a fine set of pictures as he has obtained, judging from such samples as have been given in the *Canadian Photographic Journal*. The subjects are sharp, well selected, and fully exposed. The artist gives a graphic account of the petty harassments to which he was subjected by the agents of the *concessionaire;* but, as we read, he eventually circumvented them by the expedient of hiring a gondola, or an electric launch, and photographing therefrom while going, in some instances, at full speed past the respective subjects which he has so ably snap-shotted. "The magnificent buildings," he says, "have been grouped with the greatest care, and with the surrounding landscape—which is like a fairyland, beautified with artificial lakes and canals, the latter spanned here and there with handsome white bridges—combine to make up a veritable paradise."

The Colours of Nature in Photographs. — Mr. Abraham Bogardus is evidently a conservative of the staunch old-time type, at any rate in regard to those "photographs in natural colours" which are the outcome of the experiments of Lippmann and Lumière. That the colours of nature have, in the works of the latter, been produced, is a real fact, and has been demonstrated to those assembled at the Chicago Congress over a month ago, and during the past week to the Congress of the Societies affiliated to that of Great Britain in the Society of Arts' rooms. Mr. Bogardus, in the *St. Louis and Canadian Photographer*, calls himself an "incorrigible" on the colour question. He says: "I am ready to be convinced by literal facts, but do not propose to be convinced by newspaper stories, or by the reports of scientific men who seem to be easily deceived, and who ought to know better." What evidence, then, must be adduced before Mr. Bogardus will believe? Suppose that he, himself, had an opportunity of seeing and examining the Lumière pictures, and, not being colour-blind, were to testify as to the reality of the blueness of the sky, the yellowness and redness of the flowers, the greenness of the grass, and so forth, and be met only by the cool rejoinder from his neighbour, "I don't believe you, nor do I propose to be convinced by newspaper stories, nor by the reports of scientific men." "But," continues Mr. Bogardus, "it is not producing colours to expose a chemical substance to the sunshine, treat it to another chemical solution, hold it at a certain angle, and call the iridescent effect seen photographing the colours. Countless substances can be made to do that without a camera." Were we desirous of raising a discussion, we might point out that the exposing of a plate coated with a chemical substance to the sunshine (in a camera), and then treating it (in a dark room) to another chemical solution, aptly describes the method now universally employed in obtaining form in light and shade; and it is not logically impossible that, by a strictly analogous method, iridescent colours, answering to the colours radiated from these forms, might also be produced. Of course, as regards the countless substances by which this can be done "without a camera," we prefer to think that Mr. Bogardus has selected language which does not quite accurately represent what he intended to convey. Is he, as an old and experienced Daguerreotypist, willing to admit that colours—and not only colours, but those of nature—were produced on Daguerreotype plates by Becquerel, Niepce de St. Victor,

and others, by means of the processes described in considerable detail by those *savants*, or were they, and numerous scientists and artists of the European side of the ocean, deceiving themselves and others by imagining they saw colours where none really existed?

A PAINTER'S VIEW OF THE PHOTOGRAPHIC EXHIBITION.

The exhibitions in London, especially those of the fine arts, or arts more or less allied to them, have now become so numerous and incessant that, unless for people of ample leisure, it is impossible to keep pace with half of them; hence, for several years I have not had the pleasure of visiting a photographic Exhibition, but I have recently observed several notices of the above, in which favourable mention was made of some highly artistic figure studies by Count W. von Glueden, which induced me to go, a few days ago, to see them. I was more than charmed by these and many other beautiful works which now grace the walls. I expected to have my knowledge increased and my eyes refreshed by a great deal that would be new to me after a lapse of three or four years, but I cannot say that the appearance of any great progress was very apparent; there was one negative progress, however, the *carte-de-visite* and the frames full of commercial specimens and shoppy advertisement pictures were much less in evidence than formerly. Another negative progress noticed was that greater facility of progress over the Exhibition was afforded by the removal of the central screens, thus the gallery assumed a more spacious and comfortable appearance; this also enabled me to stand in the centre and take a general survey of the *tout ensemble*. The first thing that arrested my attention was the spotty, cut-up, disjointed and inharmonious appearance of the collection, owing to the discordant, and, in some cases, very *bizarre* effect of the frames and mounts. This is a difficulty which cannot be easily surmounted in a photographic Exhibition; the Society cannot, as at the Royal Academy, make a rule that all pictures must be in gilt frames, but they might at least announce that excessive width or unsuitable character of frames and mounts might prevent pictures from being accepted, or from being hung in positions they might otherwise merit. This question of framing photographs is one that should receive more attention than appears to have hitherto been bestowed on it. The tone and colour of the print depends very much upon the tone, and colour, and depth of its surroundings. Captain Abney is one of the highest authorities on the science of light and colour, and he could, if he chose, sketch out some valuable suggestions on the subject of the harmony, juxtaposition, and contrast of colours, as applied to the framing and mounting of photographs.

I then observed an unwonted variety of colour in the prints the cold grey of the bromide and platinum pictures being relieved by a pleasing variety of warm platinum tones, of carbon, and a few of the good old silver prints, with their fine rich tones, which, though on glossy surface, are still very pleasing for small work, and still popular if one may judge by their predominant appearance in the shop windows; in this connexion I say nothing about permanency.

I shall now take a walk round, beginning with No. 1, a carbon enlargement, called *The Young Musician*; it is probably excellent photography, but the composition of the figure and hands is arranged without either character or grace. No. 2, *Fruit*, studies by J. T. Hopwood. Surely no painter can look at these beautiful delineations without feeling grateful that the glorious art of photography can preserve for him the drawing, the light and shade, the modelling, the texture and the character of the fruit and flowers, which in hot weather would have shrivelled up and lost their drawing long before he could complete a perfect painting of the subject. Then he could preserve the photograph intact for reference, or for future use in other work. Or, better still, if he has not time to make a finished painting, he could have a second print, a little lighter, and rapidly dash in the colour effect from nature, either in oil or water colour, the first print being preserved intact for reference to detail. Well-defined photographs such as these would also be very useful in drawing schools. No. 11, *Frederic Goodall, Esq., R.A.*, looks very bright and youthful here. I suppose his fine picture of the *Village Festival* in the Vernon Collection was painted nearly fifty years ago. It seems to me a defect in this portrait that the face and the neck, from the rim of the hat to the top of the collar, are both on one flat plane, thus giving the appearance of an enormous swelling in the neck; from the slight line which indicates the chin, the neck downwards should have been thrown more or less into shade. The peculiar curl of the end of his left moustache gives him the appearance of having a ring in his nose; that most prominent point of the picture should have been toned down.

No. 14, *Clouds Descending the Valley*, Zermatt, by William England, would be very helpful to a painter. No. 15, *Mont Blanc by Moonlight, from Coutter's Hotel, January 7, 1893, 10 p.m.* (bromide enlargement), by Captain Abney. This is a wonderful picture—a snow scene of great delicacy, and perfect definition everywhere; I could have believed that it was taken at midday in June, but there seems a weakness and want of depth in the shadows. I imagine that, if it had been printed darker, it would have gained the desired strength and richness without any loss of essential detail, and that it would have possessed more brilliancy and more of the character of moonlight. Then, in my humble opinion, the art value of the picture is depreciated by the unsuitable character of the frame and mount. The print is cold, grey, and weak; it is rendered still more so by contrast with the bright, rich cream colour of the mount by which it is surrounded, and by the rich, warm, dark brown colour of the common varnished wooden frame, with a gilt slip, I think, which encloses the whole. I fancy I should have tried the effect of a neutral-tinted mount of much lower tone—perhaps a cool greenish drab or mud colour—and a dull ebonised moulding. Probably the *savant* could not spare time from his absorbing scientific studies to see to the framing himself, and entrusted some one else to get it done for him. No. 23, *Against the Tide*, W. Dawes. The composition comes out well for an instantaneous study, but the atmospheric character of sky and the transparent liquidity of water have been insanely destroyed by the absurdly coarse character of the printing paper. What should have represented pure sky and water are here presented the sky as coarsely granulated stone, the water as some new composition of wool and mud, on the surface of which some shaggy boats are making frantic efforts to accomplish locomotion—a dirty, rotten result. No. 25, a legitimate photographic study by Robert Terras; head of a nice old peasant woman, about four or five inches, printed in silver on plain paper, warm in tone, and much more like nature than the miserably cold and grey bromides in the neighbourhood. No. 26, *Bonchurch Cliffs*, by Herbert Young, M.A. A pearly, delicate study, but the water is vapid and opaque; yet it is a charming picture as compared with the wretchedly grey, washed-out bromide enlargement next to it. No. 33, *The Wherry*, a carbon enlargement from negative by P. H. Emerson, possesses a charm on account of the luminous liquidity and effect of transparency in the water, an effect greatly helped by the boat in the centre. The atmosphere is hazy, but that does not account for the utter disproportion in atmospheric strength between that ugly clump of branchless foliage protruding from the top left-hand corner, and the large clump of trees immediately beyond it, which look as faint as if they were half a mile away. Here, again, the warm mount and the gold make the cold enlargement suggestive of a drawing made with washes of writing-ink; but the black moulding is much better than the white. Just above this is No. 32, a large sunset picture (platinum), by Lewis Cohen. This is a photograph of a high order, although it lacks transparency, and is too dark and heavy in parts.

PALETTE.

(To be continued.)

WET COLLODION.

[North Middlesex Photographic Society.]

REPORT OF LECTURE AND DEMONSTRATION GIVEN BY MR. W. E. DEBENHAM.

The wet-collodion process is the one best adapted for preparing plates to make negatives for line work or photo-lithography, and where clear black and white and sharpness of line are necessary. Wet collodion is also necessary for making enamel plaques, when the film is toned with platinum or iridium and placed upon a plaque and fired. Wet collodion is also used for making enlarged negatives, lantern slides, and copying. There are some essential differences in the collodion and gelatine methods. In the gelatine method the image is developed from the bromide of silver, which forms the sensitive surface; that bromide yields its silver to form the image. In the wet-collodion process the image is formed of silver, not from the iodide of silver in the film, but from the nitrate of silver, which is in the accompanying sensitising bath. Now, although the film in the case of collodion is, as I stated just now, for the most part iodide, there is an advantage in having a certain amount of bromide in it. Formerly bromide was not used for negative processes, but it was found that a little bromide gave a smoother surface, the plate was cleaner in development and less liable to fog; and, moreover, it was more fit for development by the iron method than the plain iodide, which was, generally speaking, developed with pyro.

Now to the actual work of preparing a collodion plate. In the first place, you must have glass which is clean; glass which is only *apparently* clean to the eye will not do, it must be *really* clean, or else where there is a trace of dirt on the surface of the glass—though it may be not sufficient to be seen—the silver will be deposited from the bath under the action of the developer, and will make a stain underneath the collodion between the collodion and the glass. That stain is not only injurious as a stain, but the collodion will, generally speaking, fly up off the glass when the plate is dry. The first thing, therefore, is to have your glass clean. We at one time used patent plate, but that has now gone out of use for this purpose. Sometimes you will find the glass covered with an apparently smoky stain; if you find this, do not use it, or else the collodion will fly off when it is dry, even if it does not cause a stain during development. The glass may be cleaned in various ways, according to the purpose to which it has previously been put. If it is in a very bad state, or has been used for negatives which were intensified with mercury, then you should dip it in moderately dilute nitric acid, say one in five of water

But, generally speaking, it is sufficient to take a piece of list, and roll it into a flat pad, then put a little whiting and water on the surface of the plate and rub it pretty hard with the pad, afterwards wash it under a tap, dry it with a cloth, after which it must be thoroughly polished. Do not stand the plate up to dry on taking it from under the tap, for, if you do, the water will settle and form marks on the glass which you will not be able to get rid of; and you must on no account use glass which has anything the matter with it. I have found the great secret of polishing glass successfully and tolerably rapidly is to use a cloth which is not quite dry. With a perfectly dry cloth it is almost impossible to get glass clean; the cloth must not be so damp as to leave a smear; but, if that is avoided, rubbing the glass with such a cloth will very soon bring it to a satisfactory polish. I have known photographers to suppose that, if the breath flies off rapidly, the glass is clean; but that is a delusion, it merely shows that the glass is warm from rubbing, the breath should dry off smoothly, there should be no streaks. But there is one particular mark which you may see, and that is an appearance something like flames that die away altogether; I do not know how to account for it, but, when you see that, you know it is a glass in very good condition.

Now, the glass being clean, has to be coated with collodion. I prepare my own collodion, and the following is the formula I adopt:—

A.

Pyroxiline	100 grains to 120 grains.
Ether ·720 to ·725	10 ounces.
Alcohol abs.	5 ounces.

That forms plain collodion. It is allowed to stand for a few hours at least, so that it can be decanted from sediment. The iodising solution is conveniently added afterwards, and not made with the collodion itself. It is made thus:—

B.

Ammonium iodide	60 grains.
Cadmium iodide	40 „
Cadmium bromide	10 „
Iodine	1 grain.
Alcohol ·820	5 ounces.

These solutions are then mixed, and together make up a pint.

When the plate is coated with collodion containing iodide and bromide, and placed in a solution of nitrate of silver, a double decomposition takes place. The iodide and bromide form iodide and bromide of silver in the film itself, and leave, of course, a certain amount of nitrate of cadmium and nitrate of ammonium in their place. You must, however, have a considerable excess of nitrate of silver, or else you will have nothing to develop from, as it is that from which your image is formed.

The sensitising bath is a thing which used to give old photographers a good deal of trouble, as it was so liable to get out of order. Ordinary nitrate of silver will do to make the bath, and a bath successfully made with it cannot be distinguished from that made with triple recrystallised; and, in order to make tolerably sure of success, you can adopt the method which I will describe. The nitrate of silver is first made up with about one-third of the amount of water which is to form the bulk; the strength of the bath should be—

Nitrate of silver	30 grains,
Water	1 ounce,

which is something like fifteen ounces of water to every ounce of nitrate of silver. Suppose we have sixty ounces of water to four ounces of nitrate; in the first place, put in about one-third the amount of water, add a little liquor of potash—a few drops—until it forms a slight brown cloudiness which does not redissolve; we know then that the bath is not acid, but that it is possibly alkaline, just alkaline. When in that alkaline condition, it throws down impurities which, whilst in the acid condition, would remain in it. Then add a solution of iodide of potassium, a few drops at a time, until no more of the deposit redissolves. Now fill up with the remaining two-thirds of water at once; a quantity of iodide of silver will be deposited, and in settling down it appears to carry down impurities with it.

Make your bath, so far, some time beforehand, and leave it until you really want it; then filter it, and add to every pint one drop of nitric acid; the bath should then be in good condition and fit for use. When a bath is not in good condition, the result is that, where the shadows should be perfectly clear, no deposit at all, there is a certain amount of deposit, sometimes so bad as to cause a fog, that spoils the picture entirely.

An upright glass dipping bath is customary, with a dipper to hold the plate. It is very convenient to have a millboard cover made for the bath, and the dipper, which may be of gutta percha, attached, so that when the dipper is inserted the lid comes down, and when the lid is removed the dipper and plate are withdrawn.

The plate being properly cleaned, as before explained, is now coated with the collodion. In coating the plate, number the corners in your mind 1, 2, 3, 4; hold the plate by the thumb and fingers of the left hand as near the corner of No. 3 as possible; pour on plenty of collodion, so as to be sure it will go all over, run it first into corner No. 1, which is opposite the thumb, then 2 and 3 which is the thumb corner, and off into the bottle again at No. 4. Now, if the plate is left still, it will form marks; so keep the plate in one plane, but raise alternately, the corner next the thumb and the opposite corner, so as to alter the direction of the running-off lines crossing them, and thus get rid of lines altogether, or nearly so. Large plates are best coated with a pneumatic holder, or by supporting them on a pad of paper with the hand flat underneath. After coating, the plate must be left a short time to set; it must not be placed in the silver bath instantly. The time depends upon the time of year, the quality of the collodion, &c.; if any part is perfectly dry, it will give a thin, useless image, and will ruck up in developing; if it has not set sufficiently, the edge where it has been poured off will show streaks coming down from it. In placing the coated plate into the sensitising bath, it must go in without a halt, or there will be a line; it must not be hastily put in so as to cause a splash, or there will be marks where the splashes settle, but it must be put in evenly and quietly.

The plate should remain in the sensitising bath for an average of three minutes. If, on taking the plate out of the bath, it shows greasy-looking marks, it has not been in the bath long enough, and must be put back. On removing it from the bath, it should be drained for a minute or so to get rid of the surface moisture, and it is then ready for the exposure, which, whether the plate is intended for a negative or positive, must be made in the camera, as the wet plate, coming in contact with a negative film, would ruin it at once. The wet-collodion plates are some thirty or forty times slower than an ordinary gelatine plate.

The developer consists of—

Sulphate of iron	10 to 20 grains.
Acetic acid	15 minims.
Water	1 ounce.

I use no alcohol with a fresh bath, and, on the whole, I find I get clearer pictures without; but, if the bath has had many plates dipped in it, you will be compelled to use alcohol in your developer, otherwise it will not flow smoothly, but will halt and make marks. After washing off the developer, cyanide of potassium is used as the fixing agent, of which a little may be poured on the plate, but I much prefer a dipping bath where many plates have to be fixed. It is much quicker to use than hypo, and is easier to wash out.

If the plate needs intensification, it can be done in several ways, but the usual intensifier is—

Pyro	2 grains.
Acetic acid	15 minims.
Water	1 ounce.

Flow this over the negative and back into the measure, then drop into the measure three or four drops of the sensitising solution. That which has drained from the plates, if it has been saved, will do very well. Pour it back on to the negative, and it will at once give a brown colour, and, by degrees, deepen to perhaps twice the intensity the plate originally had.

Suppose you find that your picture is slightly marked from a dirty glass, and you expect that the film will fly off when dry, but, on the whole, it is so good that you would like to save it, in that case, while it is still wet, flow over it some rather thin gum water, and then it will probably stick to the glass as it dries.

A collodion negative must be varnished, as the film is so tender that it cannot safely be printed from without this precaution. Any of the negative varnishes on the market will do for this.

There is not so much latitude of exposure with the wet plate as with the dry gelatine plates, as the developer cannot be modified to the same extent. The wet-collodion process is cheap to work, the chemicals for a half-plate only costing somewhere near a halfpenny. In case of a negative being spoiled, the film may be cleaned off easily, and the plate is then available for use again. If the plate has been varnished, hot water will loosen the film.

NIKKO PAPER.

[Croydon Microscopical and Natural History Club.]

This development paper, as distinguished from the printing-out paper, has recently been introduced by the Eastman Company, and we pro-

pose to-night to lay before the members of the Club our experience in the development and toning of Nikko paper, so far as they have gone up to the present time.

Although the ferrous-oxalate development is the only one referred to in the instructions issued with this paper, yet it is stated that any of the other developers may be used; and, if time permits, we shall endeavour to show you the results, obtained with the following developer, *i.e.*, hydroquinone, amidol, metol, and glycin, any of which may be used, the chief difference in the results obtained being the *colour* of the developed image.

Following up an opinion we have before expressed, and which has been endorsed by the editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, we again reiterate the statement that development formulæ ought always to give the quantities of each ingredient to each ounce of developer used. The want of such information was abundantly proved by the value set on the tables compiled with so much care and trouble by Messrs. Clark & Ferrero, and yet we find formulæ still being published to make anything from a pint to a gallon of developer, and, on endeavouring to reduce these to ounce quantities, some curious and interesting fractions occur, which go far to throw discredit on the published formulæ.

The ferrous-oxalate and hydroquinone developers are probably sufficiently well known; but, for those who wish to try the newer developer, we have reduced the quantities, as given in the formulæ sent out by the manufacturers to ounce proportions, as follows:—

"AMIDOL."

Pure sodium sulphite	21 grains.
Distilled water	1 ounce.
Amidol crystals	2 grains.

Dissolve the sulphite in the water, and add the amidol. As the latter is very soluble, it may, like pyro, be used dry at the moment the developer is wanted.

"METOL" SODA.

A.

Distilled water	1 ounce.
Metol	6½ grains.
Dissolve and add pure sodium sulphite	65 „

B.

Distilled water	1 ounce.
Soda crystals	54 grains.

Dissolve.

"METOL" POTASH.

A.

Distilled water	1 ounce.
Metol	4½ grains.
Dissolve and add pure sodium sulphite	45 „

B.

Distilled water	1 ounce.
Carbonate of potash	45 grains.

"METOL" STOCK SOLUTION.

Distilled water	1 ounce.
Metol	6½ grains.
Dissolve and add pure sodium sulphite	65 „
Soda crystals	54 „

"GLYCIN."

A.

Glycin	17 grains.
Carbonate potash	66 „
Pure sodium sulphite	51 „
Distilled water	1 ounce.

Dissolve.

B.

Carbonate potash	43 grains.
Distilled water	1 ounce.

For use, mix one part of A with two parts of B.

These solutions are to be mixed in varied proportions, and sometimes diluted with water, according to the instructions issued with each developer.

We will now proceed to expose and develop a piece of Nikko paper with each of these developers taking them in the order given, when we shall find that the ferrous-oxalate gives from a soft grey to a velvety black; hydroquinone more or less of a black; while the newer developers appear to give beautifully soft pictures of a colour intermediate between these two. Some prints we have previously prepared will illustrate this, and another print will show the effect produced by squeegeeing on to a pulp slab previously prepared with spermaceti dissolved in benzoline, and which we much prefer to talc.

The exposures, which were all made at a distance of three feet from a gas flame, varied from thirty to sixty seconds according to the density of the negative, and the usual device of shading some parts of the negatives, where thin, during exposure was adopted.

Nikko paper appears to give a great latitude in exposure, and to develop up slowly but vigorously, and shows no sign of fogging or staining with any of the developers we have tried.

Having developed the Nikko print, we can, if the colour is not agreeable or we wish to alter it, resort to toning. And for this purpose we have used two solutions, the results of which we shall demonstrate to you. 1. There is the now well-known acid uranium toner first suggested by Mr. Weir Brown, which gives very warm tones, but which do not appear to wash out, as they do in the case of bromide paper; this may be due either to a difference in the emulsion, or to the fact the uranium toning with Nikko paper is much slower than it is with bromide paper. Examples of this we show you.

2nd. The sulphur-toning formula issued by the Eastman Company, which, as you will see by the example before you, gives nice warm sepia tones. In using this process, however, two precautions are necessary, *i.e.* (1) Not to use the bath before it has been made *at least* twenty-four hours; (2) to develop darker than the toned print is required to be. If these conditions are not observed, the result will be as in the print before you—it will be almost bleached out of existence. Another point in connexion with this toner is that it should be kept warm—that is, from 100° to 120° Fahr.—during the toning process, as a print that was allowed to remain in it cold *all night* showed no sign of toning the next morning.

We have now laid before you some of the methods of treating Nikko paper, and we may say, in conclusion, that we believe there is a future for this paper, as it appears to be very amenable to various kinds of treatment.

J. H. BALDOCK, F.C.S.

A NEW GELATINO-CHLORIDE PAPER: DEVELOPMENT OF PARTLY PRINTED PROOFS.

THE Paget Prize Plate Company, after considerable experiment, are just placing a new gelatino-chloride paper on the market, and last week we accepted an invitation to attend at the Company's premises at Watford for the purpose of witnessing a process they have worked out, whereby advantage is taken of the circumstance that weakly printed images on gelatino-chloride paper may be developed up to full intensity by ordinary alkaline development, and toned and fixed in the usual manner. The Company anticipate that where a number of prints are wanted from one negative a saving of time may be effected, and thus a professional photographer would find it advantageous to utilise the daylight for rapid underprinting and subsequent development in preference to printing right out, which would take very considerably longer.

On the occasion of our visit a number of portrait, landscape, and architectural negatives were used for making the exposures. These latter varied from two minutes in the shade (approximately one-tenth of the time necessary for printing out) to fifteen and twenty seconds in the sunlight. Included among the prints made was a vignette, this being selected in order to show that the paper does not give double tones. The prints when taken from the frames just showed the finer details. They were then placed in a solution of potassium bromide 1 : 20, in which they acquired a yellow tone, and were then washed in plain water. After the washing they were treated with a developing solution as follows:—

Solution 1.

Hydroquinone	½ ounce.
Sulphurous acid	¼ „
Sodium sulphite	¼ „
Potassium bromide	60 grains.
Water to	30 ounces.

Solution 2.

Caustic soda	½ ounce.
Sodium sulphite	1 „
Water to	30 ounces.

Solution 3.

Bromide of ammonium	1 ounce.
Carbonate of ammonium	1 „
Distilled water to	30 ounces.

The carbonate of ammonium should be in clear lumps. If from exposure to the air it has become coated with the white powdery bicarbonate, the latter should be scraped off.

For use: Two parts No. 1; one part No. 2; two parts No. 3.

Development was complete in about five minutes, the pictures then presenting the appearance of washed, untoned albumen prints, rather less in depth, the right moment to stop development in the gelatine prints being just when the finest details are disappearing.

After about ten minutes' washing, the prints were placed in the toning bath, the following "separate" bath being the one employed:—

Sulphocyanide of ammonium	30 grains.
Gold chloride	2½* ,,
Water	16 ounces.

The toning action started rapidly and was completed in from six to ten minutes, according to the particular peculiarities of the print. The prints, as was afterwards shown, did not lose in the fixing solution, and they were adjudged to be toned sufficiently by transmitted light, that is, when so viewed, the yellow colour in them should have disappeared. In all, some thirty-six prints were exposed, "bromised," washed, developed, washed again, toned, and fixed, and several of them dried off with spirit, in about two hours and a half.

Some of the wrinkles that came out in the course of the demonstration might be of service to others taking up partial development of gelatine papers, which Mr. W. J. Wilson anticipates will be largely done. While two minutes in the shade may be accepted as the minimum printing time, a little, or even much more, is not at all hurtful, as it comes to this, that, provided the minimum exposure has been given, any stage of under-printing, however slight, is amenable to development. Slow and tolerably well-restrained development appears to be the best adapted for the case. Washing between the various operations assumes the greatest importance, particularly between development and toning, the more thoroughly the print being washed the better the toning action proceeds. Another feature of the process is that if a print, when in the toning bath, should have been found to have been under-developed, the toning solution can be removed, and the print well washed, redeveloped up, and toning again proceeded with; also that over-developed prints are easily and harmoniously reduced in a very weak solution of cyanide of potassium.

Comparing several developed prints with those printed out in the ordinary manner, no difference in quality could be detected, while the whites of the former were as pure as could be desired in every way. The demonstration was highly successful, in fact; and the Paget Company should receive the thanks of many a professional photographer for having put him in the way of a useful device.

THE PHOTOGRAPHIC CONGRESS.

The Congress of the Societies affiliated to the Photographic Society of Great Britain was opened at the Society of Arts on Wednesday afternoon, the President (Captain W. de W. Abney) being in the chair. There was a very good attendance.

A paper on *The Astigmatism remaining in Some Astigmats*, by Herr Emil von Hoegh, was read. This dealt with the application of Dr. Rudolph's method of testing for aberrations as applied to the double anastigmat of Goerz and the Zeiss anastigmat.

The proceedings were continued with the delivery of an address by Mr. Andrew Pringle on *The Present Position of Photo-micrography*, in which he pointed out that scientific instrument-makers were giving their attention to cheap apparatus, so that photo-micrography could be taken up at a moderate cost. Dividing the systems of apparatus usually employed into two, he described and illustrated by means of lantern diagrams that one in which the microscope was on one piece, and the receiving surface on the other, pointing out that with it there was a danger of the non-synchronous vibration of the parts. In the other system there was a rigid connexion of all the parts of the apparatus. Having illustrated Zeiss' and Swift's forms, he next showed a diagram of one produced by Baker for himself, which, among other advantages, allowed of the head being placed between the front of the microscope and the camera. For photographing liquids or objects contained in liquids he spoke highly of Van Heurck's arrangement. In this a box having a door at its side was placed over the microscope, which enabled one to look down on the object. A great many objects had to be photographed in a living or moving state. In Nachet's arrangement there was an auxiliary tube, along which a prism projected the image, so that an observer could watch it, and when the focus was settled the prism passed aside and the exposure was made. His own modification of this consisted of an inverted camera over the microscope, with eyeholes at the side for watching the object, and an arrangement of shutters for the exposure. Having noted recent advances in the introduction of colour-sensitive plates and apochromatic objectives, Mr. Pringle showed slides by Messrs. T. F. Smith, Comber, Dr. Bousfield, and himself, and a series by Mr. Carnell illustrating the advantages obtained by the use of colour-correct plates, and concluded by insisting on the advantages of photo-micrographs over drawings of pathological specimens, and the value of photo-micrography to scientific men.

Dr. Bousfield referred to the sweating properties of the glass of the apochromatics, and said that, while they gave exquisite sharpness in the centre of the field, they fell off at the margins. They wanted something much better than that before they could be said to have reached finality. Absolutely the best objective he had used was a "Powell & Leland."

Mr. Pringle agreed that Powell & Leland produced objectives which had surpassed those of Zeiss in flatness of field. With regard to correction, Dr. Piffard had said that the future of photo-micrography depended upon the light being near the D region of the spectrum, the objective corrected for the D line, and the plates sensitised to the D line.

The President said that Mr. Pringle's remarks about tremors were unfortunate, as the earth was always in a state of tremor. He did a certain amount of photo-micrographic work years ago, and was much troubled by the want of achromatism of the lenses. He found that the best way to cure it was by monochromatic light from a pure spectrum, by decomposing a ray of light by a prism, and interposing a slit in the path of the monochromatic ray, which was then taken up by a lens.

A paper by M. Weissenberger, of St. Petersburg, on *A Process of Photo-mechanical Printing in Natural Colours*, was then read by Mr. Warnerke. This appeared to be the well-known process of preparing three colour-sensitive negatives, and, by means of prints from three gelatine blocks, superposing the three colours, yellow, blue, and red.

Mr. F. E. Ives said he had already published what he believed to be very nearly the best conditions for arriving at results similar to those shown. If he undertook to say what were the scientific errors in the paper, it would take up a lot of time. He did not think it had been demonstrated that it was not possible to obtain negatives which did not require touching out. We could obtain three negatives of colour sensations, and those sensations existed in definite proportions, and each negative is the one we require for reproducing the object. The author seemed to think that both ends of the spectrum were given. He once thought that himself. In 1881 he devised a plan of working by cross lines, and while he could reproduce with ordinary correctness coloured photographs, he could reproduce nothing like landscape colour that was not simply bad. He had made by gelatine printing reproductions of landscapes which came near to nature, but still more satisfactory results when the colours were combined by light. He concluded by warning any one against investing money in such a process, as it was commercially unworkable.

After other remarks, Mr. Warnerke took occasion to point out that M. Weissenberger only had a scientific object, as distinct from a commercial one, to serve, in bringing the process forward.

A paper on *Photography in Compartments* was read by the author, Mr. Hector Maclean, F.G.S., and a short discussion followed.

On Wednesday evening, after Mr. Leon Warnerke had discoursed on Lumière's photographs in natural colours, to which reference is made elsewhere, the President read a paper on *Chemical Action and Exposure*, which dealt exhaustively with the experiments made to confirm previous statements of the author that the sum of excessively small exposures was not equivalent to the same exposure given at one time, and that feeble intensity of light also failed to give the calculated amount of chemical action. In a brief discussion which followed, the Chairman (Mr. J. Spiller) said he had been in the habit of considering that, if a sitter were placed twice a given distance away from the camera, the amount of light falling upon the camera would be four times what it would be in the first case, and the exposure would be regulated accordingly; it was also a novelty to be told that two exposures of half a second each were not equal to a single exposure of one second. This ought to have been discovered before.

Mr. H. A. Lawrance suggested that, as the subject covered a wide field, discussion on it should be postponed.

Mr. W. E. Debenham said the paper was contrary to his views; he had tried the experiment by printing, and had found it impossible to tell the difference in the exposures.

Mr. H. M. Elder thought the paper would have an important bearing on many departments of scientific work.

The evening proceedings concluded with a paper by Captain Hills, describing the photographic work of the recent solar eclipse.

On Thursday afternoon a paper by Dr. Rudolph was read on *A System of Measuring and Numbering the Stops of Photographic Lenses*, which discussed the existing systems of numeration, and concluded that it would be rational to take *f*-36 or *f*-50 as the unit, and, in order to minimise the occurence of fractions, to let the number vary as the relative rapidities, *i.e.*, inversely as the corresponding exposures. Taking *f*-36 = 1, the following convenient system is obtained:—

Relative aperture—	*f*-4·5, *f*-6·3, *f*-9, *f*-12·5, *f*-18, *f*-25, *f*-36, *f*-50, *f*-71.
No. of stops (relative rapidity)	64, 32, 16, 8, 4, 2, 1, 0·5 0·25.

A demonstration of collotype was then given by Mr. W. E. Debenham, and the meetings of the Congress terminated by the reading of a paper by Dr. Miethe on *The Practical Testing of Photographic Objectives*. This, together with most of the other papers, we shall produce in future numbers of the Journal.

On Thursday night, at the Exhibition Gallery, Pall Mall, a largely attended lantern entertainment was given, and on Friday evening a dinner was held at the Frascati Restaurant. The Congress appears to have been very successful throughout.

INTERNATIONAL AMATEUR PHOTOGRAPHIC EXHIBITION AT HAMBURG.

(From a Special Correspondent.)

This Exhibition was opened on October 1 by the President of the Committee, Mr. Ernst Juhl. There are about 450 exhibitors from all parts of the world, who sent nearly 6000 photographs for competition. The awards consist of fifty-nine first-class prizes and 170 diplomas, given by the Senate of Hamburg, several societies and clubs, and by friends of photography. Besides exhibitors from Germany, the representatives of the following countries took part in the Exhibition:—The United States of America, Chili, Ecuador, Japan, Australia, Belgium, Holland, Denmark, England, France, Italy, Sweden and Norway, Austria and Hungary, Russia, Spain and Portugal, Switzerland, China, and Argentine.

A Photographic Congress was arranged for October 7 and 8 by the Committee, to which all photographic clubs and societies were cordially invited.

At the first meeting of the Congress the decision of the Judges was published, the result being that the two first-class prizes were given to foreign exhibitors.

Mr. Rudolf Eickemeyer, jun., of New York, was awarded the large gold medal given by the Senate of Hamburg; Freiherr von Rothschield, of Vienna, the small gold medal given by the Society for Art and Industry.

The following English exhibitors were honoured with first-class prizes, viz.:—Mr. A. R. Dresser, London (an oil-painting, given by the ladies of Hamburg, as well as another prize consisting of a bronze plaque, size $7 \times 9\frac{1}{2}$); Mr. Paul Lange, Liverpool (an oil-painting, given by friends of photography).

Diplomas were also received by:—Rev. William Barlee, Cringleford Hall, Norwich; Miss Alice H. Brown, Norwich; Messrs. Martin J. Harding, Shrewsbury; Oct. Langtree, Craigavad, Belfast; John W. P. Norton, Sheffield; Clare Parks-Smith, Bristol; and A. E. Segnitz, Birmingham.

It is only six months ago that the International Amateur Photographic Exhibition was proposed by the Hamburg Amateur Photographers' Club, and it is due to the kind assistance of the Senate of Hamburg, the foreign consuls, the different societies and clubs, and last, but not least, to the Committee, that the Exhibition has been such a grand success.

News and Notes.

Woolwich Photographic Society.—October 26, Annual Meeting at St. John's Schools, Woolwich.

Photographic Club.—October 25, First Monthly Lantern Meeting of the season.

Northern Scientific and Photographic Association.—At the meeting of this Association on Thursday, last week, R. W. Bowers, Esq., F.R.Hist.S., delivered an address on Darwin and Evolution.

Newcastle-on-Tyne and Northern Counties, Photographic Association.—October 24, Annual Meeting and Exhibition of Slides at half-past seven p.m. at the Association Meeting Room, Art Gallery, Newcastle.

Mr. G. H. Cricks, 11 and 12, Great Tower-street, formerly of Messrs. W. B. Whittingham & Co., is now the London representative of Messrs. Stutz & Co., the agents for the "Drum" brand of photographic papers.

The Ilford Year-book for 1894.—A very handy year-book in the form of a comprehensive diary has been received from the Britannia Works Company, Limited. It is on the same general lines as that of last year, which proved so successful.

Leytonstone Camera Club.—October 21, Open Social Evening at headquarters at eight o'clock. 25, Demonstration on the *Collodion Process* by the President, Dr. W. Pickett Turner, assisted by Mr. A. J. Newton. Chair taken at eight o'clock.

Messrs. Arthur Schwarz & Co., of Dashwood House, E.C., have been appointed the European agents for Hetheringtou's Backgrounds, of which have seen several excellent collotype reproductions that show them to be of a highly artistic character.

The Bristol International Photographic Exhibition.—We understand that a large number of entries for this Exhibition have already been received. It opens on December 17, and will be divided into twenty-two classes, in which forty medals will be awarded.

Photographic Society of Ireland.—This Society has removed from 15, Dawson-street, Dublin, to larger and more convenient premises at No. 35, in the same street. All communications to be addressed to the Hon. Secretary, Mr. J. A. C. Ruthven, 40, Lower Sackville-street, Dublin.

Photographic Society of Great Britain.—Technical Meeting, Tuesday, October 24, at the Gallery, 5A, Pall Mall East. *Balloon Photography*, by Captain Mantell, R.E. *Lumière's Experiments in Printing with Manganese Salts.* Mr. R. Child Bayley will introduce the subject and show specimens. The meeting will *not* be held at 50, Great Russell-street, as previously announced, but at the Exhibition Gallery.

Central Photographic Club.—A successful inaugural smoking concert was held at the Club's headquarters, Coleman's Hotel, Covent Gardeu, last Friday evening. The premises are now ready for the use of members, and we are pleased to observe that the Honorary Secretaries are busy in providing the various Club conveniences for "social purposes." The residential value of the Club has been already put to the proof, several country members having stayed there during the past week.

Metric Weights and Measures Adopted by Druggists in the United States.—Following the seventh decimal meeting of the National Convention for revising the Pharmacopœia, the authorised revision has now been published, and will take effect as from January I, 1894. It is noteworthy that the Committee of Revision was instructed to direct that all solids should be weighed, and all liquids measured, by the *metric* system. Throughout the Pharmacopœia the metric weights and measures have therefore been adopted.

Photographers' Benevolent Association.—October 17, 1893, meeting at the rooms of the Photographic Society of Great Britain, 5A, Pall Mall East, S.W., Mr. A. Mackie in the chair. The Committee confirmed a loan of 15*l.* granted on September 28 by a Sub-Committee in a case that was partially considered by a full Committee on September 15. The following other cases were considered:—1. A discharged soldier, who had been a military photographer, and who, since his discharge from the army, owing to broken health, had been working as a carbon and process photographer until disabled by bichromate disease, applied for immediate assistance and a loan of sufficient money to purchase camera and lens. Owing to illness and time spent in hospital, he was penniless. The Committee granted a small sum in instalments for immediate subsistence, and instructed the Secretary to purchase a second-hand whole-plate camera and lens. Applicant had secured permits to photograph in several police barracks and workhouses. 2. Applicant, who was assisted four years ago with a grant of 5*l.*, applied for further small assistance until he should obtain situation. A grant of 2*l.* was made. 3. An operator, to whom a grant of 5*l.* was made on September 15 to enable him to reach a situation, applied for a further 5*l.* in order that his wife and family might reach him, and so reduce living expenses and enable him to repay the whole loan. Amount was granted. 4. An operator, who was assisted last year, and who, during the spring and summer, has been in several temporary situations, some of which were found by the Benevolent, made application for further assistance. Secretary reported that he had granted immediate relief to the extent of 1*l.* in instalments, and that, as the applicant had obtained a month's engagement, the application was withdrawn. Committee confirmed Secretary's advances. Donations were acknowledged from the following:—London and Provincial and Photographic Club Outing, 9*s.* 1*d.*; Messrs. Henry Dixon & Son, 2*l.* 2*s.*; Brighton Photographic Company per Mr. Wicks, 1*l.* 16*s.* 6*d.*; a friend of the Benevolent, 1*l.* Mr. Leon Warnerke was accepted as a subscriber.

Hackney Photographic Society's Exhibition.—This Exhibition was opened on Tuesday evening last, October 17, by Sir Charles Russell, Q.C., M.P., in the presence of a crowded assemblage. Sir Charles Russell, in declaring the Exhibition open, said he was glad to hear that the Society was flourishing, and that it was able to hold its own in open competition. Photography was now one of the fine arts, and its pursuit had many attractions. It was an agreeable means of association with neighbours, and of perpetuating pleasant memories of days gone by, and it also served very useful purposes. It was hardly too much to say that photographic science was the handmaiden of science itself, for in the pursuit of that difficult and abstruse science, astronomy, the lens of the photographer often revealed planets which even the most powerful glasses failed to discover. He wished long-continued success and increasing prosperity to the Society. A vote of thanks to Sir C. Russell was accorded, on the motion of Mr. J. Fenton-Jones, seconded by Dr. Owen Smith, and supported by Mr. J. Traill Taylor. We reserve a detailed notice of the Exhibition until next week, but in the meanwhile we give the Judges' awards:—Class A (Members Classes).—Championship Gold Medal, S. J. Beckett, 132; W. Houghtou's Silver Medal, W. A. J. Hensler, Silver Medal, C. H. Pollard, 88. Class B (Hand-camera Pictures).—Silver Medal, Robert Beckett, 217; Bronze Medal, F. E. Roofe, 164. Class C (New Pictures taken at Club Outings). — Silver Medal, No award; Bronze Medal, F. W. Gosling, 276.1 Class D (Members New Lantern Slides).—Silver Medal, S. J. Beckett; Bronze Medal, W. A. J. Hensler. Class E (Unmedalled Pictures). — Silver Medal, J. B. B. Wellington, 310; Bronze Medal, W. M. Warneuke, 360. Class F, (Portraiture and *Genre* unrestricted).—No awards. Class G (Champion Class).—Gold Medal, J. B. B. Wellington, 428; Silver Medal, No award. Class H (Lantern Slides. Open).—Silver Medal, W. England; Bronze Medal, A. Brooker; Extra Bronze Medal, W. Taverner. Apparatus.—Silver Medal, Henry Park.

Copying Pictures.—A contemporary has the following:—"We may be permitted to express a hope that there is some mistake in the story told by the *Manchester Guardian* concerning the destruction of *Love Among the Ruins*, painted by Mr. Burne Jones in 1873. The account which has already appeared credits a firm of art publishers, to whom the picture had been entrusted for the purpose of being photographed, with a singular lack of discretion. They mistook, so it is said, a water-colour drawing for an oil painting, and poured upon it some substance intended to make it shine. The effect was, of course, immediately disastrous. It is difficult to believe that any one accustomed to handling works of art could have made such a blunder over a drawing to the close examination of which there was evidently no impediment; and it is still more difficult to understand why any photographer should try to impart to the surface of the picture that shine which it is his habit to denounce as a drawback and interference. The tale seems to lack internal evidence." In a subsequent issue the same journal thus comments on the matter:—"A letter

which has appeared from Mr. Philip Burne Jones confirms the rumour about the destruction of his father's picture, *Love Among the Ruins*. It was, it seems, in Paris that the photographic firm committed the astonishing blunder that has caused so much comment, and it also seems that such reckless handling of important works of art is an every-day occurrence. The immediate effect of this last 'accident' will be to make the owners of valuable pictures exceedingly unwilling to allow them to be touched by the reproducer; and the ultimate effect, let us hope, will be to put a stop to these ignorant experiments with works of art. It cannot be too strongly urged that the owner of a picture by any artist of real importance has no moral right—whatever his legal position may be—to expose that picture to any risk of injury. He possesses temporarily an important link in the chain of evidence which establishes that artist's reputation; and upon the manner in which he and others like him deal with their art possessions depends the estimate which future generations form of that artist's work. Had there been in bygone centuries many reproducing firms with careless methods, and many owners as trustful as those of to-day, we should have had few of the classic canvases left to set the standard of the art of the world. What the restorer spared would have succumbed to the reproducer."

PATENTS COMPLETED.

AN IMPROVED APPLIANCE FOR PRINTING VIGNETTE PHOTOGRAPHS.

No. 16,481. JOHN COULSON ROWBOTHAM, 115, Thornton-road, Bradford, Yorkshire.—*September* 15, 1893.

THIS invention relates to an improved appliance to be used in printing vignette photographs, and its object is to more perfectly soften or tone down the outline of vignettes.

For this purpose I employ a zinc or other sheet metal plate having an opening or aperture approximately the size and shape of the vignette. The margin of this opening or aperture is raised or curved upwards so as to "dish" that part of the plate, and the raised or curved portion is perforated with one or more rows of holes, which may be reduced in size and number as their distance from the edge of the said opening or aperture is increased.

By this arrangement the light admitted beneath the margin of the aperture is admirably diffused and softened for vignette purposes.

IMPROVED SOLUTIONS FOR TONING PHOTOGRAPHIC PRINTS.

No. 17,768. RUPERT GREVILLE WILLIAMS, Greenfield House, Heywood, Manchester, Lancashire.—*September* 16, 1893.

MY invention relates to improvements in solutions and process for toning photographic prints, and is applicable more particularly to that class of prints which are known as gelatino-chloride, irrespectively of their having been printed from the negative upon gelatino-chloride printing-out papers, gelatino-chloride printing-out slides, or gelatino-chloride printing-out opals. I mean by the foregoing term, "gelatino-chloride printing-out," a paper, a slide, or an opal or other suitable surface prepared with a gelatino-chloride emulsion.

One of the objects of the invention is to replace the expensive salts of gold, platinum, and the like metals, which have hitherto been generally used, by potassium, sodium or ammonium sulphide.

The prints toned by my improved process are very permanent, and this permanence is the necessary result of the chemical reactions which take place during the said process.

The solution which I have found to be generally most useful for the purpose of the present invention consists of a mixture by volume of forty parts of ither potassium, sodium or ammonium sulphide, and 600 parts of strong ammonia liquor, which mixture is then made up to 2000 parts by the addition of water.

The proportions given in the preceding paragraph may be varied to any extent without departing from the invention, subject to the two following limiting considerations:—

With reference to the proportion of the sulphide:—The smaller the proportion, the longer will be the time which the process of toning will take.

With reference to the proportion of the ammonia:—As its function is only to keep the bath alkaline independently of the alkalinity imparted to it by the sulphide, any proportion capable of so keeping the bath alkaline will meet the requirement of my invention, and, on the other hand, excess of ammonia will not impede the process of toning, although too much will soften or blister the printing out.

The method of using the improved toning solution prepared as above described will be understood from a description of the way in which it is applied to a gelatino-chloride print which has been obtained in the usual manner.

After the print has been washed in cold running water for about half an hour, it is immersed in a mixture of about one volume of a saturated solution of sodium hyposulphite and three volumes of water containing a small quantity of ammonia. The print rapidly turns a bright canary yellow, and in a few minutes is fixed. All traces of the hyposulphite must then be removed by thorough washing, when the print is transferred to the toning bath, which is made up by adding one part by volume of the toning solution above described and fifty parts of water, in which it is moved to and fro for a few minutes, by which time it will have assumed a tone varying from orange-brown to chocolate-brown, according to the length of the immersion. The process just described must not be carried too far, otherwise unpleasing tones may be produced. The colour of the print after it has been dried is quite different to that which it had while wet. This being the case, it is advisable to keep a print which has been satisfactorily toned according to the present invention, and use a wetted portion of it as a guide. When the print undergoing the process of toning presents the same appearance in point of colour as the guide, it is removed from the bath, washed thoroughly, and then drained and dried. An additional alum bath, to harden the film, may often be used with advantage.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. The hereinbefore-described process of toning gelatino-chloride photographic prints. 2. In toning solutions, the combination therewith of alkaline sulphide solutions in place of solutions of gold, platinum, or the like metals, as set forth.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 23	Camera Club	Charing Cross-road, W.C.
,, 23	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 23	Lantern Society	20, Hanover-square.
,, 23	North Middlesex	Jubilee House, Hornsey-road, N.
,, 23	Putney	Boys' Gymnasium, Charlwood-road.
,, 23	Richmond	Greyhound Hotel.
,, 24	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 24	Great Britain (Technical)	50, Great Russell-st., Bloomsbury.
,, 24	Hackney	206, Mare-street, Hackney.
,, 24	Newcastle-on-Tyne & N. Counties	Central Exchange Art Gallery.
,, 24	Paisley	9, Ganze-street, Paisley.
,, 24	Rochester	Mathematical School, Rochester.
,, 25	Bath	Roy. Lit. & Sc. Inst., Terrace-walks.
,, 25	Burnley	Bank Chambers, Hargreaves-street.
,, 25	Leytonstone	The Assembly Rooms, High-road.
,, 25	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 25	Southport	The Studio, 15, Cambridge-arcade.
,, 26	Camera Club	Charing Cross-road, W.C.
,, 26	Glossop Dale	
,, 26	Halifax Photo. Club	Mechanics' Hall, Halifax.
,, 26	Hull	71, Prospect-street, Hull.
,, 26	Ireland	Rooms, 15, Dawson-street, Dublin.
,, 26	Liverpool Amateur	Percy-buildings, Eberle-street.
,, 26	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 26	Oldham	The Lyceum, Union-st., Oldham.
,, 27	Cardiff	
,, 27	Croydon Microscopical	Public Hall, George-street, Croydon
,, 27	Holborn	
,, 27	Maidstone	"The Palace," Maidstone.
,, 27	Swansea (Annual)	Tenby Hotel, Swansea.
,, 27	West London	Chiswick School of Art, Chiswick.
,, 28	Hull	71 Prospect-street, Hull.

North London Photographic Society.—October 3, Mr. Griffiths in the chair.—At the last meeting the subject of getting even toning results on P.O.P. was referred to by several members, and Mr. BISHOP now gave a demonstration of his manipulation of the paper. He used the combined fixing and toning bath made according to the original formula given by the Eastman Company for use with their Solio paper. He found the No. 1 hypo solution improved by keeping. The gold solution should be shaken up before adding it to No. 1. The prints should be printed rather deeply from plucky negatives, and not washed before being put into the toning bath. The prints must be examined by transmitted light, and when the brown colour disappears the prints are removed to the washing water. Mr. Bishop toned about a dozen prints with good results and the simplicity and rapidity of the manipulation was fully

appreciated. He preferred drying the prints on ferrotype plates in preference to glass. The plates required no preparation, and he never had any failures in consequence of the prints not coming off. If a matt surface is required, opal was preferred to ground glass for drying the prints on.

Hackney Photographic Society.—October 11.—An entertainment was given by the HON. SECRETARY (Mr. W. Fenton-Jones) entitled *My Italian Campaign*, or a trip from England to Italy by way of Paris, Marseilles, Rome, Nice, Geneva, Pisa, Florence, Venice, Naples, &c., which was illustrated by about 150 slides put through the optical lantern under the management of the Society's Lanternist, Mr. Albert Rose. Notwithstanding the inclement weather there was a numerous gathering of members and friends. The lecture was very instructive and interesting, and the slides, which were of excellent quality, were nearly all taken in a hand camera, those of Venice, Rome, and Mount Vesuvius calling for special comment, these being excellent both as regards composition and finish. The variety of subjects which were shown proves what a decided advantage and great range of subjects a hand camera can produce, for many pictures, such as those taken from the train along the route, would have been impossible to obtain with other than a hand camera. A voluntary collection was taken up on behalf of the Photographers' Benevolent Association, which realised 1*l.* 13*s.* 9*d.* A vote of thanks to the lecturer, which was proposed by Mr. C. Kemp and seconded by Mr. Puttock, brought a very enjoyable evening to a close.

Ealing Photographic Society.—The attendance at the Annual Meeting, held on October 5 at the Public Buildings), showed that interest in the Society was well maintained. The report and balance-sheet for the past year were unanimously adopted. It transpired that there had been a gain of eleven members during the year, making a total of fifty-one. A large and well-appointed dark room had been provided at an expense of about 25*l.*, more than half of which had been specially subscribed. The room, with all necessary apparatus and chemicals, was available for the use of members at any time without charge. Lockers could be obtained, if desired, at a yearly rent of 5*s.* Amongst the papers and demonstrations given during the winter session were the following:—*Photo-micrograph*, Mr. Charles White; *Sandell Plates*, Mr. S. Herbert Fry; *Gelatino-chloride Printing*, Mr. Mummery; *On the Improvement of Negatives*, Mr. R. Whiting; *Amidol as a Developer*, Mr. Morgan; *Exposure*, Mr. Howard Farmer. After discharging all liabilities, there was a small balance in hand. The officers and Council for the current year were elected as follows:—*President:* Mr. H. W. Peal.—*Vice-Presidents:* Messrs. C. Jones, W. T. White, T. Simpson, H. C. Draper.—*Council:* Messrs. Wakefield, Belt, Gregory, C. Whiting, and Drs. Gibbons and Phillpotts.—*Hon. Librarian and Custodian of Dark Room:* Mr. B. E. Peal.—*Hon. Treasurer:* Mr. A. F. Taylor.—*Hon. Secretary:* Mr. Murphy. It was decided to take immediate steps to provide an enlarging apparatus in the dark room capable of enlarging from whole-plate negatives and under up to 24×18. It was hoped that the apparatus would ultimately be furnished with the electric light. It was also decided to circulate portfolios of prints for criticism. It was notified that at the meeting on October 19 Mr. S. H. Fry would demonstrate the *Paget Printing-out Process.*

Putney Photographic Society.—October 2.—The VICE-PRESIDENT (Dr. W. J. Sheppard), in a short introductory address, briefly reviewed the progress made in photography during the past year. Referring to the Society, he said that, both in numbers and work, steady improvement had been made, and the remarkably good and enthusiastic meeting that evening showed plainly that there was a bright and prosperous future before it. He hoped the members would now shake off some of their modesty and compete at the open competitions this winter, as he believed their work certainly gave them a right to. The Society would hold an exhibition in December, and he felt certain if the members would all compete and send their best work, the show would be very successful. He had great pleasure in announcing the result of the summer competition for prints, the silver medal being won by Mr. Walter L. Colls, the bronze medal by Mr. H. Faulkner, and the certificate by Mr. W. Martin, jun. Three new members having been elected, were welcomed by the Vice-President, who introduced them to the meeting. A Committee was elected for drawing up rules and arranging the details of the proposed exhibition. Mr. ZACHARIASEN introduced a hand camera, designed by himself. After briefly stating some of the disadvantages connected with nearly every form of magazine camera, and the preference shown by many good workers for dark slides as being generally more reliable and suitable for good all-round work, he proceeded to describe his model. The only objections to the ordinary dark slide were, he thought, their bulk and weight, and perhaps more particularly the danger of stray light getting in when used in a hand camera, and frequently carried about for a considerable time with shutter of the slide drawn. To meet these objections he had constructed double dark slides weighing two and a quarter ounces and three-eighths of an inch thick; he was enabled to make this reduction in weight and thickness by the novel design adopted, in which the usual draw-out shutters and partition between the plates were dispensed with. But what he attached still more importance to was that all parts of the dark slide would, except when changing, be placed and manipulated in a light-tight chamber, so that the chance of any plate being fogged was absolutely *nil.* The camera shown was externally very like the ordinary box form, measuring five and three-quarter inches wide by four and a half inches high; it was made to hold twelve dark slides, each containing two quarter-plates. Proceeding to show the working, he opened a small lid at the back, inserted the slide in a groove, and shut the lid; when the slide is thus enclosed in the camera all that is required to make the exposure is to give a small lever on the outside of the camera a quarter of a turn. As this need only be done immediately before exposure, the sensitive surfaces are very efficiently protected against any dust which may find its way into the camera when travelling or carrying it about. A great safeguard against carelessness has been introduced here, as it was clearly demonstrated that it was quite impossible to withdraw the slide until it was securely closed. On examining the camera, it was seen that there was no delicate mechanism or springs to get out of order, and that the system was simplicity itself, merely consisting in inserting the slide and turning the lever. Mr. ZACHARIASEN said he had thoroughly tested the camera during a five weeks' tour in Norway, when about 150 films were exposed, without the faintest hitch or sign of fog in any one.

Richmond Camera Club.—At the weekly meeting, held at the Greyhound Hotel, Mr. Zacharasen showed a hand camera designed by him which, besides being light and compact, had some novel points. The plates are exposed in double dark slides of a new form, which are about half the thickness of the usual kind, and one third the weight. The slide is enclosed within a light-tight chamber in the camera, and the shutter of same opened from outside by means of a lever. Mr. S. H. FRY gave his lecture on *Lantern Slides with Gelatine Plates*, his remarks being chiefly concerning the Paget printing-out plates. He considered that the essential characteristics of a good slide were great brilliancy combined with great purity of tone. The shadows should be quite transparent, and there should be some clear glass in the picture. The question of colour was a most vexed one. At first, slides made on gelatine were cold in tone, but the result of several years' experience with them had made it possible to obtain almost any colour. For reduction purposes a fairly rapid plate was desirable, but to obtain the finest deposit the printing-out plates were the best. True, they were slow, but not as much as some believed, while a good method of development greatly overcame that objection. They could be slightly printed out and then developed, which, he thought, was the method giving the best results. He preferred a combined toning and fixing bath. It was essential to keep the bath either neutral or alkaline, hence he recommended the addition of a lump of chalk to it. To obtain warm tones on the ordinary lantern plates the exposure should be increased considerably, and carbonate of ammonia added to the developer, as it acts as a restrainer and colour-giver.

Ashton-under-Lyne Photographic Society.—October 4 and 5.—Dr. Hamilton, Messrs. Thomas Glazebrook, Samuel Woolley, and Robert T. Marsland gave an exhibition of stereoscopic views. Dr. Hamilton's contribution depicted views taken in Norway, Switzerland, and places visited by the Society during the summer. Mr. Glazebrook's were from the Isle of Man, North Wales, &c., including one or two very fine cattle studies. Mr. Woolley's views were mostly taken on the Society's rambles, and, as they were taken by his (own made) hand camera, many of them were a source of much amusement. One of the views, taken on the Marple ramble when at tea on the lawn at Joel Wainwright's, Esq., was very good. It was one of the Society's Vice-Presidents taking his last cup of tea, on the grass with an empty plate beside him, with a number of friends smiling around him. Another view was one taken on the Liverpool outing. It was at the time of the Liverpool assizes, and was taken from the top of the St. George's Hall steps as the Judge was leaving his carriage and coming up the steps. Mr. Marsland's views were nearly all taken on the river Dove, between Mill Dale and Hartington, with a few on the river Manifold. A large number of members and friends visited the rooms of the Society, and were very much pleased with the exhibition.

OCTOBER 11.—Mr. J. T. LEES gave a demonstration on *Lantern-slide Making.* There was a fair number of members present, and Dr. Hamilton, the President, in introducing Mr. Lees, said it had often been a matter of much curiosity and surprise to him to know what became of all the negatives of photographs when so many members of the different Photographic Societies were having rambles weekly all through the summer. He could not think that the whole of them were failures. One way of using those results would be shown by Mr. Lees. Mr. Lees, before giving his demonstration, had thrown on the screen a number of slides showing different faults in them, and pointing out where they could be improved. He also showed slides with clouds put on the cover glass, and then had the slide separated and showed the slide without cloud, thus showing the improvement by having a suitable cloud added to the slide. He then proceeded to expose and develop a number of plates on negatives provided by different members. He exposed six at once at different distances from the light, and after they were developed and fixed they were put into the lantern and thrown on the screen. He advised all new beginners to keep to one good brand of plates and one developer, and if they persevered they would in time become successful.

Gosport Photographic Society.—October 11, First Annual Meeting.—The position of the Society is regarded as thoroughly satisfactory, and during the year the membership has considerably increased. Special demonstrations and excursions have been held on various occasions, and were much appreciated. The Treasurer's account showed a balance of 10*s.* 11*d.*, and there were also outstanding subscriptions amounting to 1*l.* 2*s.* 6*d.* The heavy expenditure this year was caused by the purchase of apparatus, &c., which it was necessary to have. After the usual votes of thanks, Mr. Morrish proposed, and Mr. Churcher seconded, the election of Mr. R. E. Froude as President for the ensuing year. This was carried unanimously. The other officers elected were:—*Vice-Presidents:* Rev. L. J. Matthews, Mr. George Churcher, and Mr. T. E. Williams, R.N.—*Council:* Messrs. S. W. Furze-Morrish, H. Fisher, A. Fisher, E. Tucker, V. W. Misselbrook, and W. Moss.—*Hon. Treasurer:* Mr. W. B. Smith.—*Hon. Secretary:* Mr. Reginald E. Green, 8, Chapel-row, Portsea.

Leeds Camera Club.—This Club, formed a few weeks ago, has already attained most satisfactory dimensions, and promises to become one of the most popular and energetic Societies in the provinces. At the last meeting, held in the Club's rooms at the New Waverley Hotel, Call-lane, on Thursday, the 12th inst., seventeen new members were elected, and donations to the Club's Album, Question-box, Notice-board, Minute-books, &c., were promised by various members. The meeting gave its approval to a capital syllabus (which includes lectures, demonstrations, lantern exhibitions, and musical evenings), drawn up by the Committee for the coming session, after which a very instructive paper on *Exposure* was read by Dr. Thresh, the President, which was followed by an interesting discussion thereon. Next meeting, Thursday, October 26, at eight p.m.; subject, *Flashlight Photography*, by Monsieur A. Homburg.

Leicester and Leicestershire Photographic Society.—The Winter Session of this Society was very successfully opened on Thursday evening, the 12th inst., when a highly instructive lecture was delivered by Mr. H. COWDELL, one of the members of the Society, entitled *Snap-shots in the East*, illustrated with seventy lantern slides depicting scenes, manners, and customs of the Eastern people, all taken from negatives obtained by Mr. Cowdell with a snap-shot camera on his journey to Constantinople, Athens, Smyrna, and the Levant. The slides as they appeared on the screen were described with that piquancy and detail which can only be attained by personal acquaintance with the various subjects. The slides were mostly of a high-class character, as might be expected from an operator who has made this branch of the art his study, and altogether the lecture was highly successful, and may be taken as a happy augury for the progress of the Society during the ensuing season. The Mayor's Parlour, Old Town Hall, was quite filled with an interested audience, and at the close of the lecture a hearty vote of thanks was proposed by Mr. Matthews (Wigston), seconded, and carried with acclamation. Before the lecture the usual formal business was transacted. Nine members were proposed for ballot at next meeting, and one elected, and the members may be congratulated on the prosperity which is attending the efforts of the officers of the Society.

Rotherham Photographic Society.—October 3, Annual Meeting. Dr. Baldwin (President) occupied the chair.—The HON. SECRETARY presented the fourth annual report, which stated that the Society had increased in membership and local importance. It had become affiliated to the Photographic Society of Great Britain, had received official recognition from the Rotherham Corporation, having, by invitation, furnished a room in the newly opened public museum in Clifton Park, and had inaugurated a photographic survey of the district. As to the general work of the Society, there had been indications of improvement. Members were, however, urged to furnish negatives and prints for criticism, and to make fuller use of the question-box. The average attendance at the fifteen ordinary meetings held had been nearly nineteen. The papers and demonstrations had proved of great interest, while the four excursions—Ingleton, Wyming Brook (Sheffield), Roche Abbey (Rotherham), and Wingfield Manor (Derby)—were popular. The annual Exhibition in the early part of the year was very successful from a photographic point of view, and received a fair amount of public patronage. The opening ceremony was performed by Lady Albreda Fitzwilliam, herself a follower of the art-science. Acknowledgment was made of various journalistic contributions. The membership had increased to fifty-one. The report and balance-sheet (also presented) were approved. The balloting for the Council resulted as follows:—*President:* Dr. F. B. Judge Baldwin.—*Vice-Presidents:* Messrs. E. Isle Hubbard, W. H. Haywood, and G. T. M. Rackstraw.—*Hon. Secretary:* Mr. H. C. Hemmingway.—*Hon. Financial Secretary:* Mr. W. H. Shephard; Messrs. J. Leadbeater, W. Mason, J. W. Whittington, I. Wright, and W. Firth. Four new members were afterwards elected. The short time at the disposal of the meeting after the conclusion of the business was devoted to lantern-slide examinations and criticism.

Widnes Photographic Society.—October 11, Mr. V. C. Driffield presiding.—A paper was read by the Vice-President, Mr. G. J. Warner, F.C.S., on *Photography, Past and Present, and Hints to Beginners.* He briefly described the progress of the last twenty years, and compared the results of the collodion process with the present, advising beginners to use only slow plates, and to endeavour to obtain an accurate knowledge of the exposures required under varying conditions of light. He pointed out the objectionable yellowness of many old gelatine negatives, rendering them unfit for printing, and showed what were really the qualities of a good negative. The great advantage of plates correctly labelled and their relative sensitiveness was dwelt upon, and the necessity for the introduction of exact methods of work. The paper was illustrated by a number of prints and negatives extending over a long period. Five new members were elected.

Glasgow and West of Scotland Amateur Photographic Association.—October 16, Mr. Wm. J. B. Halley, President, in the chair.—Twenty-nine new members were elected. After the formal business was disposed of, the President addressed the meeting, referring briefly to the satisfactory position of the Association and the prospects of the session now opening. Mr. Stewart Smith, Vice-President, read a paper on *Enlarging*, and exhibited his apparatus suitable for daylight or limelight. At the conclusion of his paper, he made some exposures by limelight, and showed how to print-in a sky from a separate negative. Arrangements for the Annual Exhibition of members' work were discussed, the opening day being fixed for December 22. In connexion with this Exhibition, medals will be offered for sets of lantern slides with suitable lecturettes, which must be delivered before the Association during the session. The meeting terminated with the usual show of members' lantern slides.

Photographic Society of Ireland.—October 13, Professor J. A. Scott (President) in the chair.—The Society removed from the old rooms at 15, Dawson-street, Dublin, to more commodious premises at No. 35, in the same street. This being the first meeting of the session, and after the ordinary routine of the business was gone through, the PRESIDENT, in eloquent terms, welcomed the members and visitors, who together formed a good gathering, to the new premises, and in the course of his remarks referred to the past work of the Society, its present position, and the work to be done by its members in the future. After having touched upon many topics of interest, Dr. Scott notified to those present that the meeting of the Photographic Convention of the United Kingdom was to be held in Dublin next year, and further stated that members should give every assistance and make themselves useful in whatever way inclined towards making the Dublin meeting on a par with any of the former ones, and making it of special interest in order that Irish photographers might extend a very hearty welcome to a large number of their British brethren. Some very good slides were afterwards shown on the screen by the following gentlemen:—Mr. Corry, Mr. J. A. C. Ruthven, Mr. J. White, also some coloured slides by the President. Messrs. Hargrave and Cooper officiated at the lantern.

FORTHCOMING EXHIBITIONS.

1893.	
October 20–31	*Hamburg. Das Ausstellungs Committé des Amateur Photographen Verein, Schwanenwik, 33, Hamburg.
,, 20–Nov. 11...	*Photographic Salon, Dudley Gallery, Piccadilly, W. Hon. Secretary of Organizing Committee, A. Maskell, 215, Shaftesbury-avenue, W.C.
,, 20–Nov. 15...	*Photographic Society of Great Britain, 5A, Pall Mall East, S.W. Assistant Secretary, R. Child-Bayley, 50, Great Russell-street, W.C.
,, 30, 31	*East London Photographic Society, New Tabernacle, Old-street, E.C. Hon. Secretary, W. R. Gould, 61, Gibraltar-walk, Bethnal Green, E.
November 7–11	*South London Photographic Society. Hon. Secretary, C. H. Oakden, 51, Melbourne-grove, Dulwich, S.E.
,, 20–25.....	*Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, Rose Bank, South-west-road, Leytonstone.
December	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
,, 18–Jan. 22, 1894	*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

PHOTOGRAPHIC PERSPECTIVE.

To the EDITOR.

SIR,—Mr. Debenham's diagram is quite correct, and, indeed, represents a truism. But I must say that, being familiar with dogs, and breeding dogs, all my life, I cannot possibly conceive a six foot square kennel raised thirty feet from the ground. When Mr. Debenham, after writing about houses at a distance, likened them to "a row of dog kennels so near at hand and at such an elevation as to bear the same relation to the eye that the houses do in the first case," it never occurred to me that the parallel as accepted by Mr. Dennis Taylor presupposed that, to fulfil Mr. Debenham's conditions, the kennels were to be raised in the air and shifted to the right or left, or else the houses sunk into the ground instead of the observer's standpoint being altered. If that be granted, the rest is simple mathematics.

I read Mr. Debenham's remarks to refer to a row of houses and a row of kennels on a level plane. Certainly no more than this is involved in my original reference to the subject, and I repeat that under such conditions no change of position of the observer or camera would enable coincident perspective lines to be taken.—I am, yours, &c.

FREE LANCE.

WARMING THE DARK ROOM.

To the EDITOR.

SIR,—Under the above heading you inserted, in your issue of Sep. 29, a letter from me, recommending George's "Calorigen," and in this week's JOURNAL your correspondent "L. M." cautions your readers that I am "wrong in one or two points," but abstains from enlightening us upon what points. From the context, however, it would appear he falls foul of my assertion, "They will not answer connected with an ordinary chimney;" for he informs us that, eighteen years ago, he had a grate taken out and a George's Calorigen placed in the ordinary fireplace, and that it has worked ever since with perfect success—presumably in the same position.

It would have been better if "L. M." had stated more clearly where I was wrong; but, as the whole point of the paragraph lay in the statement they require "*two* openings making in an outer wall," the only legitimate inference is that he has placed his Calorigen in an ordinary fireplace *without two* communications with the external atmosphere; for obviously I laid no restriction on the actual position of the stove, "if this requirement" (two openings) "can be complied with." The chimney can be, and is sometimes, used as one of the necessary openings; but, for reasons given later (see sub-paragraph *b*), this mode, if it can be avoided, is undesirable; I much prefer to use the chimney as an extractor.

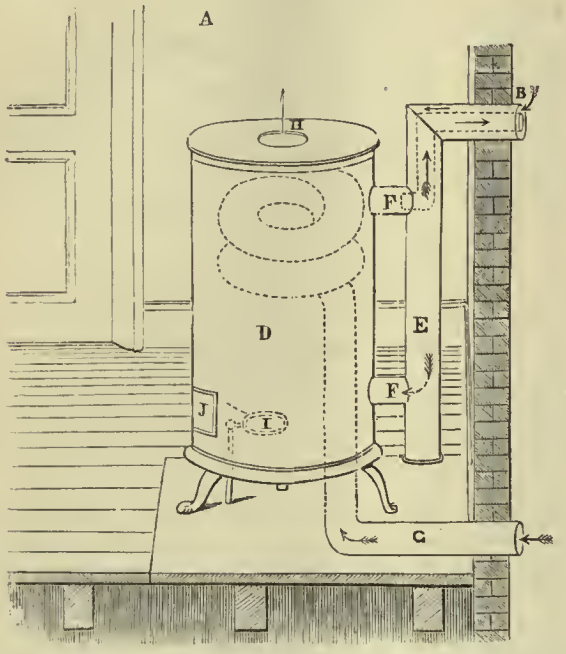
I do not for a moment question that, placed as "L. M." leads us to suppose he has placed his, the gas will burn and the room be warmed—indeed, heated more than if the stove be placed as I stated it should be. But I do assert most emphatically it is putting a really scientific invention to a degraded use, and one never contemplated by the inventor.

It reminds me of a case that came under my own notice a few years ago in Leeds. The committee of an Institute had gone to considerable expense in putting in Tobin's tubes to ventilate their lecture hall; the result, at first, was all that could be desired, but presently the benefit seemed *nil*. When I came to examine the place, I found every tube

stuffed up with brown paper. Upon asking the attendant for an explanation, he informed me had filled them up "*because they let in such a lo of air!*"

"L. M.'s" case is on all fours with this. For all practical purposes, George's Calorigen is a warm-jacketed Tobin's tube, and certainly does, when properly fixed, "let in a lot of air," which was the inventor's intention; but, perhaps, "L. M." prefers warmth to fresh air.

For the benefit of any one thinking of purchasing a stove, let me explain:—



The stove consists of a cylinder, D, containing a ring of ordinary union gas jets, I; these are lighted through the door, J, which is then closed *air-tight* by means of an asbestos packing, the two openings in the side of the cylinder supply the necessary air to the gas, G inlet, H outlet, both these should be carried by pipes through the wall, direct to the external air (these are the connexions sometimes made with the chimney, but as explained later it is an undesirable mode). It will be seen that thus the gas burns in a chamber absolutely cut off from all communication with the apartment, A, and contamination of the atmosphere is impossible. Inside the cylinder is a tube coil, for the admission of fresh air, the coil being over the flame, the lower end passes through the bottom of stove *and the wall of the apartment*, direct to the external air, the upper end opens into the apartment.

The action is this:—When the gas is lighted, an upward current is established in the coil, fresh air is drawn in from outside, is heated and passed upwards into the room. Thus, not only is the apartment warmed, but one of the main difficulties of ventilation overcome, viz., fresh pure air is introduced without the creation of chilly draughts and all other currents are *from within the room, outwards;* no mean advantage.

There has always been a difficulty in gas stoves drawing their supply of air from the room, and discharging to the outer air; shifting winds, sudden gusts, &c., so alter the balance of pressure between the inside and outside atmospheres that instances are not unknown of the gas flame being actually blown out, and most of us have at times seen a blowing forward of the flame from down draught. In the George's Calorigen, properly placed, this difficulty is ingeniously overcome by the outlet pipe, F B, being placed inside the inlet pipe, J F, the area of both pipes being approximately the same, with the result that whatever affects the pressure on one affects the other equally, and leaves the gas flame perfectly undisturbed.

Now, what happens with L. M.'s stove?

If it has no communication with the external air excepting by the chimney, it must (almost) be set in one of three ways:—

(*a*) F communicating with the chimney, B and G, with the room.
(*b*) F F communicating with the chimney, H, with the room.
(*c*) B, G, H all communicating with the chimney.

If *a*, the supply of air for the gas is drawn from the room, there is risk of contamination by down draught, and the atmospheric pressure is reduced, causing the balance to be restored by cold and often vitiated air rushing in from chinks in the floor or skirting board, or under the door.

If *b*, there must be a double current in the chimney, up and down, and very probably the gas is supplied with air strongly impregnated with carbonic acid, the result being imperfect combustion and reduced duty per cubit foot burnt. Also the ingenious arrangement of putting the tubes, F and F, one within the other must be omitted.

In both *a* and *b* arrangement, the coil is useful as a warming agent, but absolutely useless as a ventilator, the vitiated air of the room merely passing and repassing through the coil.

If *c*, The position would be too absurd to contemplate, the foul air from F merely passing into the chimney to be drawn back into the room through G.

In all systems of heating and ventilating, there ought to be provision made for both ingress of pure air and egress of foul; unfortunately, so far as I am aware, no gas stove is made that in itself provides both. George's draws air in, Fletcher's and others draw it out; but one being provided (ingress or egress), the other is usually left to chance or to a separate apparatus. It would be an interesting experiment to fix a calorigen in all particulars as I have described, excepting that the tube I, supplying air to the flame, should terminate in the apartment, the end being closed by a delicately-balanced swing valve opening *inwards*, to guard against back draught. Such a stove should keep the supply and pressure of air pretty constant, as much vitiated air being drawn over the flame as the coil admitted pure from the outside.

You, Mr. Editor, in your leading article this week on this subject, "sit" somewhat unmercifully upon my recommendation of the so-called syphon stoves; this letter is already far too long for me to trespass further on your space, but with your kind permission I may have a word to say in reply on a future occasion.—I am, yours, &c.,

Park Royd, Halifax, October 9, 1893. EDWARD J. SMITH.

P.S.—Messrs. Farwig & Co.'s address is No. 1, Upper Thames-street, not number 4.

DEVELOPMENT OF PARTLY PRINTED GELATINO-CHLORIDE PRINTS.

To the EDITOR.

SIR,—My attention has just been called to an article in the *Photographic Times* of New York (September 29, 1893, page 544), by Mr. Walter E. Woodbury, in which the writer describes the method of developing gelatino-bromide paper recently shown and published by us, giving exactly the same formula for development.

As this article is unfortunately, although no doubt unintentionally, worded in such a way that the reader may suppose that Mr. Woodbury claims the method as his own discovery, and as such supposition places us in a position requiring explanation, I will ask you to kindly allow me to state the following facts:—

The process was discovered by us more than a year ago, and Mr. Woodbury being in our employment it was shown to him, under promise of secrecy, some time last winter. I do not know the exact date, but certainly before he left our service in February.

On February 21 we deposited a sealed paper containing a description of the method with Mr. H. Sturmey, Editor of *Photography*, who, at our request, recently published it in *Photography*, October 5 and 12, together with a statement of how and when it came into his possession.

Why Mr. Woodbury has now published the process without our knowledge or permission I do not know, and can only suppose that in the change and excitement of his new position, and after the lapse of so many months, he had forgotten the circumstances under which he became possessed of the information. This seems the more likely, as he appears to have also forgotten an important detail, giving, as he does, "iodide" of potassium instead of "bromide" for the preliminary bath. Iodide is practically useless for the purpose.—I am, yours, &c.,

WM. J. WILSON,
Paget Works, Watford, October 14, 1893. *For Paget Prize Plate Co.*

MR. STILLMAN AND MR. BLAIR.

To the EDITOR.

SIR,—I regret that Mr. Stillman feels compelled to say in your issue of September 29 that "Mr. Blair neither comprehends clearly nor represents fairly" what he wrote in his letter published in your issue of July 21. I always supposed that the judges of open letters were the readers. If the first twenty or thirty lines of his letter referred to will be re-read, I think it will be concluded, by those having a knowledge of what it is "to make photography a practical affair," that I understood what he *wrote*. Whether I understood what he meant or not is another matter. It is quite apparent to me, from the reading of Mr. Stillman's letter in the September 29 issue of your JOURNAL, that he threw down the gauntlet too vehemently, and I have no desire to follow further. If Mr. Stillman was a producer of the articles which are relied upon "to make photography a practical affair," it would be easier to discuss with him. He would then realise the difference between a formula which will make a plate or film for an amateur's own use and one that makes photography by the masses practical. The same may be said regarding apparatus.

Fearing that Mr. Stillman did not mean just what he wrote, I was careful to say, in the commencement of my letter, what I understood him to mean as follows:—

"By making 'outdoor photography a practical affair,' I presume Mr.

Stillman means adapting it to be used by the masses; for photography as practised by some of the best workers is not the result of the apparatus, plate, or paper maker. Nor do I understand Mr. Stillman to mean the men who first conceived the idea of a sensitive plate without the silver bath. The knowledge of making a dry plate lay unused too many years to give to its discoverers (if such gradual gathering of knowledge could be called a discovery) the credit of the dry plate of to-day."

I will abide by the judgment of your readers, and regret deeply that the question of to whom the greater share of honours belongs should arise.—I am, yours, &c., T. H. BLAIR.

London, October 13, 1893.

WOOLWICH PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—We should like to inform your readers residing in the vicinity of Woolwich that the winter season of the Society will commence the 26 inst., with the annual business meeting, and continued the second and fourth Thursdays in the months to April inclusive. We have been enabled to draw up a good programme, and a cordial invitation to attend the lectures, &c., is given to all who are interested in photographic work.

The Hon. Secretary will be pleased to receive the names of all who wish to join us and to answer any inquiries respecting the Society.—I am, yours, &c., JOHN BOATHWICK PARTING,

3, *Friars Villas, Old Charlton, S.E.* *Hon. Secretary.*

October 16, 1893.

THE BENEVOLENT.

To the EDITOR.

SIR,—We have very many applications for the loan of a camera, or money to purchase a second-hand camera, from men who are perfectly willing to work, but who have been forced down by illness and other circumstances. If any of your readers had old apparatus that is still light-tight, though otherwise superannuated, we could make good use of it; and as our grants this year have far exceeded our income up to the present, and as we have in prospect many urgent applications, owing to the extremely bad photographic season, we feel loth to spend money on even the cheapest of second-hand cameras, if we can obtain old disused ones from sympathisers.—Yours faithfully, for the Committee,

H. SNOWDEN WARD, *Hon. Sec.*

P.S.—Stout soled boots, clothing, and hats we can well dispose of if any readers can spare them.

Memorial Hall, Ludgate-circus, E.C.

THE ACTION OF A LENS SIMPLY EXPLAINED.

To the EDITOR.

SIR,—I am much surprised and pained at your remarks in the issue of August 25, in which you practically accuse me of using Mr. Wm. Taylor's article and appending my signature thereto. In reply, I would inform you that my article on "The Action of a Lens Simply Explained" was written partly from notes and principally from my article on lenses in my *Encyclopædia of Photography*, which portion was written some five or six years ago. I have not a copy of Mr. Taylor's article, and therefore do not know how far my article resembles his, but would say that, as it is merely a written statement of the fixed laws governing the action of a lens, it is not unlikely to be similar to another article exactly on the same subject. With regard to the diagram, I discovered it among some scraps and cuttings. I sent it to the artist as a guide, with directions for a number of alterations to suit my article as first written. Except in one instance, however, these instructions were not carried out, so that the cut had to appear nearly the same. As it is an illustration of a ray of light passing through a lens, I should imagine that there was not much scope for variety.

With regard to my own article, I claim nothing original about it. The subject has been written upon thousands of times, and, so long as there are beginners in the art, will, no doubt, be written yet another few thousand times.—I am, yours, &c., WALTER E. WOODBURY.

New York.

[Having drawn the attention of Mr. William Taylor to the matter referred to in the preceding letter, we have received the following reply.—ED.]

DEAR SIR,—I have to thank you for calling my attention to a paper contained in the Convention number of the *Photographic Times* of New York, and pretending to be written by Mr. Walter E. Woodbury.

As a specimen of cool and impudent plagiarism, this work of Mr. Woodbury's is a model.

The paper, which is entitled *The Action of a Lens Simply Explained*, is a garbled transcript of a paper entitled *The Principles of a Lens Action* which I wrote several years ago, and which has been published in the *Amateur Photographer* and in all recent editions of my firm's catalogue of photographic lenses. (Taylor, Taylor, & Hobson.)

It is true that Mr. Woodbury has taken pains to say "the boy is not so tall as the man" where I have said "the man is taller than the boy," and that my diagram is shown with black lines on a white ground instead of with white lines on a black ground. This is very clever of Mr. Woodbury, and displays the character of his sparkling originality.

But from first to last, with slight periods of digression, and where there is embodied other matter whose origin is equally indisputable, the paper reads side by side with my own in the following way:—

Original.	*Plagiarism.*
As sound is transmitted by wavelike motion of the air, so is light transmitted by the wavelike motion of certain ether filling universal space.	As sound is transmitted by a wavelike motion of the air, so is light transmitted by the wavelike motions of this luminiferous ether.
A surface capable of being seen must be to some extent rough. The roughness acts in this way: Waves of light meeting the surface and reflected from it are broken up by the rough particles. Each projecting particle becomes a centre from which reflected waves of light spread out in all directions.	Waves of light meeting the surface of an object, provided it be to some extent rough, are broken up. Each particle becomes a centre from which waves of light are reflected and spread out in all directions.
The angle of view of a lens is determined by the relation of its focal length to the measurement of the image which it can usefully define.	The angle of view of a lens is determined by the relation of its focal length to the measurement of the image which it can best define.

I fancy the name of Mr. Walter E. Woodbury was not unknown to me before, but it is a surprise to find him capable of such a thing as this. It will be well for American Photographic journalism to purify itself from such impostnre and impostors.

We are accustomed to look upon America as the peculiar home of men like Mr. Woodbury, but I cannot think that the responsible owners and editors of American photographic journals contemplate with satisfaction such conduct.—I am, yours, &c., WILLIAM TAYLOR.

Taylor, Taylor, & Hobson, Slate-street Works, Leicester.

October 16, 1893.

THE PHOTOGRAPHIC EXHIBITION.

To the EDITOR.

SIR,—On my return from the Continent, and on looking through the catalogue of the parent Society's Exhibition, I find Messrs. Thevoz's book, *Zermatt*, classified as an apparatus. Here we have a new departure altogether, and about the first successful attempt to combine photography and its best application, "phototype," with letterpress. Nothing of the kind has ever been seen in the Photographic Society's rooms, and, I presume, because it cannot be hung on the walls, it is put down as an apparatus. The book is a production of art, and was not intended to be exhibited as "an apparatus."—I am, yours, &c. J. R. GOTZ.

19 *Buckingham-street, Strand, London,*

October 11, 1893.

THE MADRAS EXHIBITION.

To the EDITOR.

SIR,—Will you kindly allow me to state, for the information of intending exhibitors at our coming show,—

1st. That all pictures should be addressed to the care of the Hon. Secretary, Amateur Photographic Society of Madras, Royapuram, Madras.

2nd. That no forms of entry are required, but a list of titles for catalogue should reach me by November 20, 1893; the list should also state the particular prizes for which the pictures are competing.

Thanking you in anticipation for your courtesy, I am, yours, &c.,

FRED. DUNSTERVILLE, *Hon. Secretary.*

Amateur Photographic Society of Madras, Royapuram,

Madras, September 27, 1893.

THE FORFARSHIRE EXHIBITION.

To the EDITOR.

SIR,—The Committee of the now permanent Photographic International Exhibitions for Forfarshire for the advancement of photographic art for Forfarshire are to hold a Lantern-slide Competition in December and January next, and we shall be glad to receive slides from exhibitors. Open to all classes of photography, and to the best sets of six. The Forfarshire medal will be awarded. Particulars can be had of myself at Arbroath. I may also inform you that you may enter us in your new Year-book the officers of the above. Mr. James Watson Craik, is Local Secretary.—I am, yours, &c., W. J. ANCKORN.

THE SALON.

To the EDITOR.

SIR,—Will you kindly allow me space to correct a few inaccuracies in your notice of the Photographic Salon? You say that "the exhibits are the work of about 110 persons, *nearly half of whom* (the italics are mine), singular to tell, are also exhibitors at Pall Mall." The real facts are that out of 108 exhibitors at the Salon, 27 are also exhibitors at Pall Mall. Again, "We have already made the acquaintance of many of the pictures at other exhibitions." Out of the 294 pictures, only 11 have been previously exhibited anywhere, and even this applies, in the case of 9 of them, to the private exhibitions of the Camera Club. May I also be allowed to say that the Photographic Salon is no more intended to supplement the Exhibition of the P. S. G. B. than, for instance, is the Congress of that Society at the Society of Arts intended to supplement the annual Conference of the Camera Club held at the same place. You state that "the *raison-d'être* of the Salon rests on the most slender support, and the continuance of a second Exhibition, either in a rival or supplementary capacity, is out of the question." The predictions of last year, which have already been falsified, entitle us, I think, sir, to disregard such sombre prognostications, and, when we consider the support which the public have already given to our enterprise (a support far beyond our most sanguine anticipations) and the very general chorus of satisfaction expressed both by it and the public press, it is surely unwise to prophesy concerning the continuance of a successful Exhibition which has avowedly been instituted as the *first* of a series.—I am, yours, &c.,

ALFRED MASKELL.

Dudley Gallery, Piccadilly, W., October 17, 1893.

Answers to Correspondents.

J. DORMER.—Thanks.

A. J. GRIFFITHS.—Next week. Why not address your letter as directed?

G. W. O.—We fear that we cannot recommend any safe reducer for over-printed platinotypes.

COLLO.—You will find directions for working the collotype process at page 518 in the ALMANAC for 1893.

W. T. M. D.—You may find the information in Mr. W. T. Wilkinson's book; see also articles in back numbers of this JOURNAL.

JOHN SELF.—Possibly Messrs. W. A. Mansell & Co., Oxford-street, can supply you with oleographs and pictures of German production.

RAVEN.—A drachm was, doubtless, meant. Mix a portion of A with B and then redissolve the precipitate with the remainder of A.

J. G. RITSON.—Let the prints stop short of being quite dry and then pass through a burnisher, the roller of which is heated, several times.

B. COLLOTYPE.—1. Treat the prints successively with albumen and methylated spirit. 2. Solution of hydrofluoric acid will answer for stripping the films.

C. P. P.—1. Precipitate the gold by means of solution of proto-sulphate of iron. 2. We have found metol admirably suited for both time and instantaneous exposures.

PLATE TROUBLE.—See the pages of the ALMANAC, where several clearing solutions are recommended. It would appear that you do not use any preservative for your pyro.

D. S.—The white deposit on the Daguerreotype after cleaning is, in our opinion, caused by not having completed the final washing by *distilled* water. This is absolutely necessary.

F. W. R.—There are a number of magnesium flash lamps on the market suitable for the purpose. We cannot recommend any particular one. Consult the catalogues of the dealers.

JELLY says: "Will you inform me of any process by which gelatine can be hardened and made insoluble in water?"—Yes; mix chrome alum with it or bichromate of potash, followed by exposure to light.

INQUIRER (York).—Aluminium powder may be obtained from Mr. Horne, 2, White Horse-alley, Cow Cross-street, E.C. The metal can be had from the Phœnix Metal Co., Stamford-street, S.E., but we do not know if in the form of very fine wire.

T. T. SIMS says he has a new leather camera case that smells very unpleasantly, and asks if there is any way by which the smell can be destroyed. We know of no better way than exposing it freely to the air. Try keeping it out of doors, where the sun has free access to it, if possible.

RICHARD.—1. We cannot tell the cause of the discolouration—possibly the albumen was in bad condition. 2. We should think that if a Royal Prince had specially allowed you to photograph him you would be within your right in using the words "Under Royal Patronage."

HACKNEY AMATEUR.—Print a few sets of clouds on cover glasses. Let them be of different forms and degrees of density. Superpose them one after the other on the lantern slide, and select that which best harmonises with the subject of the picture. See also a note on this subject among our leaderettes.

T. CARPENTER.—We should say that, from the behaviour of the solution when it is spread on the paper, the gelatine contains grease. That is by no means an uncommon fault with gelatines of foreign manufacture. Try a similar preparation, but employing an English gelatine, say, Nelson "No. 1, Photographic."

A. P.—Possibly an unsuitable mountant was employed in the case where the prints deteriorated. If it was the same mountant throughout, we fear we cannot account for it.

D. W. A.—Glucose can be had from any operative chemist. When obtained from this source, a reliable article for experimental purposes can be relied upon. Glucose, in the form of a syrup, is an important article of commerce, and is largely used in confectionery, but it is not to be recommended for photographic purposes.

C. ROWE complains that last week he bought some gelatino-chloride paper at a photographic warehouse, and, upon opening it, he found it was discoloured and spotted; and from the date, or what was assumed to be a date, upon the package, it had been made over a year. No doubt, if this were pointed out the paper would be exchanged.

ALFRED R.—If a satisfactory likeness, as per circular, is guaranteed, we don't see how you can refuse a resitting if the sitter and friends do not approve of the portrait. The fact that the photograph is a good one in no way ensures a "satisfactory likeness." Most photographers consider it a matter of policy to please their sitters, although at times it is difficult to do so.

J. WITHERBY.—In the first attempts at photographic engraving it will be better to get the plates proved by a regular copper-plate printer. Although copper-plate printing seems very simple work, considerable skill is required on the part of the workman to get the best results from a given plate. A novice might mislead himself, as to the character of his plates, by his want of technical knowledge in the printing.

C. FOWLER.—The fault is not in the paper, but in the toning of it. You have taken the prints out of the bath as soon as they have acquired the tone desired when looked at by reflected light only. The tone of gelatino-chloride prints should be judged of by looking through them. The tones then seen will be much the same as they are in the finished picture when viewed by reflected light. Under-toning is the only fault.

C. H. C.—It is no use attempting to work the collotype process in the way proposed. A properly constructed drying box is an essential, as the plates must be dried in a horizontal position and not standing upright. Temperature, during the drying, is an important factor in the process, and means must be provided for regulating it. Extemporised arrangements should be avoided by the novice in his first attempts at collotype.

R. S. O.—The print in question is a collotype of inferior quality, and we should say was produced at a very cheap rate in a power press. We judge this by the coarseness of the grain. A coarse open grain can be printed from at a much quicker rate than one that is finer. With regard to the second query, machine collotypes can be produced quite as good as those by the hand press, but they require greater skill in working, and the press must be worked at a comparatively slow speed.

W. MASTER writes as follows: "I am experimenting with what I think is a new method of making typographic blocks. I have hitherto been using lead for the casting, but now I want to try with the same metal as that used by the stereotyper. On inquiring at several metal shops in different parts of London, I was told that I should have to make it for myself, and this I have no convenience for doing even if I knew how. Can you tell me anywhere where the metal can be purchased ready for casting?"—Our correspondent has been applying at the wrong places. He should have gone to a stereotyper's. We have little doubt but that any stereotyper will supply a small quantity of the metal he uses for experimental purposes.

I, 2, 3 says: "After developing some carbon pictures on the patent flexible support, and drying them, I applied the double transfer paper, just as I did with some pictures I produced on glass some years ago; but, when the transfer paper was dry, I could not get the picture to separate from the support, not even after soaking in water for two or three hours. Can you give me any reason for my want of success?"—The cause of the picture sticking is that the support was not waxed; or, if it was, not sufficiently so. In using the flexible support for the first time, it is a good plan to thoroughly wax it, according to the directions given with it, and, after it has stood for an hour or so, to treat it a second time. After the first time of using, a slight waxing only is necessary.

SUSSEX says: "I have a large glass dipping bath that was used in the collodion days, but it was left during the winter with some water in it, which froze and cracked the vessel from top to bottom. Do you know of any means of so repairing it that it could be used as a fixing bath for dry plates, as it would then be most useful to me? I may say that the crack is not open enough to run any cement in it."—The bath can be repaired in the following way: First stick a narrow slip of gum paper over the crack on the outside; then get a wooden case made three quarters of an inch larger inside than the bath is outside. On the bottom of the case—inside, of course—put a couple of strips of wood three-eighths of an inch thick for the glass to rest on, and similar strips at the sides and ends. Then pour into the intervening space melted pitch, or, better still, paraffin.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1747. Vol. XL.—OCTOBER 27, 1893.

AN IMPEDIMENT IN POPULARISING THE STEREOSCOPE.

The impediment hinted at arises out of the stupidity of photographers themselves. There are numerous photographers who, not certainly from any desire to do so, but from sheer carelessness or ignorance, act in the mounting of their pictures as if they were determined to do all that lay in their power to disgust the public with their productions, by trimming and placing them on their mounts in such a way as to render it quite impossible to see them properly in a stereoscope of the verage class.

We, and every intelligent writer and teacher on this subject, have invariably taught that, if the distance at which the two halves are mounted apart exceed three inches, such a difficulty in getting the prints to coalesce will be experienced as may lead to their unhesitating condemnation. We can sympathise with the desire of those who, having obtained a negative replete with beauty from side to side, are averse to having, as they imagine, its beauty marred by a rigorous cutting down of its sides; but it is altogether a mistaken liberality which prompts them to fill their mounts with pictorial subject, for this is the kind of generosity which impoverishes not the giver, but the receiver, as such a picture serves no good purpose, but only strains the eyes of the unhappy owner, who vainly strives to see the combination stereoscopically.

As we have often said, there is no limit to the vertical dimensions to which a stereoscopic pair of prints may be trimmed, should the subject demand it, such subject being a tall building, a ravine, or other object of like nature. But, as regards lateral dimensions, the case is altogether different, and it is in this respect where so many blunders are made.

We take it for granted that every photographer at least desires that his friends shall be able to see and examine his binocular efforts without trouble or pain—nay, more, that they shall do so with such readiness as to be insensible of putting forth any effort in doing so; and the object of this brief article is to urge in bringing about such a state of matters, more especially as this is so easy of attainment.

The condition requisite for the average human eyes seeing the stereoscopic effect of a picture at first sight, and without any straining of the muscles of the eyes, is merely to see that the distance of an object *in the foreground* of one picture from the same object in the duplicate does not exceed three inches. It would still be better were this distance an eighth to a quarter of an inch less. We say "in the foreground," because if a foot rule is passed over the near and the distant objects embraced in a binocular photograph, it will be found that similar objects in the foreground are separated to a greater extent than those in the distance; and that, whereas the former may be three inches apart, the objects in the extreme distance may not exceed two and a half inches. As a general rule, the nearer, within moderate limits, the elementary portions of the stereoscopic pair are placed together, the more easy is it for the eyes of the spectator to effect their coalescence.

But, if three inches be exceeded, the difficulty of effecting this is increased in a rapidly increasing ratio, until, when it reaches three and a half inches, coalescence becomes impossible to all but trained eyes, and passes even beyond their powers when such distance is exceeded.

And yet this distance is frequently exceeded by some makers, who fail to discover why there is evinced a disinclination on the part of the public to purchase their slides. Let it be noted that, although with a stereoscope having only a very small degree of magnifying power, wide subjects can occasionally be got to combine, this cannot be done with the better class of instrument, in which the lenses or prisms are achromatic and of considerable power, unless provision has been made to effect their separation to their utmost limits, and not even then if the separation of the pictures is much over three and a half inches.

When we consider the great influence exercised upon a stereoscopic picture by their trimming and mounting, it ought to behove manufacturers of these prints, in their own interest, as well as in that of the public, to pay some attention to this. To those who possess slides of valuable or interesting subjects, whether portraits or landscapes, which resist their efforts in bringing them into coalescence, we would say, steep them in tepid water so as to loosen them from their mounts, and retrim them to the extent of taking a quarter of an inch, or thereabouts, from the sides, finally remounting them.

Several years since we obtained a dozen slides of great interest from a foreign maker, who sinned very greatly in respect of the grievance we speak of; and it was not until we had trimmed and remounted them in the manner here hinted that we—or our friends—had any real enjoyment of the collection.

DIFFUSED DEFINITION: METHODS OF OBTAINING IT.

Some persons are apparently inclined to consider pictures of the "fuzzy" order quite a modern idea. Such, however, is not the fact, for over forty years ago, in the very earliest days of the art, the excessive sharpness given by the lens was objected to

by some, and different ways of destroying it were suggested. That advocated by the late Sir William Newton has been utilised by modern "fuzzyists," namely, the interposition of tissue paper, or other translucent media, between the negative and paper while printing. Later on, Mrs. Julia Cameron produced her extremely unsharp pictures by employing lenses possessing a large amount of spherical aberration, such as a single lenses with an abnormally large aperture. The object of the present article is not to touch upon the question of the desirability, or otherwise, of diffused definition, but rather to point out some of the ways by which it can be, and at different times has been, obtained.

It may here be explained that diffused definition produced by one system may be widely different from that obtained by another. For example, the diffusion in a picture caused by putting the lens out of focus, after focussing, is very different in character from that produced by using a lens possessing a certain degree of spherical aberration aud worked at its sharpest focus, as with a single lens with large aperture, or the lens of Mr. Dallmeyer, in which spherical aberration can be introduced at will. Unsharp pictures result in either case, but the effect is quite different. The late Mr. Claudet introduced a very ingenious way of destroying the excessive sharpness in any one plane, or as it was termed, diffusing the focus. His method was to alter the focus of the lens during the exposure. This he did, not by racking the tube in or out, but by causing the glasses themselves to approach towards, or recede from, each other, thus altering the equivalent focus while the negative was being exposed. The pictures produced in this way were very pleasing, and, although they were not really sharp, they did not appear to be blurred, or at all pertaining to the pictures of the present fuzzy school.

Many years ago a novel method was suggested for destroying excessive sharpness. It was this: A cord was tied to the camera and fastened tightly to the floor. Then, after a portion of the exposure had been made, a violin bow was lightly drawn across the string so as to produce a slight tremour in the camera. The blurring produced in this was distinct from that obtained by other means. Another plan was, during the exposure, or during part of it, to place a lighted spirit lamp some distance below the lens. This caused rarefaction of the air, and thus produced motion of the atmosphere similar to the heat haze so frequently seen near the ground on a hot summer day. This has a marked influence on the sharpness of a negative.

We have seen some very good effects produced by using a lens of the old doublet form in the following manner: The fixed stop had been removed and larger Waterhouse stops substituted. The exposure was commenced with a stop sufficiently small to give sharp definition. Then, when the negative was, say, half exposed, the stop was removed, and the exposure completed with the full aperture, which, of course, gave an unsharp image on account of the spherical aberration. Thus was obtained a somewhat sharp image as well as a confused one. Here, again, we had diffused definition of a different kind from that obtained by the other methods indicated. This system is also sometimes utilised in enlarging from small negatives in which the retouching is painfully conspicuous, or the face badly freckled. The exposure is commenced with a stop in the lens, and completed with the full aperture of the instrument. The character of the image thus obtained is quite different from that where the lens is put out of focus. Sometimes the lens is moved slightly in or out of the sharpest focus during the exposure, but the fuzziness produced by this method differs from that by the others. All the above methods of diffusing definition were chiefly utilised for ameliorating the excessive sharpness in large portraits, but it is obvious to every one that they can be equally as well applied to every other class of picture.

Reference was made at the commencement of this article to destroying the sharpness of a picture by printing through a translucent or transparent medium. That is often resorted to, but not always, perhaps, to the best advantage. Our older readers will remember a then new style of portrait that was shown in this country some quarter of a century or so ago—the invention of Denier, of Russia. The pictures appeared to be both sharp and unsharp at the same time, and were not at all unpleasing even to those who look upon excessive sharpness as an essential to a good photograph. The method by which they were produced was offered for sale as a secret process, and was never published authoritatively, though there was much speculation at the time as to what it was. It was said to consist of taking two thin negatives—identical—and printing from them with one superimposed upon the other. Be that as it may, we and others produced similar, indeed, identical and equally as good, results in the following manner. The negative, a perfectly sharp one—indeed, an every-day negative—was taken and placed in the printing frame with a piece of sensitive paper upon it and exposed to light. When the print was about half, or a little more, done, a sheet of thin glass, or, in the case of small pictures, two or three thicknesses of sheet gelatine, was interposed between the paper and the negative and the printing completed. By varying the depth of the contact printing and the thickness of the, afterwards, interposed medium, the effects could be considerably modified. It is a little surprising, considering the outcry that is sometimes made with reference to the excessive sharpness in large portraits, that this method of ameliorating it is almost, if not entirely, neglected; for, although the pictures thus obtained are not actually sharp, they can scarcely be classed as unsharp, unless the contact printing is too brief, yet they are quite distinct from the class of pictures termed "fuzzitypes." The effect can be further varied by making what may be termed the primary printing through the insulating medium, and completing it with the paper in contact.

MATT-SURFACE PRINTS ON ORDINARY PAPER.

As a matter of course, the choice of the method of sizing will depend, in a great measure, on the character of the paper to be used, for which any of the plans mentioned may be employed with a smooth-surfaced sample; it would obviously be undesirable to adopt either of the plans that involve rubbing in the size with a sponge when the surface is at all rough. Under such circumstances a very uneven coating would be obtained at the best, and it is more than probable that the surface texture of the paper would be ruined and rendered totally unfit for the purpose intended.

With moderately rough paper, a rather thin solution of gelatine, applied evenly with a brush or by floating and subsequent draining, will give the best results. The solution must not be thick enough to confer any glaze when dry or to collect in the hollows or inequalities of the surface, and one of the kinds of gelatine that swell but little under the influence of moisture will be found to answer the requirements best. For

very rough paper, such as drawing-papers, the aqueous shellac solution has given us by far the best results, as it answers a variety of purposes. It fills up the body and hardens the texture of the somewhat porous paper, without any production of gloss, better than gelatine, and is far easier of application than such substances as arrowroot. It, moreover, more completely isolates any chemical impurities, such as so frequently exist in that class of paper; but, where any special tendency in that direction is found to exist, it is advisable to apply a double coating, the first being allowed to thoroughly permeate the paper, the second, with which the salting may be combined, being applied after the first has become perfectly dry.

The second coating, under these circumstances, will be wholly on the surface, for, after the mixture of lac and borax has been once dried, it becomes insoluble in aqueous solution at the ordinary temperature. For this reason, although the salting solution itself may be allowed to soak completely into the body of the paper, the sensitising solution subsequently applied penetrates only to a very slight depth, and the image is thus kept well upon the surface. Bearing this in mind, we are enabled to secure beautiful evenness of sensitising on even the roughest paper by adopting the following course:—

The combined sizing and salting solution described last week, consisting of the aqueous lac solution to which chloride of ammonium has been added, is used, and may be applied with a brush and allowed to soak well in, or the paper may be floated on or immersed in the solution until thoroughly permeated. The superfluous solution is then removed by dabbing with a sponge or pressing gently between blotting-paper, leaving only that which has been absorbed into the paper, which is then allowed to dry completely, in which state it will keep well for an indefinite period. To sensitise it, the silver solution is applied to one surface, either by floating or by means of a suitable brush, and, after having been allowed a stated time to act, the surplus is removed as before and the paper again dried. In this manner an evenness of printing surface is easily obtained that it is almost impossible to secure by other means, as, when the size is only drained off, it is apt to collect in the irregularities of the surface, which necessarily absorb a larger proportion of the salting and sensitising solutions afterwards applied.

With regard to the sensitising very little need be said, if the sizing and salting of the paper have been first properly performed. The bath consists of a plain solution of nitrate of silver, which may vary in strength from forty to sixty grains to the ounce of water, according to the strength of the salting and other circumstances, bearing in mind that, the stronger the salting and sensitising, the richer will be the resulting prints, and the easier will it be to secure pure black tones. For grey or light tones the sensitising solution may be weaker, but it is always advisable to let the salting and sensitising bear a direct relation to one another. A sixty-grain silver bath answers well with a salting solution of ten grains to the ounce, which is as strong as is usually necessary; but for very thin negatives, or where great contrasts are required, both may be increased, or the reverse when the negatives are hard.

The ammonio-nitrate bath was a great favourite with many workers in the old days, and is made by adding to the plain silver solution, drop by drop, strong liquid ammonia, stirring well at the same time, until the precipitate at first formed is redissolved. This bath fell into disuse on the advent of albumen paper, for which it is quite unsuited, on account of its solvent action on the albumen. Its chief recommendations are that it gives greater rapidity and more vigour with proportionately weaker solutions. But the paper keeps only a very short time after sensitising, which will prove an objection in the eyes of many modern practitioners who have become accustomed to ready-sensitised and keeping papers.

The ammonio-nitrate bath formed in this manner contains a very considerable proportion of ammonia, but its advantages may be secured in a modified form—that is to say, with a reduced proportion of ammonia—by dissolving only a portion of the silver nitrate, and converting that into ammonio-nitrate, as above described, and afterwards adding the remainder of the silver. Or, it may not be generally known, if a small quantity of nitrate of ammonia, or other alkaline nitrate, be dissolved with the nitrate of silver, any quantity, however small, of liquid ammonia may be afterwards added without causing any precipitate, although, with a plain *new* solution, the first drop of ammonia would cause a dense cloudiness. After using the solution for sensitising, as old silver printers are aware, ammonia may be added without causing a precipitate, owing to the presence in the bath of the alkaline nitrate formed by double decomposition.

Plain paper keeps better after sensitising than albumen without any special precautions, but it is preferable to use it as soon after sensitising as possible. If it must be kept, the addition of a minute quantity of nitric acid to the silver solution will greatly increase the period in which it will retain its whiteness; and, though this addition raises some little difficulty in the way of securing certain tones—purple, for instance—its influence will not be seriously felt when black or grey tones are desired.

So far we have supposed our matt-surface paper to be prepared in the well-known old-fashioned style, by separate salting and sensitising; but it is equally open to apply the more modern system of combining the two operations in emulsion form. We do not intend here to give any formulæ or directions for the preparation of the emulsion, as these will be found amongst the formulæ in the ALMANAC. We wish simply to remark that the matt surface is obtainable with emulsion in ordinary papers with as much ease as by simple salting, the glossy surface familiar to the users of commercial gelatine paper being obtained by special means. When an emulsion is used, there is in a general way less necessity for the preliminary sizing, since the emulsion itself, owing to its thicker nature, has less tendency to sink into the paper than plain aqueous solution. Some papers, however, do require sizing, but where such proves to be the case we should be inclined to change the paper rather than resort to an additional operation when thoroughly suitable papers are to be obtained. When sizing is considered necessary, we remark that the aqueous lac solution is not suited for use with emulsion, owing to the fact that the alkali it contains combines with the soluble constituents of the emulsion, and not only causes irregularity in printing action, but entirely alters the character of the tone. It must be borne in mind that in sensitising in the ordinary way the salted surface has presented to it a practically unlimited quantity of silver capable of combining, not only with the soluble chlorides, but also the alkali, and still leaving an excess. In the case of an emulsion, however, containing as it does but a small excess of soluble silver salt, to which it owes its special characteristics of tone, the presence of alkali (borax) in the surface of the paper suffices to upset the balance and utterly change the nature of the sensitive surface.

While there is no great difficulty in the preparation of emulsions for printing purposes, we doubt whether many of our

readers at the present day will care to venture on the task. Still, if they do, they will not find it an insurmountable one. The chief difficulty will be in the application of the emulsion to paper; and this is, perhaps, greater in the case of the printing-out emulsion containing soluble matter than on that of a negative emulsion or one intended for development. Floating the paper upon the emulsion will be found in every respect the easiest plan for getting an even coating, but it involves the necessity for keeping the emulsion liquid without raising the temperature too high, which soon causes discolouration of the organic salts in the preparation.

Pouring the emulsion on to the paper laid, either damp or dry, upon slabs of glass, is altogether unsatisfactory without special appliances for keeping it stretched tight, besides which it is difficult to secure an even coating sufficiently thin to avoid gloss. A rough-and-ready mode of coating, introduced by Mr. T. G. Whaite some years ago, answers very well for emulsions free from soluble matter, but is not so satisfactory with the printing-out preparations. It consists in applying the emulsion in the solid or jelly state by means of a stiff brush, spreading it evenly over the paper with a sort of dabbing or stippling action, and then passing the paper over a hot plate to liquefy the gelatine and cause it to form a homogeneous coating. But even this requires a lot of care and proper appliances.

Perhaps the best plan will be found that recommended by Mr. W. K. Burton a short time back, in which the sensitive materials are applied to the paper by floating it upon a very thin emulsion—thin, so far as gelatine is concerned, but rich in silver salts. With chloride of silver, such an emulsion is easily made of sufficient thinness to cause no trouble in keeping it liquid, and will present the minimum of difficulty to the inexperienced.

Examination of Ether.—According to Herr G. Traub, good ether, in contact with caustic potash for twelve hours, should not undergo any change. At intervals during this time a few drops should be let fall upon blotting-paper, and the odour scrutinised. Also, if ether be slowly and carefully added to sulphuric acid, and the whole kept well cooled, not the slightest discolouration should take place.

Soap Bubbles.—As this subject has lately been before our readers, we may give the formula for a solution, recently given to the Paris Academy of Sciences; it is said to afford thin and very permanent bubbles. Yellow resin and carbonate of potash of each equal weights, and water ten times that weight, to be boiled together till solution is complete. Before use the solution is to be diluted with four times its volume of water.

Quick Preparation of Hydrogen.—Messrs. J. G. C. Macdonald and John Ball have recently written to the *Chemical News* stating that they have found the addition of a small quantity of solution of nitrate of cobalt to the zinc in making hydrogen leads to a greatly increased rapidity of evolution of that gas. For those lantern experimentalists who wish to use hydrogen in place of ordinary coal gas, it is evident that this "wrinkle" will be of considerable service.

Monochromatic Yellow Light.—Herr H. E. J. G. du Bois uses a Linneman burner, in the flame of which he introduces a soda rod, preferably of a diameter of 0·4 cm. and a length of 12 cm. to 15 cm. The rods are made of a mixture of sodium bicarbonate, sodium bromide, and tragacanth gum. Herr E. Pringsheim uses an Argand burner for white or monochromatic light at will. For the latter he injects a spray of salt solution by means of a T-tube into the gas current. When the latter is put out of use, of course the ordinary white flame is given.

Patents' Abridgments.—The difficulty first besetting a would-be patentee is the novelty or otherwise of his invention, and to meet this the Patent Office is publishing a new series of illustrated abridgment classes. They have been arranged according to subjects, and include all specifications of patents applied for between 1877–83. They are excellently grouped by the Comptroller-General, and will be found most useful. Optical instruments are a class of most interest to photographers, and include improvements in telescopes, microscopes, stereoscopes, magic lanterns, lenses, reflectors, &c. Various tripod stands find a place in the volume.

Light-dispersion Difficulties.—In the course of his treatise upon the photography of the most refrangible rays of the spectrum, Prof. Schumann says that the "photographic result in the most refrangible ultra-violet would have fallen out far better if the light which originates on the refractive phases, and in the interior of the prisms and lenses, had not regularly illuminated the visual field so strongly that on prolonged exposure the whole plate is coloured more strongly than the spectrum itself. We might, indeed, as I observed in 1888 with the spectrum apparatus of Simony, considerably reduce the diffused light by shortening the slit length to a minimum (0·2 mm.); but even here, on prolonged exposure, it overpowered the delicate impression of the most refrangible rays to total invisibility."

A New Incandescent Arc Lamp.—As the "glow lamp" has little actinic power in ordinary photographic work, and the arc lamp requires more skilled attention, considerable interest will be taken in the new electric illuminator described in the title of this paragraph, the invention of Mr. L. B. Mark, M.E. The arc is enclosed in a small envelope of highly refractory glass, closed at top and bottom by plugs, through which the carbons pass. A safety valve is placed in one of the plugs, to avoid undue pressure in the globe through the heating and expansion of the inside air. Upon closing the circuit, the oxygen is consumed and the gases brought to a very high temperature, at which they maintain the carbon vapour coming from the arc. This vapour is deposited upon the internal surface of the glass in a very thin coat. The glass globe must be small, and then the heat usually dissipated in the air is conserved, and raises the temperature of the enclosed gases and carbon vapour. Under these conditions, the arc itself is almost invisible, but the entire chamber becomes luminous, giving the appearance of a solid cylinder of light. There is not quite so much light efficiency from a given amount of electricity as with the ordinary arc lamp, but far more than with a glow lamp.

SOME CURIOUS EXPERIENCES WITH METOL.

I SHOULD like to place on record some rather curious experiences I have recently had with images developed with metol, and compare notes with other workers, with a view of ascertaining whether such occurrences are really due to some difference in the deposit or image formed by the new developer, or to other unsuspected causes.

Some time ago, I think, I remember reading a complaint of some difficulty or peculiarity in the behaviour of the image developed with amidol, I think, in the fixing bath, and I set it down at the time chiefly to imagination, or something like it. Possibly others may attribute my "experiences" to the same cause, though I have most carefully examined the whole of the circumstances, and can arrive at no other conclusion than that there is some difference—what, I cannot say—between the composition of the metol image and that produced by other developers.

The first case I shall mention, although it is the most recent chronologically, more particularly stamps the difference between the different developers, although, had the phenomena occurred indis-

criminately, I should have thought little or nothing of it—photographically, at any rate. A number of negatives were left in the printing frames for a period of some days—about eight or nine—in contact with ordinary printed paper which had been used as the backing pads. It was precisely the same paper—in the same publication—in all cases, and the same paper had been in the frames for several months. The negatives alone differed in character, some being developed with metol at different times during the past three or four months; one or two with hydroquinone, also recently; and the rest pyro-developed, four or five years old.

On taking the negatives out of the frames, it was found that several of them had been bleached perfectly white, or rather a dirty, yellowish-white in patches, just such a colour as is produced upon a gelatine negative by any of the hypochlorites; and, if the occurrence had been universal, and not strictly partial, as it was, I should have set it down to the action of a considerable quantity of "antichlor" in paper having been set in motion by accidental damp.

But, when I say that every one of the metol negatives was so affected and not one of the others, it would appear to be too singular a coincidence, that just those particular frames should have been touched by damp and no others. However, to test the matter, I took the pad that had been behind the very worst affected negative and placed it in contact with a recently developed hydroquinone film, selecting that because it might be that the age of the pyro negative had given them a protective hardness. Now, after more than a fortnight's contact there is no trace of any impression. There I leave that question for the consideration of others.

The next case is a most curious one, and offers absolutely no data on which to proceed to explain it. Two portrait negatives of the same individual were taken, as I can remember, amongst the first of those I developed with metol several months ago, and they were amongst those which from their quality first interested me in the new substance. I have other negatives taken on the same day, and about the same day some developed with metol and some with pyro, but these two are the only ones affected in the manner I shall describe. They have been, with others, packed away for some time in the ordinary plate packing boxes, simply placed face to face in couples, with nothing between them.

On taking out the two negatives in question a few weeks ago, the image in both cases had changed to a peculiar pinkish-brown colour, where it had originally been black, and closely resembled in appearance, I remember so well, faded negatives that had been intensified with iodide of mercury and hypo in years gone by, though it is needless to say no mercury in any form had been near these. Both, too, showed a considerable loss of detail, one being much worse than the other in this respect, the half-tones and finer details having been apparently completely eaten away, and represented by perfectly clear glass.

Now, there is no reason to suppose that those two negatives received any different treatment in the matter of length of washing or other circumstances than the rest of the negatives taken on the same day. If anything, they would have a slightly better washing than many of the others, as they were taken in the morning, and would, according to my habit, remain in the washing rack until the end of the day's work. Otherwise, I might have set the result down to insufficient washing and the consequent fading action of hypo, although neither the colour nor the appearance of the film would in any way lead to that conclusion. But these two out of many are the only ones affected.

The curious part is that under treatment, one of them with bichloride of mercury followed by ammonia, the other with plain sulphide of ammonium, the whole of the lost detail returned, and, though the negatives are by no means "beauties" to look at, they print nearly as well as at first.

The last instance I shall give is partly explainable, so far, at least, as the fading is concerned, though it remains to be explained in this case why only metol images are affected. Several negatives were found to be, some partially, some wholly, turned yellow as if converted into iodide of silver. Some time ago I tried the method given in the JOURNAL for detecting the presence of hyposulphites in the negative after fixing by treatment with iodide of potassium; but, not having that salt at hand, I used iodide of ammonium, the remnants of a bottle that I have had for fifteen or sixteen years, and which had become a mass of yellow crystals saturated with a deep brown-coloured liquor.

What the chemical action of this complex decomposition product had been upon the images to which it was applied I cannot say; but there was the result, but only on those negatives developed with metol. Can any readers of the JOURNAL throw any light on these puzzles?

W. B. BOLTON.

CONTINENTAL NOTES AND NEWS.

Thiosinamine.—Thiosinamine, which our readers will remember was employed by Colonel Waterhouse in his reversal experiments, has been suggested as a fixing agent by Herr Liesegang, who thus enumerates its advantages and properties. An aqueous solution of thiosinamine (CS,NH_2NH,C_2H_3) fixes gelatino-chloride plates as rapidly as hypo; for bromide films it takes longer to act. Chloride papers are completely fixed in four minutes in a one per cent. solution of thiosinamine. With gold chloride solution thiosinamine may be used to form an energetic combined toning and fixing bath. Aristotype prints so treated resemble platinotypes. Concentrated acids (HCl for example) do not decompose it or minimise its solvent powers; alkalies should not, however, be employed with it. It does not injure the image in any way. Unfortunately thiosinamine is very costly—120 francs per kilogramme.

Development of Partly Printed Proofs on Albumen Paper.—Herr. Valenta directs the usual exposure to light to be reduced to a fourth or a fifth, and recommends the following developer:—

A.

Hydroquinone	10 grammes.
Alcohol	100 c.c.

B.

Sodium sulphite	100
Citric acid	5
Water	500 c.c.

For use take 5 c.c. of A, 5 c.c. of B, and 100 c.c. of water. The violet tone of the print rapidly passes to a yellow brown, and development is finished in about ten or eleven minutes. The prints are next washed and toned in a sulphocyanide bath. The following combined bath, recommended by Messrs. Lumière for their citrate of silver paper, also answers:—

Water	500 grammes.
Sodium hyposulphite	200 „
Ammonium sulphocyanide	25 „
Alum	30 „
Solution of acetate of lead (1:10)	40 „

Heat to sixty degrees and filter. To each 100 c.c. of the solution add 50 c.c. of water and 10 c.c. of a one per cent. solution of gold chloride. This bath will tone in about ten minutes. The following pyro developer may also be employed for the purpose:—

Water	1000 grammes.
Sodium sulphite	100 „
Pyrogallol	10 „
Citric acid	11 „

This developer, even after use, keeps well. The prints are washed in the usual manner when taken from the printing frame.

A Solder for Aluminium.—This solder is the invention of a Norwegian, and it is composed of cadmium fifty parts, twenty parts of zinc, and thirty parts of tin. The zinc is first melted, the cadmium is added, and finally the tin in fragments; the mass is melted and well stirred, and then run into ingots. The solder may be employed for other metals as well as aluminium, the proportions of the ingredients being varied to suit circumstances. A strong and tenacious solder requires a large proportion of cadmium; to obtain the greatest possible adhesiveness, the proportion of zinc must be large; great polish is obtained by increasing the tin.

Longevity of Aristotype Paper.—M. Hoffmann has recently printed and toned some Aristotype paper which he bought in Moscow in 1886, and which had since gone through many climatic vicissitudes. Excellent results, without degradation, were obtained.

AUXILIARY EXPOSURE.

Quite early in the days of collodion, a slight exposure, either before or after the camera exposure, was advocated, but no very satisfactory results appear to have been obtained. Now and again the subject is revived, apparently only to be put aside without coming to any definite conclusion. So long as the eye alone is trusted to estimate the results, this must necessarily be so, for it is quite unable to correctly estimate the resulting alterations, also the introduction of extra fog is very misleading.

If only confined to an intentional exposure, few would be in any way interested, but, as an auxiliary exposure may be given in various ways unintentionally, its precise effect seems to need a little investigation. It may occur thus:—

1. During the manufacture of the plates.
2. Light received when changing plates.
3. Reflection from the surfaces of the lens or camera.
4. Light received during development.

1. The exceedingly careful manufacture of the present day has reduced this to a very small amount, so small indeed that Messrs. Hurter & Driffield, in their method of estimating the speed of plates, found that the reduction of silver due to this cause might be simply classed with the opacity of the glass and gelatine, and the reduction due to the chemical action of the developer; that is, that the total opacity due to these three causes combined, might be taken as uniform over the whole plate, the effect of which is simply an increase in the time required for printing, the gradation of the photograph remaining unaltered.

2 and 3. When, however, a considerable amount of light has reached the plate, the action becomes important. Instead of a uniform reduction of silver all over the plate, we have now a uniform time addition to all the exposures, the amount of which is, of course, unknown. Its true effect is easily obtained by giving certain known exposures and a known auxiliary exposure to a part of the plate, afterwards comparing the opacities obtained.

On page 458, July 21, Diagram No. 2, Messrs. Hurter & Driffield give all the necessary data by which the altered curve due to auxiliary exposure may be plotted, thus, with, say, one-candle meter second auxiliary exposure, the new curve would be found by taking from the diagram the density due to 1·312 C. M. S. exposure and marking it off upon the ·312 C. M. S. line. In similar manner throughout, 1·625 upon ·625, 2·25 upon 1·25, &c.

Notwithstanding that the densities are found to be greatly increased where the exposures are small, nothing is gained, but rather the contrary, because the total range of density has been reduced, and the shadow detail must therefore be less, seeing that the high lights remain almost the same as before. Anything whatever that may cause auxiliary exposure before development should therefore be carefully avoided. (See also p. 634.)

4. Light received during development. This will be found to vary greatly in its effect, because at first it begins by acting in a similar manner to auxiliary exposure before development; but, as development proceeds, it is really printing through a partially formed negative upon the sensitive portion still remaining. The ratios, both of density and opacity, are now completely altered, and, if the auxiliary light is excessive, not only is there much fog, but with some plates reversal of the shadows.

In order to test the action fully, plates which had received the usual test exposures for the determination of speed were partly developed, and, after giving an auxiliary exposure, the development was completed. The period of correct reversal with the best plates so far found is very small, still it is sufficient to allow of a direct positive being taken in the camera, instead of a negative, provided always that both the camera and auxiliary exposures are calculated very accurately.

It is necessary to arrange that the highest lights may come about in the position where the shadows begin to be correctly represented in a negative. Owing largely to the high lights being degraded by the weak negative developed before the auxiliary exposure is given, the results at best are poor compared with a transparency made in the usual way from a negative.

Only comparatively slow plates appear to give any available latitude; but, as the exposure required to obtain a positive is only about one-thirtieth to one-fiftieth of the time needed for a properly exposed negative, an actinograph speed of about 600 has been reached, or about four times the rapidity of the quickest plate yet put on the market.

Any attempt to alter the gradation of a negative by auxiliary exposure during development appears therefore far more likely to spoil it altogether than to result in any improvement.

J. Sterry.

THE ENGLISH LAKE COUNTRY.

[London and Provincial Photographic Association.]

If any one should contemplate making a visit to the English lake district he can hardly do better than go to Ambleside in the first instance, making excursions from that picturesque centre as opportunity may offer. I was, last June, led to take this course, and I obtained the hint by the simple expedient of consulting a map, for the map told me that within a short walk south of Ambleside was the Head of Windermere, about an equal distance north was Rydal Water, Rydal Hall and Waterfall, and that a short distance from there another lake, *Grassmere*, could be reached. There were thus three of the English lakes within the compass of a short ramble from one another, besides waterfalls, glens, and other beauties, which seemed to make Ambleside a most advantageous centre. To Ambleside, therefore, I went, and found no reason to repent my choice.

It is a quaint village beautifully situated in a valley, the hills rising all round it except in a southerly direction, where they open out towards Windermere. Windermere, although, I believe, the largest of the lakes, is tame in aspect when compared with the others, moreover, it is so narrow that it has more the appearance of a river than of a closed-in piece of water. The hills surrounding it are not high, and they mostly slope gently down to the edge of the water, park-like in appearance and studded with private residences. Beyond a few sky and water effects I did not attempt any photography on Windermere.

One of the oldest, prettiest bits in Ambleside is the mill, which I now show you. It has been immortalised by Turner and by many other lesser artists, and has evidently not changed much in appearance during the past 100 years. At the time of my visit there was very little water, for, though the lake district is generally considered to be a very damp neighbourhood, it shared in the general drought of 1893, and the waterfalls were robbed of much of their usual grandeur. Ambleside is essentially a tourist rendezvous, and there are coaches coming in and out of the town continually, which run in connexion with small steamers on Windermere. One morning, in a back lane, I came upon a picturesque smithy. There is nothing very noteworthy about my picture, save that it is taken with a hand camera. But the glory of Ambleside is Stock Gill (a gill, I should tell you, is a narrow ravine, with a rapid stream running through it). A bobbin mill stands at the entrance to Stock Gill; but when I photographed it—again with a hand camera—there was certainly not water enough to make it bob, or do anything else. Turning our backs upon the bobbin mill, we can walk for half a mile or so up one of the sweetest ravines in the lake country. There is hardly enough water to make a connected stream. It is more like a collection of deep pools, variegated by boulders. In the peat-stained water of these pools you can see the trout playing about by hundreds, and wondering when some rain is coming to refresh them. This is a lovely stream, which affords a picture at every few yards. Here, on a dull day, and in the absence of wind, with a short-focus lens, stopped down, you have a photographer's paradise. You can either follow the river-bed, or you can climb the high bank, which carries you sometimes fifty feet or more above it. The scenery is grand under both conditions. But you do not reach the highest point of the glen before you hear the sound of tumbling water, for you are approaching Stock Gill Force. The water here makes three falls, altogether seventy feet in height, and you will notice that the principal fall is divided into two by projecting rocks. After a few days' rain, I am told, the scene here is of the grandest description, the water playing over the rocks in a sheet of foam and amid clouds of spray. When I visited it, the water was half-asleep.

I have already told you that Ambleside is a convenient centre from which excursions can be made, and one of the first which I undertook was to Rydal. The village has nothing interesting about it, save the house called Rydal Mount, where the poet Wordsworth lived for so many years. I did not go there, for the whole district is flooded with photographs of the place, and I was content to leave it alone. Close by is Rydal Hall, the seat of Lady Le Fleming, and I was far more interested in this place because the grounds contain two noteworthy waterfalls. On my way thither I passed some rough ground, with a promising group of

cattle perched high up on a granite hill. I stalked them, and had a shot at them. But cattle are the most unsatisfactory models, and always group themselves as badly as possible. Nor will they take a hint to do better; if you pitch a stone at them, they simply move away.

On the main road, just outside the village of Rydal, is a mass of rock with steps cut in it so that one can reach the summit. Wordsworth is said to have chosen this point as a favourite resting-place. It is now so overshadowed with trees that nothing can be seen from the summit. Doubtless it was different in the poet's time. It is noteworthy that you are ta liberty to climb these steps without paying for the privilege. You have to pay for most things in the lake district; it generally costs you a shilling to see a waterfall. This is certainly the case with the falls at Rydal. You call at a cottage for a guide, and the guide solemnly unlocks a side gate into the park and takes you there.

The upper Rydal Fall is half a mile from the one which we just saw. You can only see it from one point, and from the nature of the surroundings I do not think there is any other choice as to the position for your camera. If you want a more comprehensive view, you must therefore do as I did, and screw on to your camera a shorter-focus lens.

Rydal Lake is one of the smallest in the district, but at the same time one of the most beautiful. It is not a mile in length, and scarcely a third of a mile across, so that you can make the circuit of it in little more than an hour. But every step will open up to view fresh beauties; and one gets so satiated with the loveliness of nature, that you feel the same kind of exhaustion as you do after an hour or two in a picture gallery. There are one or two islands on the lake, small as it is, and here the wild fowl congregate in peace, for no one can disturb them.

The guide-books to the lake district are most aggravating to read, for at every third or fourth page they quote Wordsworth. The copyright on that good man's works has run out and such quotations are cheap.

Near to this spot, on the high road, is Nab Cottage, where Hartley Coleridge lived.

In the lake country, if you want to take photographs, you must do a lot of trespassing. And this is not always easy work, for hedges, hurdles, or gates, are replaced by very stony stone walls over which you have to climb at the risk of breaking your neck.

Here, on the left of my picture, you will see the kind of wall I mean. But some of them have loose stones artfully arranged on the top, so that, although you can climb up there, you find yourself on a very insecure place, and feel as if you and the wall too were on the point of tumbling down.

Continuing on the road by the side of Rydal Water you come to Grassmere, which is also a very beautifully situated lake. Far away at the head of the lake lies the village of Grassmere and Grassmere Church. This is one of the very ugliest churches in the kingdom, but the guide-books rave about it principally because Wordsworth and Hartley Coleridge lie buried there. It is so much photographed that I did not care to add to the number of pictures. But I changed my mind when far away by the side of a mountain rivulet I caught a glimpse of it through the trees. Here distance certainly lent enchantment to the view. Besides, there was no one to worry me with quotations from the deceased poet.

A conspicuous feature of the scenery of Grassmere is a strangely shaped conical hill called Helm Crag, of which this is a distant view. It is very beautiful on a cloudy day to watch the rapid changes which come over a mountain like this, when the shadows chase one another up the sloping sides, and foreground and distance are alternately bathed in sunshine.

A good pedestrian has a great advantage over persons who have to depend upon another animal's legs. He finds his way into nooks and corners where the common tourist never thinks of wandering. I discovered this years ago in the Highlands, and I rediscovered it in the English lake country. As an example of what I mean, let me show you a few views taken of a small piece of water known as Loughrig Tarn.

"A tarn," says the guide-book glossary, "is a small sheet of water usually high up among the mountains." Now, you know why the tourists don't go there, it involves a heavy climb, and there is nothing but water to drink when they get there. But it is a beautiful spot, and well worth the barking of your shins in the climb over numerous walls, before you find yourself there. You run a chance of losing your way unless you carry a map and compass, as every wanderer should do, for houses are few and far between, and you meet no one among these solitudes.

Please observe the bit of disturbed foliage in this picture. I thought at first that this was a flaw, but showed it to a friend, and he raved about it. He was an impressionist. He said that, if the picture were his, he should destroy it, all but that bit in the corner; this he would frame, for, whenever he looked at it, he could hear the leaves rustling.

It is the fashion, as you all know, to set more store by a little figure study than by a landscape pure and simple. I do not agree with this notion. It is far easier to pose a figure by a cottage door, for example, than it is to conquer the difficulties of a view like the one before you. Any one who has tried to take a landscape like this, with distant hills bathed in sunlit atmosphere, will know what these difficulties are.

Leaving Loughrig Tarn, I made my way to Grassmere, and so home to Ambleside. On my way I passed through some exquisite scenery. Having spent a week at Ambleside and its surroundings, I resolved to go by coach to Ullswater. They charge you 5*s.* for the trip, and make you walk half the distance. Directly you leave Ambleside, the coach begins to go up hill until you reach the Kirkstone Pass, 1500 feet above, after which you come to Brothers' Water. The guide-book says that this name is derived from the sad circumstances of two brothers having lost their lives here, and it adds, "an accident which occurred twice." Now, you can imagine a man losing his life once, but he must be abnormally careless to lose it twice. These guide-books are really not reliable.

[*Mr. Hepworth then described how he arrived at Ullswater, and photographed the objects of interest round about that beautiful lake, once more returning to Ambleside through the picturesque village of Troutbeck, where he found many opportunities for camera work. His paper was illustrated by about sixty lantern slides.*] T. C. Hepworth.

DEVELOPED GELATINO-CHLORIDE PRINTING-OUT-PAPER.

[Photographic Record, Manchester.]

The following notes on my experiments in exposing and developing gelatino-chloride paper refer, for the sake of simplicity, to amidol alone. The other developers may be dealt with at some future time by myself, or some other of our members may be induced to turn their attention to it, and give us the results they may obtain. The subject is full of interest and the difficulties surrounding it are but trifling. I prepared a stock solution as follows:—

Hot water	5 ounces.
Amidol (Hauff)	20 grains.
Sulphite of soda (Johnson's)	4 drachms.
Potassium bromide	20 grains.
Hydrochloric acid	20 drops.

When cool it is ready for use, and is to be diluted with water as required.

By varying the proportions of the solution by the addition of water, in conjunction with the exposure, a variety of tones may be obtained. Thus a short exposure, with a strong solution of amidol, produces dark tones; while a long exposure, followed by a weak solution, gives warmer tones. It will be observed that the solution is distinctly acid and strongly restrained.

Three different tones may be obtained as follows:—Procure a fresh packet of Ilford P.O.P. (I have found that to act best so far), and, having selected a good quick printing negative, take them into the dark room—for the paper must only be opened in a ruby or orange light. Place the negative in a frame, and insert a sheet of the paper just as carefully as a bromide sheet or lantern plate is dealt with.

The exposure is now to be made by daylight. Expose the first sheet, say, for four minutes, and, if on returning to the dark room a faint image is visible, remove the print and put another sheet in its place. Let the second exposure be for two minutes, and then follow on with the third, giving it one minute. Mark the time of each exposure on the back of the sheets with a soft black lead while they are in the frame. This will save confusion.

To develop take

Stock solution	1 ounce.
Water	1 „

First soak the sheet that has received one minute's exposure in a weak acid-water bath (two drops of hydrochloric acid to the pint of water), and then immerse in the above developing solution. If the paper begins to darken where there has been no exposure, it is an evidence of under-exposure. If the exposure has been right, it will commence to develop very slowly. When complete, pass it direct into the fixing bath—hypo (saturated solution) one ounce, water three ounces. Over-development will produce a veil on the surface of the paper. When this is seen, the print must be placed at once in the fixing bath, and must remain there until it is removed. This may require half an hour or so. Keep the print face down in the fixing bath.

Now treat the second and third prints in the same way, using the same developing solution, &c.

If all has gone on right, we should have three prints, exhibiting three different tones. The one that has received one minute exposure should be of a black tone, the two minutes' exposure should be a warm sepia brown, and the four minutes' exposure should be a light sepia approaching to red.

I have also been able to obtain very good results with the following combined developing agents:—

Amidol	3 parts	and pyro	1 part.
Amidol	3 „	„ metol	1 „
Amidol	3 „	„ glycin	1 „

Any of these may be employed without using an accelerator, but, if development requires to be hastened, a few drops of a 10 per cent. solution of carbonate of potass, or carbonate of soda, will accomplish it.

The stock solution of acid-amidol I have already given makes a very good developer when reduced to half strength for the Nikko paper just introduced by the Eastman Co. A good printing negative will require from ten to twenty seconds' exposure at one foot from the gas.

HENRY SMITH.

A PAINTER'S VIEW OF THE PHOTOGRAPHIC EXHIBITION.

II.

WHEN I commenced this desultory article I hoped briefly to notice the most interesting pictures in the show; but, as I find so many which are both highly interesting and beautiful, I shall be compelled, from want of time and space, to confine my remarks to the few which demand special attention.

No. 27, *Sous les Couriers Roses* (collotype), by Emile Frechon. This is the first of a set of five, Nos. 30, 36, 65, 195. The subjects seem to represent native life and scenery in Algeria. They are truly artistic in treatment. The prints are about 12 × 10, mostly vignetted on large sheets of drawing-paper, texture not coarse, and the part on which the print is impressed seems to have been smoothed a little. I almost forget what the collotype process is; I know very little of processes, or of the scientific mechanism by means of which photographers produce their pictures, but, if these pictures have been printed by machinery in a printing press, they are very beautiful results. No. 195 is the finest. It is on smooth paper, with a glazed surface. The clearness, and transparency, and the perfect definition are delightful. A medal has been awarded to No. 30, *Un Harem en Déplacement*. It should have been awarded for the five. It represents an Arab caravan in full swing, the ladies of the harem, in course of removal, being sacredly guarded from the gaze of profane eyes, in large, tentlike arrangements on the backs of the camels. As might be expected, the definition of the moving objects is not *quite* sharp, but it is sharp enough, and the motion is well represented. Neither is the landscape beyond the figures sharp; if the distance had been left sharp, it would have come forward against the softened figures, and have thrown the picture out of harmony. M. Frechon probably blurred the distance to prevent this. In such an exceptional case blurring becomes a virtue, not a vice; it is neither photographic depravity nor unworthy trickery.

No. 40, *Omegna, Lake Orta*, by J. A. Sinclair. Medal. A print destroyed by the extreme coarseness of the paper used; the rough, obtrusive texture is quite out of proportion to the small size of the print and the nature of the subject; it arrests the attention, destroys all feeling of soft, delicate, and atmospheric effect in the sky and distance—or such distance as is left—and brings them right up to the foreground like portions of a rude stone wall. What is called Lake Orta is actually depicted as a rough field, the surface of which is slightly obscured by a light fall of snow. A confused figure of a woman in the immediate foreground, although it helps the composition, is placed too near, and comes out too large in proportion to the trees, &c., which it dwarfs. I observe that these prints on very coarse paper invariably destroy atmosphere and the light and tender passages, and they destroy the clear, soft, liquid, and transparent character of water, which is not often obtained in photographic pictures. The delicate and refined qualities have all suffered from this epidemic of photographic small-pox, or measles, or both combined. The injury to the darker or nearer parts is not so apparent, but the *finer* qualities of good photography are *wilfully* destroyed; its great softness, and delicacy, and harmony of gradation, its marvellous wealth of detail, and its wonderful accuracy of definition, peculiar to itself alone, and which cannot be approached by any other of the graphic arts, are all cancelled. In support of my assertions I shall call the evidence of an able expert, Mr. J. A. Sinclair himself, who shall prove, by the admirable work of his own hand, that my protest is not uncalled for.

Now turn to the opposite wall and look at No. 184, *Lago D'Orta*, three hand-camera pictures (platinum) by J. A. Sinclair. The central picture is an exquisitely delicate and beautiful representation, on a smooth surface, of *Omegna, Lake Orta*, apparently printed from the same negative from which the small enlargement, No. 40, was produced. In the small picture we have not only the soft atmospheric effect, but a clear representation of the distant mountain on the left, and much beautiful detail which has been textured out of existence in the large copy. I quite admit that coarse paper may occasionally be used, without much disadvantage, for large studies of a suitable character—for instance, Mr. J. A. Sinclair's fine study, No. 204, *An Ancient Mariner*—and I believe he is well entitled to a medal for the general excellence of his work in the gallery; but, for No. 40! No, it does not represent artistic progress, it is photographic retrogression.

No. 55, *After Sundown*. A poor little photographic scrap on coarse paper—an attempt to imitate a sepia drawing by hand. Any landscape painter could make a better sketch in fifteen minutes. The flat-streaky sky in this nondescript thing looks as though it had been photographed from a first attempt by a little boy. Medal awarded. No. 84 contains seven admirable female heads (carbon) by Gebrüder Lützel, of Munich, each in a different colour, and cleverly transferred on to one large sheet of paper. No. 79, *Portrait*, a life-size head of a girl, injudiciously got up in an enormous frame and mount. No. 80 is an autotype enlargement from a negative by F. Bayley. This picture is full of majestic solemnity and poetical suggestion, but the beauty and harmony of the whole scene are marred by the tumble-down appearance of a lake in the distant mountains; it may be in correct perspective, but it does not look so; the reflection is so white, and the outline so hard, that it seems as if a piece of paper had been cut out and pasted on to the spot; this is just one of those inherent defects which cause a mechanical photographic reflection of a subject to differ from a work of art. It is printed rather darkly, in a blue-black inky tone, which detracts from its value, which is still more depreciated by contrast with the shine of the gold flat, and the richness of the warm brown or maroon colour of the frame.

No. 103, *The Proud Turk*, by J. S. Bergheim. Medal. This looks printed on one of those sketching boards for students, embossed with a surface to imitate canvas (these imitation tricks are bad—they had better pay a trifle more and get the genuine canvas mounted on boards), but Mr. Bergheim says it is a transparency over yellow blotting-paper. The effect would have been better if the paper had not been so yellow. The background is too light—no outline of right shoulder visible; figure, face, and background all same tone. Nevertheless, the study is manifestly produced by a man with fine artistic feeling. A better effect might possibly have been obtained by a tinted glass in front of the picture. Many of these cold bromide prints might be redeemed by a glass of a light amber tone, or a moonlight effect, for instance, might be effected by a glass lightly coloured greenish-blue.

No. 146, *Fountains Abbey*. Remarkable for the definition of the architecture and the transparent purity of the shadows. No. 154, four studies in red carbon, by W. J. Byrne, in a handsome, heavy, very dark green and gold frame, which weakens and overwhelms the studies in the four openings; the red is made to look very hot, and, as the colour cannot reach any depth in the shadows, the prints look poor and faded, although they are not really so. There is a complete absence of colour harmony. A frame of this tone would have suited the Ceylon landscape, No. 80, and *vice versâ*. If a photographer would take a print, say 8 × 6, of neutral tone, and get three mounts several inches wide round the opening, one blue, one red, one yellow, and place the blue, then the red, then the yellow over the print in succession, he would observe that the blue would, by contrast, give it an orange tone, the red would give it a greenish tone, and the yellow would give it a tone inclined to purple. Of course, no one would use a positive blue, red, or yellow mount, but a light or dark mount of a blueish, reddish, yellowish, or neutral tone should be selected to suit the requirements of a print. If three prints of the same subject, exactly of the same tone and strength, are used for the same experiment, and the blue, red, and yellow mounts are applied simultaneously, side by side, the effect of the contrasts will be more apparent. The eyes should rest briefly on the colour of each mount before looking at the print.

No. 156, *Portrait Study* (direct carbon), about 16 × 14, by H. Bullingham. I mention this pleasing portrait of a young lady because it affords an instance of the *judicious* use of the texture. Here it is that of ordinary drawing-paper—not rough—and nothing could be more appropriate to the character of the subject and the size of the picture. Moreover, paper of this texture is well adapted for receiving water colour.

Nos. 189 and 197 contain some valuable studies of *Animals at the Zoo*, by Henry Sandland. These are examples from a large collection of animal studies which that gentleman has formed by great assiduity and perseverance. In the case of some of the more shy and restless animals, he has only obtained his negatives after years of patient waiting and watching for his opportunity. Many of the finest animals are now dead. In some cases specimens to replace them can scarcely be hoped for. His collection will probably form the nucleus of an important zoological picture gallery, which would be of great service both to zoology and art. Buffon said, "*Le génie n'est autre chose qu'une grande aptitude à la patience.*" If this be true, then does Mr. Henry Sandland deserve to be regarded as a man of genius.

I now arrive at the magnificent *Figure Studies* by Count W. von Gloeden, which I came specially to see. They are the finest examples of pure and artistic photography that I have ever seen anywhere. Some of them would bear comparison with classic works of fine art by such painters as L. Alma-Tadema. There are twenty of them, commencing with No. 213. Although it is a matter of no significance, I may as well mention, *en passant*, that a medal has been awarded for No. 241. It would be

doing them an injustice were I to attempt to describe the excellence of their quality within a brief space. I must therefore content myself with advising every artist who has the opportunity to go and see them for him or herself,

No. 248, by John Howson. Medal. A passable little picture, *A Calm before a Storm*—clouds, water, and boats, apparently got up in imitation of an oil painting. It is a silver print, very yellow. The yellow helps to give a glowing effect of evening light. It would have looked bad had it not been saved by being harmoniously framed close up, without any mount, in a gilt frame, such as would be used for an oil painting. But—good gracious!—what have we here in No. 254? A small, miserable abortion of photography, a female figure in a sitting posture, with a black face, and a dreadful something—meant for a hand, wrist, and arm—in front of it, the ugliest representation of a portion of the human form I ever saw. *Mirabile dictu*—medal awarded! After this shocker, how refreshing it is to look up at those exquisite *Roses* by George McDonald, M.D.

No. 306, *Portrait* (direct, untouched, carbon), by Alfred Werner, of Werner & Son, Dublin. This is the grandest example of photographic art in the Exhibition. It is a full-length, life-size portrait of a charming lady, it is hung in a corner, and the large plate of glass renders it very difficult to see it properly; in some minor points it might have been better—for instance, if the left arm had been slightly turned round to show less of the back of the arm and more of the front edge, the outline and proportions would have been seen to more advantage; and, if the skirt of the dress on the same side had been drawn out a little, the lines might have been better. But, taking the composition as a whole, if this picture had been painted in oil colour, it would have been up to the average of full-length portraits to be seen on the walls of the Royal Academy or in Continental Exhibitions. Of course, this splendid photograph is passed unnoticed by the wonderful Judges who were capable of bestowing medals on scraps No. 55 and No. 254.

No. 322, *Dr. Carlyle*, from the painting by Sir G. Reid, P.R.S.A. (gravure). Sir George is the leading portraitist in Scotland, but this is not a happy example of his work. It is a side view of the Doctor, who appears to have almost turned his back on the spectator, whom he is taunting over his shoulder, with a disagreeable, sinister expression. Now refer back to No. 268, *Dr. Carlyle*, of Langholm (taken direct), a life-size head, by J. B. Scott. Observe what a much more pleasant and genial character the Doctor looks in the photograph.

No. 323, *The Lamb*, from the painting by Fred. Shields (gravure), apparently reproduced from an engraving.—The children afford a very poor example of Fine Art, when compared to portraits, in the exhibition of children about the same size, produced by photographic art. Nos. 319 and 333 are admirable reproductions of art, by R Keene; they are mounted and framed to perfection.

No. 329, *The Newhaven Packet*, from the painting by H. T. Moore, R.A. (gravure). A most successful Autotype reproduction.

No. 334, *A Yacht Race*. A carbon enlargement, printed in colour by Elliot & Son. This is an interesting experiment, but I doubt if this kind of printing can ever rival the results already attained by photo-chromo-lithography. I must finally notice a beautiful example of artistic furniture, No. 279, *Photographs from Nature decoratively applied*, by Fred. Hollyer. This indicates a grand field for the direction of photographic enterprise.

PALETTE.

FOREWORDS: ON PHOTOGRAPHY AS ONE OF THE GRAPHIC ARTS.

[Catalogue of the Photographic Salon.]

Among the monochrome arts photography seems to hold a place nearer to the copper-plate processes than to any others. Like them, it is a negative process, a plate being produced from which positive impressions are afterwards made. As in etching, the original plate is made by chemical means; as in mezzotint and aquatint, the drawing is in tones, not lines; but, unlike any other process, this drawing is accomplished by the action of light, without the interposition of the hand.

Although not entirely limited by what is presented before it, the camera is not much used to show its power of invention, being employed, generally speaking, to reproduce more or less accurately what actually exists before it at one time. The way in which it shall do this, however, is a matter that is to a very great degree under the control of the user; to a degree far greater than is usually suspected by either artists generally or by casual photographers.

The selection and use of the lens according as either special emphasis or a generalising effect is required, the selection and relation of exposure and development, the choice of printing method, including the varieties of surface texture, and, perhaps more than all, an infinitude of devices, selection, and modifications of effects by the skill and knowledge of the handicraftsman in printing; these allow a range of variations in treatment, that is amply sufficient for the expression of the worker's individuality or idiosyncrasy, artistic and poetical, or otherwise.

Among the chief virtues possessed by photography as a medium for artistic expression may be mentioned:—

Its great delicacy of tonal gradation.

Its ready securing of aerial perspective, as shown in many cases of twilight and mist effects, and in the rendering of atmosphere and distance.

Its means of fixing the forms and positions of rapidly changing subjects, as shown in the transient effects of moving water and clouds, and in so-called instantaneous pictures generally.

Its giving absolutely faithful drawing and perspective of any subject, however difficult, from an actual as distinguished from an imaginary standpoint.

Its adaptability to very varied classes of subjects, and above all, and through all these qualities, the wonderful naturalness of its results, a naturalness which must appeal to every observer and which is compelling closer study and knowledge on the part of all draughtsmen and painters.

These and many other points might be named, to show the great range of possibilities for the artistic employment of photography.

That photographers at times do not use their process to the best artistic advantage may be true; but, if so, the fault is with the worker, not the method.

The dull diagrammatic prose of the earlier types of work is giving way to a more subtly suggestive style of treatment; and the initial blankness of wonder at its possibilities has been, or is being, gradually replaced by a clearer perception of what it can do well, and can do, for certain classes of subjects and effects, with a perfectness unapproachable by other methods.

Perhaps the greatest curse of Photography in the sense now under consideration is the fatal ease with which indifferent work may be produced by its means. But for the best work as much artistic feeling, as much technical proficiency, and as much patience and care are required as in any other of the graphic arts; among which, for the intrinsic beauty of its products, it certainly deserves to hold an honoured place.

HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

Good though it undoubtedly was, we are inclined to think that this year's Exhibition of the Hackney Photographic Society, which was held last week at Morley Hall, N.E., hardly equalled its immediate predecessor in point of average quality, particularly in those classes which were then its greatest strength, viz., those open to non-members. Again, there seemed to us to be room for improvement in the hanging of the pictures, while their classification was, perhaps, not altogether successful. Still the Exhibition was, on the whole, a very meritorious one.

Class A (members' pictures not previously exhibited for competition) might with advantage have been much smaller, and we throw out a suggestion that in such Exhibitions a restricted number of pictures from members should only be admitted. Mr. W. J. Hensler had a series of thirty New Zealand views, mostly showing great cleverness in selection and treatment, especially in combining crispness with atmospheric effect. The silver medal he obtained was well deserved. Mr. S. J. Beckett justly obtained the gold medal for a fine *Evening—Verona, North Italy*, a most effective sunset view, clouds and water being ably handled, the red tone of the picture giving it a striking effect. Mr. S. Moore's two interiors of St. Thomas's, Upper Clapton, Mr. S. J. Beckett's photographs in the Polytechnic Schools, the same gentleman's bold *Sunrise in the Hardanger Fjord*, all stood out prominently in this class. A word of praise is also due to Dr. Roland Smith for a picture of *Bricketwood Farm*, in which the commonest objects of the farm side were availed of to make up a fresh, charming, and yet unconventional study. In this class the Judges awarded a silver medal to an obviously poor piece of landscape work, which had not even the now fashionable property of being out of focus.

In Class B (hand-camera pictures, enlargements permitted) Mr. S. J. Beckett showed an interesting picture of the *Fram* (Dr. Nansen's ship) on her way to the North Pole, and Mr. R. Beckett a fine *Sunset—Trondhjem* (silver medal). Mr. Hensler's Ilfracombe views, Mr. T. E. Roofe's entertaining *Pelicans at the Zoo*, Mr. W. L. Barker's really admirable enlargement of *Southend*, and Mr. R. Beckett's other lurid-toned studies were conspicuous.

In Class C (new pictures taken at Club outings) Mr. F. W. Gosling had a view of the river Roding quite in Colonel Gale's style, and a delicate view in Wanstead Park by Mr. T. H. Smith deserved notice.

Class E (unmedalled pictures) included good and bad work. Among the former was Mr. Wellington's *Still Delight* (silver medal). *Sighting the Fleet*, a large picture of a mechanically posed woman "sighting" something "off," was an example of what to avoid in the way of constrained attitude. Other good work in the Class was shown by Messrs. W. England (*The Matterhorn*), W. Thomas, W. M. Warneuke (landscape, bronze medal—a clever unaffected study of ladies in a field of flowers), R. Frost (*Gladiolus* and *White Grapes*), Dresser (No. 369, seascape, being, however, too woolly and lifeless), Birt Acres (two admirable studies of *A Woodland Path* and *Beeches*), F. W. Edwards (architecture).

Class F (portraiture and *genre*) was a small and poor one. Mr. R. Beckett showed a study of a head, that of an elderly gentleman, which appeared as if somewhat over-touched. This year Mr. Beckett shines rather in landscape, &c., than in portraiture.

In the Champion Class Mr. Wellington easily won the gold medal with *Eventide*, a river-side study of great feeling.

Besides two classes for lantern slides there were several pictures not for competition, and among these was a series of clever *Dogs*, by Mr. Fall (by the way, we must quarrel with Mr. Fall for, in a portrait of Mr. Gladstone, having made the Premier look nearer sixty than eighty), some splendid large direct portraits by Mr. A. W. Wilson, jumping horses by Elliott & Son, &c.

Quite a good show of apparatus was on view in the centre of the Hall, Mr. A. P. Chalke having a display of artistic picture frame mouldings; Messrs. W. Watson & Sons, a selection of their well-known specialities; Mr. F. E. Morris, miscellaneous; Messrs. Fuerst Bros., amidol, metol, &c.; Mr. W. Wray, a case of lensee; Mr. H. Park, cameras and apparatus; Platt & Witte, a fine show of lanterns; Wm. Rawlings & Co. and Messrs. Doublet also having stalls.

Our Editorial Table.

Catalogues Received.

Newman & Guardia, 92, Shaftesbury-avenue, W.—Messrs. Newman & Guardia's catalogue is devoted to illustrated particulars of the firm's specialities in shutters, hand cameras, changing boxes, &c. The descriptions given are admirable in clearness and completeness.

M. W. Dunscombe, 10, St. Augustine's Parade, Bristol.—Herein are included details of a large assortment of photographic apparatus and sundries, together with much useful, practical information on the selection of a camera, development, printing, &c.

Chipper's Double Dark Slides.

Mr. W. C. Chipper, of 39, Highgate-hill, N., has submitted to us a sample double dark slide which he is supplying singly or in quantities. The slide is well made, has reeded draw shutters, and is light-tight. Its strongest characteristic is its price, a half-plate costing 5*s.* 6*d.*, other sizes being supplied at proportionate prices. The slides are cheap and efficient.

News and Notes.

Lewes Photographic Society.—Next meeting November 7, Lantern Evening of Members' Slides.

Photographic Club.—November 1, Annual General Meeting. 8, Members Open Night.

Brixton and Clapham Camera Club.—Next meeting, November 7, *Lantern Slides by Reduction*, by Mr. Butler.

Leytonstone Camera Club.—October 28, Members' Lantern Evening, Chair taken at eight o'clock. Members will please bring slides.

London and Provincial Photographic Association.—November 2, Demonstration by Mr. S. Herbert Fry, *The Paget Lantern Plates*. 9, Lantern Night.

Putney Photographic Society.—Monday, November 6, at eight p.m., at Boys' Gymnasium, Charlwood-road, Mr. S. Herbert Fry on *Unconventional Printing Methods*.

By referring to our correspondence columns, it will be seen that an open social meeting of the National Association of Professional Photographers will be held at Coleman's Hotel on November 10, to which all photographers are invited.

Messrs. Hobson & Co., Wellington, Shropshire, will shortly publish an architectural account of *The Churches of Shropshire*, by D. H. S. Cranage, B.A. It will be illustrated from photographs specially taken for the work by Mr. Martin J. Harding.

Liverpool Amateur Photographic Association.—November 2, Lantern Slide Making. *Lantern Slides, Reduction with Magnesium Ribbon*, also *Toning Chloride Slides*, by Mr. G. A. Carruthers. *Lantern Slides, Reduction by Daylight*, by Mr. Harry Holt.

Central Photographic Club.—Friday, October 27, Demonstration of *The Carbon Process*, by Messrs. Elliott & Son. We understand that "one man" shows are contemplated. The rooms are now open all day, an attendant being in charge. The dark room will be ready shortly.

Croydon Camera Club.—Fixtures: November 1, *Harmonising Harsh Negatives*, by J. Macintosh, and *A Chat on Lenses*, by G. R. White, instead of Mr. Gear's paper, postponed to December. 15, Special Public Lantern Display at Braithwaite Hall. Admission by ticket, price sixpence.

Redshaw's Backgrounds and Accessories.—Mr. W. H. Redshaw, of Bourne, Lincolnshire, has sent us numerous photographs of a great number of backgrounds and accessories prepared by himself. These, while being both artistic and tasteful, are of sufficient variety to give photographers great choice of selection, embracing as they do rustic scenes and seats, interiors, landscapes, seascapes, in considerable assortment. Mr. Redshaw's accessories and backgrounds should be very popular.

Death of "Bella Solomon."—We are sorry to have to record the death of Mrs. Abenheim, a lady at one time well known in London commercial circles as Miss Bella Solomon, for many years the reigning spirit in the photographic stores of her father, the late J. Solomon, of Red Lion-square. She was a brilliant conversationalist, an accomplished linguist and musician, and a woman of great natural parts and force of character. She died on Thursday, last week, from blood poisoning, consequent upon a severe internal complaint, from which she had long suffered. She declined permitting the attendance of a doctor till the day before she died.

The Influence of Photography on Modern Literature.—Conversing with a representative of the *Daily Chronicle* on the influences which conduce to the realism by which modern literature is pervaded, Dr. Oliver Wendell Holmes says: "I spoke of the influence of the telegraph on literature. Now, the photograph. It seems to me that the development of photography is largely accountable for the development of realism—the modern realism. You see, if a man wanted to be exceedingly realistic in olden days, to go into large detail, he had to make much trouble for himself. He could not write detail without examination; he had to go here and there to examine his subjects. To-day the photograph brings the fullest details imaginable on to the very desk of a writer. He has merely to look and dip his pen, no matter what the subject—a sewer or a laundry basket, if you like. It is realism made easy. What's easy becomes ultra."

RECENT PATENTS.

PATENTS COMPLETED.

Improvements in Photographic Washing Apparatus.

No. 16,477. Frank Alston, 211, Ladypool-road, Sparkbrook, Birmingham. *September* 15, 1893.

The object of this invention is to thoroughly wash photographic prints and plates in an ordinary bucket or other domestic utensil. It consists of a straight tube with a taper nozzle fixed at a right angle to the bottom of it, and a syphon, the short arm of which is just over a small hole in the upper side of the nozzle, while the long arm hangs down outside, and the spring holds it firmly in position. When the tube is connected with the water supply by a piece of rubber tubing, most of the water rushes out at nozzle and causes water in bucket to revolve, whilst a fine stream from the hole causes water in tube to rise above level of that outside. When this reaches top, it flows down long tube and starts action of syphon. If, however, the water falls too low in the bucket, the air is admitted through the hole, and the action ceases until the water rises to a sufficient height to restart it. The bottom of the tube is surrounded by a piece of perforated zinc, which prevents the prints being drawn into the syphon.

Improvements in Photographic Shutters.

No. 4081.—John Edward Thornton and Edgar Pickard, Altrincham, Cheshire.—*September* 23, 1893.

The improvements forming the subject of this invention apply to photographic shutters of the roller-blind type that work close before the sensitive plate or film generally known as focal plane shutters.

A shutter of this kind is usually constructed with a narrow transverse slit in the spring blind, through which the light is admitted to the sensitive plate during the passage of the blind from the winding roller on to the spring roller.

The object of our improvements is to so form the blind that the width of the slit can be adjusted when required, which we do as follows :—

The two slides of the blind, which form the edges of the slit, are turned over and stitched (or otherwise fastened) a sufficient distance to form a hem or loop through which a strut is passed. The strut is formed of a piece of thin channelled steel, like a half tube, terminating at each end in a point. A short piece of tube is fitted in or over each end of one of the said struts.

The two struts are connected together by light chains at each side of the blind, which practically form the ends of the transverse slit. These chains are permanently fastened to the two ends of one of the struts, and one of the links of each chain engages with the point on the end of the other strut. The ends of the two chains pass through the two short tubes into or along the grooved strut, and are connected together by an elastic band.

To decrease the width of the slit, it is only necessary to shorten the chains at each side by hooking the points of the strut into other links, the rubber band inside the strut taking up the loose ends of the chains into the hem.

To increase the width of the slit, the chains are each lengthened by pulling out more links through the tube, and hooking on to the points ; in doing so, the elastic band is stretched.

We do not bind ourselves to the exact details of construction hereinbefore described, as they may be varied without departing from the main principle of the invention ; for instance, the strut may be formed of a light tube, instead of a grooved strip with tubes on the end, and a spiral wire spring may be used inside instead of the elastic band. If found necessary, both struts may be provided with elastic bands instead of having the chain permanently fastened at one end.

Improvements in or relating to the Production of Photo-mechanical Printing Surfaces.

(A communication from Asa Phillip Stanford, 409, West 47th-street, New York City, New York, United States of America.)

No. 10,196. Alfred Julius Boult, 323, High Holborn, Middlesex. *September* 23, 1893.

This invention has for its object to provide means whereby printing surfaces can be produced through the aid of certain characters which can be arranged in any desired order, and from which photographs can be taken, and which photographs can be transferred or transformed into the printing surface, and this class of machinery is designated as the phototype machine. The invention consists in a machine in which the various characters can be assembled in a line, and the line properly supported in position while a photograph is being taken of the line, when the characters can be quickly restored to their normal positions, and by repetition of these operations a proper photographic plate produced, from which by any of the well-known processes a printing surface can be made.

An Improved Photographic Dark-slide Recorder.

No. 20,253. John Edward Thornton and Edgar Pickard, Altrincham, near Manchester.—*September* 23, 1893.

The object of this invention is to provide a simple device for attachment to a photographic dark slide, for the purpose of showing whether the sensitive plate or plates in the slide have been exposed or not.

It is constructed of two thin plates of metal, or other suitable material, about $\frac{3}{4}'' \times \frac{1}{4}''$, hinged together at one side. The ends of the plates may be slightly turned up, so as to form bearings for the hinge. A spring is so placed at the hinged side that it will cause the top plate or lid to stand open, or at right angles to the bottom plate. Any suitable form of spring may be used, but we prefer a straight piece of steel wire, held at one end by the lid, and the other end by the bottom plate. The word "exposed" may be printed on the inner side of the lid, so that it is visible only when the lid is open.

The bottom plate is attached to the end of the dark slide in such a position that the projecting part or top of the shutter of the slide (or a projection attached to the shutter) will fit over the lid and keep it closed when the shutter is pushed right in.

When the shutter is withdrawn to expose the plate, the lid flies open, disclosing the word "exposed," and it remains in this position when the shutter is pushed home again.

The lid may be closed by the finger to "set" it at the same time that the slide is charged with fresh plates.

The claims are :—1. The combination with the dark slide of a recorder or appliance for indicating when the shutter has been raised and the plate exposed, consisting of a hinged plate, which is opened by a spring and held closed by the top of the slide, or a projection or catch thereon, substantially as described. 2. A recorder for the dark slide of photographic cameras, constructed of two plates hinged together on a spring wire or hinge, one to be attached to the top of the slide, and the other, with the word "exposed" inscribed thereon, to be held closed by the top of the shutter, or by a projection or catch thereon, substantially as described and shown.

Improvements in Frames for Printing Magic-lantern Slides.

No. 20,679. Claud Syms Scott, Brabourne, The Drive, Walthamstow, Essex.—*September* 23, 1893.

I improve the frames for printing magic-lantern slides from photographic negatives by providing means whereby the position of the negative is adjustable relatively to the slide, whereby the relative positions of the negative and the slide can be readily and exactly reproduced at will, and whereby the adjustment of the relative positions of the slide and the negative is made with greater facility than heretofore.

My improved frame consists mainly and essentially of four parts : first, a frame of wood or other material having a front aperture approximating to the size of the slide for the admission of light, and also having a back rim provided with springs, catches, or other devices of ordinary or special construction for the purpose of holding the back of the frame, the negative, the slide, and other parts steadily in position. Second, a plate of brass or other suitable material of about the thickness of the negative, sliding in the above-described frame, and having an aperture to fit and hold the negative; this plate has one or more lugs or extensions formed on its edges, said lugs or extensions passing through the back rim of the above-described wooden frame, and serving to assist in the adjustment of the said brass plate together with the negative, which fills the aperture thereof ; the lugs or extensions are marked off in divisions on their outer ends, so that any position of the brass plate and its contained negative relatively to the wooden frame and the lantern slide can be noted and reproduced at will. Third, a sheet of cardboard or other suitable material cut to fit inside the back rim of the wooden frame, and having an aperture to fit the lantern slide so situated that the true and proper position of the said slide opposite the light aperture is ensured when it is placed in the aperture of the sheet of cardboard or other material.

Fourthly, a back piece of wood or other material, provided with a pad of cloth or leather, and capable of being fixed and held into the outside frame by the above-mentioned springs or catches.

The light aperture in the front of the wooden frame is chamfered, in order to prevent the casting of any shadows on to the exposed portion of the negative.

I provide set screws in the rim of the outside wooden frame, which screw down on to the lugs or extensions of the brass plate, and serve to hold said brass plate in position.

Brass frames, having lugs or extensions as above described, may also be advantageously applied to printing frames in which it is desired to adjust and reproduce the exact position of the lantern slide relatively to a fixed negative. Further, I may employ two such brass frames, the lug or extension of one passing through the end of the outside wooden frame, and the lug or extension of the other passing through the side of the outside wooden frame, so that the position of the negative or of the slide, as the case may be, can be adjusted and registered in two directions at right angles. By this means any relative positions of the slide and the negative can be obtained and exactly reproduced. It is obvious that when two brass frames are employed the aperture of each must be lengthened or slotted in a direction at right angles to its lug or extension, in order to permit of the adjustment of the slide or of the negative in that direction by the other brass frame.

When two brass frames are used, one of the two may be formed without any lug or extension, but in such a way that it will conveniently slide in the lengthened or slotted aperture of the other, and thereby render possible the adjustment in two directions at right angles. In this case numbered divisions would be marked on the side of the slotted aperture of the brass frame having the lug or extension, and convenient means would be provided for fixing and holding the two brass frames together and maintaining the proper position of the slide or of the negative as the case may be.

It will be seen that, when the brass frames are used to adjust the slide instead of the negative, some modifications of the parts of the printing frame, described in the earlier part of this specification, will be necessary. In order to ensure the proper action of the brass frame or frames on the thin glass of the slide, it may be found advantageous to surround said slide with a narrow frame of any suitable material, and of greater thickness than the glass.

When using this printing frame, all adjustments may be made in ordinary light, and the glass plate, with its sensitive film, which is to form the lantern slide, can then be placed in position in the frame in a totally dark room if the usual photographer's dark room, with non-actinic light, is not available.

A New or Improved Paste for the Prevention of Discolouration of Photographs Mounted upon Bristol Board and the like.

No. 21,622. Hermann Wilhelm Vogel, 124, Kurfürsten-strasse, Berlin, Prussia, Germany, and Jacob Weinberg, 50, Wasserthor-strasse, Berlin, Prussia, Germany.—*September* 23, 1893.

It is a known fact that photographs mounted on Bristol board are liable to become yellow, and all attempts to prevent this have up to the present failed.

Experiments we have made as to the nature of this discolouration show that it can only result from the presence of impurities either in the photographs or in the Bristol board. For instance, the silver prints are often treated with too small a quantity of fixing salt, and the fixing is therefore defective, the following insoluble compound remaining in the pictures :—

$$Na_2S_2O_3 + Ag_2S_2O_3 \qquad (I.)$$

instead of the soluble double salt

$$2\,Na_2S_2O_3 + Ag_2S_2O_3 \qquad (II.)$$

which can be easily washed out.

The compound I contains only half the quantity of fixing salts contained in II, and soon decomposes in the air according to the equation :—

$$Na_2S_2O_3 + Ag_2S_2O_3 + aq = Na_2S_2O_2 + Ag_2S + SO_3 + aq \qquad (III.)$$

Sulphide of silver is thus formed, producing discolouration of the picture.

Again, the fixed pictures are often insufficiently washed out, small quantities of the salt being left, and also producing in time discolouration.

Then, again, pictures properly prepared and washed out are often dried on impure blotting-paper containing fixing salts, or hung on strings containing various impurities, and in this manner again soiled.

The cardboard used for mounts can also contain impurities, the paper used being often bleached with chlorine. This, and the reagent used to remove the excess of chlorine, called antichlorine, ($Na_2S_2O_3$) are according to the following equation :—

$$Na_2S_2O_3 + 3\,H_2O + 6\,Cl = 6\,HCl + Na_2S_2O_6$$

not of themselves harmful to the paper, but unfortunately a superfluity of

hyposulphite of soda is often present, and, according to the above formula, III. causes a precipitate of sulphur which produces discolouration.

Our invention consists now in overcoming the above defects by using a means for removing the sulphurous impurities, thus preventing this discolouration.

We attain this object by employing as a glue a paste of starch mixed with iodine in varying proportions; for instance, 10 c.c. of a solution containing 1 gr. of iodine in 10 c.c. of alkali, are added to 100 c.c. of freshly prepared pure starch paste. This mixture is thoroughly stirred, the paste changing to a dark blue mass, which may be coated on paper or on cardboard by means of a brush.

Our improved glue is employed either for uniting the several layers of paper of which a sheet of cardboard is composed, or for mounting paper photographs upon paper or upon cardboard. This glue will prevent the cardboard and the photographs from yellowing. This yellowing, which is a defect occurring frequently with photographs mounted with ordinary glue or paste, is due to chlorides and sulphurous or other impure admixtures, either contained in the paper or cardboard, or adhering to the photograph in consequence of the previous operations, for instance, owing to defective fixing or insufficient washing of the photograph. Now, iodine is a very efficacious agent for destroying such compounds as are capable of yellowing the photographs. Hyposulphite of soda is caused to combine with oxygen and thus to form hyposulphite of soda, as is represented by the equation :—

$$Na_2S_2O_3+6\,I+3\,H_2O=Na_2S_2O_6+6\,HI$$

Sulphide of sodium is converted into sulphite of soda according to the chemical equation :—

$$Na_2S+6\,I+3\,H_2O=Na_2SO_3+6\,HI$$

Experiments have proved that iodine has no noxious effect upon paper photographs in which the sensitive part of the paper contains silver salts. The experiments have also demonstrated the fact that our improved glue is efficacious in preserving the photographs for any length of time. It has been further ascertained that the addition of ten parts of tincture of iodine (I : 10) to 100 parts of starch paste in the highest proportion which it will be necessary to employ when the paper contains as much as one *per cent.* of impurities. It will be obvious that the amount of iodine which is to be added will in each case depend on the proportion in which impurities are admixed in the paper, cardboard, or photographs.

It will be obvious that our improved glue may be employed with great advantage for uniting the several layers composing a sheet of cardboard, especially if such cardboard is to be used for mounting photographs thereon.

It sometimes occurs that the paste or glue is squeezed out laterally off the photograph to be mounted, thereby occasioning blue spots. In this case we take a small sponge and soak it in a solution of 1 part of chemically pure sulphite of soda in 1000 parts of water. The sponge is pressed, so as to remove the greatest part of the solution it has soaked, and is passed over the blue spots; the blue colour will disappear very rapidly, and it will be sufficient to wipe the moisture away with a clean piece of cloth.

The following are the claims : 1. As a glue for uniting the several layers of a sheet of cardboard, and for mounting photographs, a paste of starch to which iodine is mixed in solution, for the purpose set forth. 2. As a means for removing spots occasioned by a glue containing starch and iodine, the employment of a solution of chemically pure sulphite of soda substantially as described.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

October 24,—Technical Meeting, Mr. W. E. Debenham in the chair.

Balloon Photography.

Captain A. M. Mantell, R.E., read a paper on balloon photography applied to military purposes. He passed round a number of photographs taken from a captive balloon. The camera was placed in the wicker car, and was capable of being tilted. It was a whole-plate Meagher, a rapid rectilinear lens of 16 inches focus, and a Thornton-Pickard shutter being used. Views of from one to two miles' distance were taken. No distortion was perceptible, but in some of the views there was a decided blur, due to movement of the balloon; others showed blur due to the velocity of the wind. It seemed impossible to give a sufficiently short exposure to prevent this blur. They could not, however, expect sharp results in balloon photography. When the wind was travelling at more than sixteen miles an hour it was impossible to take views at all. It would be advantageous to reduce the exposure as much as possible, and therefore the lens must be very rapid and the focus should be obtained with, say, *f*-16. A smaller stop diminished the chances of giving a good exposure. Probably the best lens for the purpose was the Goerz Anastigmat, which Messrs. Ross & Co. had informed him they would soon bring out, so it would be possible to use *f*-11 for balloon work. He had not tried the tele-photo lens as it included such a small angle and was not rapid enough. He had used four different kinds of plates, rapid and ordinary, and found the latter give the best results. The exposure, as a rule, was about half that for sea and sky—that is, with *f*-16, about one-sixtieth of a second. The ordinary folding camera was unsuitable. The car of the balloon swung and danced about rapidly, so that it had been sometimes found advisable to tie the camera to the edge. The camera, therefore, should be strong, being box-shaped and not tapered. It should have a swing back and a shutter capable of giving exposures from one-thirtieth to one-hundred-and-fiftieth of a second. A changing-box should be provided, and sights on top of the camera used as view-finders. For development he had used pyro-ammonia. He had found Nikko paper suitable for printing purposes. When the wind's velocity was less than ten miles an hour, good results could be obtained; but when the velocity was greater, many failures occurred, and at sixteen miles an hour it seemed scarcely possible to get good results. Photography from a free balloon was much simpler, as the balloon moved with the wind without tossing about. The exposure must be as short as possible, and there was not the risk of blur that there was with a captive balloon, the rate of the wind making no difference. A free balloon twisted about and rose and fell. Captain Mantell concluded his paper by referring to the work in the Exhibition done by Mr. Jennings from a free balloon, and passed round a few examples taken from a captive balloon during the recent manœuvres as showing the kind of work which might be done during an actual campaign.

Mr. T. Sebastian Davis inquired why a whole-plate camera was selected; he suggested a smaller one would have been more advantageous. He thought a quarter-plate camera could have been used and enlargements made.

Captain Mantell agreed that a quarter-plate would have the advantage as regards portability. As regards steadying the camera by a weight, as suggested, he had not attempted it.

Mr. H. Wilmer suggested the use of a strong magnet to prevent the camera rotating.

The Chairman, referring to the use of the tele-photo lens for balloon purposes, said it might be made to have a perfectly flat field, although, when used for a great deal of enlargement, the field was curved. If the field were limited, that might be got over by taking three or four photographs in succession. Direct images were better than enlargements, as in the latter the texture was enlarged so as to obscure fine details.

Mr. T. Bolas said he did not think a weight would answer for preventing rotation of the balloon, and suggested Professor Piazzi Smyth's gyroscope system, with a smaller wheel at less speed.

Captain Mantell said a magnet, gyroscope, &c., would be suitable for the purpose, if not too heavy. The tele-photo lens might be of great use under some conditions, but it only included a small angle. They required to get in as large an angle as possible. Overlapping pictures, as suggested, would be of no use.

Mr. W. England said the tele-photo lens was scarcely available for instantaneous work. His experience was that it required about six times the exposure of an ordinary lens, magnifying ten times.

A vote of thanks was passed to Captain Mantell for his paper.

Photo-micrography Simplified.

Mr. W. I. Chadwick gave a discourse on this subject, explaining the apparatus he employed and exhibiting a number of specimens.

We defer our report of this subject until next week.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

October 19,—Mr. P. Everitt in the chair.

Mr. T. C. Hepworth delivered a lecture on *A Photographic Tour in the English Lake District*, illustrated by numerous lantern slides (see page 686). The lecture, which was of a humorous and descriptive character, was highly appreciated, and at its conclusion the Chairman, on behalf of the members, thanked Mr. Hepworth.

Vitro-enamelling.

Mr. A. L. Henderson made a few remarks on this subject, suggested by Mr. Henderson's recent demonstration on the preparation of plaques. He was sorry Mr. Haddon had not given the composition of the enamel he had used. Arsenic was used to get whiteness, but it was a disagreeable substance. It was cheap, and was a flux in itself. He preferred oxide of tin as a colouring matter, and would suggest, as a base, to take two parts of commercial tin enamel, and one part of flux ground up. Tin gave warmth to platinum, and he (Mr. Henderson) could get any sort of colour with it, from steel grey up to

almost brick red. His tones would have been still warmer if he had got more tin in the enamel. For many years he had used an open muffle; but, upon taking up gas, his results were less satisfactory, the blacks and whites both being bad. As regards retouching, it was easier with the substitution process than with dusting on. In reply to Mr. J. S. Teape, Mr. HENDERSON said that, in applying a portion of the same film to the enamel, it fired the same colour.

Mr. TEAPE said he found this was not always the case.

The CHAIRMAN asked Mr. Henderson if he would give a demonstration of enamel work, especially as, during the past few years, a great many new members had joined the Association who had not had an opportunity of witnessing the demonstration Mr. Henderson had already given. He (the Chairman) was of opinion that enamel work opened up a most prominent field for professional photographers.

Mr. HENDERSON regretted his inability to give the demonstration asked for on account of his health, which, though better now than it had been for some years past, was still not what he hoped it would be.

Mr. HADDON remarked that he had gone into the subject of plaque-making in order to draw new people into the field of experiment, and his object in showing how the plaques could be made was to save the cost of buying plaques, which, at a shilling each, would come expensive.

Mr. HENDERSON pointed out that, with spoilt enamels, the images could be used, and the plaque used again.

After other discussion the meeting closed.

Affiliation of Photographic Societies.—The tenth meeting of Delegates was held at 50, Great Russell-street, W.C., on Tuesday, October 17, Mr. E. Clifton (Photographic Club) in the chair.—The minutes of the last meeting were confirmed. The report of the Sub-committee appointed to consider the question of endeavouring to obtain from the railway companies concessions to photographers similar to those to anglers, in which the Committee stated that they had made inquiries, but were unable to recommend any course which would hold out a reasonable chance of success, was adopted. It was proposed by Mr. P. Everitt (London and Provincial Photographic Association), seconded by Mr. Hodsoll (North Kent Amateur Photographic Society), and carried, "That the Secretary be instructed to communicate with the principal railway companies with a view to securing for members holding return tickets the privilege of breaking the journey at any intermediate station." The report of the Conference of Judges was adopted unanimously, and the Secretary instructed to print and publish the decisions arrived at by the Judges. The question of certain additions to the Rules was taken up, and it was decided to submit the following alterations to the Council of the Photographic Society of Great Britain for its approval:—1. "That, after Rules 1 and 2 as at present standing, a Rule as follows be inserted: The object of the Affiliation is to consider and suggest lines of action to photographic societies, and to take any steps it may think fit to encourage or otherwise benefit photographic societies and similar organizations, and their individual members." 2. "That, after Rules 3 and 4 as at present standing, a Rule as follows be inserted: The Committee shall meet at such time and place as the Chairman shall decide. On the requisition of ten delegates, the Secretary shall call a meeting not less than fourteen, nor more than twenty-one, days after receipt thereof. At Committee meetings nine shall form a quorum." 3. "That, after Rule 7 as at present standing, two Rules, as follow, be inserted: *a*. A balance-sheet of the accounts of the Affiliation shall be prepared by the Treasurer up to the 31st December in each year, and shall be audited by two auditors. *b*. The Annual General Meeting of the Committee shall be held during January in each year. At this meeting the balance-sheet, duly audited, and the Chairman's report of the year's proceedings shall be submitted, and officers, consisting of a Chairman, Treasurer, and two Auditors, shall be elected for the current year." 4. "That the Rules be then consecutively numbered." On the proposal of Mr. Everitt, seconded by Mr. A. F. Taylor (Ealing Photographic Society), it was resolved to petition the Photographic Society to remit to members of affiliated Societies the wall-space charges at the Exhibitions, pointing out at the same time that they knew of instances in which other Exhibitions had received exhibits which would have come to the Photographic Society's Exhibition had it not been for the wall-space charges.

Brixton and Clapham Camera Club.—October 17, the President (Dr. Reynolds, F.R.G.S.) in the chair.—At the conclusion of the ordinary business, the PRESIDENT read a paper on the *Diazotype Process*, *i.e.*, printing in aniline dyes. About 1890 a new dye, named primuline, was discovered by Mr. Green, of the firm of Green, Cross, & Bevan. This dye, which is very soluble in water, and yellow in colour, has a strong affinity for all kinds of vegetable fibre, and so strong is this affinity that it is only necessary to soak the fibre for a few moments in a dilute solution of the dye, and a perfectly fixed primrose colour is the result. After the material is dyed, it is immersed in a bath of nitrous acid, and a surface is then obtained which is of a deep orange colour, and very sensitive to light, and if this surface is exposed to the action of sunlight, or a strong light, the deep orange colour bleaches to a pale primrose, and, after washing in water, remains at this tint. If, however, before exposing to light, a portion of the surface is protected by covering with, say, a fern leaf, or a dense carbon positive, it will be found that the portions of the surface so protected are not bleached, but remain of a deep orange colour, which they had upon removal from the nitrous acid bath. If now an alkaline solution of one quarter to one half per cent. of, say, beta naphthol is applied, the portions unacted upon by light will become of a splendidly red colour, the parts acted upon remaining simply a pale primrose colour, requiring only to be washed and dried. Other aniline derivatives applied as developers give rise to other colours, as blue, orange, brown, yellow, maroon. The process is admirably suited for ladies' use, because such articles as tablecloths, curtains, coverlets, panels for doors, mantelboards, &c., of a most ornamental kind can be readily produced. It is only necessary to print in sunlight for a few minutes. It must, however, be remembered that this is a positive process, consequently a positive must always be used to print from. If a material, such as a layer of albumen, stained with primuline, is dried, heated to 212°, and then developed with pyrogallic acid and sulphite, a deep clear sepia stain is produced on a pale yellow ground, and this will bear almost any amount of amplification, and, if a sensitive surface could be obtained quick enough for camera exposure, the negative could be enlarged to any extent without showing a trace of the structure of the substance on which the actinic impression was produced. This would, indeed, be perfection in photography for astronomical or micro-photographic purposes. A practical demonstration which followed proved conclusively the simplicity of the process, and the members present were delighted with the results produced. On being asked by the President, Mr. Cross, of the firm referred to, then kindly gave a thoroughly detailed account of the chemistry of the process, pointing out also the cheapness and uniform success of the results to be produced. His firm would be ever ready to assist those desirous of taking up this beautiful process. It may be mentioned that the materials and necessary chemicals can be obtained from Messrs. Watson & Co., High Holborn, W.C.

Croydon Camera Club.—There was a full attendance on the 18th, when Matthew's Portable Lantern was shown and explained by the Hon. Secretary, Mr. G. R. White. The general feeling was, that the instrument is characterised by several desirable features, and that it is worthy of high commendation. A number of slides were shown on the screen, the work of Messrs. Ryan (*Norwegian scenery*), Price (*Hurlingham*, &c.), Packham White (*The Chutes*, &c.), and Carden (*Croydon Cricketers*, &c.).

Ealing Photographic Society.—October 19.—Four new members were elected, and two more nominated. Mr. S. H. FRY gave a lecture and demonstration on *Paget Printing-out Processes*. Comparing gelatino-chloride with albumenised paper, he claimed for it the following advantages: Being made by machinery, the silver salts were more evenly distributed, it kept better, it gave better results with poor negatives. Its chief disadvantage was, that there was sometimes difficulty in getting even tones, especially when the print contained sharp gradations from light to shade. The methods of toning and fixing were then described. To secure even toning, it was essential to thoroughly wash the print until all milkiness had disappeared from the water, if separate toning and fixing baths were used; any toning bath would do, though the Paget Company preferred the sulphocyanide bath. In using this bath, the points to be observed were, not to exceed the quantity of sulphocyanide given in the formula, and to give the requisite quantity of gold for the amount of paper (one and a half to two grains) per sheet; to place all the prints in the bath as quickly as possible, and to keep them in motion; to judge the colour of the image entirely by transmitted light, and not to stop the toning so long as the slightest trace of yellow was visible in the shadows. The prints must be thoroughly washed between toning and fixing, and no trace of hypo must be allowed to get into the washing water, as hypo, in small quantities, caused brown stains. For the combined toning and fixing bath, the following simple formula was recommended: Water, 4½ ounces; chloride of gold, 1 grain; acetate of lead, 20 grains; hypo, 380 grains. It was most important that the bath should not get acid, and, to prevent this, precipitated chalk or whiting should be used in the bath. In no circumstances should gold be added to the bath after toning had started. The methods of obtaining enamelled and matt surfaces were explained, and a number of prints, opals, and lantern slides on Paget plates and papers were shown. The meeting then adjourned to the dark room, when Mr. Fry demonstrated the development of a partially printed print, which is a speciality of the Paget Company, and afterwards toned the print, together with another which had been fully printed in the usual way. He explained that development must stop considerably short of the required density, as the developed image, unlike the printed one, gained considerably in depth in the toning bath.

Leytonstone Camera Club.—October 18, the President (Dr. W. Pickett Turner) in the chair.—The first demonstration in the new hall and studio took place. Mr. E. A. LEBLANC demonstrated the uses of Dr. Andresen's rodinal and glycin, also metol, amidol, eikonogen, fixing, and tone-fixing cartridges. First, the different qualities of the developers was explained; second, plates and films were developed with rodinal and metol cartridge; third, bromide paper was developed with amidol cartridge; fourth, lantern slides were developed with eikonogen cartridge; and lastly, Eastman Solio, Ilford P.O.P. and Paget P.O.P. chloride papers were toned with the tone-fixing cartridge. A large number of negatives and prints which were passed round amply testified the capabilities of Dr. Andresen's specialities, one of the most remarkable and useful being the fixing salt, a quarter-pound solid bar, dropped into forty ounces of water being dissolved in about thirty seconds. Mr. Leblanc dealt with his subject in a very able manner, and gave most lucid explanations to the various questions put by the large number of members present.

Putney Photographic Society.—October 19, Dr. J. F. Farrar in the chair.—Mr. Baldwin, of the Eastman Company, gave a lecture and demonstration on *Solio Paper*. In the course of his remarks, Mr. BALDWIN said the best results were probably obtained from negatives with a tendency to softness, but good prints could also be made from negatives suitable for any of the other usual processes, as well as from some with which this was not the case. The paper has considerable keeping qualities, but, as with all commercial printing papers, it was advisable to use it when fairly fresh. Damp was a danger to be carefully avoided, and for this purpose the paper should be kept in closed tubes or boxes, and an indiarubber pad should be placed next to it in the printing frame. Printing would be found to proceed rapidly—generally twice as fast as when using albumenised paper, and it would not be found necessary to the depth required by this process. The printing should be regulated with a regard to the subsequent treatment—rather more deeply for prints to be toned in the combined bath, or to be finished with a glossy surface, than for those to be toned and fixed in separate baths, or to be finished with a matt surface. The Solio being an emulsion paper, there was no danger of it staining the negatives when placed on them in the printing frame, as was not infrequently the case with other papers having free silver on the surface. Reference was then made to the various toning formulæ given in the instructions issued with the paper, and their action and characteristics explained. These baths were, after careful experiments, recommended by the Company, but the paper could also be successfully treated with others, and no doubt many workers would find out for themselves a bath which would readily and with certainty give

them the tones which they most admired. With the combined toning and fixing bath no preliminary washing was necessary, and it was also in other respects convenient, but toning beyond the brown should not be attempted, as a greenish tinge would be the result. He recommended that this bath should only be used once, a fresh bath being made for each batch of prints. When working with the separate baths, a preliminary washing was necessary, and upon its thoroughness depended largely the success of the subsequent treatment. Temperature had great influence on the toning bath; forty to fifty degrees had been found advantageous, and in hot weather it was desirable to cool the bath with ice. The use of alum was also recommended for hardening the film. After toning, the prints should be thoroughly washed before being passed into the fixing bath. This should be made up in accordance with the formula, the sulphite of soda helping to preserve the purity of the whites. The washing, after fixing, should be continued in running water for about an hour, and, where running water was not available, in about twenty changes. The prints could be finished in various ways; if simply dried and mounted, they could be burnished, care being taken that the temperature of the burnisher should not exceed 170°; for glossy surface, the prints should be squeegeed on to carefully cleaned plate glass, or ferrotype plates, and, for matt surface, on to finely ground glass. In either case it might be considered desirable to back the prints with suitable paper to preserve the gloss or matt when mounting. Gelatine was, perhaps, the best mountant; any containing indiarubber in any form or degree should be shunned for this paper. Mr. Baldwin went fully into all details, and ably answered a large number of questions addressed to him by the members, who throughout followed his lecture and demonstration with interest.

Richmond Camera Club.—The Annual General Meeting was held on the 16th inst., Mr. C. H. Davis in the chair, when the report and balance-sheet for the year ended August 31 were submitted and adopted, and the following officers were elected for the current year:—*President:* Mr. Cembrano.—*Committee:* Messrs. Alabaster (Lanteruist), Ardaseer (Librarian), Gibson, Huddy, Neville, and Williams.—*Hon. Treasurer:* Mr. Davis.—*Hon. Secretary:* Mr. Eunis.

South London Photographic Society.—October 16, Ordinary Meeting, at Hanover Hall, Hanover Park, Peckham, the President (F. W. Edwards) in the chair.—After the close of the nsual formal business, the evening was devoted to the exhibition of slides in the Society's lantern, to enable members to select and make up the sets which they intend to send in for competition at the Exhibition to be held early in next month. Messrs. A. H. Wall and E. J. Wall were elected honorary members of the Society.

Woodford Photographic Society.—At the meeting on October 19, the Rules, as passed at the preceding meeting, were confirmed. The PRESIDENT then gave his opening address, speaking of the improvement both in methods of working and in final results that always follows the intercourse among photographers that a Society gives. He wished, too, that the members of the new Society would freely bring their work for discussion at the meetings—not their successes only, but their failures. There being no apostolic succession in photography, the only road to success must be through failure, which should never discourage, but be valued for the lessons that they teach. In concluding, he impressed upon the members the necessity of individual work if we wished to be successful, expressing the hope that, by the co-operation and work of the members, the Woodford Photographic Society might take an honoured place amongst the foremost societies. The President then vacated the chair (which was taken by Mr. Caird), and read a paper on *Some Modern Printing Processes*, passing in review albumen-silver, gelatino-chloride, gelatino-bromide, platinotype, and carbon. In regard to gelatino-bromide, he said that almost any class of picture could be obtained, the strength of the light used in printing exercising a powerful influence over the vigour of the finished print. The results, too, might be considered permanent. Descriptions of the platinotype and carbon processes, their simplicity, artistic beauty, and permanence, and the principal points to be considered in order to ensure successful results, concluded the paper. In order to illustrate the various processes, the President showed some of his own bromide and carbon prints, bromide prints by Mr. A. R. Dresser, platinotype by Mr. Frederic Hollyer, and carbon prints by the late Mr. William Bedford, and by the Autotype Company. A discussion followed on the practical working of the different processes.

Aston Natural History and Photographic Society.—The audience of Thursday last had the pleasure of hearing one of the most interesting papers as yet delivered to the Society. Mr. Cracroft was most happy in his description of the district around Cheddar, and the hints as to directions to take, lenses required, and other "tips," were well received by one of the best attended meetings of the session. The lecture was illustrated by some fine mounted prints, and was rather novel after so good a run of lantern views. At the subsequent Committee, the Secretary informed the members present that the General Committee, to whom the hall belonged, had graciously granted the free use of hall and rooms on the first floor for the purpose of the Exhibition on March 1, 2, and 3, which the Aston Photographic Society intend to organize, and which will be rather novel in its way, including "Photographic, Natural History, and kindred manual work." There will be the usual awards of medals and diplomas, and some well-known gentlemen are expected to act as Judges.

Birmingham Photographic Society.—October 17, Mr. J. J. Button in the chair.—About twenty members present. A number of fine photographs, lent by the President of the Society, were on view. They consisted of enlargements made from negatives taken by him on his recent tour in the West Indies and Brazil, which were very much admired, and of a very fine series of Irish views, which were the work of a professional. These latter showed especially wonderful skill in platinotype printing.

Derby Photographic Society.—October 17, Mr. Keene presiding.—The subject for the evening was, *Photography, and its Application to the Detection of Crime*, a paper by Dr. Paul Jeserich, and which was illustrated with about forty lantern slides. The paper was read by Mr. A. H. Bennett in a very able manner, while Mr. C. B. Keene kindly officiated at the lantern, and at the close a vote of thanks was accorded to these two gentlemen for assisting.

Eastbourne Photographic Society.—A good muster of members of this Society gathered to hear and see Mr. FRY upon *Paget Printing-out Processes*, and especially to see the new and interesting process of development of printing-out papers by alkaline development.

Lewes Photographic Society.—October 17, the President (Councillor Wightman) in the chair.—A demonstration of the process of preparing transparencies for the magic lantern was given by Mr. S. HERBERT FRY, who is lecturing on behalf of the Paget Plate Company, of Watford, and demonstrating the use of their manufactures.

FORTHCOMING EXHIBITIONS.

1893.	
October 27–31	*Hamburg. Das Ausstellungs Committé des Amateur Photographen Verein, Schwanenwik, 33, Hamburg.
,, 27–Nov. 11...	*Photographic Salon, Dudley Gallery, Piccadilly, W. Hon. Secretary of Organizing Committee, A. Maskell, 215, Shaftesbury-avenue, W.C.
,, 27–Nov. 15...	*Photographic Society of Great Britain, 5A, Pall Mall East, S.W. Assistant Secretary, R. Child-Bayley, 50, Great Russell-street, W.C.
,, 30, 31	*East London Photographic Society, New Tabernacle, Old-street, E.C. Hon. Secretary, W. R. Gould 61, Gibraltar-walk, Bethnal Green, E.
November 7–11	*South London Photographic Society. Hon. Secretary, C. H. Oakden, 51, Melbourne-grove, Dulwich, S.E.
,, 17–25	*Stanley Show (Photographic Section), Agricultural Hall. Manager, Walter D. Welford, 57 and 58, Chancery-lane, W.C.
,, 20–25	*Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, Rose Bank, South-west-road, Leytonstone.
December	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
,, 18–Jan. 22, 1894	*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

PHOTOGRAPHY IN NATURAL COLOURS.

To the EDITOR.

SIR,—In your "American Notes and News" (p. 669), referring to Abraham Bogardus' conservatism, you make one statement which I think calls for correction. You say, "that the colours of Nature have, in the works of the latter (Lumière), been produced, is a real fact, and has been demonstrated to those assembled at the Chicago Congress over a month ago." According to my source of information (have I been misinformed?), the photographs of *objects* shown at the Chicago Congress were not by Lumière, but by Lippmann, and were some of the same specimens that Mr. Cameron Swan and myself saw and carefully examined in Paris last year. If so, they did not prove what has been asserted, because the colours, besides appearing unnatural and metallic even in the absence of originals for comparison, were not even confined to the coloured objects themselves, and the high lights of the objects were rendered nearer black than the deepest shadows. In justice to honest sceptics, attention should be called to the fact that there are vitally important differences between the results of Lumière and of Lippmann, and that scepticism as to the claims made for the Lumière results was justified by knowledge of the grossly inaccurate descriptions of the Lippmann results which were published a year before.

There is still a certain amount of mystery about the Lumière productions which makes it impossible to discuss them as intelligently as could be desired, but I have observed some facts in connexion with them which appear to me to indicate an important modification of Lippmann's theory, and also to justify certain instructive comparisons with the photo-chromoscope process. These observations will be published before long; meanwhile, people who like to make comparisons will like to know that the Lumière pictures are more difficult to make than photo-chromoscope pictures, require a light twenty times as powerful to project satisfactorily to a given size on a screen, and are not as true to Nature.—I am, yours, &c., FRED E. IVES.

116, *Charing Cross-road, W.C., October* 20, 1893.

THE ZEISS APOCHROMATICS.

To the EDITOR.

SIR,—I have this morning received from Herr Zeiss a letter in which he expresses a strong and not unreasonable objection to my remarks, as

reported in your last issue, upon Mr. Pringle's paper at the Photographic Society of Great Britain. I am therein made to comment in general terms upon the bad qualities of apochromatics; and, for my own credit's sake, as well as in common fairness to a firm whose lenses I use daily and highly appreciate, I must ask you to allow me to say that my remarks were strictly confined to my experience with one of the earlier apochromatics, the glass of which, having sweated, and it having been returned to the makers for repair, I found on its being sent back to me that it was no longer so good as formerly, its field being absolutely sharp only for a small diameter in the centre, whereas it had previously given a field of about two and a half inches available for photo-micrographic purposes. The glass at present used for the apochromatics is free from the liability to sweat which that used for the earlier ones evinced, and that lens only, of all my battery, has ever shown a sign of it.—I am, yours, &c.,

363, *Old Kent-road, S.E., October* 23, 1893. EDWARD BOUSFIELD.

FILMS *VERSUS* PLATES.

To the EDITOR.

SIR,—Your readers may be interested in the results of trials of films of various makers against plates during a trip in Switzerland, the trials extending over a period of two months, and employing the films of the highest reputation for rapidity as against two brands of plates. The films in every case were so completely distanced by the plates that, while I got fair printing negatives from the latter with the exposure indicated by the Thornton-Pickard focal-plane shutter at $\frac{1}{500}$ and $\frac{1}{1000}$ of a second, the plates broke down utterly as $\frac{1}{100}$. With time exposures the films gave admirable results, but the keeping properties seem to be in an inverse relation to their sensitiveness, and the very rapid films fogged irretrievably two months after they were received from the agents, while the moderately slow ones show no signs of deterioration. The conclusion is that, for the work requiring the highest rapidity, films, as now put on the market and without regard to their make, are no substitute for glass plates.—I am, yours, &c., W. J. STILLMAN.

Rome, October 15, 1893.

WARMING THE DARK ROOM.

To the EDITOR.

SIR,—With your permission I will endeavour briefly to answer Mr. Smith's letter. [In his first letter in the JOURNAL of September 29 he said, with reference to "George's Calorigen," it has the drawback of requiring two openings making in an outer wall, and they will *not* answer connected with an ordinary chimney; "I say they will answer connected with an ordinary chimney. In 1874, wishing to warm a (painter's) studio, I had the grate removed, closed the opening of the fireplace with a sheet of iron, and connected the stove in accordance with Messrs. Farwig's printed instructions (fig. 3). I then required one opening "in an outer wall" to bring in fresh air. If I had pierced the wall at the back of the stove, I should have gone into my neighbour's studio, as the houses are not detached; I therefore carried the pipe "G" under the floor-boards to the front outer wall, pierced the brick, and so it has been ever since with perfect success. That is point one. Point two, I said that Messrs. Farwig's address was in Upper Thames-street, they were there in 1874 and have been there ever since; I said No. 4, Mr. Smith says "No. 1." I copied the address which is stamped on a brass plate on the stoves that I have in use, and you will see it is so on the printed prospectus, and I believe in their ignorance Messrs. Farwig have "No. 4" on their premises, and will, no doubt, be surprised to hear from Mr. Smith that it is No. 1. I can only hope that Mr. Smith will be more fortunate in his "facts" in the future letter that he promises you on syphon stoves. I would never have a syphon stove fitted in a bedroom for use in case of illness, which I would unhesitatingly do with George's Calorigen, backed by the opinion of Dr. Thorne.—I am, yours, &c., L. M.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

To the EDITOR.

SIR,—With reference to our next Council Meeting, to be held on Friday November 10, 1893, three p.m., at the premises of the Central Photographic Club, Coleman's Hotel, Henrietta-street, Covent Garden, London, I have received the following letter from one of our members, Mr. W. P. Marsh, Waterloo-square, Bognor:—

"I venture to suggest that the meeting might be made a little more of a social character.

"Let the members have an opportunity of meeting and making themselves known to one another.

"It struck me, when at the meeting last year, that many of those present were strangers to one another, some coming from a long distance, to meet and part strangers to each other, not having had the opportunity of an introduction.

"I am aware that there is necessarily a considerable amount of business to be got through in one evening, but I think that half an hour's interval, to enable members to have a friendly chat, would do much both to make the evening pass pleasantly and induce more to attend.

"I feel satisfied that a stronger meeting might be got together if the "bill of fare" is more enticing.

"I am, dear Sir,
"Yours faithfully,
"W. P. MARSH."

Now, Sir, I heartily agree with the kindly remarks of our excellent member, Mr. W. P. Marsh. The writing of such a letter is strong evidence of the *possibilities* of the National Association of Professional Photographers in its collective capacity.

No one can for a moment doubt that, if the Association were supported numerously by the profession, as it deserves to be, we should find, month after month, fresh subjects cropping up, suggestions made by members, and questions arising for the action or consideration of the Executive, in the interests of the members and the profession generally.

I beg to be permitted to inform your readers how gladly the profession will be received at the meeting, November 10, three p.m., and that a "General Meeting" of professional photographers will be held at 7.30 p.m. (same place), also that I shall be very pleased to entertain the members of the profession who may desire to co-operate with us at a "friendly tea," &c.—say, five p.m.—if they will honour me with their company.

An early intimation of their intention to be present will contribute to the comfort and convenience of my brother professionals.

I am convinced that social intercourse will not only break down stiffness, and promote kindliness, but that it will bring an accession of members, to the mutual advantage of the entire profession.

I would also take this opportunity of pointing out the advantages offered by the new Central Photographic Club now definitely established at Coleman's Hotel, Henrietta-street, Covent Garden, London.—I am, yours, &c.,

9, *Baker-street, London, October* 21. THOMAS FALL.

WOODFORD PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—May I ask the favour of space in your columns to call the attention of photographers residing in the neighbourhood of Epping Forest to the formation of a society at Woodford? In commencing, we have nearly twenty members, and shall welcome all who may be willing to co-operate in working to make our Society a success. Our meeting nights are the first and third Thursdays in each month, and our officers for the first year: *President*, Mr. H. Wilmer; *Members of Council*, Messrs. E. B. Caird, Henry Crouch, and H. T. Malby.—I am, yours, &c.,

HENRY W. BENNETT, *Hon. Sec.*

Dacre House, Arundel-street, Strand, W.C.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange grass mat (Marion's) for printing frames.—Address, C. E. PEACOCK, 13, Barnston-street, Hull.

Dallmeyer's 2c fifteen-guinea lens to be exchanged for American organ.—Address, JOHN WEIR, photographer, Moffat.

Will exchange Lancaster's whole-plate Le Méritoire lens for burnisher.—Address, G. GRIMMETT, 38, Rolls-road, London, S.E.

Will exchange circular print-washer, porcelain, 15 in. diameter, 6 in. deep, for landscape background.—Address, J. ALLARD, 2, Werter-road, Putney.

Will exchange Marion's embossing press, cost 5l. 5s., for Adam's binocular pantoscope or camera for making lantern slides.—Address, W. WALKER, Scotholme, Nottingham.

Will exchange a new Optimus burnisher, 8-in. bar, dipping bath in wooden case, frames, dishes, &c., for a good R. R. quarter-plate lens, or books.—Address, K. B. WILLIAMS, Mallow.

I will exchange Dallmeyer's stereographic lens, or whole-plate wide-angle landscape lens and other apparatus, for 12×10 triplet lens.—Address, J. W. HILDER, Matlock Bath, Derbyshire.

Iron-framed background stand, will carry six backgrounds, too large for studio; exchange for one good background (seascape preferred) or nice studio accessory.—Address, OCTAVIUS CARTER, Bournemouth.

Dallmeyer's 2a lens, with Cadett's pneumatic shutter, in exchange for Hume's cantilever eight-and-a-quarter-inch condenser or fifteen-inch globe-enameller. Address, A. SIMMONS, 258, Westminster-bridge-road.

Wanted, a portable half-plate square-bellows camera and six slides, in exchange for modern half-plate camera, conical bellows (all movements), and three slides case.—Address, E. LLOYD, Mapesbury-road, London, N.W.

Half-plate bellows camera, Lerebour's full-plate portrait lens, and mahogany studio stand, in exchange for good three or four-wick magic lantern. Address, ARTHUR WILKINSON, Photographer, Bradford-road, Dewsbury.

Will exchange half-plate camera and lens, three double dark slides, Tyler's metal slides, Lancaster Le Méritoire, for a good half-plate lens and camera, with a little cash.—Address, W. Cope, 88, Needham-road, Edge-lane, Liverpool.

Wanted to exchange a first-class 12×12 mahogany wet-plate camera with one single and two double dark slides, will take 12×10 plates both ways, in good condition, for modern stereoscopic camera and lens.—Address, J. Simmons, 8, Springfield-lane, Salford.

High class quarter-plate camera, latest improvements, three double slides, walnut three-fold tripod, and Taylor & Hobson view finder in exchange for whole-plate camera and slide, good condition.—Address, J. K. Smith, Little London, Rawdon, near Leeds.

Exchange a graduated flatted oil background, seven feet by five feet six inches, for three-quarter figure, lighted from the right, by F. Duran, of Handsworth, Birmingham, quite new, for a good interior or exterior.—Address, W. Jones, 272, Uxbridge-street, Burton-on-Trent.

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries and Exchanges, must be addressed to* "The Editor, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from 4 to 6, or Thursdays from 9 to 12 noon, when some one of the Editorial staff will be present.*

Photographs Registered:

Edwin Frere, Brighton.—*One photograph of Henry Frederick Plunkett.*

Samuel Beverley, Blackpool.—*One photograph of Blackpool Tower, taken from north-west; one photograph of No. 4 Section, Base Girder, North-west Leg of Blackpool Tower.*

F. F. F.—Mr. W. W. Winter, of Midland-road, Derby.

F. H.—Inquire of Messrs. Winstone & Sons, Shoe-lane, E.C.

Gelatine.—Sensitise the gelatine by immersion in the bichromate.

J. F. Hammond.—Our impression is that the idea is of little practical use.

A. E. Smith.—The address is, Guilbert Martin, 1 and 2 Falcon-street, Aldersgate-street, E.C.

Cymro (Cardiff).—The extra inch in focus accounts for the difference in rapidity of the two lenses.

J. Allingham.—Possibly Messrs. Rayner & Cassell, Chancery-lane, W.C. would meet your requirements.

Nemo.—The latest work on optics advertised in our pages is *The Optics of Photography and Photographic Lenses*, by J. Traill Taylor (published by Whittaker & Co.).

Enquirer.—By all means protect the article. Ask at any Post Office, and you will get the necessary forms giving all the information you require. It would take up a great deal of our space to reproduce here.

B. C. Wilson.—The bright planet seen near the east at night is Jupiter. This you can ascertain for yourself by looking at it through a pocket telescope or a good field-glass, by which the moons will be rendered distinctly visible.

Yorkie.—1 and 2. See The British Journal Photographic Almanac for 1893, in which orthochromatising formulæ and methods of preparing tinted screens are given. 3. Possibly the exposure is increased six or seven times. 4. Ruby glass is preferable.

K. B. says: "Will you tell me where I can find a detailed description of the process for producing relief blocks in half-tone by ruled screens, that is now in such general use for illustrating purposes?"—Yes; in The British Journal Photographic Almanac for 1893.

M. Todd.—Send us two or three examples of the negatives to see. From the description it would seem that some of the marking may be due to the plate not being sufficiently rocked during the development. But that would not account for the "straight line stains at irregular intervals."

J. E. Y.—If the mounts were guaranteed to be free from any injurious action on the prints, and you can prove that they have, you have good cause for action against those who supplied them. As you were not supplied direct from the manufacturer, or had any dealings with him, you must proceed against the dealer.

R. C. S.—The discrepancy between the price of absolute alcohol here and that on the Continent is fully accounted for by the duty that all spirit has to pay in this country. If the foreign alcohol were imported, the duty that would have to be paid upon it would bring the price up to that of English spirit, if not higher.

Hypo.—The glass in the side of the studio can be of little or no use, owing to the proximity of the adjoining building. The lighting would be improved by a large side reflector, which, if necessary, could be placed outside in the eighteen-inch space between the studio and the stores. A movable reflector inside the studio might also be employed with advantage.

A. (Essex).—At the village druggist's is not the best place to get photographic chemicals, especially such as sulphite of soda and other substances that are not improved by long keeping. Dry plates drawn from such a source are not always to be relied upon as being of recent make. We should advise having what is required from some dealer in a large town.

F. Wyllie.—Thanks; we have forwarded your communication to our correspondent.

C. S. S.—The beer and water-glass formula quoted is that generally adopted by those who employ that substratum in collotype. It is not, however, now so much used as it was formerly. The brand of gelatine mentioned is as uniform in quality as most of the foreign gelatines are. It is a good plan to obtain a large quantity at a time, so as to avoid the variation of different batches.

M. Wilson.—The marginal irridescent stain is due to the plates being old. Some makes of plates, indeed most of them, have this appearance after being kept so long as yours. Three years is more than most plates will stand and yet be perfect. We do not see that you have any valid complaint, unless, as is scarcely probable, the plates were guaranteed to keep good for so long a period.

W. Young.—The fault in the portrait arises from the sitter being placed directly opposite the window. This should always be avoided in taking portraits in an ordinary room. The sitter should be posed at the side of the window and a little distance behind it. Then the strong shadows must be softened with reflected light. A table-cloth on the domestic clothes-horse forms an excellent extemporary reflector.

A. X. O.—There is no fixed price amongst London photographers for doing outdoor groups and similar work, any more than there is for portraiture. Every one fixes his charges according to his own idea of the value of his time or that of his *employé*, and sometimes according to what the customer is willing to pay. Some London firms even make no charge for taking the negatives, but simply rely upon orders of copies for their profit.

Great Yarmouth.—Albumen pictures can be toned in the combined toning and fixing bath. Indeed, this was the original method by which prints on albumenised paper were toned. But, to get good rich prints by this system, strong negatives and strongly sensitised paper are necessary, and also considerable over-printing. Under these conditions, extremely rich velvety tones are obtainable. The combined toning and fixing bath was abandoned because it was found that the results by it were not permanent.

T. Thomas asks if "there is any rapid method of drying negatives when prints from them are wanted in a hurry without risk of injury to the film?"—Gelatine negatives can be dried very quickly—in a few minutes, if necessary—without risk in the following manner: First remove the surplus water from the surface carefully with blotting-paper. Next immerse it in strong methylated spirit, keeping it moving about the while, for three or four minutes. At the end of that time repeat the treatment with fresh spirit. Then the negative may be placed in the sun to dry, or it may be dried at a moderate distance from the fire.

F. Browning writes as follows: "I want a very hard and insoluble gelatine to which I intend to add a large proportion of chrome alum so that, when the thick solution is dry, it will form a hard and tough film for a new process to be perfectly waterproof when finished; that it is to be as non-absorbent of warm water as celluloid. The hardest gelatines we know of are "Coignet's Gold Label," and Nelson's "Opaque," but a large proportion of chrome alum cannot be added to a thick solution of either without causing it to coagulate. The effect of chrome alum on gelatine, although it renders it insoluble in warm water, does not prevent its absorbing it and becoming softened with long soaking.

Aq. Vit.—So far as we know, there is no law by which a magistrate can order the withdrawal of a portrait from a show-case or a shop window. We imagine, however, as the exhibition of the picture under the circumstances is causing pain and annoyance, an injunction from the Court of Chancery could be obtained, and that might prove an expensive matter to the exhibitor. If you are the exhibitor referred to in your letter, and we strongly suspect you are, would it not be better, even from a business point of view, to remove the picture than continue the annoyance? In a country town such behaviour is sure to be commented upon, and is sure not to conduce to an extension of business.

Rembrandt asks how the bitumen used by process workers is obtained, which is more sensitive to light than that as ordinarily sold?—The bitumen of commerce is first reduced to a fine powder, and then shaken up in sulphuric ether, which dissolves a large proportion of the insensitive matter. The liquid portion is then poured off, and the treatment repeated with fresh ether two or three times, or so long as matter continues to be dissolved to any material extent. The powder is then emptied out on to blotting-paper and allowed to dry in the dark. It is then ready to dissolve in benzol. Messrs. Mawson & Swan used to keep this extra-sensitive bitumen in stock, and probably do so now, and it would possibly be more economical to purchase it than to prepare it for oneself.

*** Several answers to correspondents, articles, and other communications unavoidably held over.

FOCUS LAMPS AND OTHER ARTIFICIAL ILLUMINANTS.

By a "focus" lamp we here mean an electric incandescent burner which has been brought out under that name by the Swan & Edison United Electric Light Company.

It is over a decade since we were asked by what sort of burner the electric light could be made to subserve the interests of those who desired to employ the incandescent burner for such optical purposes as recognise the concentration of the light by means of a condenser. The arc light, as every one knows, does this in a perfect manner, but the form of the filament in common use in the incandescent lamps is quite against it. The suggestion we made was to the effect that the carbonised filament should be of a form similar to that of a watch mainspring when released, its diameter being confined to about an inch, and the number of coils limited to, say, four or five. At the time this was proposed we were told that it could not be done. But electrical appliances are growing with a rapidity and in a state of perfection undreamt of ten years ago; and when a few days since, and in course of conversation with Mr. E. P. Robertson, of the Indian Civil Service, we learnt that he had in use such a lamp as we had long desiderated, we very gladly availed ourselves of an invitation to witness its application to projecting, copying, and enlarging purposes. The burner consists of a long carbonised filament folded or bent in such a manner as to form a zigzag surface of presumably an inch square each way, presenting the appearance of a flattened spiral, or suggestive of a small gridiron. The candle power is 100, which for lantern parlour entertainments, with a screen of about eight feet, is quite satisfactory, although Mr. Robertson expressed his intention of having another burner giving an increased intensity of illumination. Burners of this class, we learn, are made up to a power of 200 candles.

We were charmed with the facility with which the lantern was brought into operation. The house in which it was had, like most of those in that district, the electricity "laid on," and gas, colza, and even petroleum seemed things of the past. In some mysteriously hidden corner a wire from the lantern had found a port of entry, and was instantaneously connected with an equally hidden electrical main; a button or its analogue at the side of the lantern was pressed and the lightning was poured forth in a dazzling stream. Several slides were passed through the lantern and were voted to be sufficiently illuminated, that is, sufficiently well for parlour or domestic entertainments, although scarcely so for a schoolroom or lecture hall. Although the candle power was professedly 100, it appeared to us as if this figure might have been somewhat increased without impairing the fact.

Every house is not, alas! yet fitted up with electricity, although prophets, even of the tamest order, declare that many years will not elapse ere at least every hall and public building will be. In the mean time, what is to be done? Batteries are cumbersome, inconvenient things to have around when one wishes to have a little electric lighting. A few years ago, it was stated in a New York newspaper that preparations were being made to deliver a supply of electricity each morning at houses not on the circuit, simultaneous with the morning milk. This certainly is within the range of practical enterprise, thanks to the discovery of storage batteries. But suppose one desires to give a lantern show at some little distance from home, what then? Storage batteries are heavy things and are not amenable to easy conveyance. Hence for this purpose compressed oxygen will still hold its own.

The application of electricity to enlarging and copying as adopted by Mr. Robertson is simplicity itself. There is a background painted white, and on this is directed the light from two burners of less power than that spoken of. The light from these is cut off in all directions save that towards the white background now strongly illuminated. Two cameras on parallel rails are erected on the table; one contains the negative that is to furnish the enlargement, the other and larger one contains the lens and the paper or plate on which the enlargement is to be made. It is much the same as if the negative were directed against a bright sky, but is much more convenient and reliable in practice.

Reverting to electricity for projection purposes, who among electricians is to solve the problem of rendering it applicable for those not so fortunately situated as to have it form one of the regular fixtures in a house?- Fame and fortune awaits him.

The light which we saw tested was, as already stated, of one hundred candle power. This power has already been attained with some kerosene oil lamps, at the expense, however, be it noted, of some discomfort arising from great heat and unfragrant smell. Messrs. Perken, Son, & Rayment claim to have produced a triple-wick oil lamp in which the luminosity is equal to the candle power mentioned, while the light is very pure and the heat less than usual. The principle of construction recognises large air passages leading up to the level of the wicks, and, the air being brought to play upon the flames at their base, more perfect combustion is claimed. The chimney, which is long, aids this combustion. We have been present at trials made with it, and find that their allegations as to purity and intensity of flame are maintained.

TONING GELATINO-CHLORIDE PRINTS.

Although, in experienced hands, the modern gelatino-chloride printing-out papers are capable of producing results in every way equal to, and in many respects superior to, those obtainable with the best albumen paper, there can be little doubt that in the ordinary course of practice there are a larger number of failures or unsatisfactory prints turned out upon the new than upon the older paper. We are not now referring to failures arising from the physical character of the gelatine paper, such as the softening or dissolving of the sensitive surface or similar accidents, which, after a little practice, may be completely guarded against, but more particularly to defects in the colour and gradation of the image.

Indisputably, with gelatine, as with albumen paper, the chief art in printing lies in the toning, just as in production of a negative the result depends mainly upon the development, the remaining operations presenting comparatively little difficulty, or requiring an inferior degree of skill. But in conjunction with gelatine paper it may be said, with certainty, that the toning operation is surrounded by difficulties which do not attend the working of albumenised paper, difficulties arising from the paper itself, and not from any carelessness or want of care on the part of the operator.

For instance, in looking through a collection of prints by the same operator, one cannot but be struck by the great variety of tones exhibited, ranging from any kind of brown to purple, black, and grey; whereas with albumen prints the work of any individual artist will vary but slightly from the particular colour selected in the standard. Those who have had any considerable experience will know that this uncertainty and want of uniformity of tone increases with the number of prints operated upon, and that, while it is fairly easy to get uniform tones in a small batch of pictures, the case is quite different when a large number are treated at one time.

This does not appear to arise from any want of care in the manipulations, but simply from some change in the bath itself, or in its action on the prints, which causes the later prints toned not only to take a much longer time to acquire a given colour, which might be expected, but also to change to a greater degree in the subsequent fixing than is the case with the earlier ones. We have frequently noticed, and the same thing has been remarked to us by others, that, although a batch of prints before fixing may present an appearance of almost perfect uniformity of tone, they will, after fixing and washing, exhibit every variety of colour, from brown to the extreme limit of blackness, that has been attempted; and in such cases close observation will reveal the fact that it is the later-toned prints that have "gone back" most in the fixing bath.

Such results were often obtained, it is true, with albumen prints, but then there were other conditions to which they might be traced. Thus it was a common practice to use the toning bath in a tepid or even warm state, and, unless special means were adopted to keep up an even temperature, the action of the solution would necessarily vary as it got cooler. But this condition is entirely absent in the case of gelatine paper, since the bath is always employed, or should be, at the normal temperature, and is, at least, not likely to vary very much during the toning of a single batch of prints.

Of course the action of the bath must be expected to vary as the toning proceeds, from mere consumption of gold, but most careful operators, in dealing with a considerable number of prints, will take the precaution of gradually replacing the gold abstracted by the occasional addition of small quantities of stock solution. This, in the case of albumen paper—unless we except some brands of "ready-sensitised" that have come under our notice—forms a complete remedy for uneven toning, but unfortunately it does not with gelatine paper; we have ourselves more than once found the bath absolutely refuse to tone after a while, although far more gold has been added than could possibly have been abstracted by the prints toned, and this kind of behaviour is what is generally complained of by others. In fact, so great is the difficulty in this direction that some operators persistently tone their prints in small batches, using a fresh quantity of solution for each.

This, of course, adds very materially to the cost of toning gelatine paper, for, in order to secure the greatest economy, it is desirable to use the same solution over and over again, adding fresh gold as required. This was, and is, in fact, the common practice with albumenised paper, the same solution, with necessary additions to keep up the strength and volume, being often kept in use for months or years. But, so far as our own experience, as well as that of others, goes, such a course is not practicable with gelatino-chloride—under ordinary circumstances, at any rate. Even with the acetate bath, if used once for only a fractional part of the number of prints a given volume will tone, if used again the next day, its toning power seems to have altogether gone, and no amount of strengthening will cause it to work satisfactorily.

We shall not deny that part of this result may be produced by carelessness in washing the prints and similar causes, just as would be the case under similar circumstances with albumen; but it also occurs in spite of every care, and apparently in consequence of some difference in the constitution of the sensitive surface. If we consider for a moment the preparation of albumen and gelatine paper respectively—independently, we mean, of the organic portion of the films—the difference is not far to seek, and suffices amply to explain the difference in behaviour.

Take, first of all, ordinary albumenised paper sensitised at home; that is to say, not bought ready-sensitised. We have a sensitive film composed solely of chloride and nitrate of silver imbedded in an insoluble layer of albumen. Albumenate of silver is usually spoken of as forming an important element in the composition of the film, but whether in this instance it can be considered as a definite chemical compound need not be argued, as it does not concern the question. We have, however, undoubtedly chloride and nitrate of silver to deal with. In the case of ready-sensitised papers of unknown preparation, we have in all probability, besides free acid, other organic silver salts, and it is well known that these papers also present toning difficulties which the freshly sensitised paper does not.

Turning to gelatino-chloride papers, these may be taken with tolerable certainty to contain, besides chloride and a small trace of nitrate of silver, a considerable proportion of citrate, tartrate, or other organic salt of silver, which is undoubtedly the cause of the difference in behaviour. In making that statement, we do not refer to any difference in the printing behaviour of the paper, but to its behaviour in regard to the toning bath, as we shall attempt to explain.

In the case of the albumen paper, when it comes to be immersed in the toning bath, the film may be supposed to contain, besides the reduced material forming the image, only chloride of silver, the soluble salts having been removed by the

preliminary washing. The action of the toning bath, then, is confined to the image itself, gold being deposited thereon, and the chlorine given off combining with the silver it displaces. If, from imperfect washing, free silver remains in the prints, chloride of silver in small quantity will be thrown down in the bath, and a very slight reduction of gold will also take place; but this latter reaction could only occur in the event of great carelessness in washing.

But in the gelatino-citro-chloride film, although citrate of silver is, to some extent, soluble in water, it is so comparatively slowly, so that it is not probable that it is removed from the print before toning, except in the case of very prolonged washing, if even then. Consequently, the toning bath, while exerting a portion of its strength in its legitimate function, further weakens itself by giving up its chlorine to convert the citrate, tartrate, or other organic silver salt, into chloride, a corresponding quantity of gold being thrown out of use, while the displaced citric or other acid goes into the solution. Here we have at once a very serious weakening element, as well as a cause of great uncertainty. But that is not all.

Some of the salts of the organic acids, as well as the acids themselves, notably oxalic, have a very powerful reducing action upon salts of gold in solution; so we can without much difficulty understand how and why the toning bath, after once being used for gelatino-chloride paper, becomes so rapidly useless. It is simply because the unused gold is reduced by the organic matter taken into solution. The presence of the organic salt also explains why the "combined" toning and fixing bath containing hypo, and also those containing sulphocyanide of ammonium, are preferred by many operators for the new papers although they are not perfect in their action.

The simple way out of the difficulty is to ensure the removal or conversion of the citrate of silver before toning. This is easily done by means of a short immersion, after two or three washings in plain water in a weak solution of common salt, which converts the citrate or the salt of silver into chloride. The prints, after this treatment, are again washed to remove the salt, and if care be taken to do this the toning proceeds as rapidly and *more* evenly than if the salt is not used. The bath behaves with greater uniformity, and in the case of the acetic bath can be used over again with perfect safety.

Not only are these advantages gained, but the total removal of the soluble and partially soluble silver salts ensures a more permanent tone, that is to say, one that changes less in the fixing bath, and this in itself is an aid to uniformity.

EQUABLE TEMPERATURES.

Referring to our observations a week or two ago upon this topic, we may say that we have heard quite a large number of discussions upon the use of hot water in preparing the developer, some candidly avowing they had never thought of using it in daily work; others saying there was no novelty in the idea (we expressly deprecated any supposition that we were proposing something new); and others, certainly the minority, again saw nothing to gain; no one, to our knowledge, had any objections to urge. We may now proceed with our batch of developed plates, and see where heat again may be employed. It is matter of common knowledge that the solvent powers of hypo are greatly reduced when employed at low temperatures; hence, if the "fixing solution" be permitted to fall almost to freezing temperature (and saline solutions may be reduced considerably below 32° without freezing), we have two possible evils] to encounter. Firstly, an unnecessary expenditure of hypo is entailed; secondly, if the low temperature be not counter balanced by increased proportion of solution for each plate, there is danger of ultimately stained or fading negatives, for it should always be remembered that the result of fixing in presence of an insufficient proportion of hypo does not necessarily exhibit its evil effects at once. The danger arises from the production of an easily decomposable invisible salt of silver which remains in the film. Our negatives are now finished, and washing is the process next to be referred to. All that may be said is, that the osmotic action takes place more quickly in warm than cold solutions, so that, if the first washings (and all negatives are better with a preliminary "rough wash" before placing in the final washing) be done with slightly warmed water, made, say, by pouring a little boiling water into the bulk of cold, the duration of the washing may be considerably reduced without danger to the negatives. We may dismiss this part of the subject by saying that such a plan adds greatly to the comfort of the operator, especially when there is much washing to be carried out.

We may next consider printing work. At once we will point out that one prime factor, almost a secret, of good printing is to keep the silver bath at an equable temperature. It is impossible to lay too much stress upon this. What a common experience it is in winter weather for printers to tell their employers that the albumenised paper is "not so good as the last," and probably the paper dealers could have something to say on this subject! Yet the true explanation is usually what we have just referred to—temperature. If the silver bath be reduced only a few degrees in temperature, the result with the same time of floating is equivalent to reducing the strength of the bath. Every one knows, when a certain point is passed, what that means—difficulty in toning to a good colour, and a muddy milky appearance in prints even from negatives of the highest printing quality. Of course the remedy, if temperature be disregarded, is to increase the strength of the bath, or else the time of flotation. But, instead of proceeding in this hap-hazard fashion, especially when it is remembered that excess of strength is almost as great an enemy to good tones as defect of strength, a far better, more workmanlike, and equally feasible plan is to keep the silver bath warm. When it is put away for the day, let it be kept in a warm corner, if there be one. If even this convenience be wanting, the cost of a small gas flame, either in a cupboard or used to heat a tray of water, containing the bottle of bath, is an item of absolutely insignificant importance, and to devise a plan to render it available needs scarcely a thought. Some printers that we have seen at work, knowing the importance herein of equable temperature, endeavour to retain it by pouring successive jugfuls of hot water into the tray used for holding the silver bath, and then, after draining, quickly pouring the solution in the latter, when it becomes sufficiently heated to obtain uniformity of temperature.

We will conclude by referring to one other important stage where extra heat is almost essential. We refer to the fixing solution for prints. Our remarks applied to fixing negatives are applicable, but in a very greatly increased degree, to the hypo solution for prints. They apply in a twofold manner. In the first case, negative-fixing solution is not always made afresh each day, while with prints it is (or ought to be), so that in the

former case we have only to do with such differences of temperature as are experienced from day to day. With fixing solutions made afresh each day in winter, the temperature may be so low as to produce the highest possible retardation of the process, owing to the well-known effect produced in the dissolution of hypo crystals, the great reduction of temperature. Recently-made hypo solution should always be assisted by the use of hot water, for even then, and in summer time, the temperature of the solution may still be low. In winter, if no hot water be used, the low temperature, if fixing is to be properly performed, will go near to doubling the hypo bill! We think now we have shown good cause why every photographer should, in his dark room, employ every possible and available means to produce and retain an equable temperature.

Expeditiousness of the Collodion Process.—Some modern photographers have been prone to deery the collodion process without knowing anything whatever about it. However, the members of several of the Societies have of late had the opportunity of witnessing demonstrations of its working, by those familiar with it, for lantern slides and other purposes. The astonishment of most who see the process worked for the first time is generally great that no dishes are used, the developer and fixing solution being simply poured on the plate and flowed backwards and forwards over it. But the thing that usually strikes them most is the rapidity with which the different operations take place. Many of those who have been inclined to disparage the process for its slowness seemed to be quite unaware that, so far as its manipulations are concerned, it is the quickest of all proceses. As a matter of fact, a wet-collodion plate can be prepared, exposed, developed, fixed, thoroughly washed, dried, and varnished ready for printing from or for the lantern in far less time than is usually expended on the development alone of a dry plate. In less than a quarter of an hour the whole of the operation, from cleaning the glass to varnishing the negative, can be completed.

Photographic Dealers, beware!—At an inquest held a fortnight back in the case of poisoning by cyanide of potassium, one of the witnesses is reported to have said that "it was customary in the army to take cyanide of potassium as a 'pick-me-up;'" also that it could be bought "at any shop where they sell photographic appliances." One of the jurors also remarked that he had purchased cyanide of potassium for photographic purposes. The Coroner, in his summing up, said he would lay the facts before the Pharmaceutical Society. Whether the Coroner's action will have any influence on that Society we cannot say, but dealers in photographic chemicals need be very careful as to whom they supply with small quantities of this chemical as well as other poisonous ones used in the art. Every now and then the Pharmaceutical Society becomes very active in prosecuting those who infringe the Pharmacy Act. To obtain, say half an ounce, of cyanide at the chemist's, one has to go through some formalities, while, at the wholesale chemist's, he can obtain a few pounds, or hundredweights, and no question be asked. It is a little strange that in cases of poisoning with cyanide of potassium the salt is always associated with photography, in which its use is really very limited. Where a pound is consumed in photography, a hundredweight is used in electro-plating and gilding; also in other crafts.

Photography and Rioting.—It is at times amusing to note the ideas of the lay public with regard to photography—how it is utilised by novelists, and how it is sometimes applied on the stage. Last week a correspondent in a daily contemporary, commenting on a discrepancy between the evidence given by the two sets of witnesses before the Commissioners at the Featherstone Inquiry, suggests that if the camera had been employed it would have shown beyond question the state of affairs at the time—the peaceable attitude of the colliers, the flight of missiles, and other acts of violence; and, what is of equal importance, it would have afforded the means of identifying the ringleaders. There is one important factor in the use of the camera that writers of this kind overlook, namely, light. The firing by the soldiers at the riots at Featherstone did not take place till just upon nine o'clock p.m., and the light at that time in the month of September is certainly not suited for instantaneous photography. However, the suggestion is good, and one that has been made by ourselves in connexion with previous disorderly gatherings, provided the light will serve. We have frequently expressed surprise that the authorities at Scotland Yard make such restricted use of photography, particularly in the detection of crime.

REPORT ON THE NATURE AND CAUSE OF CERTAIN YELLOW STAINS ON GELATINO-CHLORIDE PAPER.

[*Photographic Scraps.*]

At the request of the Britannia Works Company, I have investigated the cause of the yellow stains which at times appear on gelatino-chloride paper.

The specimens sent to me showed a disagreeable brownish-yellow stain, which quite spoiled the prints, and which in some cases was uniform, whilst in others it was patchy and irregularly distributed. In many cases the stains were more or less apparent on the back of the paper, as well as on the face of the print. The intensity of the stain varied considerably in different cases. The accounts given of the manner in which the paper had been manipulated threw very little light on the origin of thes tains, and seem to indicate that care had been taken in the washings, &c. It may be stated here, however, that this latter indication is not confirmed by the result of the investigation. The most remarkable point, however, and one in which all the statements, with a single exception, agreed, is that the stains *appeared during the washing between toning and fixing*. Their general appearance indicated that the stains were due to the deposition of silver sulphide. In all cases the ammonium sulphocyanide toning bath had been used.

In my own experience of the paper, which has been not inconsiderable, and has involved the use of various toning baths, no stains of this kind have ever been met with, and the investigation was directed with a view to ascertain not only to what cause the stains are due, but also to what causes they are not due.

Experiments were made with paper of the three ordinary colours, white, pink, and mauve, and three distinct samples of ammonium sulphocyanide were used, two of these being obtained from well-known dealers in chemicals, whilst the third had been sent to the Britannia Works Company as being part of a sample that had been used in making up a toning bath, with which the yellow stains had been observed. Many experiments were made, but it will not be necessary to refer specifically to more than a few of them.

Paper was carefully washed until all soluble silver salts had been removed, and was then immersed for some time in solutions of each of the three samples of sulphocyanide of the strength used in the toning bath. The paper was afterwards carefully washed. *No stains.*

Paper *without any washing* was immersed in the sulphocyanide solutions for some time, and then thoroughly washed. *No stains.*

Paper, part of which had been exposed to light, was thoroughly washed, and then immersed in the sulphocyanide toning bath until fully toned, three separate toning baths being made up with the three samples of sulphocyanide. After toning, the prints were washed in the usual way. *No stains.*

Paper, part of which had been exposed to light, was immersed, *without any previous washing*, in each of the three toning baths until fully toned, and was afterwards washed as usual. *No stains.*

Paper, partly printed upon as in the preceding experiments, was carefully washed, toned in each of the three toning baths, and then washed, *a very small quantity of hypo* (sodium thiosulphate) *being added to the first wash water.* The washing was continued in running water for some time, and at first the paper remained perfectly white, but, as the washing continued, *dirty yellow stains made their appearance, and when dried the prints were precisely similar to the stained prints about which complaints had been made.*

Paper partly printed upon was toned without any previous washing. No stains appeared whilst in the toning bath. The prints were then placed in a dish of water containing a very small quantity of hypo, and were then washed in several rapid changes of water, and afterwards in running water. At first the paper remained white, but gradually dark brownish-yellow stains made their appearance.

A portion of a toning bath was sent to me by the Britannia Works Company as being part of a bath used by a customer on one occasion on which had yellow stains were produced. I toned in this bath prints upon the three varieties of paper (white, pink, and mauve), both with and without previous washing, but *in no case were any yellow stains produced.*

From these and other experiments, to which detailed reference is unnecessary, I draw the following conclusions:—

(1.) *The yellow (or brownish-yellow) stains are not due to anything in the paper itself, and with proper manipulation no such stains are produced.*

(2.) They are not due to any impurity ordinarily present in ammonium sulphocyanide.

(3.) They are not directly due to imperfect washing before toning, *but, at the same time, this washing should always be carefully done, for other reasons that will appear subsequently.*

(4.) They are not due to acidity of the sulphocyanide toning bath, even when it is sufficiently acid to turn blue litmus paper decidedly red.

(5.) The stains that appear between toning and fixing appear *only when the paper comes into contact with small quantities of hypo* (sodium thiosulphate) *during the washing that follows toning.* The quantity of hypo required to produce bad stains is very small, and is such as may easily be introduced into the wash water in any one of the ways to which reference will be made presently.

The production of the stains in this way is easily explained. It is well known that when hypo (sodium thiosulphate) comes into contact with silver salts three compounds may be formed, namely, silver thiosulphate, or a silver sodium thiosulphate, or another silver sodium thiosulphate containing a larger proportion of the sodium salt. The first and second of these compounds are insoluble, and are very unstable, decomposing rapidly into dark brown silver sulphide, which when spread out in a thin film appears to be brownish yellow. One or other of these is formed when the quantity of hypo that comes in contact with the silver salt is small. The third compound is soluble and stable, and is not liable to decompose unless mixed with an acid. It is formed when the hypo is present in excess.

If the water into which the prints are put when they come out of the toning bath contains a small quantity of hypo, the change that takes place is as follows: The hypo acts upon the silver salt in the paper, and produces one of the insoluble and unstable thiosulphates, and the latter decomposes spontaneously as the washing proceeds, producing a small quantity of silver sulphide, which imparts a yellow or brownish yellow stain to the paper, the depth of the stain depending on the amount of contamination. At first the change is not apparent, but as the decomposition continues the discolouration becomes more marked, and this explains the statement, made by some of the complainers, that the stain became worse the longer the prints were washed.

There is also no difficulty in explaining the fact that in some cases the first prints put into the wash water showed stains, whilst the remainder show no stains. If the quantity of hypo with which the water is contaminated is small, it is all absorbed and used up, as it were, by the first lot of prints put in, and consequently, whilst these may be stained, those that follow remain white because the contamination has been removed from the water before they get into it.

Several different ways in which the wash water may become contaminated with small quantities of hypo will readily suggest themselves. The following are amongst the most obvious and probable:—

(1.) Using for washing after toning a dish that has been used for washing prints or negatives after fixing, or a dish that has been sued for fixing prints.

(2.) Wiping the fingers on a towel or duster that has been used for wiping up hypo splashes, and afterwards putting the fingers into the wash water.

(3.) Putting the fingers into the wash water after they have been in contact with crystals resulting from the drying up of hypo splashes on the work table.

It should be borne in mind that *a very small quantity of hypo indeed is sufficient to produce the stains.*

In those cases where stains begin to make a frequent appearance, although they have never previously been observed during several months' work, the explanation is probably not so difficult as it might seem at first sight. If, for instance, some hypo solution has been splashed on the bench or table, and has not been wiped up quickly, part of the solution will have been absorbed by the wood, and, even after the table has been wiped down, the hypo thus absorbed will slowly and gradually make its way to the surface in the form of an efflorescence of minute crystals, and it is obvious that these crystals may very easily get transferred into any dishes, &c., that may be used. This gradual oozing out of the salt from the wood sometime goes on for several weeks.

In concluding this part of my report, I can only repeat that I have failed altogether to produce the yellow stains between toning and fixing in any way except by allowing the wash water to become contaminated with small quantities of hypo.

Occasionally, though very rarely, yellow stains appear whilst the prints are in the toning bath. These may be due, and, probably, in most cases are due, to the accidental introduction of small quantities of hypo into the bath. If this should happen when the bath has been partially exhausted of its gold, the effect will be just the same as from the introduction of hypo in the wash water.

Personally, I have been unable to produce yellow stains in the toning bath, except by the introduction of hypo, but from the evidence of others it would seem that if the same bath is used over and over again, the gold being renewed from time to time, it may in the end begin to decompose in such a way as to produce stains on the prints. The probability of such decomposition is greatly increased if the prints are not properly washed before being toned. The practical conclusion to be drawn is that a new bath should be made up at short intervals. Such a course involves merely a trifling expense, since ammonium sulphocyanide is not expensive, and very little is required. Moreover, it is easy to remove, practically, every trace of the gold from the bath by the action of the prints, and this can, of course, be done before the old bath is thrown away.

It is stated that sometimes a toning bath begins to decompose so rapidly that gold is deposited all over the surface of the print, from off which it can be rubbed. If ever this should happen, it can only be due to the toning baths having been prepared with very impure materials.

The appearance of yellow stains either in the fixing bath or after fixing is too familiar in the case of all kinds of printing-out paper, and the causes are too well known to require any very detailed mention.

The stains that appear whilst prints are in the fixing bath are almost always due to the paper having been put into the bath whilst in an acid condition. In other words, the prints have not been properly washed between toning and fixing. Sometimes the stains are caused by the prints being allowed to stick together. They are thus prevented from coming freely into contact with the hypo solution, and, instead of the soluble stable thiosulphate being formed, the insoluble and unstable compound is produced and decomposes with formation of silver sulphide.

The yellow or brownish-yellow stains that appear after removal of the prints from the fixing bath are due to silver sulphide formed by the decomposition of the unstable compound to which reference has already been made so often. That is to say, the stains are the result of imperfect fixation, which may be due to—(1) Allowing the prints to remain for too short a time in the fixing bath; (2) the use of too weak a solution of hypo; (3) the immersion of too many prints in the same quantity of hypo; (4) the use of an old (and consequently a weakened) solution of hypo; (5) allowing the prints to stick together so that the fixing solution does not come freely into contact with them.

It is perhaps scarcely necessary to point out that all the causes of staining referred to in this report will operate in the case of any printout paper containing silver salts.

C. H. Bothamley, F.I.C., F.C.S.

THE NAISSANCE OF ART IN PHOTOGRAPHY.

[*The Studio, London.*]

Since first the world developed a written language, vain attempts have been made from time to time to define the term Fine Art. The reason for this failure is not hard to find; human minds are so variously constituted that no one definition of an abstract quality could be acceptable to all intellects. That what we call "Art" is an abstract or psychological entity is sufficiently proved by this very fact; the concrete we can always define. Definitions covering some phases of art, or representing art as it is accepted by the definer and those who are of his "turn of mind" have, indeed, been formulated. Such terms as "Beauty," "Good Taste," "Fitness," "Truth," "Naturalism," "Idealism," and so on, serve very well to represent one or more aspects of art, but each and all are utterly incompetent to express art as a whole.

Fine art appeals not merely to the senses, nor only to the intellect, though it must not displease either. In music it must not offend the ear by inharmonious discords; in poetry it must not offend the intellect by gross untruth or contemptible bathos; in painting or sculpture it must

not offend the eye by grotesque infidelity to fact or by inherent ugliness But, provided it accept such restrictions, there remains in each of these arts a wide field for imagination, for idealism, if you will; and we take it that in the something beyond mere fact or mere imitation lie the qualities which constitute the essence of fine art. A poem which describes an episode or a material sensation, however elegant the diction, however forcible the expression, however sensuously pleasant the rhythm, is but a triumph of words and no more, unless the indescribable "something" lies behind to appeal to our heart. Although a musical work be composed in strict accordance with every rule of the science, it will not be a work of fine art unless it goes to the soul as well. And so a painting, although it may have in it every element of truth, all the grace of form, all the interest of a deftly depicted episode, will yet not be a true work of art if it lack the "something" not seen, not even understood, which must be present to make the painting a "heartfelt" work of art.

It is necessary to express so far our own opinions, be they right or wrong, facts or dreams, to prevent misunderstanding of what follows. There are many who by no means accept such a standard of fine art; some because they are unable to comprehend it, some because they are unable to act up to it, some because they honestly believe it to be false. The truth or falsity of our idea is of no consequence provided we make clear the claims of photography to rank as a fine art.

Accepting the highest sense of the words, photography has no part in fine art. It has the power to select the fit, and to make the best of what is actually and materially put before it, but when all is done it remains simply a delineator. To photography is denied the capability of bringing together diverse beauties from various sources; we can photograph the handsomest man, or the prettiest woman in the world, and we can even make the most of the existing excellencies of their forms and features; but we cannot photograph a demigod with an aggregate of beauties unknown in any one body, nor an angel, nor a devil. If any one were bold enough to produce a fancy photograph of a "Christ," he would be instantly and justly reproved. We have seen "fancy" studies of Tennyson's heroes and heroines produced by photography; these, even had they not been ludicrous, would have been wholly unsatisfying to the many who hold Tennyson to be almost more than human. If photography could collect the beautiful, the fitting, the perfect, from various quarters, and could endow its graphic productions with the *simulacrum* of what we call art, even then the fact that we knew the production to be a matter-of-fact rendering projected by a lens upon a plate, would of necessity break the spell, and bring the whole performance down to the level of a clever piece of copying. If the capability possessed by the painter, who collects from various sources, and introduces into his work beauties which exist only in his imagination, be called "idealism," and if idealism be the highest phase of fine art, then we say at once that photography cannot aspire to the highest realm of fine art.

But is there any quality inherent in photography which places it for ever and wholly outside the pale of the Fine Arts? We reply without hesitation, No. Much photographic work has been done, and more is daily being done, which is beyond question artistic in the true sense of the word. An exhibition of photographs at the present day consists broadly of the following classes:—First, a great number of topographical prints, technically good, but with no pretence of being pictures. Second, a smaller number showing some intention of the worker to be artistic; occasionally these are more painful to behold than the undisguised transcripts of bare fact, but at any rate they show a good intention. Lastly, we find some few—but in a proportion that is daily increasing—which are pictures in all but the highest sense of the word; quite as good, so far as they go, as the average of those to be seen on the walls of exhibitions of paintings. Leaving out of the question what we have called idealism, what have we to look for in in a graphic representation of any subject? Composition, chiaroscuro, truth, harmony, sentiment, suggestion? All these, and more, are quite within the scope of photography. Photographs of the "impressionist" type have been successfully produced, and this is perhaps the most promising class we have at present. Colour is certainly denied to us; but, on the other hand, we have the power of catching fleeting effects, of securing truth in detail and perspective, and of depicting with ease atmospheric phenomena which can only with difficulty be reproduced at all, even by the ablest painters. The question is not what photographers do, but what photography can do. Photographers commit mistakes, without doubt, but the blame must not be laid at the door of photography. If many who have been trained to art were to express the results of their training by photography instead of with the brush, the capabilities of the camera would soon be better understood and more appreciated. And it is no part of our present object to shut our eyes to the faults of photographers, or to attempt to excuse them; on the contrary, we propose to dwell upon them at some length. Only it must be steadily kept in mind that photographers, and not photography, are thus attacked.

The very facility of the technique of photography has been one of its greatest enemies. In a few days any one of average intelligence can learn to make what is, so far as technical quality goes, a good photograph; consequently we have an enormous number of persons who have no idea of the most rudimentary principles of art rushing about all lands photographing. The science is so full of varied fascinations that it procures many followers, and these become so much enamoured of it that they do not lightly give it up. Every class of person seems to find something congenial in photography; the mechanical genius takes to devising hand cameras and instantaneous shutters; the chemical student wallows in strange combinations of "reducing-agents;" the globe trotter who glories in his travels has a handy means of proving his peregrinations; in short, every one finds photography so easy and so interesting a method to produce graphic and lasting results without lengthy or expensive preparation, that there is little cause for wonder that so many more or less unoccupied persons, having taken to it, stick to it. There is no reason why they should not do so; picture-making is not one of the cardinal virtues imposed upon mankind, and we have every right to make topographic photographs if we see fit. But among the legion of such those which are really pictures are apt to be overlooked. This is, however, the fault of our societies and not of photography. It is true that a few exhibitions have been held where artistic effect alone was supposed to be considered; but, although these showed a distinct advance in the quality of some exhibits, the others were in no way more worthy to be called pictures than are those in ordinary exhibitions, unless we find abnormal merit in mannerism and *réchauffage* of the ideas of others. Yet, amid all the merely mechanical works, one must remember that some "pictures," be they few or many, are also to be found.

There is no denying that not only the general public, but also many who are well qualified to judge of such matters, find one photograph to be "more artistic" than another; it is notorious that on several occasions several photographers have taken the same scene, and that one set of operations resulted in a picture, while the others gave mere topographical photographs. In such a case the artistic qualities can be compared, and have been compared, and it is evident that comparison of non-existing qualities is impossible. Further, there are a few men whose work almost always claims attention as standing far above the average in the matter of pictorial effect; the quality in such work which compels acknowledgment is at least of the nature of fine art. Moreover, it is a fact these men have, in almost every case, systematically studied the principles of art, and can wield a brush or pencil as well as a camera and lens.

ANDREW PRINGLE.

(To be continued.)

THE ALUMINIUM FLASHLIGHT.

[London and Provincial Photographic Association.]

ALUMINIUM has a much higher kindling point than magnesium, and consequently, when aluminium filings are blown or dusted through an ordinary flame, they do not ignite, as they are not in the flame sufficiently long to become heated through. Again, aluminium, if heated in a crucible to a white heat, scarcely oxidises, as the metal does not boil at this temperature, and a very thin film of oxide protects the surface. Magnesium would boil and blaze in a white hot crucible, as the vapour would burn.

If, however, we take the fine powder of aluminium, now so largely sold as a "silver" bronze, and blow or dust this through a flame, it becomes heated to the igniting point, and, weight for weight, yields a more powerful light than magnesium.

The commercial aluminium bronze powders contain, however, a trace of greasy material, which prevents the grains readily separating, and, if the powder contaminated with grease is blown through a flame, or used in an ordinary flash lamp, it tends to blow through in clots, and a large proportion escapes combustion.

This grease may be driven off or destroyed by heating the bronze powder to about the melting point of zinc; and, for operating on a small scale, it is sufficient to heat it in a test tube over a spirit lamp. The powder which I bring before you to-night has been thus heated, and it is readily blown about by the slightest breath. It ignites readily, and burns completely when used in an ordinary flash lamp; indeed, it burns more completely than does magnesium dust, as it is impracticable to use magnesium in an extremely fine state of division, owing to its tendency to oxidise spontaneously. Aluminium, on the other hand, can be stored in a minutely fine state of division without fear of deterioration by oxidation.

One incidental advantage of aluminium over magnesium is the non-iritating character of the fumes of oxide, magnesium, on the other hand, being an irritating alkaline earth.

The sample of aluminium powder before you consists of scales about a five-thousandth of an inch thick, and it is manufactured in Germany, the English agent being Mr. W. C. Horne, of 2, White Horse-alley, Cowcross-street, London. T. Bolas.

SOME PRACTICAL REMARKS ON THE WORKING OF GELATINO-CHLORIDE PRINTING PAPERS.

There can be little doubt that, since the efforts of several enterprising firms to bring before the general public gelatino-chloride printing paper of excellent quality and at a moderate price, the use of albumenised paper has, to a large extent, been superseded. More especially is this the case on the part of a large number of amateur workers who print their own negatives, and also by a goodly number of professionals who aim at keeping pace with the times, and who find that the highly glazed—or, as some choose to term it, patent leather gloss—does go down with the general public, no matter how inartistic others may deem it.

For small work, such as quarter-plate cabinet or half-plate sizes, a more highly glazed paper is preferred by nine out of ten people on account of the fine detail brought out by this class of paper, but for larger sizes the employment of matt-surface papers, such as platinotype or plain salted paper, are decidedly to be preferred, and the leaning on all sides seems to be against albumenised paper. Nor is it to be greatly wondered at when we come to consider the numerous troubles casual workers had to contend with, such as blisters, &c.; hence it is not to be wondered at that so many should hail with delight the introduction of such excellent qualities of papers as the market is now supplied with by at least three prominent firms in the photographic trade.

Notwithstanding the beautiful results obtained by the employment of such paper for printing small sized negatives, there are a very large number of workers who look upon the manipulations necessary to obtain such results with a good deal of doubt, the opinion being freely expressed that it is not so easily worked as albumen, and that, by the employment of glass as the final glazing support, an element of much uncertainty is introduced into the operation, for frequently they find the prints refuse to leave the glass, and become, as it were, hermetically sealed to the surface of the enamelling glass. But are such objections to the working of gelatino-chloride papers well founded? I think not.

I am quite aware that there is a marked difference in the treatment necessary in the case of gelatino-chloride as against that of albumen, and any one who decides upon working the former must make up his mind to discard many of the manipulations resorted to in albumen; but, once the working of gelatino-chloride is properly understood and carefully conducted, the results are perfect, and failures are almost *nil*, for the routine is simplicity itself, and in no sense is it more difficult or troublesome than in the case of albumen.

From time to time, however, we hear of no end of failures and other insuperable difficulties attending the glazing and mounting of these highly enamelled prints, and judging from the numerous queries constantly put forth in the columns of the various photographic periodicals respecting the best way to overcome the trouble of prints refusing to leave the glasses, &c., and the best means to employ for the mounting of them, it would seem as if the proper method of treating these papers was but little understood. At least, I know that, in my experience lately, I am more frequently asked questions relating to these imaginary difficulties on the part of amateur workers than on any other branch of photography.

In the following articles I shall endeavour to pen a few practical remarks on what I know to be a subject of interest to a great many amateur workers, and, perhaps, professionals also.

In the first place, the idea must be discarded that gelatino-chloride will yield good prints from bad negatives. I find an opinion generally held by amateurs that, no matter how poor or thin a negative may be, gelatino-chloride will pull off a good result. Now, this is a great mistake; in a sense, it is quite true that a thinner class of negative, properly treated, will yield excellent results on gelatino-chloride as against albumen, but the best negatives will yield the best results in all cases. I don't know if my experience tallies with that of other workers who, from time to time, pass an immense number of strangers' negatives through their hands for printing purposes; but I am compelled to state that, since the introduction of the hand camera and the indiscriminate use of very fast plates for all purposes, there has been a sad falling off in the average quality of negatives turned out by ninety-nine out of every hundred workers who really pride themselves on the superiority of their work. The great majority of negatives are poor, thin productions, very frequently almost entirely ruined by fog in some shape or other, and from which many printers turn away in disgust, when they remember the pleasure and satisfaction of printing such negatives as were generally produced on plates of a much less exalted degree of sensitiveness, and which were properly timed in exposure and well developed. Alas! this is entirely changed, and the bulb-squeezer's, or button-presser's negatives of 1893 are as unlike such as can well be imagined; but it pays the plate and camera makers, and, so long as a moderate degree of pleasure is experienced by those who practise it, I suppose it is all right, and will continue, but do not let it be supposed that gelatino-chloride, or any other class of printing papers, will yield satisfactory results from such productions. The best results are got from the best negatives, and at this season of the year a word of warning is not out of place to those who are about to undertake the printing of good negatives by means of gelatino-chloride paper. In the summer season, when the atmosphere is drier, and the weather not so liable to sudden changes of dampness and humidity, the same precautions are not so necessary, but in early autumn or winter-time considerable precautions ought to be taken to avoid bringing the surface of any gelatine negative, that is in the slightest degree damp, in contact with gelatino-chloride paper as a printing medium. In all cases, when a negative that has been stowed away for any length of time is brought out for printing, such should be carefully warmed, and assimilated to the temperature of the printing room, and on no account should the frame be exposed at a window or outside all night, whereby dampness would be liable to affect the surface of the paper as well as the negative. With those casual workers who are not able to give the necessary attention to the printing of a negative during the business hours of the day this is a practice very frequently resorted to, so as to get the benefit of any morning light that may offer; but such practice, sooner or later, will ruin the negative, and, on the other hand, tends to prevent the best results in tone being arrived at. I have said that the best negatives will yield the best results. As a rule, however, negatives that are judged too thin or weak for good printing by means of albumen may be made to turn out fairly good results with gelatino-chloride, and thin negatives may be further improved by a judicious use of a ground-glass varnish, which has been caused to assume a greenish hue by means of a suitable pigment or pigments.

In my practice, whenever a negative comes to hand that is judged too weak or thin for good printing, it is treated to a coating of green ground-glass varnish. This I make up by adding to a good sample of ground-glass varnish a sufficient quantity of yellow and blue oil paints (gamboge and Prussian blue) so blended, and in quantity sufficient, as to yield the desired density of tint. Small tubes of these oil colours can be bought for a copper or two from any well-appointed artist colour shop, and any novice can strike a good green by judiciously mixing a little of each on a glass slab, and afterwards adding the green colour to the sample of ordinary ground-glass varnish. This coloured coating is, of course, flowed on the glass side of the negative, and if the proper quantity of colour is added the varnish will set with its usual matt surface and of a delicate green tint, that materially improves the printing quality of an over-thin negative. The bottle should, however, be well shaken after standing for a time. Sheets of green glass may be substituted for the varnish in such cases, but the varnish applied to the negative is the most convenient form, and a golden rule to follow is not to over-tone a print made from a weak negative. T. N. Armstrong.

AMMONIA AS A FIXING AGENT.

Despite the rapid advances which in recent years have been made in the art of photographic reproduction in permanent pigments, and notwithstanding the beauty of the results that in many cases have been obtained, there is, nevertheless, no room for doubt that the old-fashioned silver print on albumenised paper still occupies the leading place in the popular favour and preference. Public taste, so frequently founded on mere caprice, seems, in this particular instance, to have formed a fairly just estimate of the merits of the case.

The question of colour apart, there exists in the silver print a certain depth, a certain grateful combination of richness of tone with clearness in detail, which few of the more permanent processes have succeeded in imitating with any degree of success. Indeed, were only the resulting print of a lasting character, there seems little reason to doubt that the silver process would be the process of the future, as it has been the process of the past.

The question of the want of permanence of the silver print leads

us naturally to the consideration of the subject of fixing agents, and, from the very narrow range of fixing agents in general, it is but a step to the consideration of sodium thiosulphate in particular.

The disadvantages of sodium thiosulphate as employed inthis connexion are so widely known, and have been known for so long, that it is somewhat remarkable that no one seems to have thought of providing anything in the form of a substitute. It has always seemed to the writer that such a substitute might be found were a careful and systematic course of experiments instituted with that object.

Since the date when this salt was adopted as a fixing agent, the science of chemistry has made gigantic strides, both in theory and in practice, and in many of its applications has proved so beneficial to photography that it may be confidently expected to render important service in any inquiries in this particular direction.

There is a singular absence of intelligible data on the subject of the merits and demerits of fixing agents, and what little information there does exist, being chiefly to be found in the scanty records of the infancy of the art, is necessarily seldom seen and still more seldom read by the average photographer. This being so, any inquiries which may be made as to the feasibility of finding a substitute for sodium thiosulphate must be almost wholly tentative.

The employment of liquor ammoniæ as a solvent for the unreduced silver salts remaining in the toned trint is probably no new suggestion; but the writer, after considerable trouble, has not succeeded in finding that the results of any regular series of experiments on the fixing power of that alkali have ever been made the subject of communication to the photographic world.

In qualitative chemical analysis this solvent property of liquor ammoniæ has for long been taken advantage of in the well-known test for salts of silver. Hydrochloric acid, in neutral salts of that metal produces a white, curly precipitate of argentic chloride, *readily soluble in liquor ammoniæ*, and reprecipitated by the addition of an excess of the acid. This important reaction suggested to the writer that application of the article which forms the title of this paper, and a number of experiments made by him at intervals during the last three or four years have resulted in demonstrating the value of this reagent for fixing purposes.

A brief sketch of these experiments and their results he now proposes to lay before the readers of this JOURNAL.

At the beginning of this inquiry, with the object of testing the effect of ammonia on the untoned silver image, a print was taken in the usual way upon sensitised albumenised paper. This, after preliminary washings in several changes of water, was immersed for twenty minutes in a fixing bath composed of equal measures of concentrated liquor ammoniæ and water. The fixed print was well washed in cold water until it no longer showed an alkaline reaction. The resulting picture was of that disagreeable orange-yellow colour characteristic of an untoned silver print which has been fixed in a solution of sodium thiosulphite. In addition to this, the strong ammonia solution was found to have acted detrimentally on the albumen coating of the print, which it rendered slimy and irregular. Subsequently, a weaker fixing bath, containing only twenty-five per cent. by volume of the concentrated ammonia solution, was employed, and was found to have no sensible action on the albumen surface; but the prints so fixed still retained the former unpleasant orange hue.

The action of ammonia upon the toned silver image was the next branch of the inquiry. A print, similar in all respects to the first, was washed and toned in the ordinary manner, the borax bath being employed. It was then fixed in the twenty-five per cent. ammonia solution for twenty minutes. The resulting print, though agreeable enough in tone—being of a shade of warm brown—was found to be very weak, the ammonia bath having to a certain extent undone the work of the gold solution. The obvious remedy, a prolonged immersion in the toning bath, was then tried, and the prints so treated, after fixing were found to resemble in all respects those fixed with sodium thiosulphate. A corresponding increase in the time of printing was made at the same time, in order to maintain the strength of the image under the lengthened reducing action during toning.

The results of these latter experiments, in so far as mere appearance was concerned, were, as has been shown, fairly satisfactory; but that very important end, the permanence of the image so formed—which, after all, was the real object of the inquiry—proved to be less readily attainable. In the course of a few months a marked deterioration was visible in the majority of the prints so fixed. It showed itself as a reddish discolouration, appearing in the form of large irregularly shaped discs, and extended over the greater part of the surface of the print.

This discolouration was most apparent in the prints which had received toning previous to immersion in the ammonia bath, but was more or less visible in all. Careful examination of this phenomenon disclosed a fact which seemed to give an important clue as to the cause of the change. The original image in all cases retained its purity of tone and depth of colouring. The discolouration seemed to have no effect upon the finished picture otherwise than to show as a red stain or fog superimposed, so to speak, on the original colour foundation. This seemed to indicate that the markings were not due to chemical changes taking place in the metallic image. That fact being admitted, the inevitable conclusion presented itself, namely, that the discolouration was due to the decomposition of the albumen surface of the print. This conclusion the subsequent experiments fully confirmed.

A thin and tough sheet of unsized paper was taken, salted on a bath of sodium chloride, dried, and sensitised in an aqueous solution of nitrate of silver of a strength of fifty grains to the ounce. Prints were then taken on this paper, and, after washing, immersed untoned in the ammonia fixing bath for fifteen minutes. As there was no longer reason to dread the dissolving action of the concentrated alkali, the strength of the bath was slightly increased, a thirty per cent. solution of strong liquor ammoniæ being employed. The finished prints were of the same orange hue as those produced on albumenised paper by the same treatment.

Pursuing these experiments on the same lines as before, the action of the ammonia solution on the toned image was next investigated. The borax bath was again employed, and the washed print (previously rather over-printed) immersed therein until it assumed a deep purple tone. It was then washed and fixed in the same way as was its untoned predecessor. The picture so produced could not be distinguished in appearance from a silver print on plain paper fixed in the usual way.

After a sufficient number of toned prints had been so treated, they were well washed to remove the free alkali, dried, and, when dry, subjected to severe tests as regards their permanence. The method of procedure was as follows:—

An unmounted print was fastened at the corners to a thick cardboard mount by means of little triangles of gummed paper. The card was then placed in a situation where it was exposed day after day to the full strength of the sun's rays, and was occasionally shifted to the end, that the surface of the print might receive as much of the light as possible.

This treatment was the means of revealing some interesting and hitherto unsuspected facts, which may perhaps throw some little on those much-discussed reactions of which the fading of the silver print is the visible outcome. Certain of the finished prints had been a comparatively short time in the toning bath, and, after leaving the ammonia solution, were of a warm shade of brown. These, after continued exposure to sunlight, visibly altered. The purity of the high lights became slightly tinted, and at the same time the shadows suffered from a faint blurring, which was still more apparent on further exposure to the light. On the other hand, the prints which had been for a lengthened period in the gold solution, and which, when finished, were of an agreeable purple tone, showed not the slightest trace of deterioration. They were again subjected to the full strength of the sunlight for a number of days. On examination afterwards the most careful scrutiny failed to reveal any diminution in the purity of the whites, or any detectable increase in the depth of the shadows or half-tones. This exposure to light has been continued up to the present time; but, so far, not the slightest change has resulted. Time will, of course, be required to demonstrate the actual permanence of the prints fixed in this way. All that can be said or legitimately inferred in this matter is that, under certain conditions easily complied with, toned silver prints on plain paper may be fixed in a solution of liquor ammoniæ in such a manner as to resist the severest tests that can be applied within a certain limited period.

It is to the conditions for the successful working of this process a few words may be said for the benefit of such readers who may feel inclined to devote their attention to the practical side of the inquiry.

In the first place, in respect to the quality of the paper used, the writer has found that one of a thin character is to be preferred, as being more readily sensitive to the solvent action of the ammonia bath. Care must also be taken to choose a paper with a perfectly smooth surface, as prints taken on a coarse-grained paper have been found to require a prolonged immersion in the fixing solution.

For sensitising, a silver bath of not less than the normal strength of sixty grains to the ounce should be employed. If the fibre of the paper be sufficiently tough, the strength of the bath may be slightly increased, say, to seventy grains per ounce.

As has been already said, the operations of printing and toning (more

especially the latter) must be prolonged beyond what is thought necessary in ordinary circumstances. Upon the length of the toning process the permanence of the finished image seems, in a great measure, to depend, and, accordingly, prints should not be removed from the gold bath until they exhibit a deep purple tone in the shadows, which remains unaltered by the subsequent treatment in the ammonia solution. Prints which, when finished, are of a reddish-brown colour should be rejected, as unlikely to resist the action of light. The fixing bath is made by adding to ten fluid ounces of water four and a half fluid ounces of concentrated liquor ammoniæ. Prints should remain in this solution for a quarter of an hour.

Half an hour's washing in repeated changes of water, with constant agitation of the prints, and a final rinse in warm water, has been found amply sufficient to eliminate all free alkali. In this respect the advantages as to saving of time and of trouble, which the new process presents in comparison with the old, must be obvious to all photographers.

Such, then, are the few conditions which seem indispensable to the obtaining of satisfactory results.

Prints produced with due regard to these conditions have been found to resist the few influences which, under the ordinary condition of things, are brought to bear upon the finished image. Resistance to these influences must ever be regarded as the most satisfactory test of permanence. That term, being a strictly relative one, must always be understood as referring to the normal conditions and causes which it withstands. The abnormal, being capable of almost indefinite extension, must ultimately reach the degree beyond which the stability of the print becomes endangered, and, accordingly, it has been considered unnecessary to subject the finished picture to any severer tests than those likely to be met with under the ordinary circumstances of wear and tear.

Regarded from an artistic point of view, prints by this process have a certain charm of effect which is lacking in prints produced by the carbon and other pigment processes. On the other hand, it cannot be denied that the absence of the albumen coating is, in some degree, detrimental to the richness of the image. The greater advantage of permanence should, however, prove to the photographer an ample compensation for the slight loss in brilliancy ensuing from the non-employment of the unstable organic body.

In conclusion, the writer desires to point out to those interested the necessity for further experiments in the direction indicated in this paper. By experiment only can any additional light be thrown upon this rather obscure subject, and such a line of research is rendered still more desirable by the fact that the question of the permanence of the silver print has not yet received that amount of attention which, in the interests of photography, it seems to deserve.

MATTHEW WILSON.

ON THE PHOTOGRAPHY OF THE LUMINOUS RAYS OF THE SHORTEST WAVE-LENGTHS.*

(Chemical News.)

THE extension of the ultra-violet spectral region is in close connexion with the invention of photography and the discovery of fluorescence. The main region of the ultra-violet light was opened up with the aid of fluorescence, but in its exploration photography has given brilliant evidence of its superiority. The fluorescence method of observation has since gradually lost ground, whilst the efficacy of sensitive plates in the ultra-violet region has increased.

The first observations in the ultra-violet region were undertaken by Edmond Becquerel (*Bibliothèque Universelle de Genève* (new series), vol. xxxix. pp. 341 to 367 [1842]), when he was studying the chemical action of the solar rays upon Daguerre plates. The solar spectra of Becquerel were formed, however, under the influence of the absorption of the glass, and they extended, therefore, only to Fraunhofer's P line.

Stokes, who recognised the greater transmissive power of quartz for light (*Phil. Trans.*, vol. cxlii. pp. 463 and 559 [1852]; vol. cliii. pp. 599 to 619 [1862]), succeeded with prisms and lenses of quartz in following the ultra-violet of the solar spectrum to an extent which, measured from Fraunhofer's H line, was twice as long as the total visible spectrum. Still more surprising was his result with the electric light. The ultra-violet of his spark spectra extended from six to eight times the length of the visible spectrum. The most refrangible rays of all substances were given by aluminium, the spectrum of which bounded the region of the smallest perceptible wave-lengths with a strongly luminous pair of lines of the wave-lengths 160·0 $\mu\mu$ and 185·2 $\mu\mu$. More strongly deflected rays do not seem to have been ever recognised in this region by Stokes and his successors. On the same day (June 19th, 1862), when Stokes submitted to the Royal Society of London his treatise on the above subject, W. A. Miller gave in to the same Society his no less important memoir "On the Photographic Transparency of Various Bodies," &c. (*Phil. Trans.*, vol. cliii. pp. 861—887 [1862]).

Both these memoirs pursued the same object—ascertaining of the ultra-violet spectra of electric origin, and the behaviour of these spectra with substances in all three states of aggregation. But, whilst Stokes made his observations with the aid of fluorescence, Miller utilised the photo-chemical action of the rays and took photographs of his spectra. The method of fluorescence showed itself strikingly preferable to the photographic method in one point: Stokes arrived at the wave-length 185·2 $\mu\mu$, whilst Miller did not get beyond the wave-length 202·4 $\mu\mu$. Miller afterwards, induced by Stokes, repeatedly attempted to photograph the remaining rays, but always without the desired result (*Phil. Trans.*, vol. cliii. p. 882: 52 aluminium). The fluorescence spectrum retained here and in the sequel an advance which extended to the considerable extent of 172·0 $\mu\mu$.

This photographic ill success in the extreme ultra-violet excites hesitation if we see that L. Soret, Edouard Sarasin, and others, in their extensive researches, observed this part of the spectrum only by means of fluorescence. Hence it might seem as if photography was not suitable for the observation of the most refrangible light. Such an assumption is, however, completely refuted by the fact that Cornu made use of photography for determining the wave-lengths of the most refrangible rays of Mg, Cd, Zn, and Al (*Archives des Sci. Phys. et Nat.*, III. Période, vol. il. pp. 119—126 [1879]).

Cornu, driven to photography by the feeble light of his grating, adopted here the moist process, but, in contradistinction to Miller, he used the precaution of bathing the sensitised collodion plate in distilled water before its exposure to light. In this manner he obviated the most important photographic hindrance which the most refrangible rays encounter on a plate which has not been bathed, and secured at once a better photographic result.

A further difference between the experimental arrangements of Miller and Cornu deserves notice. The apparatus of these two investigators differed widely in their focal lengths. The focal distance of Miller's apparatus was by far the longer of the two. Hence the absorption of the rays in the air must have come into play to a different degree whilst the proof was taken. The experimental arrangement of Cornu was consequently preferable also in this respect.

The photographic result of Cornu for the smallest wave-lengths seemed to open out a favourable prospect for the investigation of the ultra-violet region which had hitherto been neglected. Unfortunately the future did not answer this expectation. Experimental hindrances of an unknown kind have again estranged the region of the most refrangible rays of aluminium (198·8—185·2 $\mu\mu$) from photographic spectroscopy. The majority of all researches extends even at present to the neighbourhood of the most refrangible lines of cadmium (226·55—214·41 $\mu\mu$), and only occasionally the region of the most refrangible lines of zinc (214·41—198·8 $\mu\mu$) is taken into consideration. This phenomenon is the more striking, as since Cornu's investigations spectroscopy has obtained, in silver bromide gelatine dry plate, an auxiliary which throws into the shade, in every respect, all the results of the collodion plates formerly employed.

The gelatine plate has for a series of years conferred invaluable services upon spectral research. It is only since its introduction that photographic observation has made successful way in spectroscopy; with it the conviction has been secured that a study of the visible spectrum alone does not suffice for the comprehension of spectral processes, but that there is required as thorough a knowledge of the invisible spectral regions, especially the ultra-violet. In recent observations this necessity is taken into account wherever possible.

In view of the fruitfulness of the efforts in the ultra-violet regions which recent years have matured, it seemed to me desirable and highly remunerative to open up to photographic study the remaining ultra-violet, as far as the wave-length 185·2 $\mu\mu$, by means of a more suitable process than those hitherto applied, and at the same time to consider the extension of this region of observation in the direction of greater deviation.

For several years I have been approaching the execution of this thought. My task resolved itself into two portions. The first was the photography of the spectral region between the wave-lengths 231·35 and 185·2 $\mu\mu$; the second was the opening up of the unknown region beyond 185·2 $\mu\mu$.

The present report discusses the first part of the work, and at the same time the preliminaries for the second.

Its results, as also the representations of the apparatus used and of the

* From the Reports of the Session of the Imperial Academy of Sciences at Vienna (*Mathemat. Natur. Class.*, vol. cii. part 2, April, 1893).

spectre obtained, will form the contents of a brief subsequent second report.

Each of these portions has engaged a considerable time, and the second portion still awaits completion.

If I now venture upon publicity with the results already obtained, although years must probably elapse before the completion of my work, the step has been induced, on the one hand, by the requests of a number of eminent physicists to whom I have had the honour of submitting my chief results; and, on the other, by my own wish to bring the facts ascertained to the knowledge of the most extended circles.

Photography of the Spectral Region between the Wave-lengths 231·35 *and* 185·2 $\mu\mu$.

A. With ordinary apparatus permeable for the ultra-violet.

The Photographic Spectral Apparatus, with particular reference to its Optical portion.—The photography of this spectral region requires an apparatus of great permeability to light. Glass (G. G. Stokes, *Phil. Trans.* 1852, cxlii. Art. 202), which keeps back most of the ultra-violet rays, is unfit for the prisms and lenses of such an instrument. Calcareous spar is not much better (L. Soret, *Archiv. des Sci. Phys. et Nat.*, lxi. 334 [1878]). Its availability for the ultra-violet ends where the above-named region begins. The only media which can be taken into consideration are quartz (L. Soret, *ibid.* p. 332, and G. G. Stokes, "On the Change of Refrangibility of Light," *Phil. Trans.*, 1852, Art. 204) and white fluor spar (W. A. Miller, "On the Phot. Trans. of Various Bodies," *Phil. Trans.* clii. p. 865 [1862]; A. Cornu, *Archiv. des Sci. Phys. et Nat.*, III. Période, ii. p. 119).

Fluor-spar in its white variety—all other kinds of fluor-spar are coloured and less permeable for the ultra-violet—is more transmissive than quartz; but it has hitherto been applied only in isolated cases on account of its rarity and as it frequently contains defects in crystallisation which imperil the clearness of the image (H. Deslandres, "Spectres des Bandes Ultra-violet des Metalloids avec une faible dispersion," p. 32. Paris: 1888).

In the photography of the ultra-violet region, quartz presents, upon the whole, greater advantages than any other medium. It yields spectra of faultless definition, and its lower transmissibility—just mentioned—is according to present experience, not so important as seriously to impair the photographs.

The Quartz Prism.—Not every quartz prism is fit for spectral photography. Every prism whose refractive edge runs parallel with the optical axis is unsuitable. The reason lies in the partial superposition of the ordinary and extraordinary ray, and in the circumstance that the photographic result on the extinction of one or other of the two spectra, which is certainly practicable with a Nicol prism, is destroyed by the non-transmissive character of the calc spar.

The relations are more favourable with a quartz prism, the refractive edge of which is cut at right angles to the optical axis in such a manner that the latter forms equal angles with the refractive planes. If the rays traverse the quartz in the direction of its optical axis, they no longer experience the ordinary double refraction, but they undergo circular polarisation, and in so palpable a degree that, *e. g.*, in a prism of 60°, every line of the spectrum is split up into two very nearly adjacent but clearly resolved components. It is plain that such a spectral image must be uncertain even if the lines are mutually isolated, but must be completely obscure in the case of crowded lines. This scission of the lines may indeed be avoided if a system of lines is cancelled by a quarter-wave plate with a Nicol inserted in the emerging ray. But the plate, as it consists of mica (W. A. Miller, *Phil. Trans.*, clii. p. 865 [1862]), is so impervious, that it absorbs almost all rays beyond the wave-length 325 $\mu\mu$, and, without considering the inconvenience in photographing occasioned by the impervious nature of the Nicol, it renders any photographic result in the ultra-violet at once impossible.

The only expedient to preserve the image from the disturbing effect of linear and circular polarisation, without interfering with brightness, consists in the use of a double prism (A. Cornu, *Comptes Rendus*, 1885) composed of a lævo- and a dextro-rotatory quartz, each of an equal refractive angle (30°). In preparing such prisms care must be taken that the optical axes of the semi-prisms are placed vertically to their common plane of contact. To avoid the loss of light the semi-prisms may be joined together with glycerine or distilled water; but this is not necessary. Double prisms of this kind, whether single or when several are connected in a circle, give spectra of a faultless definition.

The Quartz Lens.—The lenses for the collimator and the camera are best of a plano-convex form. They may either be of a like or of an antagonistic rotary power. It is, however, essential that the geometric axis has the same direction as the optical axis of the crystal, or, as the opticians call it, are cut at right angles to the axis. Quartz lenses consisting only of one part never double the image. Therefore double biconvex lenses, composed like the double prism just mentioned, of lævo and dextro rotatory plano-convex quartz lenses, afford no advantage in spectral photography.

The focal distance of the lenses must be equal, and not exceed one metre. If larger, it may easily happen that the aperture of the apparatus is too small. Although lenses of sufficient diameter can be procured without too great difficulty, the aperture of the prism still remains; but quartz prisms with a rather large aperture rank among rarities. Insufficient apertures easily occasion the formation of inflection fringes, which appear on both sides of the brighter lines of the spectrum, and may easily prove serious in interpreting the spectrum.

On the other hand, the focal distance must not be reduced too far, not below three-quarters of a metre, as the spectrum is otherwise too short. An increase of dispersion by the application of several prisms is not to be recommended. With a combination of several double prisms the spectrum appears clearly defined only for a short extent. The greater the number of prisms the shorter is the clearly defined extent. The simultaneous photography of extensive spectral regions should therefore be effected at the outside with a few, but preferably with a single double prism. This applies especially to a general photograph of the ultra-violet region.

It will be understood that the selection of crystals from which prisms and lenses have to be cut has to be effected with great care. Distortions, which are not rare in quartz crystals, make every crystal unfit for use.

As great attention must be given to the nature of the refractive planes, curvatures which, on account of their moderate size, have in glass prisms no effect on the spectrum, may greatly interfere with the effect of a quartz prism.

Quartz prisms with faulty planes always give an impure image of lines, though less when used singly than when several are associated in a circle. Such a circle is capable of bringing the spectrum into complete confusion.

Excellent prisms and lenses of quartz are made by the optician, Bernhard Halle, of Steglitz, near Berlin. As a proof of the excellence of his work, the fact may serve that a circle of nine double prisms supplied to me by Herr Halle, in which the rays have to traverse thirty-six refractive planes, gives in an extent of 3¼ mm. all the eighty-five lines which H. C. Vogel's Atlas of the Solar Spectrum shows between the lines H and K.

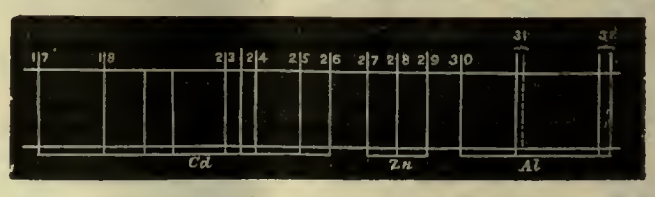
The moderate sensitiveness of the spectrum to certain defects of the lenses is remarkable. This applies to the centering and the direction of the optical axis of the crystals. I have been able to use continuously, without disadvantage, a pair of quartz lenses which showed unusual deviations for resolving dense groups of lines.

This circumstance deserves attention the more as the spectrum is very sensitive to all kinds of faults in the quartz.

The adjustment of the prism and the lenses is effected in the same manner as in the spectral apparatus.

The slit tube of the photographic spectral apparatus is of the ordinary construction. Only the photographic part of the apparatus differs from well-known instruments, and this only as regards the holder of the dark slide, by which I understand that part of the camera which serves for the reception of the dark slide.

The slide-holder is much more capable of being turned than in the ordinary camera, for the following reason:—Quartz lenses, as their focal lengths decrease considerably with the wave-length, require frequently, in photographing the spectrum, a very unusually inclined position of the photographic plate to the axis of the camera lens. If, *e.g.*, the focal length of the sodium line, D (589 $\mu\mu$), is 1000, the focal length for the most refrangible line of aluminium, No. 32 (185 $\mu\mu$), is only 806·2 (E. Sarasin, *Archives des Sci. Phys. et Naturelles*, lxi. p. 109, 1878). This oblique position is not constant; it varies with the dispersion and with the



proportion of the focal lengths of the collimator and the camera. If the focal length of both is equal (the usual case), the angle between axis and plate, measured on the more refrangible side of both, varies from 22° in a single prism (60°) to about 90° for twelve double prisms (two circles of

prisms placed the one behind the other). But the angle is not constant, even for one and the same prism-body. It varies here with the selection of the rays for which the prism is adjusted as at the minimum of deflection, also requirements made for the resolution of single parts of the photograph. Under these circumstances it varies in a single double prism from 28° to 22°. According to a circuit of the angle above named, the plate, with the dark slide and the slide-holder, must be capable of rotating on one of the middle lines of its sensitive side, and have such a position that this medium line forms a parallel to the refractive edge of the prism cutting the optical axis of the camera lens.

VICTOR SCHUMANN.

(To be continued.)

Our Editorial Table.

EDWARDS' NEW DARK SLIDES FOR FILMS.

B. J. EDWARDS & CO., The Grove, Hackney, N.E.

IN the dark slide for films or plates which Mr. Edwards has invented will be found many points of novelty and utility, in addition to lightness and portability. The slides are made to take two films, or two thin glass plates. The draw shutters are made of xylonite, one side being black, the other dark red; the latter, when facing outwards, indicating that the film or plate next it has been exposed, and also serving for the inscription of memoranda.

The holder, too, containing the plates, is easily removable. It has an end piece, which folds back, thus allowing of the insertion of the plates or films back to back, a sheet of black opaque material being placed between them. The end piece being replaced, the two plates are held in position, and the carrier is then easily returned to the slide proper. The new slide is very compact and small, and should acquire a great popularity among those anxious to reduce bulk and weight in camera impedimenta.

Mr. Edwards has also designed a simple film-carrier for ordinary dark slides. In this, a thin metal frame, with turned-back edges,

holds a stout card, which, to insert the film, is removed by being slightly pressed on the centre through the opening in the frame. The film is then placed half way in the groove, the card put in under the film, and both pushed home together. It should form a useful, as it is, undoubtedly, a simple and effective film-carrier.

BURNET'S ART ESSAYS.

MESSRS. PERCY LUND, & Co. have issued a reprint of these excellent essays at a very cheap rate. The three essays comprise "Hints on Composition in Painting," "Practical Hints on Light and Shade in Painting," and "The Education of the Eye." These were originally published separately; the first in 1822, the second in 1826, and the third in 1837. The original price was 2*l.* 18*s.* 6*d.*, while that of the reprint, including the photo-lithographic illustrations, is half-a-crown. Although written for painters, they afford invaluable information for photographers, and we are glad to see a good book issued at so low a price.

NEGATIVE-MAKING.

By CAPTAIN ABNEY, C.B., F.R.S., &c.

MESSRS. PIPER & CARTER have published a second and revised edition of this primer, which is written with Captain Abney's well-known accuracy, while it is couched in simple language, for it was originally contributed in the shape of articles to the *Boy's Own Paper*. It is eminently practical, and has been brought up to date. Price 1*s.*

AN INTERCHANGEABLE SCRAP ALBUM.

MARCUS WARD & CO., LIMITED, have published a series of albums adapted for holding unmounted photographs, when properly

inserted, which can be done with great readiness. The accompanying cut shows the appearance of one of those albums when the scrap photographs have been inserted, in all but one from which will be seen the mode of insertion. Its utility is undoubted.

News and Notes.

LEEDS CAMERA CLUB.—November 9, Lantern Lecture, *Old and New Flanders*, by Dr. Thresh.

WIDNES PHOTOGRAPHIC SOCIETY.—November 8, *Flashlight Photography*, by W. Priestnall, at Bedford Chambers.

THE BRISTOL EXHIBITION.—Intending exhibitors are requested to note that form A need not be sent in till *December* 1.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—November 9, Lantern-slide Competition Slides.

OUR readers will be pleased to know that the Exhibition of the Photographic Society of Great Britain has so far beaten the record, both in a financial sense and in point of attendance.

WE understand that Mr. F. E. Ives will shortly address the Photographic Society of Great Britain on the subject of the recent advances in colour photography by M. Lumière.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—November 7, Ordinary Monthly Meeting. Discussion on *Printing Processes*, opened by Mr. J. P. Gibson. 21, Lantern Evening. Exhibition of prize slides.

WOOLWICH PHOTOGRAPHIC SOCIETY.—The second annual Exhibition of this Society will be held at the Polytechnic, William-street, Woolwich, on Thursday, Friday, and Saturday, February 8, 9, and 10, 1894. Entry forms and prospectuses will be ready shortly.

HARRINGAY AND FINSBURY PARK PHOTOGRAPHIC SOCIETY.—November 9, Metol Demonstration, by Mr. E. A. Leblanc. 23, Cresco-Fylma Demonstration, by Messrs. Hill Bros. December 14, *Photo-autocopyist*, Americo-European Company. 28, *Conversazione.*

LEYTONSTONE CAMERA CLUB.—November 4, Open Social Evening at eight o'clock. 7, Last day for receiving Entry Forms for Exhibition. 8, Demonstration, Wheatstone's Stereoscope, and how to make pictures for it, illustrated with models, diagrams, &c., by Mr. A. P. Wire.

CROYDON CAMERA CLUB.—November 15, Prize Slides, at Braithwaite Hall also Croydon Cricket (Foss Challenge Cup Final), and various slides by members of the Club. Tickets now ready, sixpence each. 29, *Modern Developers*, by Mr. Leblanc. December 13, Lantern Night. 20, *Various Methods of Slide-making*, by Mr. John H. Gear.

N.A.P.P.—Members are requested to note following arrangements:—Friday, November 10, 1893, at the Central Photographic Club, Coleman's Hotel, Covent Garden, London, Council Meeting at 3 p.m.; Friendly Tea and Social Meeting, by the kind invitation of the President, Mr. Thomas Fall, London, at 5 p.m.; General Meeting at 7.30 p.m. The Photographic Society of Great Britain, and the Photographic Salon, will both be open during this period. All members of the profession will be welcome on presentation of business address card. Early intimation of intention to be present is requested. The Secretary is Mr. D. J. O'Neill, 47, Charlotte-road, Birmingham.

Messrs. Elliott & Son, of Barnet, are issuing gratis, a pamphlet on the carbon process. It is capitally written, and comprises, within a small space, a practical introductory guide to printing and enlarging by this admired process.

Ashton-under-Lyne Photographic Society.—November 7, Lantern Exhibition. Delineator, C. E. Redfern, Esq., J.P. Chairman, J. W. Kenworthy, Esq., J.P. 15 and 16, an Exhibition of Cameras at the rooms. They will include Mr. S. Wooley's own made hand camera, the British, the Frena, and several others. 22, A Demonstration by Mr. William Moss, entitled, *Micro-photography*. Chairman, Dr. Hamilton. 29 and 30, Exhibition of Negatives and Prints by several members.

The Polytechnic.—The twelfth session of the photographic classes commences with Mr. Howard Farmer's introductory lecture, *Can Gradations be Varied: Can Incorrect Exposures be Corrected by Development*, on Tuesday, November 7. There are over twenty classes for all branches of instruction, conducted by well-known men in the trade. There are also classes for photogravure, collotype and process blocks.

Central Photographic Club.—October 27, a Lantern Evening by Messrs. Acres & Wellington, when a large number of really good slides were shown by these two gentlemen. To-night, Friday, November 3, there will be a general show of hand cameras, and firms are invited to bring up their latest developments in this way. Messrs. Teape, Snowden-Ward, Wall, Acres, Wentworth, among the members, will bring up the ones they use, which will be supplemented by well-known firms sending. The first "one man show" will take place about the middle of the month, November, when Mr. Fall will exhibit. Messrs. R. Keene and F. W. Edwards will follow suit at later dates. The Club premises are now open all day, and the Hon. Secretaries are always ready to enlist new members. November 10, Mr. S. H. Fry, on *Print-out Processes*.

The Photographers' Benevolent Association.—Mr. A. Mackie in the chair. Two applications for assistance. First case, the Secretary reported that the applicant had called personally. He was resident in a London workhouse, had been out of work for some months, and seemed to have no definite prospect of obtaining any. On making personal application he gave two references, who had been applied to, and who had replied favourably of the man. Secretary had given him food to the value of fourpence, and advised him to continue in the workhouse till his case should be considered. Applicant had been advised to attend the meeting, but did not appear, and had not sent a written application. Case referred back to Secretary. Second application, from an assistant out of work, who had been confined to the house for five months through serious accident, and since recovery had had only one temporary situation. The testimonials from recent employers were satisfactory, but applicant, who had been advised of the meeting, was not present. The case was referred back, and Secretary empowered to grant immediate relief. An advance of five shillings made by the Secretary to an operator to enable him to reach a situation was confirmed by the Committee. The Secretary reported *re* several cases that had been dealt with, and was instructed to press for payment of two loans that were made some time ago, and which it was thought applicants were now able to repay. Subscription of six shillings collected in the box of the editorial office of The British Journal of Photography was acknowledged. Final arrangements were made for the lantern evening at the room of the Photographic Society of Great Britain, 5A Pall Mall East, on November 10.

Is That the Law?—Frank Smith *v.* H. Bown. On Tuesday, October 26, before the Registrar at Southwark County Court, Frank Smith, photographic assistant, of Hanley, Staffordshire, sued H. Bown, 43, New Kent-road, for 4*l.* salary due, and salary in lieu of notice. The Plaintiff was represented by Mr. Henry Philcox (Chipperfield, Ingham, & Philcox), and Defendant was also represented by solicitor. The Plaintiff stated that he saw an advertisement as follows in The British Journal of Photography, August 25, 1893:—"Wanted, a respectable Operator and Retoucher; must be good and quick. Few hours on Sunday. Close at five on Thursdays. Wages, 40*s.* per week. No duffers need apply.—H. Bown, 43, New Kent-road, near Tarn's." In reply, he wrote a letter on August 28 (produced in Court), stating his experiences, giving particulars of his former situations, agreeing to the terms of the advertisement, and enclosing a sample of his work. On September 6 Plaintiff received a telegram (produced in Court), which said:—"Yes, you can, at once. Wire reply, Bown, 43, New Kent-road." The same day the Plaintiff wrote a letter (produced), saying that the telegram was received too late to reply by wire, as office closed at eight p.m., and accepting the situation. On Thursday, September 7, Plaintiff called at Defendant's studio, and was told to commence work the next day. On Saturday evening, September 9, Plaintiff received 12*s.* wages for two days, and Defendant told him to come to work on the following day. On Sunday, September 10, Defendant came into the studio, stated that the Plaintiff was no good, and ordered him to leave the place, refusing to pay him any salary. For the defence, the facts as stated were admitted, but Defendant stated that when Plaintiff arrived on Thursday, September 7, he—Defendant—had offered to give him a trial. It was contended that the advertisement, letters, and telegram did not constitute an engagement, and that, therefore, there was no liability to pay salary or necessity to give notice. The Defendant had not paid Plaintiff's fare from Hanley, and swore that he had no idea that "Hanley, Stafford," was very far from London. For the Plaintiff a witness was called to prove the custom as to engagements. For the defence two *employés* of the Defendant were called to prove that they heard him say to Plaintiff that he should "have a trial." Verdict for the Defendant, with costs of two witnesses.

RECENT PATENTS.

PATENTS COMPLETED.

Receptacle for Refilling Camera Magazines with Photographic Plates without the use of a Dark Room.

No. 16,126. Ladislas Nievsky, 14, Gransden-road, Shepherd's Bush, Middlesex.—*September* 30, 1893.

The general object of this invention is to provide a simple and efficient means for refilling the magazine in a magazine camera with plaques or sensitised dry plates in broad daylight without the use of a dark room. Another and special object is to further expedite and facilitate the use of my so-called simplex photographic machine, described in the Specification of my Patent dated October 19, 1891, No. 17,860. By that machine or apparatus each plaque delivered from the magazine to the camera proper is, after being exposed, opposite to the lens and the object to be photographed, conveyed into a tank, where it is expeditiously and conveniently developed, fixed, and washed, and can then be removed from the tank as a finished photograph. But, by my present invention, I do away with the necessity for going into a dark room each time the magazine has to be refilled, and the machine can thus do much more work in the same number of hours than heretofore, because the speed at which the machine works is so very great that the magazine has to be refilled very frequently during a busy day.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 26,—Mr. A. Haddon in the chair.

Mr. J. T. Truscott was unanimously elected a member.

The HON. SECRETARY, in drawing attention to the forthcoming Lantern Evening at the Exhibition Gallery of the Photographic Society of Great Britain, in aid of the Photographers' Benevolent Association, stated that the Association was in great need of funds.

DEVELOPED GELATINO-CHLORIDE PRINTS.

Mr. R. BECKETT showed a developed print on gelatino-chloride paper, the image having been just barely visible before development. It had from five to ten minutes' exposure. He thought that a better print was obtained than would have been the case by printing right out, and that the process gave a tendency to greater softness. Control was obtainable over development by diminishing or increasing the alkali. The prints were toned.

Mr. E. J. WALL had tried the development process with the Paget, Ilford, and Solio gelatine papers, and found that it proved more successful than by printing out in the ordinary way, as it gave greater command over the results. Development with a brush enabled one to get almost any effect one liked. He had satisfactorily used the method with rough paper. One must be careful not to develop too much, and to well wash the last traces of the developer out before toning. He thought that the "toning" should be called an intensification process, as he did not think in this case the action was entirely a toning one. The image, when developed, was very faint, but, when put into the toning bath, it developed up rapidly. The paper should not be exposed to white light. In reply to a question, he said the process gave pure whites with vignettes. There was besides a decided absence of double tones. By the process he had printed, developed, and toned sixty-four whole-plate pictures in one day from eight negatives.

ACETATE OF LEAD IN A HYDROQUINONE DEVELOPER.

Mr. L. MEDLAND referred to a published formula for a hydroquinone developer which contained acetate of lead, and asked what its action was supposed to be? With ordinary water it gave a milky precipitate, but, with distilled water, no such precipitation took place.

The CHAIRMAN said that it must be due to the impurities in the ordinary water if a clear solution were only obtained with distilled water.

THE ALUMINIUM FLASHLIGHT.

A paper by Mr. T. Bolas on the subject was read [see page 702.]

Mr. J. G. HUDSON pointed out that aluminium would ignite in an ordinary Bunsen burner if blown straight through the centre of the tube. He did not, however, see any advantage in aluminium over magnesium. In reply to a question, he said the magnesium fumes could be done away with by using casing.

Mr. WALL alluded to some experiments which showed that aluminium was decidedly inferior to magnesium in actinic power.

Mr. R. CHILD BAYLEY thought that aluminium leaf burnt in oxygen would be better for photographing interiors than magnesium.

Mr. HUDSON showed a portrait taken by magnesium light with three seconds' exposure.

The CHAIRMAN thought the paper showed the possibility of using metals other than magnesium for illuminating purposes. It had been stated that aluminium did not tarnish, but that was a mistake, as, when exposed to the air, it became covered with a very thin film of alumina, which was transparent, and allowed the metallic lustre to be seen through it.

"LADIES AT THE LONDON AND PROVINCIAL."

The meeting then became a special general one, consequent upon a formal requisition asking the Hon. Secretary to convene it for the purpose of virtually deciding whether ladies were eligible for nomination as members or not.

Mr. W. E. DEBENHAM proposed the following addition to the rules: "That ladies are eligible for all the privileges of membership."

This was seconded by Mr. STEINMETZ.

Mr. THOMAS BEDDING proposed an amendment the effect of which was to make the rule read, "That gentlemen only are eligible for the privilege of membership."

This was seconded by Mr. C. H. COOKE, and, upon being put, was carried by twenty to six.

The inclusion of the word "ordinary" before membership having been formally moved and carried, the amendment was put as a substantive motion, and carried.

MANCHESTER PHOTOGRAPHIC SOCIETY.

OCTOBER 12,—Annual Meeting.

The following gentlemen were elected members of the Society:—Messrs. J. B. Pettigrew, W. Donyan, and W. T. Burrows.

The report of the returning Council recorded a quiet but generally successful year's work, many of the ordinary meetings having been devoted to the examination and discussion of the various brands of plates, &c., and newly introduced developers, the social part of the evening at tea preceding the formal business, continued an enjoyable feature of the ordinary meetings. The exhibition of members' work, held in March, was very successful, and showed marked advances in technical work. The lantern meetings had all been open to friends, the lecture and other acts of slides displayed being of good quality and well received. The outdoor meetings had, with the exception of one or two rambles, been disappointing both in attendance and results. The Society had lost two members by the death of Mr. C. Duval, a local professional, and Mr. J. Kershaw, of Buxton, one of the earliest members, and well known as the inventor of the roller-blind form of shutter. Although the membership remained about the same, the Council would welcome a few more friends as a slight increase in the number of members would be an undoubted advantage in enabling them to provide better for the general requirements of all.

The Treasurer's statement was adopted, and the election of officers for the coming year proceeded with. During the necessary interval for counting the votes, the meeting resolved into a *conversazione* for general discussion and the trial of slides in the lantern. The election resulted as follows:—*President:* Mr. J. Wood.—*Vice-Presidents:* Messrs. A. Brothers, F.R.A.S., T. Chilton, T. R. Cobley, A. Heywood, and H. M. Whitefield.—*Council:* Messrs. W. Blakeley, J. Brier, C. H. Coote, S. L. Coulthurst, F. Edwards, H. V. Lawes, J. Peddie, W. Tomlinson, J. Warburton, and J. Whittaker.—*Hon. Librarians:* Messrs. C. H. Coote and H. V. Lawes.—*Hon. Curator:* Mr. H. V. Lawes.—*Lantern Committee:* Messrs. Coulthurst, Edwards, Lawes, and Whittaker.—*Hon. Treasurer:* Mr. W. G. Coote.—*Hon. Secretary:* Mr. W. H. Farrow.

Croydon Microscopical and Natural History Club (Photographic Section), October 27, Mr. Sparrow in the chair. Subject, *Mounts and Mounting.*—As the annual *soirée* of the Club would shortly be held, when there would be an exhibit of the work of members, the opportunity was taken of assisting them in the mounting of their prints. An extensive selection of the newest patterns of mounts for exhibition and general use was sent down by Messrs. Adams & Co., and the evening was profitably spent in inspecting and comparing them. A very effective mount, said to be an old pattern of forty years ago now revived, was one consisting of a tinted cut-out mount, the opening being surrounded by narrow strips of the same tint, but of a different shade, edged with white or black. Several specimens were shown of the new "slip-in" albums, particularly adapted for glazed prints, as no mounting was required. Mr. Gower showed some mounts tinted by spraying with a comb and toothbrush, a plain centre being left for the print by masking. An example of platemaking on drawing-paper, produced in a copying press, was also shown.

Hackney Photographic Society.—October 24, Mr. E. Puttock in the chair.—Mr. Guest showed two bromide prints (enlargements), one at twenty minutes' exposure with gaslight, and the other with half-an-hour. The former was developed with amidol, the latter with hydroquinone. The one developed with amidol was stained, and the reason asked. Several members stated it was not due to the developer, but contamination with dirty dishes or hypo. Mr. DEAN showed an over-printed view on P.O.P., fixed direct with hypo, without toning, and asked the cause of black spots upon the face of it. Mr. BECKETT said that the print must have been imperfectly washed, and the citric acid left in paper in combination with hypo produced sulphur toning.

Leytonstone Camera Club.—October 25, Mr. W. J. Parsons in the chair.—The President (Dr. W. Pickett Turner), assisted by Mr. A. J. Newton (instructor, People's Palace), gave a very elaborate demonstration on the *Collodion or Wet-plate Process.* The lecturer having gone very fully into the theory, giving all the formulæ for the various solutions, and the necessary appliances required, a negative glass was cleaned, coated, dipped, exposed, developed, intensified, and varnished, the whole of the operation being done before the members, making a most complete exposition of the process, particular reference being made as to its advantages for transparency work, and a large number of lantern slides passed round, showing results of various defects, such as over-exposure, under-exposure, and different conditions of the bath, and the result of different mistakes made in preparing the negative, the most noticeable being the coating of the plate, the lecturer observing that the man who hesitates at this operation is lost. Saturday, October 28, first members' Lantern Evening of the season. A large number of slides were put through the lantern on the new screen, made by one of the members, Mr. F. F. Weeks, who also showed a number of carbon slides from his own drawings, those of the legend of the willow plate being very beautiful. Mr. D. G. Riddick manipulated the lantern. The new studio only awaits the painting of the background on the screen already prepared to be ready for operations. Several new members were elected. The meetings wil be held in future twice weekly, every Wednesday and Saturday.

Richmond Camera Club.—The second "Ladies' Night" of the season took place on Monday, the 16th ult., when the President described a *Trip to Spain with the Camera*, which he illustrated with a series of slides depicting scenes in Valencia, Cordoba, Madrid, Toledo, and Seville.

West London Photographic Society.—October 24, Ordinary Meeting.—The PRESIDENT, Mr. J. A. Hodges, delivered his inaugural address. For a full review of the year's programme he referred members to the address of Captain Abney before the Congress of Photographers at the Society of Arts. He would mention as of special interest the recent improvements in lenses, notably the new anastigmatic lens of Goerz, which was a remarkable production, giving marvellous defining power, with large aperture, compared with the older types of lenses. His own experience of some recent new lenses of the anastigmatic type was that their power was over-rated, and he considered that they show their superiority only when the objects are approximately in one plane, a condition of things not usually met with out of doors. Mr. Dallmeyer's photo-telescopic lens the so-called artist photographer would find a useful instrument, particularly in mountainous districts. Referring to the Photographic Salon at the Dudley Gallery, at which was to be seen the work of several members of the West London Photographic Society, the President said that it was apparent that to the teachings of Dr. P. H. Emerson, once a member of this Society, was to be ascribed the present position of photography as a graphic art. "Naturalistic" photography fell like a thunderbolt at the feet of photographers. Coming to the Society's own affairs, the President referred to its success at the National Photographic Exhibition in obtaining the challenge cup from a much stronger Society. The Society's own Exhibition had succeeded in a gratifying manner, and he looked forward to still better things. He hoped *every* member would send at least one print. The present fine weather was favourable to those who had neglected the opportunities of the late summer. The postponement of the date of the Exhibition for a few weeks later would also assist them. He would suggest that the proposal of another member,

that the technical social meetings be utilised for demonstrations for the benefit of the younger members of the Society, be put into practice, and promised to co-operate by himself conducting one such demonstration. Referring to the survey work being undertaken by the Society, he said that the prints already contributed more than justified the starting of the scheme. Already some of the buildings photographed had disappeared. The work faithfully carried out would redound to the credit of the Society, and give it a status it could in no other way attain.

Woolwich Photographic Society.—Annual Meeting, October 26.—The chair was taken by the President (Rev. E. Chettol) at eight p.m. The report of the Council, together with the balance-sheet, were received and adopted. The officers and Council were then elected for the ensuing year, and are as follows:—*President:* Rev. S. E. Chettol.—*Vice-President:* Major C. D. Davies.—*Council:* Messrs. Maskell, Penson, J. Calder, W. H. Dawson, P. Hobson, and B. G. Kimber (the last four named were the retiring members of the Council).—*Treasurer:* Mr. H. H. Barker.—*Hon. Secretary:* Mr. J. B. Panting. During the evening Messrs. A. Stone, Ludworth, H. Lawson, H. Dalby, Newman, and Harris were elected members of the Society.

Birmingham Photographic Society.—October 24, Ordinary Meeting, Mr. G. F. Lyndon in the chair.—Mr. CHUBB read a paper entitled *The Naissance of Art in Photography*, which was written by Mr. Andrew Pringle, and appeared in the *Studio*. He also read a number of letters by eminent artists of the day in reply to a question addressed to them by the Editor of the *Studio* as to whether they considered photography had been on the whole a help to art or not. The opinions expressed were very various, and they may be summed up by saying that photography is a help to the artist or not, just according as it is properly used or not.

Hull Photographic Society.—A special meeting was held to receive a demonstration and lecture upon *Paget Lantern Plates*, the *pièce de résistance* being printing-out slides and development of same. In the course of his remarks, Mr. FRY stated the characteristic qualities of a lantern plate to be (1) the stain like character of image, (2) translucency of the shadows, (3) the power of giving brilliant density and clear glass shadows if required. The printing-out plates of the Paget Company give an image without perceptible grain, and the shadows do not block up. In this they are fully equal to the best collodion, but they are not suitable for reduction in the camera. With partial printing and development the result can be modified in the direction of greater contrast by a preliminary bath of five per cent. (of each) solution of carbonate and bromide of ammonia in place of the ten per cent. bromide bath as given in the Paget Company's instructions. Less contrast can be obtained by using a dilute developer, or less of the actual reducing agent, in the developer. Mr. Fry passed through the lantern some examples of the process, and also an interesting set of slides, all from one negative, and illustrating the range of colours from black through brown and red to yellow, which are possible with the Paget lantern plates.

Leeds Camera Club.—October 26.—Mr. A. HOMBUBO gave a lecture on *Flashlight Photography* in the club rooms of the above. The lecturer, in a most interesting, instructive, and amusing discourse, gave his experiences, his successes, and his failures from his first commencement up to the present time, and, in plainly worded terms, gave the flashlight aspirants some valuable hints how to go on and what to avoid as a means of success. Practical illustrations of methods, together with a collection of prints and negatives, the results of his endeavours, were shown by Mr. Homburg, and received with interest. A vote of thanks to the lecturer was proposed by Mr. Irwin, and seconded by Mr. Vevers, and was enthusiastically responded to by every member present. The above Club, which has only been formed a matter of nearly two months, may now be deemed a success, having on its list over sixty members, six new ones being elected last Thursday, and has every prospect of being one of the strongest in this district. On Thursday evening, November 9, the President, Dr. T. Thresh, P.L.D., L.R.C.P., will give a lecture, illustrated by magic-lantern views, describing his recent trip to Flanders, and it is requested that every member, in addition to attending himself, will bring a friend interested in photography.

Liverpool Amateur Photographic Association.—October 26, the President (Mr. A. J. Cleaver) in the chair.—Messrs. F. A. Schierwater and Benjamin Cookson were appointed Auditors for the year. Special mention was made by the President of the success achieved by the Association in the recent lantern-slide competition in London, and a special vote of thanks was accorded to the six competitors who represented the Association, Messrs. Fred. Anyon (silver medal), Joseph Earp (bronze medal), G. A. Carruthers, Anthony Dod, Harry Holt, and T. Sutton. Mr. ADOLPH W. BEER then gave a lecture entitled, *By River and Hill*, some by-ways among the Ardennes and in Rhenishe Prussia, illustrated by 130 lantern slides, made from negatives taken by the lecturer and Mr. J. H. Day. The slides were of high quality and artistic merit, and were very graphically described by the lecturer.

Newcastle-on-Tyne and Northern Counties Photographic Association—The Annual Meeting was held on the 24th inst., Mr. T. P. Gibson (President) in the chair.—The Secretary's report showed the Association to be in a flourishing condition, the membership being 155, and the attendance at both outdoor and indoor meetings having greatly exceeded any previous year. The Treasurer's report showed a small balance in hand. The election of officers resulted as follows:—*President:* Mr. J. Pattison Gibson.—*Vice-Presidents:* Messrs. M. Anty, W. Parry, J. H. Robinson, and Lyd. Sawyer.—*Council:* Messrs. J. Arnott, J. S. B. Bell, W. E. Cowan, G. Hall, J. J. Kirkwood, E. G. Lee, T. O. Mawson, G. L. Snowball, L. Williamson, and John Watson.—*Treasurer:* Mr. Frederick Park.—*Secretary:* Mr. James Brown, 31, Market-street, Newcastle-on-Tyne.—*Assistant Secretary:* Mr. W. P. Brewis.

Widnes Photographic Society.—October 25, Open Meeting, Mr. V. C. Driffield presiding.—A large number of the members present brought negatives and prints, which were handed round and commented on. The question-box contained questions which gave rise to some interesting conversation and discussion. They were: 1, "What is the cause of the yellowing of the whites of gelatino-chloride prints in toning?" Mr. NEWBURN suggested that it was caused by traces of hypo in the washing water. Mr. Warner did not consider the reasoning set forth in the Britannia Company's publication, *Scraps*, satisfactory, as he had found yellowing of the whites to take place when using the combined toning and fixing bath. 2, "What is the best way to burnish Ilford P.O.P., and what is the best lubricator?" A number of members expressed the opinion that P.O.P. prints needed no burnishing, and the CHAIRMAN said that, if it was considered advisable to burnish, it was necessary that the prints should be perfectly dry, and he recommended white curd soap as a good lubricant. 3, "What is the best method for illuminating, by artificial light, a whole or half-plate negative in reducing to lantern-plate size; and what exposure should be given with this light, using a negative of average density with a bromide lantern plate?" Mr. DRIFFIELD pointed out that, no matter what means of illumination were employed, the exposure would depend on the density of the negative and speed of the lantern plate, the value of the light being ascertained. Illumination by condenser was the best method. 4, "What is the rule for ascertaining the time of exposure to artificial light by reduction, the time required for the same plate by contact being known?" No definite answer to this was given, but the Chairman said it would be necessary, by means of a photometrical observation, to ascertain the value of the light upon the sensitive plate, and measure the density of the negative. 5, "Does pyro and soda make the best developer; if others are better, then, in what respect?" This question produced a lively discussion. It was considered by those who joined in it that less exposure was required with amidol and metol developers. Mr. DRIFFIELD advocated strongly ferrous oxalate. While admitting that pyro was a grand old developer, he had found that, with different plates, it gave different colours, and even with the same plates behaved differently with modified solutions, and this occasioned much trouble when working by calculation, whereas, with ferrous oxalate, the results were always constant. Question 6, addressed to the President, "What is the ratio of exposure required for two negatives of equal density, one developed with pyro, the other with ferrous oxalate?" produced the reply, as 0·8 is to 1·0. The President exhibited a print showing the relative size of a photograph taken with an ordinary rapid rectilinear lens, and one produced by the new tele-photographic lens.

FORTHCOMING EXHIBITIONS.

1893.		
November 3-11	.....	*Photographic Salon, Dudley Gallery, Piccadilly, W. Hon. Secretary of Organizing Committee, A. Maskell, 215, Shaftesbury-avenue, W.C.
,, 3-15	.....	*Photographic Society of Great Britain, 5A, Pall Mall East, S.W. Assistant Secretary, R. Child-Bayley, 50, Great Russell-street, W.C.
,, 7-11	.....	*South London Photographic Society. Hon. Secretary, C. H. Oakden, 51, Melbourne-grove, Dulwich, S.E.
,, 17-25	.....	*Stanley Show (Photographic Section), Agricultural Hall. Manager, Walter D. Welford, 57 and 58, Chancery-lane, W.C.
,, 20-25	.....	*Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, Rose Bank, South-west-road, Leytonstone.
December	.....	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
,, 18-Jan. 22, 1894		*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE BRISTOL EXHIBITION.

To the EDITOR.

SIR,—In reply to an invitation to contribute to the Bristol Exhibition, I have felt it necessary to send the following reply. As my letter may have more than this single application, and be of general interest, I forward it to you for publication.—I am, yours, &c.,

Wimwood, Tunbridge Wells, October 27, 1893. H. P. ROBINSON.

[COPY.]

To the Hon. Secretary, International Photographic Exhibition, Bristol.

DEAR SIR,—I am obliged for your invitation to contribute to the Bristol Exhibition, but I regret that among your very numerous classes I cannot find one to which I, or those who think with me, could contribute. The loan collection is out of the question. It is the universal experience that, where there is a large competition, the pictures marked "not for competition" are neglected by the press and public, and, perhaps, rightly, for the hunt after medals is the chief amusement for which recent exhibitions seem to be instituted. There are some capable photographers who possibly may not object to contribute to the Champion class, but are barred by your rules. No picture may be sent to this class that has not already taken a medal, and none may be sent to the other classes that *has* taken a medal. Nearly all the best pictures for the year are shown for the first time in the Salon or the Exhibition of the Photographic Society of Great Britain, and therefore they have little or no opportunity o

qualifying for competing in the Champion class by taking medals elsewhere and even if they had had time and opportunity very few of those who produce really good work feel inclined to send in competition in the minutely assorted classes into which some exhibitions are now divided. The present Exhibition of the Photographic Salon seems to show that the best pictures are attracted to those exhibitions which offer no medals. For these reasons, then, I must decline to accept your invitation to exhibit.

But there are also other reasons for not exhibiting, and now I am on the subject I may, perhaps, be excused for going a little further into it.

It is agreed by all those who give the matter sufficient consideration that the awarding of large numbers of medals is encouraging bad work, and doing injury to the best interests of the art. Many attempts have been made to check the evil with indifferent results; at last the Photographic Society of Great Britain endeavoured to formulate a set of rules for the use of exhibitions. Many who do not agree with the Photographic Society of Great Britain in some things, heartily agree with them in this attempt. The result was that twenty-four of those who have had practice in judging undertook not to act when the rules and recommendations they formulated were ignored. The almost immediate reply was the issue of your prospectus, in which nearly all the recommendations are disregarded, and not even the usual discretion as to the awards is left to the judges except in the apparatus department.

Now I quite admit that you have every right to conduct your Exhibition as you please, and, except for the regard I have for the progress of the art, that I have no right to object; but it will, of course, be impossible for any photographer who agrees with the action of the Photographic Society of Great Britain to contribute to an exhibition which ignores its rules.—Yours truly,

H. P. Robinson.

FILMS.

To the Editor.

Sir,—Mr. Stillman's experience with films is so completely at variance with mine that I venture to send you my experience. I have used films almost exclusively since the time of Vergara films, before the introductions of celluloid, seven years or more. About four years ago I took a large number of ——'s celluloid films to Egypt; they were fairly rapid, about 22 Warnerke. Some of these were brought back, and exposed more than eighteen months later. They had not deteriorated in any way. Other makes, the most rapid obtainable, after nearly or quite a year, were as good as ever.

In the last few months I have used several different makes, all very rapid, and no perceptible deterioration in two months. Films developed several weeks after exposure have been as good as ones done at once. Negatives stored with no more than ordinary care show no alteration, any more than ones on glass.

One word more as to exposures. I admit I have not given exposures of one-thousandth of a second; with double or more than double that exposure, and developing with amidol, it is difficult to get fairly exposed negatives on glass or anything else.—I am, yours, &c.,

H. G. M. Conybeare.

6, *Courtenay-place, Teignmouth, October* 29, 1893.

HEATING DARK ROOMS BY ELECTRICITY.

To the Editor.

Sir,—I observe that the subject of warming dark rooms and studios is at present under discussion in your columns, it may therefore interest your readers to know that electricity may now be employed with great advantage for that purpose; this is a practical realisation of electric heating which I have long hoped for. Two or three years before Prof. W. K. Burton left for Japan, he gave a brilliant demonstration on the subject, "Electricity the Light of the Future," before a crowded audience, at the Kensington Town Hall, at which I was present by his kind invitation. The Duke of Argyle presided, supported by Prof. Huxley and other eminent men, and the lecture was received with great applause. Since then, electric lighting has made gigantic strides.

I went yesterday to the "Cookery and Food Exhibition," which was opened on Tuesday by the Baroness Burdett-Coutts, to see the demonstration of "Cooking by Electricity." At the tables a lady was engaged cooking a dinner; she looked as nice—and everything was as clean and tidy—as if she had been entertaining her friends in her own drawing room. There was a large cooking oven which can be heated up to 500° or 600°, and saucepans, stewpans, frying-pans, grills, and kettles, all at work cooking the various dishes, yet not a particle of smoke or dust to be seen; the heat was under complete control, and could be turned on or off instantaneously, and the pans be moved easily about; a great success. Mr. H. J. Dowsing, M. Inst. E. E., presided, and afforded popular explanations to those who desired them, on behalf of Messrs. Crompton & Co., the engineers, of Mansion-House Buildings; show-rooms 148 Brompton-road. He favoured me with the following information. The cost, he said, would, on an average, be about the same as gas, but that would depend on your district, as some companies charged less or more than others. The electric light is the purest known, and does not burn or contaminate the air; it is also the safest when properly installed. It does not injure our pictures or household gods, books, and decorations. The current may be used for driving sewing machines, coffee mills, ventilators, &c.; the advantage to health is very great.

It is a well-known fact that electricity, if obstructed in its passage through a conductor, will produce heat; and this knowledge has been turned to account in causing electricity to generate heat in a most convenient form. With electric heating there is no combustion, and consequently warming apparatus made on this principle requires no flue to carry off products of combustion and foul gases, which are given off by all other systems of heating. In fact, heating by electricity revolutionises our ideas of stoves and other heating apparatus, for, up till the present, no system has been employed which did not entail combustion. If the cost is a little more than gas, less heat is required, as there is no waste of heat in the room or up a chimney. Water for breakfast or tea may be made on the table, without vitiating the air and with perfect cleanness. The dangerous spirit lamp may then be discarded.

I think these advantages will give a great impetus to the supply of electric lighting to private houses throughout the kingdom, which will receive a still further impulse from the fact that the Edison incandescent lamp patent expires on November 10, when the present price of 3*s.* 9*d.* will probably be reduced to one-third that amount. The advantage to photographers will be obvious. Personally, I have suffered dreadfully from gas and other stoves in my studios.—I am, yours, &c.,

October 26, 1893. Palette.

WARMING THE DARK ROOM.

To the Editor.

Sir,—A very few words and I have done, for the discussion between "L.M." and myself has now reached a point where it can have no possible interest to the general reader; and were it not for his open sneer at my "facts" I should not now have thought it desirable to make any reply.

Surely it is the veriest quibble to contradict my statement that these stoves require "*two* communications with the external atmosphere," and proceed to prove that he is right by saying he only required one opening because he had used the chimney as the other. One and one usually make two.

I am aware No. 4 is on the name plate, and is also printed upon the prospectus; but if L.M. had been as careful to substantiate his statements as I have been to verify my facts, he would have learned that there is such a thing in this world as change, and that, when I courteously corrected his slight error in the address, I only stated what is absolutely true. As L.M. has sheltered himself under a *nom de plume*, I have no means of communicating with him direct; may I therefore ask you, Mr. Editor, to have the kindness to forward to him the enclosed telegram, the date stamp on which (October 7) will prove that before I made the correction I had taken the necessary steps to be certain of the accuracy of my "facts."—I am, yours, &c., Edward J. Smith.

Park Royal, Halifax, 30 *October*, 1893.

Copy of Telegram.

"Calorigen Works 1 Upper Thames-street London correct address will write to-day Farwig."

NEWCASTLE-ON-TYNE & NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

To the Editor.

Sir,—Will you kindly permit us to notify through your columns that we purpose holding an International Exhibition of Photographs in April 1894. We will offer medals in the following open classes:—Landscapes, Portraits Genre, Architecture, Instantaneous, Enlargements, Hand-camera work, Lantern slides and Stereoscopic slides; and in a Champion class we will offer medals in three sub-classes, viz:—Landscape, Portraiture and *genre*. Our prospectus will be out in a few weeks, and I shall be glad to forward one to any intending exhibitor.

I may say that we intend to observe the "Judges Conference 'Regulations'" in their entirety.—I am, yours, &c., Jas. Brown,

31 *Market-street, Newcastle-on-Tyne.* *Hon. Secretary.*

JUDGES AT LEYTONSTONE.

To the Editor.

Sir,—Will you please make known through your columns that, owing to ill health (a fact which, I think, all who know him will deplore), Mr. Andrew Pringle has been ordered abroad by his medical adviser, and consequently will be unable to assist in the judging of the exhibits sent in to this Exhibition. The Rev. F. C. Lambert has kindly consented to take his place, and will act with Colonel Gale and Mr. F. P. Cembrano, jun. May I also call attention to the fact that Tuesday next, November 7, is the last day for receiving entry forms.—I am, yours, &c.,

Albert E. Bailey,

Rose Bank, South West-road, Leytonstone. *Hon. Secretary.*

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange lantern, 3½-inch condenser in case, and 17 Newton's slides on *Agriculture*, for camera extending to 20 inches.—Address, S. E. KELF, 189, Southampton-street, Reading.

Wanted oxygen gas bag, 8 or 10 feet, in good condition, in exchange for landscape lantern slides of high class, values adjusted.—Address, H. EARL, 47A, Broad-street, Worcester.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

H. G. MC.—Received; thanks.

W. M.—We have forwarded your letter.

E. H. D.—Protosulphate of iron will precipitate the gold.

TYRO encloses no name or address, hence his query is not attended to.

CALCIUS.—Messrs. Tunny & Co., Edinburgh, undertake vitro-enamelling.

E. H. BOOTY and L. J. STEELE.—Thanks for your suggestion, which we will bear in mind.

SAXON.—We do not think development of carbon prints in an enamelled tin vessel would injure the prints.

L. NIEVSKY asks, "Can you oblige by telling me what is the principle of Elishau Grey's telautograph?"

C. CARTER.—Potassium chloro-platinite is listed in most dealers' catalogues. We presume the sodium salt can also be obtained from them.

L. M.—Twenty-six feet approximately is the distance at, and beyond which, using a five-inch lens at *f*-8, all objects would be in focus.

D. S.—In our last and the preceding volumes will be found articles on copying Daguerreotypes which may possibly help you.

COL. SPENCER NICHOLL.—The solutions should be kept separate. You do not specify the one in which the precipitate occurs. Kindly say, and we may be able to assist you.

MISS C. PARKS SMITH (Quarry Lodge, Lichfield).—We have no entry forms for the Madras Exhibition. Perhaps some correspondent seeing this may be able to supply one.

W. ROWLAND desires to know the address of the head-quarters of Green's, Landscape Photographers. They publish series of views of England, Scotland, Wales, the Continent, &c.

A. M. L. SHIELDS.—Such an adapter will be useful. It is not, however, a subject for registering, but for patenting. Nothing in which there is "a combination of parts" can be registered.

T. BROWNING.—If the solution of pyrogallic acid, prepared with old sulphite, works all right, that is all that is required. What matters it if it be a little discoloured; it is wanted for use, and not to look at.

ALPHA.—1. You had better obtain the 1891 volume, which has numerous references to the subject. 2. Divide the equivalent focus of the lens by eight. The answer will be the diameter of a stop working at *f*-8. 3. No.

R. S. O.—Your Lerebour lens requires no alteration to enable it to be used with the optical lantern, but a ten-inch focus lens will only give a small disc unless it is removed to a considerable distance from the screen.

AJAX asks: "Could you tell me by what means a tone like that of the 'Ferrier et Soulier' slides of thirty years ago is produced? Of course I know they are albumen pictures, but the tone I get by development with gallic acid is not at all the thing."

A. W. W.—A varnish composed of dammar resin, dissolved in benzol, makes a very good protective for negatives, and it can be applied cold. Dammar varies much in quality, and only the finest should be used. Some are almost as brittle as common rosin.

H. C.—There is no definite position for the stops of a single lens, but the deeper the curvature of the front surface, the nearer may the stop be placed to it, and *vice versâ*. There is one position by which a flare spot may be produced, but this can only be discovered by trial.

ALF. COLLINS.—Eosine can be obtained from most of the drysalters or dealers in dyers materials. There are many kinds of it. In one manufacturer's list, now before us, nearly twenty varieties are quoted. If it is required for photographic purposes, better get it from such a house as Hopkins & Williams. The right sort will then be ensured.

EXPERIMENTALIST.—Yes, it is a fact that by far the larger proportion of those who work photo-mechanical processes do very much prefer, in some cases will use no other than, collodion negatives. It is not, as you infer, a question of economy at all, it is the fact that it is found in practice negatives by that method answer the purpose better than those by any other.

T. C. H.—You have been correctly informed. Plates that have been accidentally exposed to light can be restored by treatment with bichromate of potash. But it will not pay, now that plates are cheap, for any one to go to the trouble of treating a dozen or two of small plates. So far as we are aware, there is no simpler method than that referred to of restoring exposed plates.

S. O. C.—Yes, it is the same thing over again. Some of the illustrated periodicals are very unscrupulous in the matter of photographs. They know quite well that photographers rarely take the necessary steps to make their work legally copyright, hence so much piracy by them. In your case we doubt whether your copyright would, in a court of law, hold good if contested.

H. H. H.—If you want a plate to cover the quarter-plate size, with the full opening, up to the corners, you must have one of considerably longer focus than that you have, whoever may be the maker. No lens of four and a half inches equivalent focus will cover a quarter-plate sharply to the corners with an aperture of *f*-6. Of course there is a great advantage in a lens that will work with such an aperture over one with an aperture of *f*-8 for winter hand-camera work.

G. SIMMONS.—It is impossible to say what exposure will be required to make an enlargement on bromide paper on such data as "fair light," "average negative," "medium stop," &c. The simplest way for a novice to arrive at the correct exposure is to make one or two trial exposures on small strips of paper, giving different times to each piece. After a few experiments in this way, sufficient experience in judging the light will be gained to time exposures with comparative accuracy.

G. EDWARDS writes asking if one is allowed to photograph any of the objects in the British Museum, and, if so, is special permission necessary, and by whom is it granted?—Special permission has to be obtained to photograph anything in the Museum. This is obtained by writing to the trustees, who seldom, if ever, refuse. There is an excellent studio and dark room, the use of which can be obtained. It is scarcely necessary to say that nothing can be removed from the building, though, upon application, some objects can be taken from their place to the studio.

PROVINCIAL AMATEUR.—We cannot say how you can sell the negatives unless by advertising them in the columns devoted to such purposes. In the mean time you might communicate with some of the large publishing firms, such as Frith, Valentine, and others. We, however, do not think the negatives will meet with a ready sale if the prints sent are a fair sample. The work is very second-rate, and the subjects, though good, are of no real interest. Country lanes and woodland scenery may be had everywhere, and are very similar all over the country. We note that you sign yourself an amateur; but, in taking negatives for sale, you are not entitled to style yourself as such.

E. BONNER writes as follows:—"I have lately been practising the carbon process, which I like very much on account of the variety of effects obtainable. Up to the present, acting on the advice usually given to beginners, I have only worked by the single transfer method, and have been fairly successful on the whole, but I often meet with this difficulty: On attempting to develop the picture, the backing paper will not strip off in the warm water, even when it is very warm, and after ten minutes' soaking. On using force, the tissue comes entirely away from the transfer paper. Of course I use a safe edge on the negative. Can you help me at all?"—The trouble is clearly due to insolubility in the tissue, from some cause or other—possibly from its being kept too long after sensitising, or through its being dried too slowly. The solubility of tissue can easily be tested before using by placing a small piece in water at about 110° Fahr., when the pigmented coating should slowly dissolve away. Unless it does so, it is useless to attempt to use it.

CHLORIDE PAPER FOR PRINTING OUT OR DEVELOPMENT.

One of the most recent photographic novelties consists of a positive paper which may be used either for printing out or for development, as circumstances or convenience may decide, and we have recently given an account of a visit to the Paget Plate Company's factory to witness the working of the new paper.

Although to the latter Company belongs the credit of the first introduction of an article specially adapted to the dual purpose, the idea is by no means a new one, as for several months past formulæ have appeared in these and other pages for the development, up to proper depth, of prints that have been accidentally under-exposed in the printing frame. But, as a practical process for converting such under-exposures into prints at all equalling in quality those produced in the legitimate manner, development cannot hitherto be said to have proved a conspicuous success, whereas those who have carefully tested the newest method pronounce it to be equal in the character of its results, if not, indeed, superior, to the direct printing process.

Whether there is any radical difference in the nature or preparation of the new paper, we are, of course, unable to say; but at least a great portion of the success secured with it must be set down to the method of after-treatment of the print when it comes from the printing frame. The Paget Plate Company must, in fact, be awarded the credit of having shown the way to success, in the development, or partial development, of print-out papers generally. For, while we are not yet prepared to assert that we have produced results equalling the very perfect specimens exhibited by the Company on their special paper, we have, with the ordinary gelatino-chloride paper of commerce, and even with sensitised albumen paper, succeeded in developing images that it would be difficult to distinguish from those printed out and toned in the usual way. A few remarks on the *modus operandi* may not be out of place.

Developed positives on gelatino-chloride paper are, of course, no novelties; but such as have been hitherto produced have been on specially prepared papers of the "Alpha" type, whose sole function is development. The "print-out" papers differ from these in that they are prepared with and contain at the time of printing a certain quantity of free silver, that is to say, of a salt of silver in a more or less soluble condition, without which the chloride alone will not give the necessary vigour of image. The soluble silver salt also continues to form more or less of an organic compound in the paper, which, under the action of light, confers on the image qualities that cannot be obtained with the chloride alone. This organic reaction may take place between the nitrate of silver and the gelatine itself, or it may result from the presence of organic salts purposely added; but in any case the best results are only obtained when the sensitive surface contains a trace of soluble silver salt.

It is this last circumstance that has formed the chief stumbling-block in the way of the successful development of such papers hitherto, the difficulty having been to preserve the purity of the whites and half-tones. In our own attempts, we have previously succeeded the best with developers of the "physical" kind, that is to say, in which a reducing agent, such as "pyro," gallic acid, or hydroquinone, is employed in the acid state, with the addition of a minute trace of nitrate of silver. Under such treatment, it is true that fair results may be achieved with care, but they cannot be said to resemble in any way, either in brilliancy or tone, those obtained by the ordinary routine of printing out.

When the "chemical" methods of development have been resorted to, that is, when the reducing agent is employed in conjuction with an alkali, the difficulty of entirely freeing the print from all traces of soluble silver salt, as well as the extreme ease with which silver chloride is reduced under such circumstances, have combined to render the production of a perfectly clean print almost, or practically, an impossibility. The treatment of the print with a soluble chloride to convert the silver salts availed but little, as the unreduced silver chloride retained its proneness to reduction; but it is worthy of note in conjunction with the Paget Plate Company's method of treatment that, when an old spent negative developer is used, containing a large proportion of soluble bromide, the purity of the half-tones and lights is vastly improved.

It is in the employment of the preliminary bath of bromide of potassium that the secret of success lies. This converts all the soluble and organic salts of silver in the paper into bromide of silver, and, although, unless the action is very protracted, it can scarcely be supposed to have the same action upon the whole of the silver chloride, it must undoubtedly tend in that direction, and by decreasing the liability to abnormal reduction it renders clean development perfectly easy. A developer heavily loaded with soluble bromide works in a similar manner, but its retarding action is very much greater, with the consequence that, if there be enough bromide present to preserve the purity of the lights, the half-tones suffer and hardness results.

If prints upon Solio or Ilford paper be treated with a ten- to twenty grain solution of bromide of potassium, they will be

found readily amenable to development by means of any of the reducing agents commonly used for negative purposes of suitably reduced in strength. It does not seem very material whether the prints are immersed directly in the bromide solution or subjected to a preliminary washing, nor does it greatly matter how long the immersion is continued unless it is sufficiently long, as occasionally occurs with a very feebly impressed print, to almost remove the impression. Two or three minutes' immersion in the bromide solution, followed by a very thorough washing to remove the excess, will probably suffice in all cases.

The immediate effect of this treatment is to change the image to a bright yellow, and, in the case of light impressions, to very considerably weaken them, to the extent, in some cases, of nearly removing them. But whatever detail was visible before the treatment with bromide appears to be capable of reproduction by the developer. Whether details not visible to the eye when the print comes from the printing frame can be brought out by subsequent development or not, we are not prepared to decide, our own observation inclining to a negative view, though we have heard others assert the contrary.

After careful washing, the print is ready for development by almost any of the usual developers, though naturally those which most recommend themselves for bromide-paper work will be better for this purpose. Thus amidol, metol, hydroquinone, and ferrous oxalate are to be preferred to pyro, although the latter may be used, if it be the favourite; the choice may rest with the individual, but we have succeeded best with amidol and hydroquinone. The developer must, however, be much weaker than for negative or even bromide-paper work, though the conditions will vary to some extent with the degree of exposure and the tone required. The exposure does not, however, make such a marked difference in the character of the developer required as might be imagined, or as would be the case with a bromide print. The action in this case seems to be more in the nature of an intensification of the image already produced rather than of actual development, and the process is more or less protracted accordingly.

The chief effect of variation in the strength of the developer is on the tone of the resulting image. If too strong, it will be black and heavy, and incapable of satisfactory toning; but, if properly diluted, the process of development is easy and gradual, and the colour will be practically indistinguishable from that of an image printed out in the usual way. A very careful washing must now follow, bearing in mind that any of the developers named will promptly reduce the gold in the toning bath if allowed to remain in the film, and the print is then toned and fixed in the ordinary way.

So far as we have found, moderate exposure of the paper to diffused daylight, in examining the progress of the printing, has no effect upon the after-development.

GLASS POSITIVES.

The old, and by many despised, wet-collodion process has engaged some little attention at Society meetings before which it has recently been demonstrated. This has been chiefly in connexion with negatives or the making of lantern slides. There is another phase of the collodion process that is seldom referred to nowadays, although it is still an important one amongst a large number of humble workers. We allude to the glass positive process. Those who only know this process in connexion with the itinerant beach operator, or the man who, with perambulator tent, stands at cross roads to photograph "'Arries and 'Arriets," traps, &c., on bank holidays, may be surprised at such a process being alluded to here. But to such we would say that the collodion positive process is not one to be despised even now, as it is capable of producing exceedingly beautiful pictures, and with this advantage, that the portrait can be finished and delivered within a few minutes of the sitting.

In America the positive process always assumed greater importance than it did in this country, and, at one time, there was in New York a society composed entirely of "positive" workers. Here the process, after the earlier days of it, was generally looked down upon as being *infra dig.* to work by the better class of photographers, though there was really no reason why it should have been. The pictures were good, and considerable skill was necessary to produce them in high perfection. They were exceedingly soft and brilliant, while the detail was much finer than can be obtained in a paper print. We have in our mind just now a series of stereoscopic glass positives of the Crystal Palace, interior and exterior, published in its earliest days by Messrs. Negretti & Zambra. These pictures were wonderfully fine in detail, and, by treatment in the development, they had a metallic-like lustre not unlike a Daguerreotype. Indeed, we were shown some of these identical pictures only a few months ago, and were told that they were Daguerreotypes.

The collodion positive process is essentially the same as the negative process, but with slight modification in the working. It may be mentioned that a glass positive is both a positive and a negative at the same time. It is the former when backed by any dark material and seen by reflected light, while it is a thin negative when viewed by transmitted light. In working the positive process the silver bath is usually made a little weaker than for negatives, seldom exceeding thirty grains of the nitrate of silver to the ounce of water. It is also more strongly acidified, nitric being the acid used. The collodion is also made a little thinner than that employed for negatives, and requires to be tolerably ripe, that is, iodised some time before it is taken into use. The exposure is only about half that required for a good negative, so that it is a more rapid method of taking pictures. The developer is very similar to that for negatives, namely, an acidified solution of proto-sulphate of iron. But the proportion of acetic acid is less, from one to three or four minims of nitric acid being added to take the place of a larger quantity of acetic. The proportion of nitric acid in the developer has a marked effect on the character of the image, the greater it is the brighter and more metallic it becomes, and an excessive quantity causes the deposited silver to assume almost a crystalline appearance, with a lack of half-tone in the image. The development is very brief, for as soon as there is an indication of the deepest shadows it is stopped; this is often only a question of a few seconds. The picture is then fixed in a solution of cyanide of potassium, again a question of seconds only, and after a minute or two's washing under the tap it is finished.

The picture may be varnished or not. If it is varnished, it is better protected, but some varnishes, to an extent, deteriorate the purity of the whites. The best varnish for positives is Dammar resin, dissolved in benzole, as this does not degrade the picture as a spirit varnish is liable to do.

A glass positive may be reversed as regards left and right or not, at will. If it be backed up with black velvet or black varnish on the glass side, the picture will be reversed; but, if the backing be applied to the film side, it will be as seen in nature. The reason why this was not always done was, that the delicate half-tones were not so well preserved when the image was seen through the glass.

Sometimes these pictures were treated with a solution of bichloride of mercury, either with or without the addition of other substances. They then assumed a pearly whiteness in the lights, which gave them an additional charm. They were then termed "Alabastrine" pictures. Some of the most successful workers, instead of using the proto-sulphate of iron for development, preferred the proto-nitrate. This they formed by adding a solution of proto-sulphate of iron to one of the nitrate of baryta, and then filtering out the precipitated sulphate of baryta. This developer certainly did give a different character of image from that obtained with the proto-sulphate, which in some respects was decidedly better, but this developer was not extensively employed.

The above brief outline of the positive collodion process is sufficient to indicate to those who have seen the negative process demonstrated wherein the two processes, though identical, differ in manipulatory details. To those who are not familiar with the fine positives that used to be produced five-and-thirty years ago, we would say, Judge not the process from the standard of the itinerant worker of it at the present time.

Convention Finances.—We are pleased to hear that the Photographic Convention of the United Kingdom, thanks to good management, possesses a balance on the right side of the ledger. At its last meeting the Council voted a sum of 10*l.* to be sent to Birmingham as a contribution towards the deficit incurred there when the Convention was held in that town five years ago.

The Photographic Salon.—The Photographic Salon closes to-morrow (Saturday) at ten p.m. Thanks to the energy displayed by the executive and Mr. Maskell, the honorary secretary, it has proved very successful. A considerable number of the best pictures bear in the corner the pleasant word "Sold." The object of the Salon-ists has been accomplished. They have emphasised the fact previously recognised by many, that pictures, real pictures, may be made by photography.

The Photographic Club.—We understand that this old-established and excellent body has decided in future to communicate its technical proceedings to the photographic press. Such a step cannot but redound to the advantage of photographic progress, inasmuch as the Club numbers among its members some of the foremost men in photography, while we also hope that it will result profitably to the Club itself.

Non-Shrinkable Wood.—One of the great difficulties experienced by the photographer in damp, hot climates is the swelling of his camera or slides, which is apt to occur with even the highest class of work. If, however, we can rely upon the statements of the *Indian Textile Journal*, there is a kind of wood named "billian" which grows plentifully in Borneo, and is famous for its strength and durability both on land and water, and is quite unaffected in bulk by the action of water. It is exceedingly weighty, being nearly as heavy as water (sixty pounds to the cubic foot). It is half as strong again as oak, and still stronger compared with Borneo teak. It is deep red when seasoned, and after long exposure becomes as black as ebony. It resists the white ant, and is almost indestructible. If these statements prove founded on fact, and the wood is of a workable texture, it would be simply invaluable to the camera-maker whose products are to travel in the far East.

A Novel Use of Oxygen. — If there is one point more strongly impressed than any other upon the tyro in the use of oxygen and hydrogen, it is that he must be most careful to prevent any possible admixture of the two. The advice is most desirable, although it is well known that for explosion to take place the proportion of the mixed gases to each other must be within certain well-known limits. Outside those limits no explosion will take place. The knowledge of this fact underlies the novel application we refer to. At Huddersfield, Brin's Oxygen Company have erected oxygen plant for the purpose of supplying that gas to mix with the illuminating gas to be issued to the public. About six per cent. is added just before it enters the station meter, and is then stored in special holders. The Corporation gas is enriched to the extent of five and a half candle power by this addition, a fact which is most singular when it is remembered that atmospheric air is looked upon as a deleterious adulterant of ordinary coal gas.

Geographical Longitude by an Ordinary Camera.—Herr O. Runge, of the Hanover Technical High School, has recently published an interesting account of his success in obtaining, by an ordinary camera, furnished with a Steinheil group antiplanat lens, of about ten inch focus and *f*-13 stop, and a watch as his time-keeper, the exact longitude of a place. The camera was pointed to the new moon (on June 17). Eight exposures were made, at intervals of about two minutes. Then, in half an hour's time, the camera remaining unmoved, another series of exposures were made on the same plate, the objects this time being some stars in the constellation Leo. They were allowed to act on the plate for about an hour and a quarter, with regular intermittent breaks of five seconds. The measuring of the plates was done with an accurate micrometer, and the accuracy of the method was such that the declination of the moon was given to twenty seconds, and sometimes still more exactly. Using the same apparatus, he obtained the local time and the latitude with excellent results.

Novel Photo-astronomical Instruments at Manila.—An important astronomical observatory will soon be established at this place, the chief instruments being a novel photographic meridian instrument and a large 19·2 inch Merz refractor, the latter being provided with a photographic correcting lens. According to the October number of *Astronomy and Astro-physics*, as quoted by *Nature*, the instrument will consist of two telescopes in the same tube or what is equivalent to that. There will be object-glasses, one at each end of the tube, their foci coinciding. These will be of the same diameter (six inches) and focus (three feet), the tube being equal to the sum of the two focal lengths. The sensitive plate is placed in the focus of the two objectives, *i.e.*, in the centre of the tube. The upper objective throws the image of the first star on the upper side of the sensitive film, while, by the help of a basin of mercury below, and the lower objective, the trail of the second star is recorded on the under side of the same film. Besides visual work, the Merz refractor will be used for photographic observations of double stars, spectrographic work, photographic parallax, &c.

Possible Cause of Fire.—Professor Vivian B. Lewes, in his lecture on Spontaneous Combustion at the British Association Meeting, gave some interesting data which reveal a little-known danger of fire. From stove pipes highly heated, high-pressure water pipes, steam pipes, and so forth, it is not uncommon to see semi-charred timber in the vicinity which is thought to possess no danger on account of the heat never approaching the ignition point of wood. But

Professor Lewes pointed out that it had been experimentally determined that, when wood had been charred at a temperature of 500° it would take fire spontaneously when the temperature was raised in the presence of air to 680°, but that, when wood had been carbonised at so low a temperature as 260°, it was quite sufficient to raise it only to 340° to cause its spontaneous ignition. He thus shows a very grave danger to exist, where, at first sight, the charring might be looked upon as perfectly innocent. "If a beam is in contact during the winter months with a heated flue or even steam pipe, it becomes carbonised upon its surface, and during the summer it absorbs air and moisture, and during the next winter it again becomes heated and further carbonised, whilst the moisture and air are driven out, leaving the pores in a condition eminently adapted for the absorption of more air as soon as the temperature is allowed to fall, and in many cases sufficient heat is generated to cause the charred mass to smoulder, and when air is freely admitted to it to burst into flame." It is enough to call our readers' attention to these remarks to induce every one using heat in this manner to look to a possible source of danger.

GREAT TELESCOPES OF THE FUTURE.

[Congress of Astronomy and Astro-Physics, Chicago.]

I HAVE been asked by the local committee, through their secretary, to prepare a paper for the Astronomical Congress, embodying my ideas on the future possibilities in the construction of great telescopes. I accepted the invitation somewhat reluctantly, for, while I appreciate the honour extended to me, I feel that the subject chosen by the committee is a somewhat delicate one to deal with, as I may say many things which do not coincide with the preconceived ideas of some that may be present. I beg therefore that they will regard the subject of this paper as simply the embodiment of my ideas. I shall endeavour not to state anything as a fact that has not been demonstrated as such by repeated experiments.

Much has been written and more said regarding the great telescopes of the future. It seems to me that the best method of studying the subject is by a careful consideration of what has been accomplished with the instruments already made. From my personal comparisons I find that most of the important original discoveries in the truly visual line have been made with the largest telescopes in use at the time. In making this statement I would say that I do not include such discoveries as have been made from observed irregular proper motions of stars, such as, for instance, the companion to Sirius, which was known to exist some years before it was seen, although this required the largest refracting telescope then in existence to show it to the human eye. When once seen, however, with the large glass, it was readily seen with small ones. Nor would I ignore the many double stars discovered with smaller telescopes. These discoveries have been made with instruments of superior defining power, under fine atmospheric conditions, and are valuable contributions to astronomy, yet I do not believe that a small telescope was *necessary* to make these discoveries. I am of the opinion that, had the discoverers had at their command the largest telescope, the discoveries would have been more numerous and important. When the two 15-inch telescopes were made in 1846, one for Pulkova, the other for the Harvard Observatory, they were considered monsters. I believe it was thought by most astronomers that the limit in size had been reached. No larger refracting telescope was made for a period of more than fifteen years, the next largest being an 18½-inch. I mention this fact to show how and at what time the demand for larger telescopes came. I think that the order for the 18½-inch was given in 1860. As soon as the companion to Sirius was discovered with this glass, at once there seemed to be a desire for something larger. The next larger telescope was made for R. S. Newhall of Gateshead, England. Then came the 26-inch for the U.S. Naval Observatory, and then Leander J. McCormick presented the University of Virginia with one of the same size. After that, the 30-inch for the Russian Observatory was constructed, and, finally, the 36-inch for the Lick observatory. Besides, there is now in process of construction, and well under way, a 40-inch telescope for the University of Chicago.

I have always been a believer in large telescopes for special work. I have had great experience with them, and it is from testing these instruments that I have been convinced that large instruments are needed to make original discoveries, such as new satellites to planets, and faint companions to bright stars, in fact to any stars, as well as for studying the planets and nebulæ. For astro-physical work they are vastly superior to smaller ones. The trouble that early opticians experienced in procuring good discs of glass seems to have passed away, and we are now able to procure discs of almost any size, the only obstacle being the time required to make them, and the money to pay for them.

Having given you some of my reasons for believing in large telescopes, I will now proceed with the subject of this paper, viz., my ideas of the future possibilities in the construction of great telescopes. It is my idea that the great telescopes of the future will be refractors, not reflectors, and I shall confine myself entirely to the refractor. I would not wish to say anything that might lead you to suppose that I under-estimate the value of the great discoveries made with reflecting telescopes, or the great minds that have made and worked with them, yet one person of eminence did remark that *large* reflecting telescopes have never accomplished much except in the hands of the opticians who made them; and my own experience has been sufficient to convince me that the reflector is extremely sensitive to any changes, either of temperature or air currents, or more particularly to flexure, and that, while the refractor is also affected by these changes, it is by no means so injurious to the definition.

As I have said, I believe that good discs of any size, both crown and flint, may now be procured. Having once procured them, all that is required is an optician to work them. He must be an artist in light and shade, and in colour also, for the very best correction of the chromatic aberration. As in the light and shade we search for and locate the spherical aberration, so we work among the different colours for the chromatic corrections. It is a very difficult task, and, as the size is constantly being increased, the difficulties also increase. Personally I do not believe this work can ever be accomplished by machinery. Not that machinery might not be made available for the rough work and the first polishing, for we ourselves polish all our large surfaces in a machine in a preliminary way. The fine grinding and smoothing, however, is always done by hand. It is after the first machine-polishing is done, and the glass appears to be finished, that what I have referred to as artistic work begins; that is, the work to locate the errors from observations, and correct the surfaces of the glass by the tentative method till all the light from a point at an infinite distance will be refracted to a point at the focus of the objective so accurately that the image there formed will bear the highest magnifying powers without showing any distortion. I believe that this can be accomplished only by most careful study of the light that has passed through the objective, and that all the errors must be worked out by what is termed local corrections.

When the time is ready, I think the man capable of making the necessary observations and locating the errors with precision, as well as skilful enough to work them out on much larger objectives than have yet been attempted, will be found. The simple preliminary grinding and polishing of large lenses is not a very difficult operation; this, with the centering is purely mechanical; but, if the glass itself has the slightest unevenness in its density, be it ever so small, the refraction will be different through the different densities. This cannot be determined with certainty until the discs have been worked into an object-glass, or at least, ground and polished for that purpose. If, after this grinding and polishing has been done with the greatest care, we find the image produced by the lens which is achromatic is not symmetrical, and that a star at the focus is not round, but possibly is elliptical, rectangular, or in fact of any shape, what is to be done? After so much expense and labour, shall we condemn the glass, and wait perhaps years for other discs, which, after going through the same process, may give no better result? I will state here that of all the large glasses, that is to say, over 18½ inches aperture, that have been made by Alvan Clark & Sons, only one, viz., the Princeton 23-inch, came from the polishing machine giving a perfectly round image. All the others we had to round by local work.

I believe the optician that is to make the large telescopes of the future, as well as the present, must be able to do this work. In my opinion it is not more difficult than the correction of the spherical aberration proper, though, if much out, it may prove more laborious. Surely I believe this work should be done rather than condemn the discs and try others. Each glass can be rounded separately. For this purpose set the combined lens in front of a collimating mirror. An artificial star is produced from a lamp by reflecting the light from a minute lens within the eyetube, and close to the optical axis and focus of the objective. The light from this artificial star passes through the tube to and through the object-glass, then on to the collimating mirror, which should be as flat as possible. From the mirror the light returns to all portions of the objective in parallel rays. There must, however, be a little off-set, so that the returning ligh from the star will not fall on the minute lens where the star was first formed, but the deviation from the true optical axis is but a mere trifle. Of course it would be almost impossible to secure perfect definition under

these circumstances with a very large glass, as the combined errors or imperfections are made to appear twice as great as they really are, from the fact that the light has passed both ways through the objective, so that the imperfections in the material, that is, the glass itself, and workmanship also, are made to appear double what they will be when used as a telescope for viewing celestial objects direct. Nor is this all, for we have the imperfections of the mirror to contend with, and who can conceive of a mirror of five or six feet in diameter resting on its edge being perfectly symmetrical? You may thing it strange if I say that, while I should much prefer to have everything perfectly correct for this work, I believe it impossible, and we must do the best we can under the existing circumstances. I remember a time when a distinguished professor was shown by my father our apparatus and methods of testing lenses. The professor asked, "Which are you testing, the mirror or the objective?" My father's reply was, "We are testing both, and surely we can test both by the method used."

After observing all the appearances in one position, the next thing to be done is to give the whole or combined glass, that is, the crown and flint together, a partial turn. If appearances are changed, it is certain there is some error in the objective, for, if the glass worked perfectly, no matter what imperfections were in the mirror, they would be the same whichever way you turn the objective. Having ascertained that the combined glass is not round, or rather does not give a round image of a star a little out of focus, the next thing is to locate the error or errors. Are they in the crown or flint lens? Probably in both. This is, however, ascertained by first revolving one glass. If an irregularity is detected that rotates with the glass, it must be corrected by skilfully working the surfaces, so that the portions that are of short focus shall be lengthened, and those of long focus shortened, until the rays shall come together at the general focus. After having rounded this lens so that no apparent change is visible by rotation, this glass must remain fixed, and the other must be examined and worked in the same manner. This work having been carefully carried out on both crown and flint lens, they are surely round, though they may not give a round image from the mirror. After the glass is rounded, the mirror itself may be corrected in the same way, but this is not absolutely necessary, as we already know the errors. This rounding of a large glass is very laborious, and sometimes requires months to accomplish. Yet the party that is to make great telescopes in the future, as well as the present, should in my opinion make himself familiar with all these tests, and have the ability to work out the errors that I have described, together with those that may arise from concentric rings of different foci.

Having stated my ideas as to the necessary requirements to make large telescopes, I will now call your attention to my idea of the great telescope itself. As before stated, I am of the opinion that it will be a refractor, and that its size will progressively increase. It will be mounted equatorially, and provided with the best driving clock that can be devised. I am in favour of the long polar axis, known as the English plan, for such an instrument, my reasons being, first, that a large driving wheel may be applied without setting the telescope to one side of the axis. The polar axis itself may also be braced in any or all directions, without interfering with or obstructing anything. This axis can be made exceedingly stiff by bracing, and the tube itself can be braced to the axis in any position. Such mounting could be easily provided with all the clamps and slow motions that are needed. To make it all complete, we should have two telescopes, one for visual and the other for photographic work, so hung on trunnions as to counterpoise one another, thus requiring very little or no extra weight. I think an instrument mounted in this way would be much more stable than the style Americans have generally adopted in the case of great telescopes.

Now that I have spoken so favourably of these instruments, I must say in conclusion that very much will depend on the localities in which they are placed. To ensure the best results, the best places should be selected as the result of thorough preliminary examinations. Doubtless there are many places, both at ordinary and high altitudes, of fine atmospheric conditions. A great telescope, even when used under ordinary circumstances, must be productive of great results, but under the very best conditions of still greater. The increase in size of even our present great refractors is not a possibility, but a fact, and with this will come large acquisitions to our present stock of knowledge. The new astronomy, as well as the old, demands more power. Problems wait for their solution and theories to be substantiated or disproved. The horizon of science has been greatly broadened within the last few years, but out upon the borderland I see the glimmer of new lights which wait for their interpretation, and the great telescopes of the future must be their interpreters.

ALVAN G. CLARK.

ON THINGS IN GENERAL.

It is late in the day, perhaps, to make many comments on the Photographic Society of Great Britain's show, but it teaches so many lessons that I cannot refrain. Very much has been said of late years about the uselessness of awarding medals, and now we have the Photographic Salon Exhibition to show the kind of collection that can be brought together with no medals in prospect. Pall Mall has adopted the very best plan possible to discredit medal-giving, for it is an unmistakable fact that this year the awards are a complete fiasco. There seems to be a considerable diffidence—or, should it be called, fear to wound the adjudicators' feelings?—displayed by those whom all are accustomed to look up to as authorities in expressing in plain language a fair judgment on the awards, some of which, in the almost unanimous opinion of outsiders, are simply ludicrous. Medals have been awarded to photographs which would cause any professional photographer to discharge a junior operator if he had exhibited them as a sample of his ability. Why have such awards been made? The nearest guess is, because the medalled prints have aimed at producing something as unlike an ordinary photograph as possible. Workmanship has been utterly disregarded, feeble attempts to imitate a texture, or to copy the *motif* in a well-known painting, have been crowned with laurel. Photography has been made a laughing-stock, and any possible claim to a photograph being a work of fine art killed by the ridicule that must fall on such medalled photographs as representing the utmost that photography has been able to attain in the year eighteen hundred and ninety-three. In the "Forewords" of the Photographic Salon catalogue may be read, "the dull diagrammatic pose of the earlier types of work is giving way to a more subtly suggestive style of treatment, and the initial blankness of wonder at its possibilities has been, or is being, gradually replaced by a clearer perception of what it can do well, and can do for certain classes of subjects and effects with a perfectness unapproachable by other methods." "The initial blankness of wonder" will most truly overcome most spectators when they see the magic word medal against some of the Pall Mall photographs, especially upon one characterised by "Palette" as a miserable abortion of photography.

It must not be understood that this condemnation applies to all the awards. Some of the adjudications are very proper. I do not like to mention names, still I cannot but express the pleasure I experienced in examining some of the nude studies that are hung on the wall almost facing the visitor as he enters the Exhibition room.

Even the hanging must come in for severe condemnation. If we take some of the trash that is hung as representative of a higher class of work than the rejected, the latter must be very poor. Yet, when we hear the names of the producers of these rejected pictures, we know them to be incapable of doing bad work. What is the moral? I would rather leave that for my readers to decide.

I mentioned the name of "Palette" just now. I do not know if he is the same writer who gives an interesting letter upon electric heating. If so, I am afraid his sanguine hopes about the economy of electricity for heating purposes will be doomed to disappointment. He had been informed that the cost of heat from electricity would be about the same as gas. This is moonshine. Let him turn on the electric lights in any apartment for an hour, and then, after ascertaining the increase in temperature, burn at an ordinary gas burner, gas costing, say, less than one-fourth the electricity, and see which gives the greater increase. I am one with him in his praise of the cleanliness and healthfulness of eletricity, but it is a toy for heating when any ordinary comparison of cost is instituted. I should like "Palette's" informant to tell him what it would cost to heat enough water for a hot bath, and then to ask Mr. Fletcher what he would undertake to do it for with gas.

"Is that the Law?" is the heading to a paragraph in last week's JOURNAL describing how an assistant went from Hanley, in Staffordshire, to a situation in London, and failed in the County Court to get compensation for wrongful dismissal, without notice, after a few days' work. The employer, among other things, swore that he did not know Hanley, Staffordshire, was very far from London! Of course from a brief report it is not possible to form a correct judgment as to what really were the merits of the dispute, but my strong opinion is

that it is a case not of "Is that the Law?" but of "Is it not the absence of a lawyer?"—on the assistant's side, that is to say.

I am very anxious to learn what the general verdict will be upon the remarkably interesting process for treating gelatino-chloride prints by development suggested by the Paget Company. If what we are credibly told about the matter really turns out not to be an overstatement of the case, it amounts to a great assistance in printing. The question of permanency will, of course, have to be considered, but there is no *à priori* reason to apprehend failure in that direction.

"As close an approach to permanency as possible" should be the watchword for every photographer, hence I view with a certain amount of disfavour all such silver-printing methods as that described by Mr. W. Lindsay a month ago. Let it be understood I refer only to doing such prints other than as an occasional thing for some special purpose. For serious work they should be avoided. The plan is good and practicable, as I can say from experience of certain enlargements more than twenty years ago; but, at its best, it never equals platinotype, so again I would advise, "Leave it alone," except for a casual experiment or trivial print. FREE LANCE.

PHOTOGRAPHS IN NATURAL COLOURS PRODUCED BY THE IMPROVED PROCESS OF L. LUMIERE, AFTER PROFESSOR LIPPMANN'S INTERFERENCE METHOD.

(Photographic Congress.)

THANKS to the great kindness of M. L. Lumière, of Lyons, we are able to examine to-night the latest results obtained by him. A few explanatory remarks are necessary to make the method of their production generally intelligible. About two years ago Professor Lippmann, of the Sorbonne in Paris, succeeded in producing photographically a coloured image of the solar spectrum, based on the well-known principles of interference. He used for that purpose a plate coated with an albumen, collodion, or gelatine sensitive film. This sensitive film was, during exposure, brought into contact with metallic mercury, the image of the spectrum being projected on the film through its glass support. The light, after penetrating through the thickness of the film, was reflected back from the surface of the mercury, the direct light-waves encountering the waves of reflected light, producing the phenomenon of interference in the thickness of the film. The waves of light propagating in opposite directions cause the vibrations at certain intervals to be neutralised, while at others they are intensified. If such a plate could be developed, fixed, and dissected we should find it to consist of strata of the black deposit of silver, produced by the developer in the parts corresponding with the maximum of light succeeded by transparent strata, corresponding to the minimum of light where the developer had no action. The distance between the strata is equal to half the wave-length, which is 600 ten-thousandths of a millimetre for red light, 583 for orange, 551 for yellow, 475 for blue, and 423 for violet. In a film of $\frac{1}{20}$ mm. thickness there will be about 200 such strata. It is evident that, on examining such a plate by reflected light, we shall observe the colours, because it is formed of a series of films of the thickness requisite to produce colour sensations. Subsequent experiments proved that, by using a gelatine film sensitised with a chromium salt, a similar result is obtained, the action of interference producing strata of soluble and insoluble gelatine.

The exposure of the plates produced by Lippmann was very long, and, owing to the variation of sensitiveness of different rays of the spectrum, necessitated the masking of the portions exposed to the more actinic rays while the others are exposed. L. Lumière succeeded in producing coloured images in one operation, and in last May, in a paper read before the Paris Académie de Science, gave full particulars of the process as follows:—

ABSTRACT.

To prepare the emulsion the following solutions are made:—

A.

Distilled water	400 parts.
Gelatine	20 „

B.

Distilled water	25 parts.
Potassium bromide	2·3 „

C.

Distilled water	25 parts.
Silver nitrate	3 „

One-half of A is added to B, and the other half to C. These two solutions are mixed by adding the silver to the bromide. A suitable sensitiser is added, such as cyanine, methyl violet, erythrosine, &c. and, after filtration, plates are coated on a tourniquet at a temperature of 40° C.

When the emulsion is set the plate is immersed in alcohol for a very short time, and washed in a continuous stream of water. The film being very thin, the washing is soon effected. This emulsion should not be washed in bulk, lest coarseness of the particles of silver be produced by reheating results, and in order to have the films as transparent as possible; for the same reason a great excess of bromide is to be avoided. The plates are dried, and just before use are immersed for two minutes in—

Water	200 parts.
Silver nitrate	1 part.
Acetic acid	1 „

This bath helps to produce brilliancy of the image, and to increase the sensitiveness; but the plates cannot then be kept long because the sensitive surface soon deteriorates. When the plate is dry it is ready for exposure *à la* Lippmann, viz., with a reflecting surface of mercury next to the film.

For the developer the following solutions are made:—

I

Water	100 parts.
Pyrogallic acid	1 part.

II.

Water	100 parts.
Potassium bromide	10 „

III.

Ammonia D. 0·960 diluted to 18°.

Solution I.	10 parts.
„ II.	15 „
„ III.	5 „
Water	70 „

The degree of concentration of the ammonia has a great influence on the result, even a slight alteration destroying the brilliancy of the colours. For fixing, the plate after washing is immersed for from ten to fifteen seconds in a five per cent. solution of potassium cyanide, washed, and dried.

In order to lessen the action of the ultra-violet, violet, and blue rays, a parallel faced bath of Victoria yellow, uranin, or primuline is used in the camera.

The pictures lent by M. Lumière are 6 by 8 cm. in size, and when seen at a certain angle show colours of unsurpassed beauty—beyond anything we are accustomed to see in the way of the reproduction of colours—somewhat metallic in appearance, but very bright and of a very decided and definite colour.

To examine them direct the best plan is to use the reflected light of a bright sky, or if a lamp must be used it is preferable to have the light reflected from a white shade or opal globe.

To fully appreciate all the beauty of these photographs the image should be lit by a powerful light, preferably electric, and a projection made on a screen by means of a portrait lens (four inches diameter). The result is then of such beauty as to defy description—it is not like an oil painting or a water colour, it is like real nature on a bright summer's day. Seeing these first photographs in natural colours we feel we are in the presence of one of the greatest inventions of the nineteenth century, and we may sincerely congratulate our friends on the other side of the Channel upon so splendid an achievement.

LEON WARNERKE.

"SOME PRIMARY CAUSES OF FAILURE.

DURING the past few months, including some weeks of the finest weather of recent years, I have made the acquaintance of some amateur workers, who appear to have fallen on dismal times with regard to their experiences of photography; who, in fact, in spite of the beautiful weather aforesaid, and, from a casual glance, averagely good apparatus, have exhibited a crop of failures such as I have not met with for a long while—failures which would be enough to make most men give the thing up in disgust, and, it must be admitted, failures for which, on the whole, they can hardly be held responsible.

If we look at photography as a serious pastime, as a healthy change of work, designed to refresh the brain and to enrich our portfolios, we shall take a serious view of our apparatus. From this standpoint it is obvious that much of the cheaper varieties of outfits are, *as sent out*, practically useless for the purpose of doing clean and satisfactory

work. The design is usually good enough, but the outfit often exhibits that condition of things known as "spoiling a ship for a ha'porth of tar." The pity of it is when a good design is spoiled for the want of, say, a little more velvet in the construction of the apparatus.

One of my friends was working with "a guinea detective." I need hardly remind my readers that a most excellent hand camera *fitted with three double slides*, is to be bought for a guinea; but the one I refer to just now has an arrangement of sheaths. As supplied, the back door of this set was very ill-fitting, letting, as any experienced person could see, light in all round; the result was foggy negatives, until, at my suggestion, a velvet cover was made for the "hinder quarters" of the camera; this done, more satisfactory results appeared. I would suggest that the back door referred to would be much safer, and would cost no more, if made of one single piece, and made to slide in in velvet-lined grooves, and then buttoned.

I am doubtful as to whether the metal sheaths are as good as they might be; the principle is all right, but I have many reasons for believing that, where a lot of these loaded sheaths are exposed one after the other, light often overleaps the foremost plate, and makes a slight impression on the one behind. The plates would be much safer if placed in little wooden frames, shut in all round, securely buttoned in. This method would mean, of course, a slightly increased size of camera; but that is a trifle compared to the risk of fog. I have lately adopted a plan similar to this in a home-made hand camera of my own. Lancaster's make an excellent quarter-plate carrier, which takes two quarter-plates, back to back, a thin blackened partition intervening. Six of these I have had cut down to within a quarter of an inch or so all round; The plates are secured with buttons let into the wood and flush. The camera has at the back a long sleeve, and the plates are shifted by hand in a well-known manner. When the six *front* plates have been exposed, I turn the pile bodily over, and start away on the "backs." However, whatever we do, too much importance cannot be laid on the necessity for every precaution against "light," other than through the lens, reaching the plate. If the camera on receipt shows any defects—and, unfortunately, only an expert would be able to detect them—they can mostly be put right by at once having a thick velvet cover made, which should be put on the apparatus after loading and while in the dark room. The shutter may prove a source of trouble; it will not always work when wanted to, unless purely mechanical. Not only this, but we want to see that it works, or can be worked, without exposing a plate; in other words, we want to be able to cover the lens at the back, during the time we are trying the shutter. Of course, this is provided for in the better-class and higher-priced hand cameras. It is no troublesome matter, however, to make and fit, at home, what we want. I make a small blind roller of suitable length, and fit this up inside the camera, then adjust over the roller a length of American cloth, in which have been cut two apertures. A piece of string is fastened to each end and passes through the bottom of the camera, a tiny patch of velvet inside and out making the small holes safe. When the strings hang down the same length, the lens is uncovered. Pull one down, and it is covered again. This little arrangement is also useful for time exposures. It undoubtedly prevents failures from the shutter going off in an untimely manner by the giving way of an elastic band or from other causes.

Another of my amateur friends experienced the hardest luck with a five-guinea set. He fitted his slides and started off. Arrived at the scene of operations, he rigged up the apparatus—no easy matter—focussed his view, then, with considerable trouble, inserted a dark slide. This little business required so much strength that the camera was quite put out of position, and consequently the operation of focussing, &c., had to be gone through again. The next trouble was to *withdraw* the shutter. This proved an impossible task. We had not a bag of tools with us, and our fingers were quite unequal to the effort. I am not exaggerating when I say that the shutter could only be drawn by using a pair of pliers! Now, I think nothing rouses the "Old Adam" in a man so much as experience of this kind. To get the most enjoyment out of photography, everything must be kept in good condition for work; easy-working apparatus, made of hard, well-seasoned wood, tried in the house and found perfect before going into the field, is of paramount importance. We may think it a simple matter, but this is where the error lies. Too much attention cannot be given to details; therefore, on purchasing a camera, see that it opens out easily, without sticking anywhere. The front should give a good range up and down; this is, I consider, of much more importance than a swing back. The front should move up and down over a strip of velvet inlaid on the fixed front. See that the struts hold the camera back and reversing frame firmly in position; the latter should fit perfectly, and take out and put in easily. Try the slides, which should move into place with easy pressure, and do not forget the shutter. We want to be able to pull these out and put in again without disturbing the arrangement. Any "sticking" is most trying to the temper, almost fatal to any good results, and, in spite of a liberal application of black lead, is sooner or later sure to be troublesome. A reversing frame has now become almost a necessity, but I often think with regret of the beautifully made horizontal cameras of little more than ten years ago; there must be hundreds about in old stores and places, scorned and despised maybe. Would that many of our cameras of to-day were made of such stuff, they would then be perfect, or as nearly so as we want them. The ingenuity displayed on apparatus nowadays is really wonderful, but no display of brass and French polish will make a bit of green wood anything but a fertile source of failure.

J. Pike.

A PAINTER'S VIEW OF THE PHOTOGRAPHIC SALON.

When we hear of "the Salon," we naturally think of the great national exhibition in Paris of the fine arts of France, to which the best artists from every civilised country in the world are glad to contribute, or of the Triennial Exhibition, sometimes called the Brussels Salon, representing the fine arts of Belgium and other countries. Having in mind the magnitude, importance, and grandeur of "the Salon," I could not suppress a smile when I heard that a new exhibition was about to be opened under the somewhat pretentious and arrogant title of the "Photographic Salon." It does not appear that this show is representative of any society or club; it seems to have been got up by a committee of eminent amateur and professional photographers, animated by the very laudable desire of promoting the study of pictorial quality in their art. They had to find some sort of title, and, in the exaggerated, self-puffing fashion of modern advertisement, they borrowed one of high-sounding, artistic associations. They might have selected a more expressive title—one more characteristic of their aims and more consonant with their status. "The Photographic Art Exhibition," or "The Photographic Art Saloon." Saloon is a good English word, meaning "a large, lofty hall;" but that would not have been sufficiently pretentious, so they must needs import a title from Paris, and call their little show, "The Sahlong."

I found the exhibition in a room at the Egyptian Hall called the Dudley Gallery, and a capital show it is. There are 285 prints on the walls, most of them small, many displaying cultivated artistic taste combined with the highest technical skill, resulting in splendid examples of legitimate photographic art. The general average is high, but I regret to observe the prevalence of that photographic epidemic which has obscured the better judgment of many good operators, and caused them to forsake the splendid qualities of photographic art in the vain attempt to produce manufactured imitations of the mere technique of oil and water-colour paintings—to neglect the substance for the shadow—in the feverish pursuit of that rank in the fine arts which must ever be to them a "Will o' the Wisp."

The mighty services rendered by photography to science, to literature, and to art; its vast employment in commercial enterprise, in portraiture, in pictorial delineation, and innumerable other fields, give photographic art a high and distinctive character and a dignity of its own, which place it above any necessity for demeaning itself by crowing in self-assertion around the precincts of the Temple of Fine Arts, and ignobly appealing for recognition and admission within its portals:—

"Oh, restless spirit! wherefore strain
Beyond thy sphere?"

A photographic picture is a production of the old-established and highly respected firm of "Chemicals, Lens, Camera, Operator, & Co." (Limited), of which the Mr. Operator is the managing director and ruling spirit. No one of these partners could withdraw from the firm without inflicting ruin and collapse on all the others. Mr. Operator would be stranded and left utterly helpless without Chemicals, Lens, Camera, & Co.; he could go nowhere and do nothing, much less obtain a position for the work of the firm—as representative of fine art—on the walls of the Royal Academy. Volumes might be written in discussing the various theories which have been propounded in the attempt to give an absolute definition of the term "fine art," but for practical illustration it may be enough to deal with the living fact.

The Royal Academy represents the fine arts of the British Empire. It embraces under the shadow of its wings the fine arts of painting, sculpture, architecture, and engraving. On the titlepage of the Academy catalogue for the present year is the motto and definition: "Fine art is that in which the hand, the head, and the heart of man go together."—Ruskin. No admission for mechanical products in that incontrovertible definition of fine art; it must be the pure and unalloyed product of the hand, the head, and the heart of man—a definition under which photography can never come.

The spirit of art, or, in classic phraseology, the Muse, cannot be projected through a photographic lens, to be transfixed on a transparent film within a camera, at the will of any operator; the impalpable qualities of poetical and artistic feeling and sentiment would vanish before they could undergo *that* ordeal.

I will venture on a wild hypothesis for the sake of argument. Suppose the President and Royal Academicians agreed to form themselves into a little private photographic club with the object of practically testing the value of photography as an auxiliary to art in the way of taking studies and accessories, no doubt many finely composed and thoroughly artistic works would be produced; but would even the high artistic skill and status of the Royal Academy operators entitle even the best of these to be regarded as works of fine art? No; they would at best remain the products of mechanical art-science, of chemicals, lenses, cameras, and printing frames, no matter what amount of technical skill and artistic taste had been brought to bear on them. Even the great achievement of securing the reflections of Nature in the natural colours would still be the same—it would not be fine art.

I shall not here attempt to discuss the subjects of poetry and music as branches of the fine arts, but I may appropriately mention that a few weeks ago—shortly before his lamented decease—Gounod, in conversation with a writer on *La Vie Contemporaine*, remarked: "Artists are men to whom God has given greater visual power; they see more of the infinite than others." But photographers are not the only aspirants to rank as professors of fine art. I went last week to see a demonstration of cooking and heating by electricity at the Food and Cookery Exhibition. I have since read a long and ably written preface to the official catalogue by George Augustus Sala, in which he remarks: "Naturally, being myself a strong believer in cookery as one of the fine arts—and a humanising and refining art to boot—a competent knowledge of which can only be acquired by sedulous study and lengthened experience," &c. Verily, good food well cooked is of far more importance to the human race than good pictorial photography.

Turning to the catalogue, I find on the first page an advertisement, commencing, "Take your pictures with the Kodak, a most compact and portable camera. No previous knowledge of photography necessary." Over another leaf I find the preface, to which is (rather affectedly) added a second title, "Forewords." It merely amounts to a very brief essay on photography, containing nothing new, except some remarkable statements which must be noticed. The last paragraph commences in these words: "Perhaps the greatest curse of photography, in the sense now under consideration, is the fatal ease with which indifferent work may be produced by its means." This assertion is as incorrect as it is ungenerous. Ease of production is not a fatal curse, it is a vital blessing. Everything must have a beginning. Did not the gentlemen responsible for this statement produce indifferent work at first? Did not the ease with which they could produce it encourage them to go on until they could produce better, and still encourage them to persevere until they can now produce the excellent work which adorns these walls? Is it not a fact that travellers, with no practical knowledge of art, with but slight knowledge of photography, yet with cultured taste, can and do bring home with them photographic illustrations of their travels in far distant, unknown, and almost inaccessible regions—illustrations of the highest value in the promotion of human knowledge? The ease of production is not the greatest curse of photography; its greatest curse is the ease with which it can be prostituted by bad people for the vilest of purposes, thus becoming the instrument of unspeakable evil and wide-spread depravity. I have heard Captain Abney say that, if you wish to give a boy a scientific education, you cannot do better than start him with a lens and camera. No better advice could be given. Provide an intelligent lad with a good set of apparatus, the necessary materials, and half a dozen lessons from a good operator; he will be astonished and delighted by the ease with which he can produce beautiful and useful results. He will not be content to do a certain thing by rule of thumb, but will want to know the reason why he should do it. His mind will be opened; he will be led step by step to study the cognate sciences and arts, and may, in due time, become a *savant*, or an artist, or both. This ease of production has led hundreds of thousands of amateurs, all over the world, to take up photography, much to their own happiness and the delight of their friends. It has provided readers and supporters for numerous photographic journals; it has sent visitors to the photographic exhibitions, and supplied them with their welcome shillings, and it has created a new and a vast industry, affording employment to hosts of artisans and assistants in the various trades which supply the requirements of the art. So much for the "curse." Another great curse of photography is the ease with which it can be employed by photographic thieves for the purpose of piracy, to the immeasurable detriment of Fine Art and its producers.

PALETTE.

(*To be concluded.*)

THE NAISSANCE OF ART IN PHOTOGRAPHY.*

WERE we to get together a gallery of the best photographic pictures, it would be found that almost every exhibitor had "studied art" to some extent, and, of the illustrations chosen for this article, nearly every one is by a worker who has been as painter, architect, or in some way or other more or less intimately connected with art. This gives further proof that, when photography fails to be pictorial, the fault lies with the manipulator rather than with his craft.

It may be well to inquire in general terms into the most salient faults, not only in ordinary photographs as we see them, but in the art itself. In the first place, we are confronted with a glaring defect depending on scientific facts. We may call this false tonality, but this rather explains our objection than defines what we mean by tonality. The constituent parts of light which chiefly act on the eye are not those which chiefly act upon a photographic plate. The brightest visual rays of the solar spectrum are those in the yellow and yellow-green regions, but ordinary photographic plates are comparatively insensitive to these, while they are relatively much more affected by violet and blue. This, of course, under common conditions, often leads to false renderings of Nature; parts of a subject which ought to be represented as high lights appearing as dark, and the subdued tones of Nature telling as the highest lights. This grave defect is fully admitted by photographers, and to a considerable extent is being overcome by the use of what are called "orthochromatic" plates, wherein the sensitiveness to yellow and neighbouring spectrum rays, is relatively increased to a marked extent. This relative increase of sensitiveness is, in our science, enhanced by the use of yellow media in the camera, or in some part of the light way; we can, so to speak, eke out the discriminating action of the orthochromatic plates; for the yellow medium acts as a filter, and arrests a certain proportion of the violet and blue which otherwise would exercise undue influence on the sensitive salts in the plate. It is necessary to refer to this common defect by way of noting the advance made lately in the art. There is no reason to doubt that this defect of false tonality will be eliminated in process of time. It is true that no graphic art is able to represent the whole gamut of Nature's tone, and photography not only falls short of painting in the extent of its colour scale, but it is very apt, as we have seen, to render Nature with flat contradiction of her true light and shade.

The next important fault which confronts us in general photography, is redundancy of detail. In a photograph of a landscape of the usual type, we may admire the precision of the optical instrument used, we may admit the scientific accuracy of the rendering, but we revolt against the "finicking" minutiæ of the details, and miss sadly the effect of breadth of treatment and the satisfying result of massing. A print of this kind is either exasperating from its spottiness or contemptible for its weakness. One cannot call such a production "beautiful," nor even "rich," it is simply extravagant. If there is one defect which destroys all nobility in a picture, it is "spottiness," and, as this is one of the faults into which photographers are most prone to fall, we venture to state, without dogmatism but with confidence, that the awaking of photographers to the evil of over-detail has chiefly given us the right to use the word Naissance in the heading of this article.

It may be said, "Vixere fortes ante Agamemnona." But the word "multi" cannot with justice be added in the present case. From almost the earliest days of photography some were, indeed, found who used the science as an art, but they were very few. None of these is better known to fame than one who passed away some years ago, Rejlander. He may be said to have been the first to produce photographs, crude though their execution may sometimes have been, that, nevertheless, had distinct claims to be considered pictures. In access of ambition, he produced pictures which were made from many negatives, a task of extreme technical difficulty, and still more difficult from an art standpoint. The most noted of his productions in this class is the *Two Ways of Life*, which might be compared in some respects to a conception of Hogarth. It was composed of a great number of figures brought together in printing by a process which came to be called Composite Photography. Rejlander was followed by Henry P. Robinson, who has given us a number of composites. Although there have been some much applauded, there are not a few of his pictures by ordinary methods which we must prefer. On the whole, his most successful composite picture was *Carolling*. Mr. Robinson, who at one time intended to follow painting as a profession, did great service to photography by drawing attention to some of the leading precepts of artistic composition in a small book, *Pictorial Effect in Photography*. Mr. Adam Diston, of Leven in Scotland, is also among the number of our old and good artists. Contemporary with Rejlander was Mrs. Julia Cameron, who produced portraits and figure studies of large size, and full of character, which are looked upon as models worthy of imitation to this day. Some very fine figure subjects have been lately produced by Mrs. Myers, who has evidently and happily followed in the steps of Mrs. Cameron. Mr. F. M. Sutcliffe, of Whitby, though a comparatively young man, has been for a long time known to the

* *Concluded from page* 702.

photographic world as one who is essentially an artist. Mr. Sutcliffe, the son of an artist, and carefully trained in art, seems to have developed highly the talent of snatching the "happy moment" for the best aspect of his subjects. Few would attempt, and still fewer would succeed, with such a subject as that which forms our "tailpiece." Mr. J. Gale must also be included among the number of those who have long and successfully followed photography as an art.

We do not mean to say that here we have named the only men who used photography as an art before our "Agamemnon," but we have named the best known, and we have omitted but few. Towards the end of the "eighties" some works by Dr. P. H. Emerson attracted much notice, partly on account of the novelty of treatment, partly because of the boldness of departure from the beaten track. These photographs, chiefly of subjects from the Fens and Broads, were severely criticised by many, utterly condemned as pictures by some, but all thinking men owned that here was something new and something good. For the first time we saw detail ignored, and place given to impression and massing. Dr. Emerson followed up practice with precept in his book, *Naturalistic Photography*, which at once aroused no little excitement. In no measured terms he pointed out what he considered the faults of photographers, and gave to the world his own ideas of true art. Many objected to the tone of the book, which was considered offensive, but there was much of value in its pages. The most important argument was against "spotty-lighted, sharply focussed, brightly developed negatives," which were stigmatised as "noisy, and garish, and inartistic." In this book Dr. Emerson offended some, and by later actions he displeased others; but he by no means always gets the credit he deserves for his services to photography, for we firmly believe that his pictures and his writings first drew serious attention to the most flagrant sins of photography as an art; and it is certain that very soon a school of photographers sprang up whose leading principle was to avoid sharpness of focus and to obtain increase in breadth of treatment. This school, the outcome of Dr. Emerson's teaching, has been variously dubbed the "Naturalistic," the "Impressionist," and the "Fuzzy." It is not to be supposed that all our artistic photographers deliberately put their lens out of focus to obtain the advantage of breadth; but misty effects, which previously would have been avoided, came to be much in request; simpler subjects are chosen, and we have thrown off many trammels which took the form of rules for composition and lighting, and were a bar to originality and expression.

This crusade against superfluous detail led to many follies and extravagances. For a time we had quite a run on very rough papers for prints, even of the smallest sizes. These prints were simply smudges in most cases; true texture was lost. We ran riot in fuzziness. Pictures were, and are, made so much out of focus, that the outlines are doubled, and spotty "areas of confusion" are seen with an effect almost sickening. One set of evils is eliminated at the expense of the introduction of another set no less objectionable; but it is to be hoped that in time we may return to moderation. Many have accepted the example of Dr. Emerson without rushing into extremes—none more successfully than Mr. Davison, Mr. Horsley Hinton, Mr. Wellington, and Mr. Wilkinson. In the hands of artists such as these, we believe that photography must, and will, take its deserved place sooner or later in the world of Fine Art.

The prevailing style of professional portraiture has always been a sore point to those who wish photography well. We allude particularly to the practice known as "retouching." A painter who should represent in a portrait a lady disfigured by freckles would not be wise, and would certainly not be successful, in his profession; and the same may be said of a photographer. But, when the removal of accidental and evanescent blemishes was carried to the extent of complete "modelling" of the features, and when the result of this modelling was to produce faces with the appearance of putty or dough, and to obliterate every trace of character from the features, then, indeed, great damage was done to photography. We have a perfect right to portray a face at its best, to remove fortuitous blemishes; but the line must not be drawn at falsification, and the human face must not be represented as similar in surface texture to a butcher's ball of suet. Portrait photography has also been degraded by the use of commercial backgrounds and impossible "properties." The best of these backgrounds and properties are not in themselves objectionable, but from their frequent repetition. Among professional portraitists who have discarded both "stock backgrounds" and "properties," may be mentioned Mr. Crooke, of Edinburgh, whose studio is fitted up in the style of an ordinary room, or rather of several ordinary rooms, with special arrangements for lighting the sitter. Mr. Crooke, a few years ago, woke us up by a set of portraits, in the Kitcat style, of Scots Judges in their robes, printed in platinotype on tinted paper with a plate mark; in each portrait the character was admirably preserved. Mr. A. Burchett has also done good service in figure studies, some of them being on the borderland of pure portraiture. This gentleman selects good models and paints his own backgrounds. His *Girl with a Violin* is one of his simplest and, to us, most pleasing achievements.

The use of hand cameras is at once a danger and a boon to photography—danger in the abominable facility it offers for a vast amount of careless work, and the consequent dulling of the artistic discrimination; a boon to those who use the instrument aright. By it a faculty of quick observation is cultivated, and we are put in possession of many natural effects which are lost to the tripod camera. We do not allude to the *very* rapid exposures on quickly moving objects, but to exposures having some proportion to the physiological "persistence of vision." As an example, we have the work of Mr. A. R. Dresser, who, in the course of a year, makes an almost incredible number of exposures with a hand camera. Many of these, when enlarged to about 12×10, or 15×12 inches, are held in high esteem by those qualified to judge. The hand camera has given birth to a school of workers in small sizes, some of the productions being gems in their own way. Among works of this kind may be noticed those of Mr. Ramsay and Mr. Cembrano; but, on account of the minuteness of the detail, it is almost impossible to obtain suitable reproductions of the originals by any mechanical process, such as required for illustrating a book or journal.

When Mr. Willis introduced the platinotype process of printing, a great stride was made in photographic art. The brown tones and glazed surface of albumen paper are now replaced in our exhibitions, to a great extent by images in the paper, rivalling the finest engravings, and, in some respects, superior to them. Those who prefer glossy surface and warm media, which undoubtedly have their advantages for some styles, can now obtain gelatino-chloride papers, which bid fair to supplant the albumen.

Photography is seen at its worst in a photographic exhibition, and our critics ought, in justice, to remember this. The monotony of colour is depressing to those accustomed to the variety of an exhibition of paintings, just as we, accustomed to photographic collections, are confused and almost blinded on entering an exhibition in colour. But we believe that the unprejudiced will find, in every exhibition of photographs worthy of the name, works which will prove the capability of photography to stand, and entitle it to the credit of standing, as a fine art, juvenile though at present it may be.

ANDREW PRINGLE.

LANTERN-SLIDE MAKING.

[Liverpool Amateur Photographic Association.]

A PRACTICAL demonstration on lantern-slide making was given on Thursday evening, the 2nd inst., by Mr. G. A. Carruthers and Mr. Harry Holt.

Reduction by Daylight.—Mr. Holt pointed out that the first thing to do was to settle down to one make of plate and thoroughly master the manipulation of that; each brand had some special feature which required a little practice to understand. The reducing camera which gave the best results in his opinion was the Pearson & Denham's, both for simplicity of working and compactness. When once the focus was ascertained for the different sizes of negative, these should be accurately marked on the baseboard of the camera. Nearly all of his slides were from whole-plate negatives, and he found the exposure was to judge by the light at the time, and the question if it was necessary to use a small stop was an open one. He was inclined to say that it did not improve and make the slide sharper, it was only a question of seconds; that it was best to err on the safe side, using a sheet of ground glass in front of negative; this is only necessary when the camera is not pointed direct to the sky, but is absolutely necessary if trees or buildings are in the way of direct light. North light, if possible, as a standard for the time of the year, using a Mawson plate (really a very quick brand) reduction from whole-plate, *f*-22, one minute's exposure was found to be the correct exposure, using a fair negative, full of detail, but not over-dense. Hydroquinone he considered the standard developer for transparency work, and the same solution could be used for several plates. After answering several questions, Mr. Holt concluded by explaining the method of putting in clouds as follows:—Clear the sky off the slide with ferridcyanide of potash, a few drops of saturated solution in two ounces of hypo, and use a very fine camel's-hair brush, then expose another plate for the cloud only from opposite corners; after the cloud is developed, place the slide and the clouds film to film, say about half an inch apart, and trace the outline of the picture of the glass side of the cloud slide, then clear with the brush, wash well, and use cloud as cover glass.

Mr. Carruthers followed, generally agreeing with what Mr. Holt had said, but pointed out the great difficulty experienced by the average amateur in finding time to make slides by daylight; where it could be done, he strongly recommended it, but with the present speed of lantern plates it required very little practice to get good results by artificial light, his plan of working being very simple, using a Pearson & Denham's reducing camera; it is a very easy matter to focus, a candle close up to the negative is quite sufficient. A sheet of ground glass between the negative and the light is necessary, close up to the negative is the best. About nine to twelve inches of magnesium ribbon held about a foot from the negative, taking care to keep the light moving about right and left, up and down, so that you get an equal illumination all over the negative. For weak negatives England's rapid chloride plates will require about the exposure.

The lecturer rather emphasised the use of fresh hypo, also the spotting of negative and slide, and the introduction of suitable clouds; this appeared to be a simple matter in experienced hands, and success can only be obtained after a little practice. Mr. Carruthers also gave a lot of useful hints about chloride slides by contact, explaining that full exposure will develop warm tones; these can be toned any time after fixing, a good bath being the P. O. P. toning bath. A lot of excellent slides were passed through the lantern, showing the most suitable tone.

COBALT PRINTING.

Before the Leeds Photographic Society, on November 2, Mr. B. A. Burrell, F.I.C., read a paper on Messrs. Lumière's process of cobalt printing. This process is of very recent origin, the first notice appearing in the *Comptes Rendus*, June, 1893. The method is based upon the unstable nature of the cobalt salts, and their conversion into cobaltous salts by the action of light. The formation of cobaltous and cobaltic hydroxides were shown, the latter being formed by the action of sodium peroxide (NaO_2) on a solution of cobaltous sulphate ($CoSO_4 7H_2O$). The sodium peroxide requires to be dissolved in water with care, otherwise great heat is evolved, and decomposition ensues into sodic hydrate and free oxygen. After precipitating, the cobaltic hydroxide requires careful washing to free it from the sodic sulphate formed during the reaction; it is then dissolved by means of saturated solution of oxalic acid (one part in 10·5 parts water). The method of calculating the amount of cobaltic hydroxide ($Co_2 H_6 O_6$) formed from a given quantity of cobaltous sulphate was described, as it is important not to add an excess of oxalic acid. The oxalic acid solution is allowed to react upon the moist cobaltic hydroxide for about three hours in the dark, the mixture being kept well cooled. The resulting cobaltic oxalate is of a dark green colour, and is used at once to sensitise the gelatine paper. This is done in the usual way, and, after drying, the paper is used for printing under a negative. When exposed to light under these conditions, the parts acted upon lose their green colour, being converted into a pale rose colour, owing to the formation of cobaltous oxalate, a substance but slightly soluble in water. The print now requires developing, this being done by means of a five per cent. solution of potassium ferricyanide, leaving untouched the cobaltic oxalate still remaining in the print.

The resulting prints, which are of a deeper rose colour, require thorough washing (about half an hour in running water) in order to wash out all traces of unaltered cobaltic oxalate. When this is effected, the prints are put into a dilute solution of ammonic sulphide, and allowed to remain for varying time, depending on the desired tone—a short time for sepia tone, and a lengthened period for black tones, any desired tone being obtainable, depending on the time of immersion. The prints should be washed for a few minutes and dried. The image consists of sulphide of cobalt, and is almost as permanent as one composed of platinum.

The process possesses the following advantages:—First, its extreme cheapness; second, the short time required for washing; third, the absence of toning and short time for printing; fourth, the great permanency of the prints, whilst its disadvantages are:—First, having to prepare one's own paper (at present none is in the market suitable), and to sensitise it, and using it almost as soon as it is dry, as it rapidly deteriorates. Specimens of the sensitised paper and prints in the various stages of development were shown, and several prints were developed.

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

Not merely in the quality of the work shown, but also in the classification and arrangements of the exhibits, do we congratulate that useful and practical body, the South London, on a marked advance in this year's Exhibition over its immediate predecessor. The Exhibition, which opened on Tuesday night, contains a great deal of really good work by members, while in the open classes there are some conspicuously meritorious examples by men of wider renown. About a hundred exhibitors contribute between 300 and 400 photographs. There are four lantern-slide classes well patronised, and the exhibits not for competition include a choice collection of animal and architectural studies by such men as Thomas Fall and F. W. Edwards (the President). The Judges were Messrs. F. P. Cembrano, W. E. Debenham, and Leon Warnerke, and their awards, we should imagine, must have given great satisfaction, as they appear to have been carefully and evenly distributed.

In class A (Members: Portraiture and figure study, including animals), the most noticeable frames were a large direct portrait of a girl by Mr. C. F. Dickinson, some charming pastoral studies, *Feeding Time*, *Haymaking*, and a *Group of Sheep*, (bronze medal) by Mr. W. E. Harman, and a clever study of an old couple seated by the fireside, *Peaceful Old Age*, by Howard Esler, for which a bronze medal was awarded. This is printed on a very rough paper and in lighting, composition, and sentiment does Mr. Esler credit. Class B (Architecture) is a remarkably good one, containing as it does many fine examples of architectural work, in which members of the South London have collectively no superiors. Messrs. Harman, W. J. Symes, C. H. Oakden, H. E. Farmer, E. R. Bull, and W. Howell shine in the class, the last three gentlemen securing silver and bronze medals for *Across the Octagon, Ely*, *Tomb of Edward the Black Prince*, and *The Choir, Rochester* respectively, examples of sound photography. In class C (landscape and seascape), Mr. G. H. Cricks takes a silver medal for a realistic picture of an *Essex Swamp*, and has other equally good examples of his powers. Mr. H. E. Farmer's *On the Essex Hills*, a study of trees on the hillside is a free and pleasing transcript of a simple but effective subject. Class D (landscape and seascape half-plate or under) is a large one, and, perhaps, the weakest of all, the dead level of mediocrity obviating criticism. The most interesting exhibit to our thinking was a small picture by Mr. W. Howell, *A Smith's Shop*, that seemed to breathe the life and bustle of the smithy. The awards went to Miss Smyth (silver) and Mr. W. F. Slater (bronze). In Class E. (enlargements) the Judges make no awards, which somewhat surprises us, as Mr. C. F. Dickinson's enlargements from small originals of the *American Bison*, *Indian Adjutant*, and the *Martial Hawk Eagle*, and Mr. Symes's enlarged *Portrait of a Lady* struck us as extremely good. Mr. Dickinson obtained the silver medal in Class F (members' lantern slides).

There were four open classes. In G (Pictures which had previously received awards) many "old stagers" were entered, Mr. Wellington taking the silver medal for *Eventide* and Mr. Oakden the bronze for his *North Aisle, Ely Cathedral*. The latter gentleman by the way also received the "general excellence" medal, and richly deserved it. Mr. A. G. Tagliaferro in this class shows a homely study of an old lady dressing the *Cut Finger* of a small boy; and other exhibitors are Messrs. Terras, Byrne, C. S. Roe and E. M. Stone. Class H (for pictures not previously medalled) is undoubtedly the strongest. Mr. E. M. Stone's cattle study, *An Evening Bath*, is full of great charm. The rugged head of the old fisherman *Mending his Nets*, by Mr. D. J. Scott, is one of the finest portrait studies in the Exhibition—natural and above all lifelike. To Mr. Byrne was awarded the silver medal for a large direct portrait study and a bronze medal for another portrait in red carbon, both in Mr. Byrne's best style. A bronze medal goes to Mr. Tagliaferro for a devotional subject, a girl making *A Humble Offering* of flowers to the statue of a wayside Virgin, presumably in some southern country. This is an unaffected piece of composition, the treatment being refined and the subject being unhackneyed. English photographers must envy Mr. Tagliaferro the command of unconventional subjects which his periodical flights to southern climes gives him. Mr. T. G. Hemery shows good portrait work; Mr. Terras, among other exhibits, a "study" of a girl's head, a well executed piece of work; Messrs. Charles Sweet, and West & Son, yacht studies; Mr. E. A. and Miss Golledge, some striking views on the River Roding. Lack of space compels us only to mention the fact that Messrs. C. S. Roe, Dresser, W. M. Warneuke, T. E. H. Bullen, H. Avery (with an unconvincing "nocturne"), D. Pym, and other good workers contributed more or less well-known pictures to this class. In the class for lantern slides, which had previously received awards, Messrs. G. E. Thompson and W. Taverner were successful with silver and bronze medals respectively, and in the class for slides, which had not been previously medalled, Mr. G. Hankins obtained the silver and Mr. J. H. Gear the bronze medal.

On the whole, a capital exhibition, supplemented by an interesting loan collection, examples of carbon printing by Messrs Elliott & Son, and stalls of apparatus by Mr. W. F. Slater (who has many choice things in picture frames), Messrs. Howell, The Prosser Roberts Drug Co., Mr. T. H. Powell, &c.

Our Editorial Table.

Specimens of well-designed and well-printed Christmas and New Year's cards have been received from Messrs. Percy Lund & Co., Bradford. They are, of course, intended to receive photographic portraits.

Amateur Photographic Requisites.

The London Stereoscopic and Photographic Company, Limited (Regent-street and Cheapside), have issued a very beautifully printed catalogue of 207 pages of requisites for amateurs. It comprises several complete sets, hand cameras, including their latest novelty, the new "Race-glass" detective; Kodaks; lenses of their own make as well as those of other leading makers; dry plates and films; lanterns, chemicals, albums, shutters, stands, and, in fine, everything that an amateur can possibly require. This fine catalogue, which has numerous illustrations, has, we learn, been printed in the Company's own works. Price 6*d*.

A New Film Hand Camera.

Messrs. Perken, Son, & Rayment have perfected, and are to have on sale in January, a hand camera to carry forty-eight films on celluloid, the important feature of which is that the films will be used as supplied by all manufacturers—*i.e.*, without any notching or interference with the films. The outside of the instrument measures $9\frac{1}{2} \times 5\frac{1}{4} \times 5\frac{3}{4}$ inches. We have had submitted a sample for examination, and we find that by moving a lever it acts automatically without a hitch. It takes plates as well as films—a fewer number of the former, of course. The movement of the one lever releases the exposed film, and sets the next one ready for exposure. The mechanism is exceedingly simple and not likely to get out of order. We predict great popularity for the new camera.

Intensity Coils: How Made and How Used.

By 'Dyer.'

This little shilling manual, published by Perken, Son, & Rayment, has now attained its eighteenth edition. It is not written for the advanced electrician, but for the *paterfamilias* or the boys at home who desire to spend the winter evenings in a rational and improving manner. Various batteries are described, and instructions given in the making and using of intensity coils. The electric light, electric bells, the telegraph and the telephone all find a place in its pages.

The Magic Lantern: Its Construction and Use.

From the same firm we have received a new edition of this useful little book. It supplies a capital introductory guide to the beginner in optical lantern work, the chapters on lantern experiments and the lantern microscope being extremely clear. The book is illustrated, and at this season should be popular.

News and Notes.

West London Photographic Society.—November 14, *Figure in Landscape*, by Mr. J. C. Dollman.

The Exhibition of the Photographic Society of Great Britain will close on Wednesday, November 15.

Lewisham Camera Club.—November 10, *Common Defects in Negatives, their Cause and Cure*, by Professor Carlton J. Lambert, M.A.

In the report of the Photographic Section of the Croydon Microscopical Society, published last week, "Messrs. Adams & Co." should read "Messrs. Hannam & Co."

Central Photographic Club.—November 10, *Printing-out Processes*, by Mr. S. Herbert Fry. 15, Smoking Concert. 24, *Norway* Lantern Lecture, by Mr. Paul Lange (of Liverpool). 31, *Films v. Glass*, by Mr. H. M. Smith. 27, Mr. Thomas Fall will give a one-man show.

The Polytechnic Photographic School.—The following are the arrangements for the photographic classes during the winter session:—Mondays, at eight p.m., Lectures: *Art in connexion with Photography*, by Mr. Valentine Blanchard; *Technique and Elementary, Practical*, by Mr. Alfred W. Dollond. Practical Classes: *Studio Posing, Lighting, &c.* (at three p.m.), by Mr. Valentine Blanchard; *Studio Work (Elementary)*, by Mr. Samuel J. Beckett; *Wet Collodion*, by Mr. C. R. Whiting; *Negatives and Printing*, by Mr. A. W. Dollond; *Gelatino-chloride Printing, &c.*, by Mr. Ernest Beeson; *Retouching*, by Mr. Wolfgang Arndt; *Finishing Enlargements in Black, White, and Monochrome*, by Mr. Ernest Wesson. Tuesdays, at eight p.m., Lectures: *Technique and Practice of Studio and General Photography*, by Mr. Howard Farmer. Practical Classes: *Air Brush-work*, by Mr. W. H. Harrison; *Lantern Slides and Lantern Work*, by Mr. J. H. Gear. Wednesdays, at eight p.m., Lectures: *How to obtain Pictorial Excellence in Photographs*, by Mr A. Horsley Hinton; *Elementary Practical Chemistry for Photographers*, by Mr. Robert Avey Ward, F.C.S. Practical Classes: *Photogravure*, by Mr. Howard Farmer; *Negative-making, Practice and Technology*, by Mr. C. W. Gamble. Thursdays, at eight p.m., Lectures: *Photographic Optics and Photographic Chemistry*, by Mr. A. W. Dollond. Practical Classes: *Collotype*, by Mr. G. Holtzhausen. Fridays, at eight p.m., Practical Classes: *Enlarging*, by Mr. J. H. Gear; *Process Blocks*, by Mr. H. Colomele; *Carbon and Platinotype Printing*, by Mr. E. Beeson; *Retouching*, by Mr. Wolfgang Arndt.

PATENTS COMPLETED.

An Improvement in Photoorapiic Cameras and Dark Slides for same.

No. 21,946. Lars Severin Zachariasen, 57, Charing Cross, London, S.W. *October* 7, 1893.

This invention relates to an improved form of double dark slide and the means of working it in a camera. The dark slides are, by preference, made to hold two sensitive films or plates, and each slide is to consist of two folding parts hinged together or to a back common to both, the joints between the two parts and the back being made light-tight by means of beads and grooves, or other convenient manner.

Each of the two folding parts is to consist of a suitable framework, and of a back plate, made of wood, cardboard, metal, or other suitable material; grooves are cut in the framework near the back plate, in which grooves the sensitive film or plate is inserted and held in place against the back plate, the sensitive surface being on the side away from the back, so that, when the slide is closed, the two sensitive surfaces will be facing each other. When folded, the slide is locked by means of suitable fastenings acting automatically.

The camera to be used in connexion with this form of dark slide I prefer to make with a parallel body, the lens being fixed on the front in any convenient manner. The back of the camera may be made so as to hold any number of the dark slides, and is to be fitted so as to hold one of them in position for exposure, and with a door to cover in the slide or slides, which will thus be entirely enclosed in a light-tight chamber, and therefore securely protected against stray light. When pushed home in the camera, the automatic fastenings of the slides will engage with suitable projections, and are thereby released, leaving the front part of the slide free to be swung on its hinges by means of a lever or levers operating from the outside of the camera. When the front part is thus swung out of the way, the sensitive film or plate contained in the back part faces the lens, and may be exposed to the action of the light through the lens. During the exposure, the sensitive film or plate contained in the front part of the slide is protected by a screen or curtain, made of some opaque material and of a suitable form, hinged to the front of the camera behind the lens, and caused to move into position so as to screen the sensitive film or plate from light. The screen or curtain may be moved by independent mechanism, but is by preference actuated by the same as that which is used for the double slide.

Improvements in and in connexion with Photographic Dark Slides or Changing Backs.

No. 8122. Joseph George Reid, Woodley Cottage, Bloomfield, Belfast, Ireland.—*October* 14, 1893.

A box used as a dark slide, made of wood or other substance, to hold any number of plates, in carriers made of sheet zinc or other substance. The box is fitted in front with sliding, light-tight, double-back shutter, to which is affixed a spring pin, which acts on an indicator inserted in framework of box. The indicator is for showing the number of the plate in position for exposure, and consists of a barrel axle, round which are affixed or engraved numbers on cog-wheel. The pin affixed to the shutter causes the wheel to revolve on the shutter being closed. The wheel has cogs or teeth, according to the number of plates the box is made to hold. The back is detachable for the purpose of filling the box with plates, and is light-tight, being fitted into grooves and held in position by clasps. Affixed to the back, on the inside, are springs, which press on the backs of the carriers, so that, when the shutter is withdrawn for exposure of plate, a plate, by the action of the springs, comes into the position which the shutter occupied. At one side of the box is affixed an opaque bag, made of cloth or other substance, and in the side of the box to which the bag is affixed there are two slits, one being to allow the plate which has been exposed to pass into the bag. This is done by the closing of the shutter, a plate having, by the action of the springs, been forced into its place. On being closed, the shutter drives the plate forward, through the slit, into the bag. The second slit is for the purpose of passing the exposed plate from the bag back again into the box, and is so arranged that the plate comes in at the back of the box in a position between the springs and the last plate, thus ensuring the full pressure of the springs and the safety of the plates. The bag is collapsible, and can be folded over the box.

Improvements in Cameras.

No. 19,929. Thomas Charles Naylor, 13 Greek-street, Soho-square, London.—*October* 14, 1893.

This invention relates to improvements in cameras, and is designed for the purpose of enabling the respective parts of the camera, when closed, to instantaneously come into position ready for use, by merely pressing upon a spring catch, or the like, with which the camera is provided. The act of pressing upon said spring catch, or the like, causes the baseboard and the front to immediately fall into position ready for exposure, this movement being effected by springs connected to the stretchers and the baseboard, and by others connected to the front of the baseboard. The lens and shutter being also ready, the trouble and delay due to screwing, &c., are avoided.

The camera has a double extension, closes into a small compass, and is provided at each side of the back frame with a slot in which works a pin or stud connected by a stretcher or link to the base, thus enabling it to be used as a "swing back." By means of a stop, situated near bottom of said slot, the back frame can be kept upright or perpendicular to the baseboard when the camera is opened.

Improvements in Clamps or Rests for Photographic Cameras and other Instruments similarly supported.

No. 23,010. Thomas Binnie Ralston, 234 Buchanan-street, Glasgow.—*October* 14, 1893.

This invention has for its object to afford steady support for cameras and like instruments upon walls, bars of railing or fencing, and similar situations, where it is impracticable to employ an ordinary tripod stand or otherwise to obtain a steady support for the instrument. The apparatus constituting the invention consists of a horizontal bar, the underside of which has a series of ratchet teeth made upon it. This bar may, in circumstances where a tripod stand is provided in conjunction with the instrument, be a section of one of the ordinary legs. At one end the bar has a pin or stop, against which a vertical leg strung on to it abuts. This vertical leg, at its upper end has jointed to it a stand or angled piece capable of movement through an arc, and to which the camera or other instrument is screwed in the ordinary manner, the stand being fixed in the required position by a thumb nut or equivalent device upon its centre of movement, or the stand may have a ball-and-socket joint to enable it to be moved in every direction.

On the horizontal bar there is also strung a clamping leg which has a tooth engaging with the teeth on the lower surface of the bar, the said leg being capable of movement backwards or forwards to suit the thickness of the wall, railing, or other situation to which the rest for the camera or other instrument is to be secured, and the apparatus is fastened in position by a screw passed through the said clamping leg, and having a head or flange at its inner end which grips upon the source of support. The screw is carried in a slot in the clamping leg, and is capable of adjustment vertically.

When the apparatus is to be attached to the top bar of a railing or other comparative thin horizontal or vertical body, the clamping leg and the horizontal ratchet bar may be dispensed with, the leg which supports the camera or other instrument being provided with a jaw and pinching screw to fix it in situation, and in some cases the said leg may have a stand or feet, and be merely rested upon any horizontal surface.

Liverpool Amateur Photographic Association.—November 15, Lantern Lecture in City Hall, Eberle-street, *Life in Tripoli*, by Mr. G. E. Thompson. 16, Lecture, *Hand-camera Work, with Special Reference to the Frena System*, by F. O. Bynoe (Messrs. R. & J. Beck, London).

Photographic Society of Great Britain.—Ordinary Meeting, Tuesday, November 14, at the Gallery, 5A, Pall Mall East. *Photography in Coal Mines*, by Herbert W. Hughes, F.G.S., A.R.S.M. *On the Range of Light impinging on a Plate during Exposure in the Camera*, by Professor W. K. Burton, C.E.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 2,—Mr. Alexander Mackie in the chair.

Developed Gelatino-chloride Papers.

Mr. S. Herbert Fry prefaced a demonstration of development of partly printed proofs on Paget printing-out paper by saying that the plan should be useful to the professional in dull weather, and to the amateur who endeavoured to get the best representation from his negative that could be got. The paper had been put on the market as adapted for development, a very thin coating of gelatine being the leading feature of its manufacture. A large quantity of gelatine on the paper interfered with the chemical reactions. The paper would tone more easily on account of the less amount of gelatine, while the tones would also be more regular. He (Mr. Fry) had before now emphasised the great objection to double tones in gelatine papers. He did not suggest that this was the fault of the papers, but the fact remains that a large number of photographs had those double tones. Coming to the depth to which printing should be carried, he said it was immaterial whether it was too much or too little within certain limits. When developing by a yellow light, a slight degree of printing out would do; if the prints were nearly printed out, it was easier to over-develop them. The time recommended by the Company was two minutes, or about a tenth of the time required for printing out. When taken from the frame, the prints are passed into a ten per cent. bromide solution. The older the paper the stronger the bromising bath should be. He would recommend that the prints be left in it for about five minutes. It was better to wash out the bromide well, but it did not appear a vital matter. The toning had been called an intensification process, but it depended on how it had been done; if the developer were not well washed out, the toning would be by intensification, so much so, that the print would go far beyond the depth intended. If the developer were well washed out, the depth could be judged better. Solution 3, containing ammonium carbonate [see p. 672 *ante*], could be used instead of the bromising solution, as a preliminary bath, for the purpose of obtaining more contrast. He recommended that the proportions of the solution be kept constant; he got better results with caustic alkali than with the other alkalies, a better image for toning being obtained. As to light action on the paper, he said he got better results by being very careful of the light; a paraffin lamp or gas was a good light to work by. He used the developer given diluted with an equal quantity of water.

Mr. Fry's remarks were followed by the development and toning of several prints. He gave as the difference between printed-out and developed prints, that with the latter there was less loss of detail.

Mr. W. E. Debenham remarked that he considered the separate sulphor cyanide-toning bath better than the combined bath as regards permanency. He suggested that makers should supply two or three kinds of paper to suit different kinds of negatives.

Mr. H. M. Smith said that with the combined bath warm tones could be obtained, and, so far as the permanence of such pictures was concerned, he would emphatically say that, if the combined bath were used in the proper manner, the prints so toned were as permanent as anything made by separate toning and fixing baths. Mr. Debenham's suggestion as to two or three kinds of paper showed that he did not understand the commercial aspect of the matter.

Mr. Debenham said that, if the sulphocyanide bath took more gold to produce a good tone than the combined bath, it practically promised the most permanence.

Mr. FRY pointed out that Mr. Dobenham suggested that the sulphocyanide bath required more gold than the combined bath, but that the whole of the gold went into the print had not been shown.

After further observations and discussion a vote of thanks was passed to Mr. Fry.

Croydon Camera Club.—November 1.—Messrs. Walter Burr and J. Irving Dickson were elected members A paper on *Harmonising Harsh Negatives*, by Mr. Macintosh, was read by the President, Mr. White's paper being postponed for lack of time. Questions and answers elicited (1) that Welford's rapid toning bath had not yielded satisfactory results to those who had tried it; (2) immersion of gelatino-chloride prints in methylated spirits was the surest safeguard against blisters; (3) no exposure tables or meters at present in use will entirely supersede judgment and experience; (4) 150 gelatino-chloride prints may be safely and evenly toned together in a bath whose superficial area does not exceed four times that of each print. This Mr. White offered to demonstrate.

Croydon Microscopical and Natural History Club (Photographic Section).—November 3, *Paget Printing-out Lantern Plates*, by Mr. S. H. Fry. Mr. J. Weir Brown in the chair.—Mr. FRY confined his remarks and demonstrations to the lantern plates, stating, however, that the treatment of the opals and the P.O.P. was practically the same. The image on these plates partook more of the nature of a stain, and density was easily obtainable without blocking up the shadows. There was no difficulty in printing them in an ordinary printing frame, being sufficiently printed when, on looking through from the back, they had a reddish appearance all over. If found over-printed, they could be reduced in a weak—two-grain—cyanide bath. Mr. Fry then proceeded to develop two partly printed plates. Stress was laid on the thorough "bromising" and washing before being placed in the developer. He preferred the "hydroquinone" developer, as given for the paper, diluted, however, with an equal quantity of water, as it was more easy to wash the developer out before toning, and unless this was done, the gold, in the presence of hydroquinone, acted as an intensifier, and produced an enormous density, whilst toning was very slow After development the plates were toned and fixed in a combined bath. The appearance of the resulting slides was greatly admired by the members, as also were a number of finished slides which were shown.

Ealing Photographic Society.—November 2, Meeting in Princes' Hall, Public Buildings.—Messrs. Roland Whiting and T. Stephenson were elected members. A set of lantern slides, illustrative of Yorkshire scenery, contributed by the Leeds Photographic Society to the Affiliation of Photographic Societies, and lent by the consent of the latter body, was shown. The remains of the once splendid abbeys, in which Yorkshire is so rich, were well represented, the slides including views of Bolton, Kirkstall, Rievaulx, Whitby, and Fountain's Abbeys. Amongst them *A Peep Through the Transept Arch at Bolton Abbey*, by Mr. J. A. Walker, and a view of the *Crypt at Fountain's Abbey*, were much admired for their excellent lighting and stereoscopic effect. Beauties of wood and moorland, of lane and stream, were plentifully depicted, and there were several views of the picturesque town of Knaresborough. The curious rocks at Brinham, near Harrowgate, were thrice depicted, and there were numerous specimens of the coast scenery at and near Whitby. Amongst the seascapes *Flamborough Head* and *Sunset o'er the Sea* were most pleasing, though the former suffered from the absence of clouds. After the Yorkshire slides, a number of home manufacture were shown. These comprised views in Surrey, on the Thames near Marlow, flower studies, &c., by Mr. T. Crisp, and views at Strand-on-the-Green, Brentford, in Scotland, &c., by Mr. Vallance. The pictorial qualities and excellence of technique of these slides elicited much applause. At the termination of the lantern display, an adjournment was made to the dark room to inspect the enlarging apparatus, which is in process of construction, from designs by, and under the superintendence of, Mr. Charles Whiting.

Hackney Photographic Society.—October 31, Mr. W. L. Barker in the chair.—Members' work was shown by Mr. Henzler, viz., views taken upon the "Rocket" and Cadet lightning plates. Owing to the wide range in subjects treated, a decided opinion was unobtained as to which plates yielded the best results with an equal exposure. The Hon. Secretary showed the Thornton-Pickard automatic camera stand, which has many advantages, viz., automatic locking joints, lightness and compactness consistent with rigidity. Mr. FRY, of the Paget Prize Plate Company, then gave a demonstration upon the new rapid Paget printing-out paper by partial development. Amongst its advantages may be claimed that prints only require partially printing, the rest being developed up to the necessary strength and detail. They are then toned and fixed in the usual manner. To briefly describe the process, it consists of taking the partially printed print and immersing, without washing, in a solution of potassium bromide 1 ounce and water 10 ounces, leaving two minutes or more. It is then washed in water for about five minutes, and then developed with hydroquinone, according to formula given by the Company. It should then be washed for five minutes and toned with the following combined bath:—Make a stock solution of 80 ounces of water, 1 pound of hypo, 1 ounce of acetate of lead, and about 1 ounce of chalk. Then take 5 ounces of this solution, after well shaking, and add 1 to 1½ grains of gold, which will be sufficient to tone the sheet of paper. The prints tone rapidly, and give a large variety of tones, according to the taste of the operator. The prints are then washed for a couple of hours in running water. The demonstrator recommended not to carry the prints too far in development, as they gained in density in toning. The paper, although very sensitive to daylight, may be manipulated with a very fair amount of gaslight without having any effect upon the finished print.

Leytonstone Camera Club.—November 1, Mr. Albert E. Bailey in the chair.—Mr. J. CARPENTER gave a most interesting evening on *Flower Studies, and how to make them.* In opening he observed that, although he had made flower studies a speciality, he found it much easier to produce a passable picture than to impart to others the necessary knowledge of how to proceed to make them. All flowers were not suitable, and, although he had gone to great trouble to secure some of the most beautiful exotics, he found the well-known flowers, such as the primrose, lily of the valley, &c., were more appreciated by the general public. Light colours gave the best results; arrangement and grouping were a most important factor to success. No hard-and-fast line could be laid down, but much must depend on the individual taste. A number of prints were passed round, showing good and bad grouping. Lighting and backgrounds were next dealt with, which required varying to suit the subject. For plates he preferred isochromatic, and was quite satisfied that they were quite indispensable for this class of work. Pyro-ammonia was his favourite developer. Some negatives were passed round showing the density required, and a few hints as to exposure concluded a very interesting lecture. About fifty of his well-known and beautiful lantern slides were next put through the lantern, and, pausing over each, questions were asked and answers freely given in an explicit manner, showing Mr. Carpenter was a perfect master in his speciality. All exhibits for the Exhibition must reach the Clubs' headquarters, the Assembly Room, High-road, Leytonstone, on or before the 14th inst., addressed to the Hon. Secretary.

Woodford Photographic Society.—November 5, Ordinary Meeting, the President (Mr. H. Wilmes) in the chair.—Paper by Mr. H. CROUCH on *Lenses.* The lecturer said that his object was not to give information that could be found in any elementary text-book, but rather to give reasons for lenses taking certain forms, and show the advantages that different types had for special work. Specimens of Jena glass, grinding tools, and lenses in different stages of manufacture were shown; among others, the two elements of a single lens not cemented together, so that the surfaces that would be cemented when finished could be seen, the curves and the reasons for the form of the two elements being explained with blackboard diagrams. It was stated that the exterior surface of the lens controls its whole character, and that the flare spot, which is rarely seen in modern lenses, could always be cured by altering the position of the stop. Next meeting (informal), November 16. Subject for discussion, *What Form should the Work of a Photographic Society take in order to be of the greatest Assistance to its Younger Members?*

Aston Natural History and Photographic Society.—In the course of the practical demonstration on the manipulation of the dry-collodion lantern plate, Dr. HILL NORRIS said that exposures were, to his mind, more satisfactory when made to a paraffin lamp, as the variation in the pressure of gas often defied true judgment. The guide given for reduction in the camera was, mid-day, sun shining, facing north light, stop *f*-16, from thirty to sixty seconds. Contact printing was next dealt with, and the recommendation was ten to twenty seconds at a distance of two feet from a No. 6 batswing. The brilliancy of the negative is, however, always proportionate to the whiteness of the light. The developing should be conducted in a temperature of 60° to 65° Fahr., and should be continued until sufficient density is obtained, which may be judged by observing three rules, viz., (1) till all veil has disappeared; (2) that the image should be black; (3) that it appear dense and black by the transmitted light of the ruby lamp. In cases of over or under-exposure the results will be thin and flat. Over-exposures may be remedied by cutting short the development, fixing, washing, and then redeveloping with the silver and pyro. The plate must on no account be touched or brushed when wet, but the films are very tough when dry. Dr. Norris then passed round the following formulæ:—No. 1. Hydroquinone, 160 grains; sodium sulphite, 2 ounces; citric acid, 60 grains; potassic bromide, 40 grains; water, 20 ounces. No. 2. Sodium hydrate, 100 grains; water, 20 ounces. Take equal parts of each to develop. *Fixing:* Potassic cyanide, ¼ ounce; water, 10 ounces. Rinse well under tap. Or, hyposulphite soda, 4 ounces; water, 20 ounces. After immersion of plate, bring out of room into white light, and wash at once as soon as all unaltered silver bromide has gone from film. If No. 2 is used, more washing is required. *Redeveloper:* No. 1. Pyrogallic acid, 10 grains; citric acid, 25 grains; water, 2 ounces. No. 2. Silver nitrate, 20 grains; distilled water, 2 ounces. To ½ ounce of No. 1 add 30 drops of No. 2. The Secretary then exhibited a new film slide by Tylar, and a magazine camera by Archer & Sons.

Birmingham Photographic Society.—October 31, Mr. J. J. Button in the chair.—Mr. MIDDLETON gave a lecture entitled, *The By-ways of Warwickshire.* He described, in a very interesting way, a great many of the less-known places of the county, giving many valuable hints. Mr. Middleton strongly urged those present to adopt a definite object in their work. Thus would they add greatly to their own interest, and also be the means of obtaining valuable records. This is well demonstrated by the work of the Warwickshire Survey, of which Mr. Middleton is an active member.

Brighton and Sussex Natural History and Philosophical Society (Photographic Section).—At the ordinary monthly meeting, held in the Librarian's room, Public Library, Church-street, on Friday, November 3, competition slides were exhibited, also a selection of members' slides.

Munster Camera Club.—Annual Meeting. The President (Major Lysaght) occupied the chair.—The report of the Committee showed the Club to be in a flourishing condition. Mr. W. R. Atkins submitted a statement of accounts, showing that the total revenue of the Club was 27*l.* 3*s.* 6*d.*, and the ordinary expenditure 19*l.* 13*s.* 1*d.* The exhibition account showed a loss of 8*l.* 19*s.* 11*d.* The out-going Committee were re-elected, substituting Mr. L. Egan for Mr. D. Franklin, resigned.

FORTHCOMING EXHIBITIONS.

1893.	
November 10, 11.....	*Photographic Salon, Dudley Gallery, Piccadilly, W. Hon. Secretary of Organizing Committee, A. Maskell, 215, Shaftesbury-avenue, W.C.

GELATINO-CHLORIDE PAPER YELLOW STAINS.

To the Editor.

Sir,—While I fully endorse all that Mr. Bothamley has stated in his report on the cause of yellowing of gelatino-chloride prints, I do not think he has quite exhausted the subject.

Undoubtedly hypo is the cause of yellowing *between* toning and fixing where separate baths are used, and the knowledge of the fact led me astray for some time. Mr. Bothamley has probably not been asked to seek the cause of yellowing *after* toning and fixing, whether by separate baths or the combined one, and this, I think, is the ghost which so many are desirous of laying.

Hypo has got such a bad name for staining that anything in the shape of a discolouration is sure to be attributed to its agency, and thus, I believe, it has been credited with a much larger share of spoilt prints than it deserves. Given a yellow stain, and hypo is hunted for high and low, as a matter of course, and I must plead guilty to having joined in the chase.

The practice at my studio is to wash and tone in one room, and fix in another, using separate dishes for every operation. One sink is used exclusively for fixing and washing prints, which are toned and fixed separately. (Albumen ones have a bath to themselves.)

Despite all these precautions occasionally a crop of yellow prints would appear, sometimes only one or two, at others a dozen or more, and then all would, perhaps, go well for a week or two. This went on till I had arrived at my wit's end to think of fresh fields for investigation, when a waste bromide enlargement gave me the clue. This had been put to wash with others early in the day, but, being a waster and intended only to work by, instead of being pinned up to dry in the evening, it was left in the running water and forgotten till the morning, when I found the once-clear white paper stained to a dirty yellow brown. My conscience wouldn't allow me to accuse friend Hypo of this, so I began to suspect the washing water (direct from the main).

As a preliminary test I tied a bag of clean cotton-wool over the tap and allowed the water to filter through it for several hours. Result—a filtrate resembling slimy mud in character and strong coffee in colour. That, in my mind, settled the *colouring* matter of the stains, it only remained a account for their streaky character 1

Some prints were carefully prepared and put to wash in the usual manner. Not a trace of stain was visible after two hours' washing. Two prints were pinned together diagonally, and two more were crumpled and allowed to jam at the point of overflow, the whole being left till the next evening, some twenty-two hours in all. (I at that time practised the old-fashioned plan of washing prints, chloride and albumen, all night.)

An examination of prints proved them all to be yellowed, the free ones being slightly tinted all over; of those pinned together the under one remained fairly white in the part protected by the print in contact with it, the upper one having a deep yellow patch where the pin was inserted. The crumpled prints exhibited streaks of yellow corresponding to the ridges facing the overflowing water, and in depth of colour according to the angle each ridge presented to that overflow, proving that *pressure* has some influence.

Here, then, was the cause. Remedy:—shortest possible washing to ensure elimination of hypo. Two hours I found ample, and no hypo could be detected after even one hour, provided prints were frequently taken from one dish to another and well rinsed. Result—have not seen a yellow stain since, now over twelve months.

I could not detect any difference in *colour* of stain by too prolonged washing, and that purposely produced by weak hypo before fixing; but in the former the shape takes a more definite outline, mostly well defined and following a crease or fold. Moreover, my experience of hypo stains (fortunately very limited) is, that age accentuates them rather than not while stains from washing certainly decrease in a strong light, and I'm sorry I did not save some to see whether they would eventually disappear altogether. I have found the same stains on albumen prints from the same cause, and have no doubt others have done the same, and given, as I did, hypo the credit.

It is well known that water varies enormously in different districts, and this will account for the immunity of some fortunate workers from such pests as the yellow plague.

If these remarks should help any one to convalescence, my time will not have been wasted.—I am, yours, &c., J. Thos. Pentney,

6 *South-parade, Huddersfield.*

IRIDESCENT STAINS.

To the Editor.

Sir,—Referring to a complaint by M. Wilson in last week's Journal with respect to a "Marginal Irideacent Stain," a repetition of a complaint printed a few weeks ago, it may interest him and others of your readers to know that these stains, if not very deeply seated, may be removed by placing the negative, direct from the fixing bath, in a dish of water tinted straw colour, with perchloride of iron solution. This effects a slight reduction in density, which should be allowed for in developing.—I am, yours, &c., T. Stokoe,

Clare, Suffolk, November 1, 1893.

FILMS *VERSUS* PLATES.

To the Editor.

Sir,—Mr. Conybeare seems to have a very vague idea of what constitutes a test in respect to the comparison of films with plates, and when he says that his experience is so completely at variance with mine, that he gives it to prove that I am wrong, I am tempted to show him that his experience is a very trivial one, and not at all in variance with mine. He has not tried exposures of the thousandth of a second, and therefore can say nothing of the difference between plates and films at minimum exposures; he has used slow films which had not deteriorated after eighteen months, and I have just been using some of ——'s films which have been lying in my cupboard more than that time, being the most rapid which the maker of them sends out, and find them, if slower, still clear and as free from defects as when I got them, so that unless he has used the same films that I alluded to in my letter, which are much more rapid than those I allude to above, he proves nothing opposed to my statement. I say that Mr. X's films fogged two months after I got them from the agent. As he does not know who Mr. X is, he does not disprove me. He has evidently used Messrs. A, B, & Co.'s films instead—he tries exposures of more than the double of mine, and with amidol he finds it difficult to get fairly exposed negatives on anything—who advised him to use amidol? He has not found rapid films to deteriorate in two months; what test has he applied? Does he not see, without straining his mental vision, that he has not made an experiment with the precision which is necessary to give it any scientific value? It is a fact, I suppose, generally admitted, that very rapid gelatine emulsions lose their rapidity somewhat in proportion to their sensitiveness, while the slow ones deteriorate as slowly. To prove an exception to this rule, it would be necessary to compare such emulsions with some plate of known constant qualities of fresh manufacture, and to expose them with a mathematical precision, by a mechanical contrivance in a constant light, and to develop them with the same developer, and besides this, it is necessary to give a minimum exposure, because when a margin is allowed, it becomes impossible to calculate the extent to which that margin has been drawn on. Exposures made by guess and on different days, developed according to the exposure, and with developers which may differ materially from each other, have no value as indication whatever.

A correspondent of the Journal wrote, not long ago, to say that he had found plates that had been kept for some years to be more sensitive than when they were new, and the Editor asked the very sensible and, it seems, unanswerable question, how he knew it? It is quite impossible to compare an exposure on one day with one made on the succeeding day, sometimes one made on one hour of the day with one made on another hour of the same day. What is the use, then, of comparing what we got in July with what we got in October, or what was done in this year with what was done last? Any such tests are utterly unscientific, and, except as indications for general practice in a loose way, utterly worthless. If I want to test two films or plates, I choose a day without a cloud, and between the hours of ten and twelve. I expose them as quickly as possible, lay them side by side in the tray, and pour on the developer, and in the exposure I employ some shutter which operates mechanically, like the Bausch and Lomb, or the Thornton-Pickard, where the smallest fraction of a second is required, and where there is not even the uncertainty of an elastic band to lead to a doubt. Unless experiments are made in

this manner, they are absolutely worthless for exact comparisons, whether they be of developers or of plates and films. I am not so arrogant as to say that my experiments and methods are better than those of any other student, but my conclusions, drawn from a great many trials with different brands of plates and films, are that no films have yet been so coated as to give a sensitiveness equal to that which can be got with glass, and that the more sensitive the emulsions, the more rapid will be the deterioration, both in sensitiveness and in their tendency to fog. But a photographer who depends on amidol for rapid work can have only limited knowledge of what can be done.—I am, yours, &c.,

W. J. Stillman.

To the Editor.

Sir,—I have long had a lurking fancy that there is something in a celluloid film which tends to impair the sensitiveness of an emulsion spread upon it. Some years ago I was using Fry's ordinary plates for landscape work, and when on a tour I took a packet of films of that brand with me as well as the plates. The films proved to be hopelessly underexposed, while the plates were all right. More recently, a packet of Edwards' medium isochromatic films proved to be less than half the speed of the same brand of plates tested at the same time. In testing for speed a number of different brands of celluloid films, I have generally found them slower than I should have expected in comparison with similar plates.

All this, of course, is inconclusive, because the speed of different batches of emulsion varies from time to time, and I might have come across unusually slow batches on the celluloid.

Within the last few weeks, however, I obtained from the makers a box of Edwards' special rapid plates, batch No. 5306, and a packet of the same brand of films bearing the same batch number. On exposing plate and film side by side in the camera and developing together, the plates developed much more rapidly, and had the appearance of greater rapidity than the films, the latter giving a negative more brilliant in character, just as if some strong restrainer, such as citrate of soda, had been added to the developer.

On further tests I estimated the films to be only two-thirds the speed of the plates. Mr. V. C. Driffield also kindly tested the relative speeds of these same plates and films by the Hurter & Driffield method, and also found the plates to be faster than the films in the proportion of 1·88 to 1·00.

Of course, it is quite possible that some celluloid films do not exercise this influence over the emulsion, and I am not aware that celluloid films generally are inferior in quality to plates; it is merely a question of speed. Early films were not always even in coating, but I think this failing is now overcome.—I am, yours, &c.,

Alfred Watkins.

Hereford, November 3, 1893.

BRISTOL EXHIBITION.

To the Editor.

Sir,—Mr. H. P. Robinson's letter, published in the photographic press of last week, would have elicited no reply whatever from me, had it not contained such evident misrepresentations, such animus, and desire to damage this Exhibition, and such a display of discourtesy in publishing his letter without any intimation to me that he was about to do so. This action has rendered plain speaking imperative.

Firstly, Mr. Robinson says, "I cannot find a class to which I or those who think with me could contribute." If that be so, I am sorry; but it is evident very few "think with him," as is proved by the large number of entries already received from leading workers. If Mr. Robinson cared to send his exhibits, they would have been properly hung and fairly judged; he prefers not to do so; well, he must please himself; we shall simply have one exhibitor the less.

His next reference, that to the Photographic Society of Great Britain, is quite incomprehensible to me. The Photographic Society of Great Britain no more concerns my Council than would the Bristol and West of England Association influence the Exhibition rules of the former Society or any other society "of Great Britain."

I may here remark that our rules, which Mr. Robinson refers to as an "almost immediate reply" to the deliberations of the Photographic Society of Great Britain, are the same as were formulated thirteen years since for our first Exhibition, and which gave then, and have since given, universal satisfaction to all, save Mr. Robinson himself.

With regard to that gentleman's reference to the Photographic Society of Great Britain, it would interest us to know whether he is authorised by them to write so, as in that case we should be pleased to reply to his expressions at an early opportunity.

And let me say I write with no ill-feeling whatever towards the Society in question, but as Mr. Robinson throws it in our teeth, I am compelled to answer his reference thereto. As that gentleman kindly allows that we have a right to make our rules as we please, we ought, I am sure, to feel very grateful to him; but when he tries to play "Sir Oracle" in the last paragraph of his letter, and endeavours to coerce others, with such an evident and petty desire to injure this Exhibition, let me say he may spare himself the trouble, as *already, with a month to spare, we have such a large number of first-class entries that the complete success of the Exhibition is assured.*

Mr. Robinson appears to have overlooked the paragraphs in our schedule which have placed in the hands of the judges the power of withholding medals, and the awarding of extra medals at their discretion. We are the more surprised at this, as he has exhibited in Bristol previously, and has taken awards, and herein, apparently, lies the sore point. Let me explain. Mr. Robinson has probably not forgotten some unpleasant correspondence which originated with himself relative to one of his awards, and which, if published, might interest your readers, as throwing light on, and giving the reason for, his published letter of last week. Will Mr. Robinson oblige?

Finally we shall, in due course, publish the list of the Jury, who will in every respect command universal confidence, and who will—as have our Juries in the past—make their awards according to *merit*, and quite *irrespective of tradition*. We have every reliance on the great bulk of exhibitors fully approving our rules and supporting the Exhibition.

I regret, Sir, that Mr. Robinson's most unusual procedure should have caused me to occupy so much of your valuable space, for which many thanks.—I am, yours, &c.,

Frederick Bligh Bond,
Hon. Secretary Bristol International Photographic Exhibition.

THE BENEVOLENT.

To the Editor.

Sir,—Will you kindly, as in former years, direct the attention of your readers to the Benefit Night of the Photographers' Benevolent Association, which will be given at the Exhibition of the Photographic Society of Great Britain, 5*a*, Pall Mall East, on Friday, November 10? At the same time may I have a few lines of space for a very special appeal? We are just completing the twenty-first year of the Benevolent Association. The calls are more numerous and more urgent this year than they have ever been in the past. We have already granted relief to the extent of 134*l.*, and our income for the year to date has been 59*l.* It is an unfortunate feature of the Benevolent that it is supported by such a small number of subscribers. The income almost entirely comes from amateurs and the photo-material trade, and very little from those who really benefit by the Association. The committee is most anxious to increase the number of subscribers. The minimum subscription is only 2*s.* 6*d.* There are few photographers or assistants who cannot afford this, and we earnestly appeal to those who are not subscribers to become so. We are specially anxious to celebrate the twenty-first birthday by instituting run of greater usefulness than ever before.—I am, yours, &c.,

H. Snowden Ward, *Hon. Sec.*

Memorial Hall, Ludgate-circus, E.C., November 6, 1893.

OPERATOR'S SPECIMENS.

To the Editor.

Sir,—Allow me to protest against what I have found to be a common practice amongst professional photographers, viz., advertising for an operator, &c., without disclosing their identity, and failing to answer letters, or return specimens, which have been sent in the ordinary business good faith, which is usually warranted outside photography.

As this practice not only causes disappointment and loss to a great number of helpless assistants, but also tends to bring into disrepute the unsuspecting medium of these unbusinesslike and dishonourable men, I believe my protest is justifiable.

I know also that you, Sir, will not willingly allow a custom to exist for one moment longer than is necessary, when you find that it casts a shadow upon the respectability of the office of your highly valued paper.

I am glad to be able to admit that I have written to some (though sadly exceptional) photographers, who have not only replied, but that in a most courteous and kindly manner.—I am, yours, &c.,

A Turning Worm.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange a good imitation stone seat for rock-work seat or set of stones for studio.—Address, W. Hobbs, Gold-street Studio, Saffron Waldon.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

PHOTOGRAPHS REGISTERED:

James Leach, Carnarvon.—*Three portraits of Rev. John Hughes, D.D.*

John McLaren, Larbert, Stirlingshire.—*Portrait of Rev. John McLaren.*

Ralph Starr, Cambridge.—*Two groups of the Executive of the High Court of Foresters, 1893-4.*

THOMAS MOLLERSHEAD.—We will bear your suggestion in mind.

P. C.—1. Apply to the Platinotype Company, Southampton-row, W.C. 2. Citric acid and alum.

W. H. W.—You would be safe in taking the relative values as 1 : 1½; but it depends entirely on circumstances.

SUUM CUIQUE.—Sorry we cannot reopen the subject. It has already been referred to in our correspondence columns.

R. R. LIVINGSTON.—Thanks; we are much interested in the moonlight picture. What you term lightniug in it, however, is not such.

G. CLAVIGO.—1. You would have to employ a method of spectroscopic examination. 2. Mr. Ives referred to rapid printing in colours.

ENGLISHMAN.—It is probable that the indiarubber of the squeegee has perished—that is, lost its elasticity, in which case the remedy is renewal of the rubber.

HADLEY.—The most convenient solvent for amber, to make a photographic varnish, is chloroform. It is somewhat expensive, but the methylated kind answers as well as the other.

W. A. BROWN.—1. and 2. Probably the Welsbach light would suit. Apply to the Company, Palmer-street, Westminster. 3. Bromide enlarging is dealt with fully in our back volumes.

VERAX.—It is difficult to say the cause of the markings without knowing more about the manipulations. It rather appears, however, that they proceed from the prints leaving the glass at the edges before the other parts are dry.

SIZE.—We must confess we are not well versed in the practical details of making *papier-maché* goods. No doubt you will find them fully described in *Spon's Workshop Receipts*, or, at least, sufficiently for you to get a general insight of the work.

C. H. REED.—We are not aware where the graduated measures in enamelled ware referred to a short time back are to be had, but funnels, and cups, and the little ladles may be obtained, we imagine, at any of the shops that supply this kind of ware.

W. C. NORSE.—The studio, according to the sketch, is good. It might, however, be improved a little by making the ridge a foot or eighteen inches higher, continuing the glass to the top; but much will depend upon the aspect, which is not mentioned.

INQUIRER.—Several formulæ have from time to time been given both in the JOURNAL and in the ALMANAC. Those who supply the medium for sale do not publish how it is compounded; but, as a shilling bottle is sufficient for some hundreds of negatives, you will probably find it cheaper to purchase it than to make it yourself.

CONSTANT WORKER.—The difference in cost of building a temporary studio to resist a windy and rainy season and a permanent one will not be great. We should advise you to consult a horticultural builder in the neighbourhood. He would possibly construct you a suitable building, and take it off your hands at the end of the season, for a moderate price.

C. W. A.—White lac, when dissolved in spirit, *is* turbid; but, by standing for a time in a warm place, the undissolved portion subsides, when the clear solution can be decanted. We have, however, seen a white lac that dissolves perfectly, and gives a clear solution at once, but have failed to obtain any in this country. We are told this kind of lac is expensive.

NEWCASTLE.—Unless the copyright is registered, it will be of no use to institute proceedings. On comparing the engraving with the photograph, there can be little question as to the piracy of the picture. The figures being your own family would be convincing evidence if there were otherwise a doubt on the subject. But, as we have said before, the copyright not being registered, you cannot proceed.

T. LLOYD.—It is not necessary that the word "copyright" appears on the mount of the photograph. There is no means of knowing if the picture is copyright or not, except by searching the register at Stationers' Hall. As the firm who ask you to reproduce the picture is a substantial one, we advise you to get a guarantee from it to hold you harmless, in case the picture is copyright and proceedings are instituted.

E. GEORGE says: "In preparing the etching ground for the Klic process with bitumen, I find, after dusting the plate and heating it, that I do not get an even granular coating, but a uniform layer without grain, or with very little indeed, through which the perchloride of iron will not act. What is the reason?"—Apparently too much powder is on the plate, or that it is overheated. Or, possibly, the two things combined.

R. E.—The cause of the paper printing so unevenly and so faintly is that it is not properly sensitised, the bath was much too weak. On exposing the piece enclosed to the light, we had proof of that by the way it behaved. Although the solution was made forty-five grains to the ounce, it has become, as is usual, weaker by use. Judging by the paper, we should say the solution is not more than half its original strength, if so strong.

T. GROSSMEN.—I. Yes: a lens of *f*-16 can be used for instantaneous pictures at the seaside, but not at this time of the year, unless, indeed, the light is exceptionally good and very quick plates are employed. We are, of course, assuming that fully exposed negatives are a desideratum. 2. You will not improve upon the formula supplied by the makers, that is, according to our experience. 3. Don't trust to "saturated solutions," particularly at this season, but make up solutions of a definite strength.

H. INWOOD.—The north light is the one more generally selected for enlarging by when that aspect is available. The reason why it is preferred is that with it the sun gives no trouble, and the light from that quarter is more constant the day through than from any other. When, however, the solar camera is employed, a southern aspect is to be chosen. We cannot recommend you to adopt this instrument, for this reason, that, with it, sunshine is imperative, and that is a scarce commodity in the large towns of this country.

R. E. X. asks how he can copy a painting the whole-plate size; the largest lens he has is a half-plate rectilinear. He says he is told that, if he uses one of the lenses as a single lens (fifteen inches focus), the copy will be distorted, and wishes to know if that is correct.—Yes, it is quite correct; but, with a lens of that focus on a whole-plate, the distortion at the margin will be so slight that it may be totally disregarded in a subject like a painting. It would certainly not be detected when the print is trimmed.

F. WYLLIE.—The quarter-plate portrait lens cannot be made to cover eight inches. Much better buy another of not less than nine or ten inches focus. It is quite immaterial that your other lenses are for dry plates, for they will equally answer for wet-collodion plates. By removing the back cell with its lenses, and using the front lens only, with a small stop placed about the middle of the tube, it will cover a larger field than it can do in its combined form. But it will somewhat distort architectural subjects, although it will serve for ordinary landscapes.

A NEW SUBSCRIBER.—I. A copious outline of the different photo-mechanical processes is given in the ALMANAC for the current year. 2. Nelson's are the most uniform gelatines in the market that are suitable for the purpose. The "No. 1 sheet" will answer well. 3. Use a five per cent. solution of bichromate of potash, and keep this as a stock solution. Foreign writers are very fond of giving "saturated solutions," in their formulæ, and they often lead to trouble with a change of temperature. 4. We have no competitions, periodical or otherwise.

S. E. W. writes as follows: "What do artists apply to photographs to cause them to take the colour easily? I get on very well with albumenised paper and gelatine prints, but my trouble is with carbon. Directly the surface is touched with water colour it is repelled as if it had been greased. I am told this is only the case with prints that are done by double transfer. Can you tell me of anything to apply?"—The repellent nature is due to the waxy material applied to the temporary support upon which the prints are developed. It is easily cleaned off by treating the print with a little benzole.

No. 1750. Vol. XL.—NOVEMBER 17, 1893.

CONSECUTIVE AUTOMATIC EXPOSURES.

To Mr. Ead. Muybridge, so far as we can ascertain, must be accorded the position of having been the originator of the valuable system of producing, by photography, pictures in a series of extremely rapid successive exposures, by which it has been rendered possible to analyse such motions as those of the limbs and feet of horses and other animals in rapid movement.

Previous to the advent of Muybridge, the true actions of these were very imperfectly understood, if understood at all, owing to the impossibility of the eye being able to note the various positions consecutively assumed. The first of these attempts resulted in mere silhouettes, being all that were capable of being produced at the time, owing to the incapability of the wet-collodion process to record the detail of objects taken with the inconceivably brief exposure required for the purpose in hand. This was subsequently remedied on the introduction of the more sensitive gelatine plates.

The original camera, with its battery of lenses, was rather a formidable and costly affair, and was manipulated by electricity, and, unless we greatly mistake, it is protected by patents, the infringement of which we should be very sorry to encourage.

A few years ago, when in the establishment of M. Vanneck, of Antwerp, we saw a portion of a rapid shutter in an unfinished state, which gave us an idea for the construction of a camera to carry twelve or any desired number of lenses. The principle of the action is such, that when the button of the first lens has been pressed, and an exposure made, the mere act of the completing of the exposure causes the uncapping of lens No. 2, which in its turn, on its completing its exposure, acts in like manner as the first one the part of a starter for the one next to it, and so on till the last of the series has been exposed. The time required for the exposure of the twelve lenses need not, if the mechanism be well constructed, exceed one second, but the duration of the consecutive exposures can be extended to two, three, or more seconds, this depending on the nature of the subject.

The camera must be sufficiently wide to be capable of receiving the number of quarter-plates for which there are lenses, and it must be partitioned so as to separate one lens and plate from its fellows, in a manner similar to what is adopted in a stereoscopic camera. In brief, if one can imagine, *more Hibernico*, a binocular camera fitted with six, nine, or twelve lenses, he has got an accurate idea of what we mean.

A suitable class of lens for the purpose is that known as a Sixth Size Portrait Combination, which is the size immediately below that of a quarter-plate. It is one of the Petzval form, and works with a degree of rapidity considerably exceeding that of the average rapid rectilinear class. The hoods should be unscrewed and laid away, and the front ends of the lenses inserted in, or, at any rate, placed close up against, circular apertures cut in a board which extends the whole width of the camera. Each aperture must be covered by a vertical sliding drop shutter, and, by explaining the construction and action of the first and second ones, we do so of all, for all are alike.

The second of the series is kept in position by a paul or lever, the upper end of which falls into a notch, or other similar resist at the side. The lower end of this lever, that at the other side of the fulcrum, has its tail projecting, so as to be touched and acted upon by a projection on the side of the first drop shutter. Here is how it acts.

Premising that each of the series of shutters has a strong downward tendency, owing to the tension of a rubber band, the camera is directed to a point a little in advance of that in which the trotting horse, the flying bird, or other object in motion will presently be found, and, at a fitting moment, the first shutter is released by any of the mechanical devices now so well known. No sooner has the aperture in it passed the lens opening than, in its fall, it liberates the second shutter, which does the same for the third, and so on in automatic succession till the last has been exposed. The duration of the total exposure may be regulated by increasing or diminishing the tension of the rubber bands, several very weak ones answering much better than one of greater strength.

In the first camera of this kind we had constructed the shutters were kept in position by a steel rod passing horizontally through a metallic loop placed in each shutter. As this was being steadily withdrawn, one exposure followed the other with a rapidity determined by that of the withdrawal of the rod. This forms the easiest way to effect successive exposures but it cannot be said to be automatic in its action.

Of course, this successive principle is applicable to cameras with less than a dozen lenses; nay, for certain purposes, it may be applied to an ordinary twin lens or binocular camera.

PAPER IN PHOTOGRAPHY.

Some of the earliest photographic results were produced on paper, and at the present day nothing else is used for the vast majority of photographs; yet there is, perhaps, scarcely one material in the whole range of photographic technics which has received less attention than the subject of our article. Possibly the reason may be that it is the one substance least under the worker's control; as regards its essential qualities, selection must be exercised in choosing it, but there the matter ends. It cannot be said of paper that it must be "ended or mended." We cannot do without it, and we must

take it as we find it. It is a little unfortunate that such should be the case, for the result is, practically, that for the paper employed in the production of chemical prints we are compelled to go to one district on the Continent—almost to one single maker. If it were that such singleness of purpose in paper-buying were owing to general excellence and superiority of quality, there would be no cause to complain. If a man make an article so excellent in quality that all the world are his customers, he deserves the trade; but the probability is that the superiority of the paper for the purposes in question is owing to its possession of certain mechanical properties which no other paper manufactured has, so far, been able to rival—this combined with general good quality also. The amount of paper now required for various kinds of photography is a hundred-fold the requirements of a score of years ago; it seems most singular that a reliable quality at a reasonable price should not be produced in this country. Cannot our paper-makers be roused? We hope that something we write may be the means of inducing them to experiment to a greater extent than they yet have done, and see if a process essentially British in its modern developments cannot be carried on with British materials. Paper of almost every quality is made in this country. Granted a paper of the right substance and freedom from metallic impurities, surely a series of experiments with sizings of various kinds might be made, the results put into competent hands to report upon, and eventually a paper equal, if not superior, to what we purchase out of the country be manufactured at home.

Paper is essentially fibrous cellulose obtained from various sources, purified, made into a species of felt, and ultimately hardened by impregnating with various glutinous materials, technically called sizes. The easiest mode of seeing the manufacture is, perhaps, to go through a small paper factory, where hand-made paper is produced. We have comparatively recently been in such a mill where none but hand-made paper is produced. We saw the rags cleaned and introduced in the usual apparatus for disintegrating them into a fibrous cream. This, transferred to a tank and kept constantly stirred, is made into paper by the simple introduction, slightly below the surface, of a sort of woven wire framework, which is withdrawn, holding on its surface the wet pulp; the water drains away, a sheet of wet paper is left, it is placed to dry, and there we have a piece of pure white paper. Not a particle of bleaching material was used, consequently no "antichlor," as hypo is called in that trade, was needed to get rid of the chlorine, with its destructive action. The paper thus produced, however, was practically neither more nor less than "blotting-paper." If it were made wet, it could scarcely be lifted up without tearing; it was useless for any other purpose. It is after this stage where the essential property which gives the superiority to paper from Rives comes in—the material used, and the manner of using is as "size."

For photographic purposes it is essential that paper should really be pure—as nearly as possible pure cellulose and size. One of the causes of the difficulty in rivalling the paper we speak of consists in the fact that, in the race for cheapness, so many materials are added, either to give weight or fictitious appearance of quality, that a pure paper is rather an exceptional article. Much of the highly glazed printing paper we see owes its gloss to the introduction of earthy materials—kaolin, for example, and many other bodies being employed.

To obtain pure and white paper, either linen rags of first-rate quality must be used, or inferior coloured rags bleached with chloride of lime; as this latter involves, as we have just said, the use of thio sulphate of soda to get rid of the free chlorine or chlorous acids, we are at once face to face with another scarcely less insidious evil. It would be highly instructive if one of our Societies were to take this matter in hand, examine samples of paper used for various purposes in photography, and report as to how many were contaminated with sulphur salts in such manner as to render their use for such purposes injurious. Of course, we know that hypo exposed to the air gradually becomes converted to sulphate; but, even for this, some amount of moisture and some access of air is needed to facilitate the action. If the material be imprisoned in the texture of a mount, packed away in large heaps, little air will gain entry, and the actual result of the decomposition there is doubtful, and certainly not likely to be free from danger to photographs pasted upon them.

These, however, are not the only evils to be guarded against. Another potent factor in the degradation of the purity of a photographic print may be the use of wood-pulp in the paper. Many samples of paper so made will turn brown, through, probably, the decomposition of the resinous accompaniment of the fibre not sufficiently removed in the preliminary treatment. It will be useful to collect a few methods for readily examining a paper to be used for photographic purposes; but, as to do so would unduly extend the length of our remarks, we propose to do this in a subsequent article.

THE RELATIVE PERMANENCY OF PRINTS.

It is customary to regard the carbon process and similar methods of printing as giving absolutely permanent results, while the various systems based upon the employment of silver salts, but particularly in conjunction with albumen, are as commonly set down as more or less liable to fade or change. But a brief examination of a collection of old prints will often discover anomalies in connexion with the usually accepted ideas as to permanency, and raise questions as to whether some processes are so far above suspicion and others so little to be trusted as is usually supposed.

In turning over such a collection a short time back, our attention was arrested by the remark, "How evenly these prints have faded." The prints in question had the appearance of having been made upon highly surfaced or double albumenised paper and were mostly of a warm brown tone, but the whites and half-tones exhibited a palpable and uniform yellowness which told an evident tale of sulphuration. Our friend was not a little astonished, and somewhat incredulous, when we assured him that the pictures were in reality photo-mechanical prints, being, in fact, specimens of collotype printing of a high quality, produced some twelve or fourteen years ago in America, and sent to us at that time in illustration of what could be accomplished in that style of printing.

Since they came into our possession they have been constantly kept in the portfolio in which they now lie, and may therefore be fairly said to have been well protected from the usual vicissitudes to which photographs are subjected. The change which has taken place, so far as we are able to judge at the present time, is solely confined to the yellowing of the lights, the image itself being apparently perfect, and, it is scarcely needful to say, can scarcely be attributed to similar causes to those that produce a like effect in albumen prints. In fact, but for one circumstance, we should have had no

hesitation in setting it down to simple discolouration of the paper.

That this is not the cause, however, may, we think, be assumed from the fact, that amongst the prints are some possessing a matt surface, or at least are free from the high glaze presented by the majority, which is, of course, produced by means of a varnish applied subsequent to printing. In every case the matt prints are quite free from the discolouration shown by the others, and there can be little doubt therefore that it is to the varnish or glaze that the fault is really attributable.

The discovery of these altered collotypes caused us to make a careful examination of the rest of the contents of the portfolio, some of which are at least thirty years old, and the results were of a decidedly interesting character. For instance, amongst the pictures were a number of carbon prints by various artists and of different periods, some dating back almost as far as the publication of Swan's specification in 1864. One such print, produced as far as we can tell about 1865, presents very much the same appearance as the collotype already referred to, though the discolouration is more marked; but, in addition to that, the image itself has acquired a disagreeable greenish tone, more especially noticeable in the half-tints, and undoubtedly due to the presence of chromium compounds left in the print.

Other carbon prints of a much later date—from twelve to fifteen years old—while still remaining perfect in gradation, as well as pure in the lights, present an unpleasantly cold black tone that was certainly not their original colour; whilst others, of at least the same age, still possess the warmth and freshness of tone that we can imagine to have been theirs originally. This is particularly noticeable in a couple of small prints received from abroad a dozen years back, the rich, warm brown tones being apparently as fresh as if produced yesterday.

Platinotypes are usually regarded as representing the acme of permanence, and such, no doubt, so far as the image itself is concerned, is the truth. But amongst our collection are several prints representing some of the very earliest productions in that process, and dating probably as far back as 1878. The images present, no doubt, exactly the same appearance as when the prints were newly made, but in all cases, or nearly all, the whites are very seriously degraded; but whether from the effects of chemicals left in the prints, from natural discolouration of the paper, or from simple dirt, it is impossible to decide at a glance. The last is more than a probable cause, as from the character of the surface of the prints they are more likely to suffer from the combined effects of dust and friction than would be the case with either albumen, carbon, or other surfaced prints.

Several very early speciments of developed gelatino-bromide prints exhibit, without exception, decided signs of yellowness—in some cases of a very pronounced character—while others of a later date are entirely free from any discolouration. The change in the earlier prints can readily be traced to the want of sufficient care in the removal of the last traces of the ferrous-oxalate developer, then invariably used; while the absence of colouration in the later ones may be due partly to greater care and the use of clearing solutions, and partly, no doubt, to the employment of other developers not so liable to cause the yellow stain. In no instance is there any sign of deterioration of the image itself, or of loss of the finer details by fading or sulphuration.

The same remark applies to the earliest samples we possess of gelatino-chloride prints, although necessarily these do not date as far back as the others mentioned. Many of these are upwards of seven or eight years old, and, except for the wear and tear of handling, show no signs of deterioration. The oldest print by this process is one which the endorsement on the back tells us was sent to us in an untoned condition, as an example of what could be done with gelatino-chloride emulsion. This was, we believe, in 1883 or 1884, long before gelatino-chloride paper was an established article of commerce, and the print was toned by ourselves and put away as a curiosity.

Amongst the other curiosities is one worthy of mention, in the shape of a collodio-chloride, or highly enamelled gelatino-chloride, print—we are not sure which—that was sent to us by Dr. Liesegang, some eight or nine years ago, to illustrate the fixing power of common salt. The print, after toning in the usual way, was fixed in a saturated solution of common salt, and at the present day is as fresh and bright as when received. In this case, if any change had occurred, we should naturally not expect it to take the form of sulphuration, but rather of general discolouration from the presence of silver salts remaining from imperfect fixation; but there is not the slightest symptom of any such change.

Lastly, strange as it may appear, some of the best preserved of the old pictures in this collection are upon the much-maligned albumenised paper. A print of Mr. Francis Bedford's well-known *Brook at Kenilworth*, that must be nearly, if not quite, thirty years old, is only slightly yellowed, and that is more from dirt and age than from actual fading. Another print, of almost the same age, by Mudd, of Manchester, is absolutely as fresh and bright as if printed yesterday, and many others are nearly as well preserved. It is worthy of note, in connexion with albumen prints, that those upon rough or Saxe paper appear to have kept the best, probably from some difference in the sizing.

A plain paper print, of the details of the production of which we have no particulars, though it is over thirty years old, is apparently as good as when newly made, proving again that silver prints are not necessarily evanescent.

In conclusion, we may remark that, in estimating the probable permanency of any process, it seems that at least as much attention should be paid to the care devoted to the manipulations and to other usually neglected details as to the actual constitution of the image itself.

Judgment versus Exposure Tables.—Amongst the replies given to a series of questions at one of the provincial societies was this: "No exposure tables or meters at present in use will entirely supersede judgment and experience." With this every practical photographer will agree. Exposure tables may be of some service to a novice in his first attempts, but the sooner he learns to discard them the better it will be for his future convenience, and often his work. It sometimes happens, as in early spring, for example, when fleeting clouds are rapidly passing, that, by the time the calculations are completed as to the exposure to be given, the character of the light has completely changed, and a picture becomes lost, though a negative may be obtained. "Rule of thumb" is no more to be relied upon in exposures than it is in any other photographic operation. Therefore the beginner should, from the commencement, learn to judge of the exposure required from the appearance of the image on the focussing screen, and the character of the light at the time.

Bursting of a Gas Cylinder.—A lamentable and fatal accident, which may tend to shake the confidence of the nervous, happened one evening last week at Bradford by the bursting of a gas

cylinder. It appears that a boy, in the employ of a local firm of chemists, was carrying a couple of cylinders of compressed gas to be used for lantern purposes in the neighbourhood, when, according to report, he dropped one, and it burst. The greater part of the lad's chest, head, and arms were blown away. Fortunately, although a considerable number of people were near at the time, no one else was injured. In some experiments a year or more back, to test the safety of charged cylinders, one was thrown from a considerable height on to a hard surface without suffering any injury. But here is the case of a fall which could not exceed a foot or two producing disastrons results. Only a short time ago we were at a provincial railway station when some twenty or more cylinders of extra size, accompanying the paraphernalia of a theatrical company, were being transferred from one train to another, and the concussion each received as it was thrown by the "careful" railway porter on to the pile must have been much greater than by the cylinder when it was dropped by the lad who was killed.

Artificial Light for Contact Printing.—In several demonstrations of lantern-slide making by artificial light, the question has been raised as to the best light to employ for contact printing. Some advocate magnesium ribbon, some a gas flame, and others, and not a few, a paraffin lamp. So far as result is concerned, it matters not which is used, it is simply a matter of convenience. The principal thing is to have the light always, as nearly as possible, under uniform conditions. This is not always obtainable with magnesium, even when it is carefully weighed or measured, as the metal is liable to oxidation, which diminishes the light; also, it is not easy to burn it always at exactly the same distance from the negative. Gas has been objected to on the ground of the constantly varying pressure on the mains at different times of the day and evening. This may, however, be obviated by the use of a governor burner. Then, with the cock full on, the flame will remain the same, however the pressure of gas may vary. The form we have used for some time past is what is known as the "Christiana burner," and it answers perfectly. Paraffin is excellent, provided the oil used is always the same and the flame adjusted to the same height. This is not easy to accomplish with the ordinary flat wicks, but with the circular ones a uniform height and light is more easily obtained, as the length of the flame is readily measured. We recently saw an excellent paraffin lamp for the purpose. It had a flat wick and a circular burner, the wick being pressed into the cylindrical form in its passage through the tube. The burner was stamped as being made in Vienna, but similar ones are, doubtless, made here.

Another Fatal Accident from Ether.—A brief telegram from Berlin announces that a terrible accident has occurred in the Russian province of Grodno. Owing to carelessness, it is stated, of an *employé* at a chemist's, an explosion of ether took place, and the entire building was blown in the air, while the houses in the vicinity were seriously damaged, twenty persons were killed, and many others were seriously injured. The above, even if the account may be somewhat overdrawn (and it is to be hoped it is) should serve to emphasise the warnings we have so frequently given, when previous fatalities have happened in this country, to those unfamiliar with the properties of this material. Ether is frequently dealt with by artificial light, and it is then that it becomes dangerous. Its vapour is inflammable like coal gas, and when it is mixed with a certain proportion of atmospheric air it becomes as explosive as does gas under similar conditions. Not long ago we saw an ether saturator being refilled by the light of a paraffin lamp under most dangerous conditions, inasmuch as the lamp was placed below the level at which the vessel was filled, and this was done for imaginary safety. Because ether is one of the lightest of liquids, it was assumed that its vapour was proportionally so, whereas it is very much heavier than the atmosphere. The vapour of ether can be poured from one vessel to another in the same manner as the liquid itself. Therefore, in decanting ether in the vicinity of an open flame, it should always be done at a lower level than that of the light, and the precaution should be taken that there is no draught that would waft the vapour towards it.

Offensive Smelling Oil Lanterns and Heating Stoves.—*Apropos* of the coming season we have received three or four queries relating to the above subject. One correspondent, in addition to the smell, complains of the excessive heat given off from the lantern while in use. All the writers, curiously enough, ask if nothing can be added to the oil to prevent the obnoxious fumes. As the subject is just now of interest to more than the querists, we reply here instead of in the "Answers" column. In the first, we may say that various substances have from time to time been suggested as an addition to mineral oils to prevent their smelling when burnt; but, so far as our experience goes, they have very little, if any, effect in practice, whether used in connexion with the lantern lamp or the heating stove. We use both, and are not troubled with smells because we always keep them scrupulously clean, and the wicks in good order. When a well-constructed lamp or stove gives off offensive smells, it may be safely assumed that the smell is caused by vapourisation of oil on the outside of the burner and fittings, or, perhaps, from an ill adjustment of the wicks. Many lanterns and stoves have been standing out of use since last season with oil in them, which, by capillary attraction, has become distributed all over the fittings, and no amount of wiping will completely remove it. Consequently, when it becomes heated, it is volatilised, and hence unpleasant experiences. In nine cases out of ten, when a paraffin lamp or stove proves offensive, it is not from the oil consumed, but from that which is allowed to exist on the outside of the lamp and the burner. With regard to the excessive heat evolved by the lantern, much of that can often be avoided by proper attention to the burners. The wicks are frequently turned unnecessarily high, and, as a result, although no more effective light is obtained, the heat is materially increased. Lamps and stoves are frequently condemned when the fault really rests with those who work them.

THE ILLUSTRATED PAPERS AND COPYRIGHT PHOTOGRAPHS.

The following circular has been sent to a few London and country photographers, and we have reproduced it for the benefit of the profession at large, who, we hope, will not be slow in profiting by the example set. In a matter of this kind, affecting the interests of so many photographers, we should have thought the guiding spirits of the movement would not have hesitated to give the whole of their brethren an opportunity of participating in it:—

"A Meeting of Photographers held at the Hotel Victoria, Northumberland Avenue.

"*November* 1, 1893.

"At a meeting held at the Hotel Victoria, on July 19, 1893, it was resolved that a fee should be charged for all *copyright* photographs reproduced in any illustrated paper or periodical, and that the minimum charge should be one guinea; also that the name and address of the photographer should be legibly printed under each impression. The above has been given a three months' trial, and a second meeting was held on October 19, 1893, when it was unanimously agreed to continue the original resolution. And it was then further resolved that this brief statement should be sent to our leading provincial brethren, asking for expression of opinion on this or any other subject of interest to the profession.—I am, yours faithfully,

"C. M. Schomberg, *Hon. Secretary.*

"55, *Baker-street, London, W.*

"N.B.—A copyright photograph is one taken at the artist's expense, without any charge being made or fee received for the sitting, whether registered or not.

"The following is a list of the firms agreeing to the foregoing resolution:—Mr. Bassano; Mr. Frank Bishop, of Marion & Co.; Mr. Byrne, of Byrne & Co.; Mr. Cameron, of Cameron & Smith; Mr. Wm. Downey and Mr. Wm. Downey, jun., of Messrs. W. & D. Downey; Mr. Elliott, of Elliott & Fry; Mr. Alfred Ellis; Mr. Fox, of Maull & Fox; Mr. Grove, of Window & Grove; Miss Alice Hughes; M. Lafayette, of Dublin; Mr. Bedford Lemère; Mr. Mendelssohn; Mr. Taylor, of Barraud, Limited; Mr. Thompson, of Grosvenor-street; M. Walery, of Walery & Co., Limited; M. Van der Weyde; and Mr. Young, of Fradelle & Young."

JOTTINGS.

A MONTH ago I voiced a rumour concerning a projected new photographic paper. The only hints that I gave as to the quarter of the sky from which it would burst upon us were (1) that it would take art photography under its wing, and that (2) its promoters had been cultivating the gentle art of advertisement. The editor of your amateur contemporary thereupon delivers himself of sundry remarks about "another weekly photographic paper," "English energy," and "recently imported American gold," to neither of which did I make direct or indirect reference; and then, having told an awestricken world that he is "somewhat more behind the scenes than others," says that the report is "merely a canard," and that "the American eagle will not flutter either weakly or weekly." Well and good. But what a pity it is that some people are so ready to trumpet forth their highly privileged presence "behind the scenes" at the expense of their reputation for common sense. I never said anything about a weekly paper, and never for a moment supposed (or said) that English energy and American gold would be the moving spirits of the rumoured venture. The reckless precipitation with which the proverbial bull is said to attack a five-barred gate is nothing to the lightning speed with which some people jump at conclusions of an erroneous nature.

Mr. James William Fawcett, of St. Kilda, near Melbourne, Colony of Victoria, the specification of whose patent for "improved means for regulating the rays of light passing through photographic lenses" is published in the JOURNAL of October 13, is evidently a simple-minded gentleman who started photography about the first of April, 1892. He not only "patents" the inverted V-shaped stop for giving more exposure to the foreground than to the sky, but "partly to impart a stereoscopic effect to the photograph." He says the latter effect is obtained by sliding a shutter with a V-shaped aperture horizontally across the lens, when "a stereoscopic effect is given to the finished photograph by reason of the light being allowed to enter first at one bottom corner, then gradually being allowed to pass through the whole of the lens aperture, and finally through a small opening at the opposite bottom corner, thus, as it were, to a certain extent photographing the object from two different points of view, and so producing the desired effect." Holy Moses! what next? "To a certain extent, photographing the object from two different points of view" with a fixed lens is very funny, but it is a crying shame that the Patent Office should batten and fatten year after year on such ignorance as this.

The London and Provincial Photographic Association has had the question of the admission of ladies as members before it, and has, it seems from your report, decided not to admit them as ordinary members. What a pity it is that your reporter restricted himself to a mere outline of this part of the proceedings. I feel sure that a great deal must have been said *pro* and *con*, and, looking at the nature of the subject, no doubt some wise, foolish, and amusing things were uttered before the vote was taken. I do not envy Mr. Thomas Bedding, who moved the amendment excluding ladies from the "L. and P.," the disagreeable reputation that must attach to him for the part he took in the business, though, in the absence of his arguments, it is impossible to condemn him and his majority so freely as one would like. In these days of enlightenment and progress the opposition to the admission of ladies to learned and similar societies smacks of mediæval tyranny and narrow-mindedness. The sex that gave us Mary Somerville, George Eliot, Harriett Martineau, Angelica Kauffman, Florence Nightingale, Caroline Fry, and Phillippa Fawcett has surely won its right to share in all the intellectual advantages of men; and I hope it will not be long before the London and Provincial succeeds in obliterating the stigmata of boorishness which the selfish action of the gentleman named and his friends has cast upon it.

In passing, I noted among the Society intelligence during the last month the remark of a lecturer as to the "objectionable yellowness of many old gelatine negatives rendering them unfit for printing." Such negatives must have been very yellow indeed. Every photographer knows that harshness and shortness of scale of contrast are reduced by the presence of a certain amount of discolouration in some negatives, and therefore what is in essence a defect becomes in practice an advantage. Of late years there has been a dead set made against the presence of any developer stain in the negative, not always, I fancy, to the advantage of the latter. To systematically clear all negatives is, I believe, a mistake, for in some instances one may be taking away just the property which gives the *cliché* its proper wished-for printing value. Moral for my amateur readers: Don't "clear" your negatives until you have taken a trial print from them.

Yet, again, the old complaint about the detention of specimens. "A Turning Worm" in your last issue protests against photographers advertising for assistants not disclosing their identity, failing to answer letters, and not returning specimens. The last item is the only head under which complaint can be legitimately made. Why will not "A Turning Worm" and those of his kind adopt the plan of writing their names and addresses across their specimens, so often recommended in these pages? If this did not ensure the return of the specimens, it would prevent their misuse by unscrupulous advertisers, which would be something gained, at any rate.

Dearly beloved brethren, for many years past you and I have been using the alkaline sulphides for toning (or intensifying) silver images; but we may do so no longer, for Mr. R. G. Williams, of Greenfield House, Heywood, Manchester, has made the astonishing discovery that "the expensive salts of gold, platinum, and like metals" may be replaced in toning by "potassium, sodium, or ammonium sulphide," the use of which he has patented for toning gelatino-chloride prints! (see *ante*, page 675). The makers of gelatino-chloride papers will be glad to know that "prints toned by my improved process are very permanent." Mr. Williams, I wish you joy in your "invention," and would like to know your price for the patent rights?

"Log-rolling" is one of the most prominent and disagreeable features of modern literature. Lest my readers should not know what it means, I will explain. In brief, it is the habit known as "You scratch my back and I'll scratch yours." Journalists and authors, who may be reviewers and critics, praise, puff, and paragraph their friends' productions, and, in turn, secure for their own work like recognition. I regret to find that this kind of thing is creeping into photography, particularly in connexion with the public exhibition of pictures. Most of the principal exhibitors also happen to be Judges and pressmen. In the latter respect, the amount of log-rolling that has recently gone on is simply sickening. In some instances critics have not hesitated to praise their own work. The game of mutual admiration, as played by a small coterie of "art photographers," ought to be exposed. Some pretty little revelations in the way of exchange puffs for pecuniary ends would, I believe, come out.

COSMOS.

THE POSITION OF PROFESSIONAL PHOTOGRAPHY.

[President's Address to the National Association of Professional Photographers.]

Now that the time has come for me to address you on the subject of professional photography and the aims of our Association, I feel a degree of diffidence for several reasons. First, there is an amount of assumption, which, in my position and capacity, I ought not to take upon myself; but, feeling that something requires to be done, I volunteer to make the attempt, and if I accomplish the object we all have in view—objects far-reaching in their nature, and affecting the best interests of us all—I shall feel satisfied I have not spoken in vain. It is patent to every one that photography, as a profession, is not what it once was; but it is not alone in this, so many causes are contributory to the prevailing universal depression. New studios, in localities already congested, are being opened, the supply far exceeding the demand. In addition to this, there are many influences at work

tending to reduce our chances of success; some of them may be removed or lessened, and others we have it in our power to modify.

How Business Suffers.

Now, we all know, in large establishments especially, that enlargements with a photographic base, also oil paintings, crayon and pastel portraits, and other styles painted direct, are the backbone of a photographer's business, and I ask, that being so, why have we allowed these, especially the former, to pass into the hands of others? Some few of us, I admit, have from early days made our own carbon and bromide enlargements, and, if photographers had been united in purpose, we might have retained this industry, and still be obtaining remunerative prices. Unfortunately, the trade generally rushed off to the factory, and helped to build up colossal concerns, and held them together till the advent of the amateur; and now where are we? I will tell you. I some time ago photographed a child since deceased. I carefully named and numbered the negative and stored it (the negative, not the child) in a room specially arranged for the purpose, hoping it might be required for future orders. The parent, in good circumstances, applied to me for prices of enlargements; and, knowing that he was associated with an amateur who obtained all he required from the factory, I quoted low terms for a 24 × 18 bromide and three duplicates, with the result that he ordered a plain, unmounted copy of the picture for copying purposes, and a well-known firm agreed to give him a finished portrait, 24 × 18, for 19*s.* 6*d.*, and duplicates for 10*s.* 6*d.* each, a price a trifle beyond the charge to the trade, and less than I could have produced them for. I know for a fact that the person was prepared to pay considerably more had he been asked.

I give another case to show the facilities the public have for getting their work done at trade prices. The amateur goes to headquarters himself, and puts his non-photographic friends in the way of doing the same. He carries about with him the dealers' trade list, which he must have had given to him, and the poor professional is checkmated at every turn. Here is an experience of my own. I made for a client several 24 × 18 carbon pictures from landscape negatives, charging not a great excess over factory prices. The account was sent in, and my customer promptly produced his trade list, pointing out the variation in prices, with the usual result—he paid his account, and I saw him no more.

Amateur Capitalists.

There is one phase in connexion with our profession I think is dying out. You will have observed what a many outsiders possess themselves of the idea that to open a studio in a good district is like striking a gold mine—a perfect Eldorado—and capitalists have shown themselves eager to ally themselves with an operating photographer, and to back the idea by investing their capital in a swell concern. They begin with a flourish; then, having exhausted their sitters, who are generally their immediate friends, the struggle begins. Reducing prices, touting (which may be legitimate in a sense, but I consider very demoralising), and finally a dissolution of partnership, with the usual *finale*—I hold all this has a tendency to degrade.

These amateur capitalists, before they get the experience of business, simply calculate the cost of the plate and the piece of paper, ignoring rates, taxes, wages, &c., and seldom place any value on the hard-earned experience of the photographer.

An incident occurs to me of a lady whose collie dog I had recently photographed, and supplied five proofs. (I believe I have the reputation of knowing something of dogs). She called to give her order, and I heard an altercation with my attendant as to the excessive charge of 31*s.* 6*d.* for six cabinets; and, putting in an appearance I politely asked her if she knew what she was paying for:—"I suppose for six cabinets." 'Oh, no!—if that was so, you would be justified —you are paying for nearly forty years' experience; or, as Whistler puts it, 'the experience of a lifetime.'" And thus the photographer goes on, each day bringing its cares and annoyances, constantly assuming different forms.

One more experience. A lady brings in her carriage a well-executed and framed carbon enlargement, and requests to have a companion picture from the negative of a child I had recently taken, and she quoted the price she had paid—viz., four guineas. I reply at once it cannot be done for the money, and politely tell her it would be better to go to the same man again. Sad to say, and thanks to her and others similar, she replies, "The man is DEAD." And having killed him—perhaps not her first victim—she tries her wiles on myself. Fortunately I was equal to the occasion, and I got my price without losing my self-respect.

More Unity Wanted.

These experiences, I am happy to say, are rare with me, but I give them, because I am afraid the photographer too often forgets himself by charging profit only on the bare material he uses, and placing insufficient value on himself; and how often does he do even worse than this, in the form of giving a bribe and emulating the shopkeeper who gives his customer a teapot with a pound of tea! I admit rates, taxes, and wages must be paid, and in depressing times it is a fearful temptation to resort to practices which become played out and are ruinous in their consequences. But, better far improve the quality of your work; but if we became united in membership, and the more experienced in artistic excellence would give help to those around them by showing examples and methods in the club-room, and by one man exhibiting, &c., I hold that, if the artistic element and a higher standard of work in the profession was raised, photographers would be more valued and able to more than hold their own against the trading amateur (some of them do trade by a side wind, notwithstanding all that has been written). I feel assured the status of photography would be higher, we should become more respected as a body and be better paid for our work. The amateur question has long been a vexed one. Are there not amateurs and amateurs? I have fortunately and generally met with the genuine ones, and turned them to good account, and found them genial and generous.

As to competitive exhibitions, I have had little experience, but on one occasion I was asked by the respected President of the Parent Society to exhibit my dog pictures—and, mark you, they were not the result of snap-shots and hap-hazard exposures. I had visited the dog shows, and consulted the Judges, scrutinising their judgment, so as to secure the best points in my pictures. I thought I had succeeded, and, as far as the opinion of dog-fanciers and the owners went, I was satisfied; but not so the Judges, they passed them over in their class for some sharply, small-focussed snap-shot cabinet pictures of circus animals—elephants standing on their heads, spotted hares on their hind legs, and you know the rest—a frame of photographs, to my mind no doubt mechanically good, but unworthy of such an exhibition as the Parent Society. However, the series were awarded a medal. We have seen pictures medalled over and over again so worked on that it was impossible to tell where the photography ended and the stippling began. I consider exhibitions are a powerful incentive and a great help to the photographer; he sees there something to emulate and possibly much to avoid. The "Proud Turk" may not rouse his ambition, but there are always specimens which he can study and learn from.

I have given you some of the obstacles we have to contend against, to prove that, if we as a profession would unite and at regular intervals record our experience, and for the benefit of our brethren in remote places have a trade journal confined purely to professional photographers (there is an existing journal which we could utilise, and arrangements could be made to have a supplement to ourselves), and by reducing the subscription to the National Association of Professional Photographers to 5*s.* per year, so as to secure the united help of every photographer in the country, infinite good would ensue. Let it be observed that merely subscribing is not all the assistance required, the Association needs what it has not hitherto had, viz., the sympathy and advice of the many who are well able to give it. I put the question, Why cannot photographers do for themselves what every other trade and profession have done, viz., protect their own interests from injustices which are constantly cropping up? The desultory mode of fighting which some have adopted by firing off in the journals—though the motive may be good, is not dignified; better far contribute to our Association and, by your presence at our Councils, make the Association what it should be, then some practical good would result.

The Copyright Question.

There is much to be done, the copyright question ought to be taken up in earnest; Mr. Snowden Ward, ever ready with his fertile brain, and with a characteristic disinterestedness, has a scheme which, with modifications, ought to work well; he proposes that every photographer should have a trade mark (registered) which would protect our photographs from being made the plunder of every journal (whether respectable or otherwise) in the country, and also secure to us a better chance of keeping enlarging orders in our hands.

A select number of photographers recently met and arranged amongst themselves a method of protecting their copyright portraits by making a minimum charge of a guinea to all journals using them. I protested to several of their number that I thought they ought to include all photographers, and at their second meeting they agreed to make a further edition to their numbers by making a selection of some of our leading firms. I think it would have been better to have started the movement on a broader basis, and let all photographers share in the benefit; at any rate, though limited, it is a step in the right direction, and one which our Association are taking up for the benefit of those left out in the cold.

I will now speak on a question which has long been on my mind—Why have photographers let chemists, stationers (and I have heard of shoemakers), being agents for photographic stores? I know a man in a suburb of London who has increased his sales for our materials that he makes more profit by their sale than from his own legitimate business.

Photographers should become Dealers.

I strongly advise the photographer everwhere taking up an agency where amateurs abound; he not only will get the full percentage of material he uses, but, as the amateur is in our midst, and is inevitable, it is well to fraternise with him, and make the best of him.

Again, in the great fight for patronage, and the tendency to lower our price lists in order to do any business at all (and here I must admit some of the cutting businesses have been successful) we have been creating a false position, as we all know low prices and good work cannot run side by side, and must end in failure; but, meanwhile, our assistants in many cases have had to suffer. I have always held that an industrious, clever, well-paid assistant is by far away the cheapest. I don't mean the man who, on a busy summer's day, watches the clock strike the hour, forgetting the long winter fogs when no man can work. The rent and wages go on as usual. Young assistants must bear in mind that the success or non-success of a business can be contributed largely to by their activityand forethought. Then I argue that the young in our profession ought to make the question of unity their own, and rally round any effort set on foot to establish and well found an association that has for its object the elevating and maintaining of our profession on a higher level. Thus, by mutual work, both master and assistants will profit, though it will not be by paying the *5s.* subscription only, but by taking some of the responsibilities in hand.

The Training of Young Photographers.

Writing to the journals complaining of inertness is inexcusable, because here is an association which can be moulded, as you, with most of those on its Council, are men who ought to be set aside from active responsibility, and only engage in the social part of the work, dropping a word of sage advice now and again. The training of the young in our profession has been left mainly to outsiders. I admit apprentices have been taken by some, and this has not always been successful.

The Polytechnic Institution has been doing good work, though only about eight certificates of efficiency have been given yet, I may say large number of assistants are availing themselves of the excellent advantages offered. I have had interviews with the Secretary and Mr. Howard Farmer, who I am glad to see here to-night, and they would welcome any assistance we can give them.

I should be glad if to-night we could secure a large accession of town members so as to have a central working Council (so far it has been our difficulty having the Council scattered over the country, making it a serious matter to get together). The social element has been a great source of attraction and inducement. Our genial country friends it has always been a real joy to meet, and some good has been effected, but we have only touched the fringe of the work yet to do; but unless more interest and sympathy is forthcoming the whole, I am afraid, must collapse.

The Photographers' Benevolent Society next claims a few moments of your time. It is a Society which has existed many years, having gone through many vicissitudes. I have the more right to press it on your notice, as I took an active part in its inception. It has done much good in the past, and I may say at the present time it is more active than at any time of its existence. It has considerably extended its operations. It not only grants immediate relief in pressing cases to all assistants connected with the profession, but it grants loans in cases where an assistant would be benefited by help in going to a situation which the Society, through its labour bureau, may have secured for him. In some instances it has provided clothing for those needing it. Of course, strict inquiry is made to avoid imposition. Hitherto its funds have been augmented by subscriptions from the amateur and the trader. The professional, as a rule, is not wanting in generosity. I have known many instances where he has been called upon for help, and not in vain, so that I am sure he will not forget in the future the claims of this Society.

It has been the practice lately at all exhibitions and social meetings in London to make, say, a sixpenny lead, and may I suggest this to-night. The nimble sixpence is not much in itself, but, when added to, it may make a goodly sum. I may say the Secretary is present, and any young assistant willing to join may do so by giving his name and paying but his *2s. 6d.* yearly subscription either now or when convenient.

I thank you for listening so patiently to my disjointed address. I have expressed my individual opinions, and the responsibility in giving them rests with myself. Thomas Fall.

AMERICAN NOTES AND NEWS.

Tuition in Pressing the Button.—We read in the *Pacific Coast Photographer* that the services of Mr. Archibald Treat have been secured to write a series of articles on photography which "will gradually advance up into the higher branches." This is all right and as it ought to be, but is it quite wise in Mr. Treat to write, as he does, in the first of these articles: "I will confess to you at the outset that my own knowledge of chemistry is confined to the fact that chloride of sodium means common salt?" But Mr. Treat, who, says the editor of our Western contemporary, "is well able to handle a series of letters on photography," continues: "As with chemistry so with the mechanics of the art; technical knowledge is convenient, though not necessary to successful photography." If chemistry and other technical teachings are not to be considered necessary in a course of lectures or letters on photography, are these to be confined to the art of pressing the button, and getting some one else to do the rest? Is it not written, Who drives fat oxen should himself be fat?

Death of Mr. C. Gentile.—We are sorry to learn of the death of Mr. Gentile, editor, and we think, proprietor of the *Photographic Eye* of Chicago. The *Eye*, somewhere about twelve or fourteen years ago, began to devote a large portion of its space to photographic matter, and eventually, under Mr. Gentile's management, went in exclusively for photography. As a considerable period has elapsed since we saw the paper, it is possible that it has succumbed to the growth of rival publications. Mr. Gentile was a man of gentlemanly instincts, and was well up in all that concerned photography.

Protection against Piratic Publishers.—In view of a good deal of photographic piracy that appears to prevail in America, much as it does in this country, Mr. D. Bachrach suggests (in *Wilson's Photographic Magazine*) that a provisional protection be given for five years to every picture by stamping on the face or back with the words "provisional copyright," with the month and year of making the negative. In that time, if any should prove valuable enough for the regular copyright, this right should still be open by payment of the proper fees. In addition, infringement should be made liable to either criminal or civil prosecution at the option of the plaintiff. This would, in Mr. Bachrach's opinion, enable the producer of a valuable piece of work to get the kernel instead of only the shell. Now, he continues, for a pittance, the photographer has to use all his skill and effort to get a pleasing portrait, cabinet size, which is to be used by some mere copyist for enlargement and profit, without any permission from the photographer. Under such a law as that suggested he might have a chance to obtain something proportionate to his skill, unless a price was paid for the work in anticipation of such use of it. In this country the fees for registration are fortunately so low—one shilling, with a penny extra for a form, in contrast with those which prevail in the United States of America—that the same objections to making every photograph copyright do not hold. But the question to be settled first of all is the fundamental one, To whom does the copyright of a commissioned portrait belong? Legislation in both America and Great Britain is badly needed to settle this and other matters connected with photographic copyright.

Drying Gelatine Negatives.—In the magazine previously named, there is a translation from the *Photo. Nachrichten*, which we had no difficulty in recognising as an editorial article that appeared some months ago in The British Journal of Photography, on a quick method of drying gelatine negatives and which need not occupy more than five minutes. On this our American brother exclaims, "What a job for a busy photographer! In the United States we dry

our negatives at a hot stove in five minutes, after applying Helmold's fireproof hardener, long since for sale by all stock dealers." On looking up the directions for using this tanning fluid, we find that the plates have to be immersed in it for a period of from ten to fifteen minutes, which, with the subsequent drying of five minutes, say, nearly twenty minutes altogether, as against our five minutes, represents the percentage of loss of time sustained by the busy (!) American photographer. By the way, we are glad to learn that some photographers are busy, as American papers and magazines have led us to believe quite the contrary.

The "Photo-American."—We have to thank the publisher of the *Photo-American*, Mr. Charles H. Loeber, New York, for a bound volume of his beautifully illustrated magazine, which we always peruse with pleasure. But we have searched in vain among the illustrations for the portrait of the esteemed lady who edits that department entitled "Our Women Friends." Our album of photographic brethren (and sisters) has still some vacancies. Perhaps Miss Skeel will oblige.

HOW LENSES ACT.

[Photographic Society of Ireland.]

The first thing necessary to the proper understanding of how a lens acts is to get a proper idea of how light acts. Suppose we have any small body, that body sends out rays of light in all directions. Whether the light is from its own illumination, or is reflected light, matters not, the rays depart just the same. A bundle of these rays entering our eyes enables us to see the body, and, according to the character of the rays thus received, we form our opinions as to what the body consists of, and what is its shape and position. The thing to be remembered is, that every body capable of being seen, and every individual point on it, is sending out rays of light in every direction.

Now, suppose we have such a body, and we place a piece of tinfoil, pierced with a small hole, in front of it, we will find that some particular ray from the top of the body will pass through the hole and continue its journey. Now, if we intercept it by a screen, the ray of light will fall upon it, and form a little spot of light. If this ray be strong, weak, or coloured, the little spot will be strong, weak, or coloured in proportion. Now, the bottom of the object also sends one of its rays through the hole, which will also form a little spot of light upon the screen, which will be strong, weak, or coloured also. Every other part of the object also forms its spot of light on the screen, so that we have an endless number of little spots adjoining each other, and varying in intensity and colour according to the rays sent from the object, and this aggregation of little spots forms the image. This is, as far as I am aware of, the simplest possible means of forming an image.

There are two things to be noticed here: First, that the image is *inverted*—that is, turned upside down; and, second, that the screen may be at any distance from the pinhole. The effect of the distance being greater or less is to make the image larger or smaller. If the distance be twice as great, the image will be of twice the diameter, and consequently four times the area. To illustrate this, suppose the screen be six inches from the pinhole and the image of an object to fill a quarter-plate. If the screen be removed to twelve inches, the image of the same object will now fill a whole-plate—that is, four times the area for twice the distance.

It might be thought that the smaller the pinhole the smaller the little spots of light on the screen would be, and consequently the sharper the image; but this is not so.

If you watch waves in a heavy sea passing the end of a pier, you will see them approach straight, and most of them pass on straight, but those near the pier get bent inwards, and are deflected from their original course. Now, rays of light, which also travel by waves, act in a similar way, and, if the pinhole be too small, too large a proportion of the waves will be bent out of their course, and will sadly interfere with the sharpness of the spots formed by those rays which go straight.

The most suitable size of pinhole varies with the size of the picture, and the best results are said to be obtained with holes varying between $\frac{1}{30}$ of an inch and $\frac{1}{20}$ of an inch diameter. I recently saw a good way for estimating the exposure to be given with a pinhole without having to work out the angular aperture every time it was desired to make an exposure. The pinholes in this case were made of different sizes, say, $\frac{1}{30}$ of an inch, and $\frac{1}{20}$ of an inch, and therefore the same size that the stops *f*-32 and *f*-20 of a lens, of an inch focal length would be.

If using the $\frac{1}{20}$ of an inch pinhole, and one inch from the screen, we would be working at *f*-20, and consequently should give the same exposure as we should give with an ordinary lens working at *f*-20, neglecting the very small difference due to there being no glass to stop part of the light. If using the same stop, $\frac{1}{30}$ of an inch, at two inches from the screen, we should be working at *f*-40, and consequently would have to give four times the exposure required with a lens working at *f*-20. If using the same stop, $\frac{1}{20}$ of an inch, at three inches from screen, we should be working at *f*-60, and should therefore require to make the exposure nine times as long as for a lens at *f*-20. These are all tabulated here, and you will notice that there is a sort of family resemblance between them, and that the multiple is the square of the distance between pinhole and screen. Hence, to find the exposure with pinhole $\frac{1}{30}$ of an inch at any distance from the screen, you first estimate a the exposure required for a lens at *f*-32, and multiply it by the square of the distance betwen hole and screen.

Pinhole image are by no means so uncommon as is generally imagined. You will all have observed when walking through a wood on a sunny day a number of bright spots on the ground, and, strange, to say, these spots are all circular. They are simply pinhole images of the sun formed by interstices between the leaves. In very hot and bright climates, where dark blinds are used to keep out the glare, similar images of the road outside are occasionally to be seen on the ceilings, and indeed I have once seen a similar image in Dublin, but it was not good.

But a pinhole is not a good means of forming an image, it does not give good definition, it is very slow, you cannot see what you are taking, &c.; so we use something else, and that something else, is a lens.

Now, when light passes from a medium of a certain density into another of different density, it is bent, or refracted, as it is termed. Suppose we are looking at an oar which is partially immersed in water, the ray of light going from the end of the oar to the eye does not go straight, but takes a bent course, as shown. The eye cannot recognise that the light is thus bent, and we apparently see the oar in a higher position than it really occupies; every part of the oar which is under water similarly appears to be higher, hence the oar appears to be bent sharply at the surface of the water.

Light passing through glass at an angle does not go straight, and this has some effect upon lenses, especially thick ones; but how much it effects them I cannot tell you.

If a ray of light be sent through a triangular piece of glass, called a prism, it is bent on entering it, and again, on leaving it. Placing another prism underneath, and drawing the corresponding rays through it, we find that the outer rays meet in one place, and the inner rays at another, thus *partially* forming images at both places. If the angle of the lower part of the prisms be decreased, the refraction will be lessened, and the point where the inner rays meet will move outwards to the other point. There are other rays besides those, and, by altering the angle for them also, they can be made to meet at the outer point.

But, as the number of rays are innumerable, so also must the changes of angle be innumerable; or, in other words, the surfaces of the prisms must become curves, and such an arrangement is called a *lens*, and is such that all the rays from the object meet at a point, and consequently form an image there. If we take another object, the rays from which reach the lens parallel, these rays will come to a focus nearer to the lens at a point called the *principal focus*, while the first object and its image are at *conjugate foci*.

Now, a lens which will cause *all* direct rays to meet in a focus must be ground to a certain curve, which, I believe, is a parabola, and for important visual work I believe they are so ground. A photographic lens has also to bring the oblique rays to a focus, and this requires a modification of the curves. Again, lenses are ground in lathes, and it is comparatively simple to grind spherical curves, much easier than any any other curve, hence all ordinary photographic lenses are ground to spherical curves.

Now, I have just mentioned that a parabolic curve is necessary to bring all rays to a correct focus, and, as photographic lenses are not parabolic, but spherical, it follows they will not bring all rays to a correct focus; and this undesirable quality in a lens is called spherical aberration, and it may be greater or less, according to the skill of the maker, in selecting the glass and the curves, or it may be left there purposely, in order to gain some other advantages, which the maker thinks more requisite. All the good qualities cannot be put into one lens, so the maker has to make either the best average or the best lens for a spherical purpose.

Spherical aberration is useful for the advanced school of photographers and for portraiture. If a screen be placed about the focus, some of the rays will form a sharp image thereon, but the other rays do not, and the result is a certain blurring or softness, with no obtrusive sharpness anywhere to contrast with the blurring of other parts of the image, which may not be in focus.

Spherical aberration also gives a sort of false depth of focus, to which I shall refer later on.

Single lenses of long focus and large aperture have a large amount of this spherical aberration, and hence are considered by some to be excellent for portraiture. Mrs. Cameron, whose pictures were thought a very great deal of, used, I believe, a lens of this description. Dallmeyer makes a lens with an arrangement for diffusion of focus, which is merely an arrangement for introducing more or less spherical aberration at will.

When we come to make negatives for lantern slides, or for scientific work, or to preserve records, all the sharpness procurable is desired, and spherical aberration becomes a fault in the lens. Luckily, however, we have a remedy for it in the shape of a diaphragm, or stop, as it is wrongly called. If a stop which will exclude the extreme rays be placed before a

lens, it will be seen that the remaining rays meet more nearly in a point. If the stop be made smaller, so as to exclude still more outer rays, those remaining meet still more nearly in a point; so that, by making the stop small enough, an image can be had free from aberration, and consequently sharp. But a small stop cuts off a large amount of light, and, to make up for it, the exposure must be longer.

Now, the amount of light which can pass through a stop depends upon the size of the opening; and if we consider two stops, say 1" and 1½" diameter, the second, although of half the diameter, has only a quarter the area of the first. Hence, if the first requires one second exposure, the second will require four seconds; in other words, the amount of light admitted, and consequently the exposure, vary as the square of the diameter of the stop.

Now, from what I have said, if we have a single lens with a certain size stop in front, a certain amount of light will get through, and consequently it might be thought that the exposure would be proportional to the actual size of the stop, as the lens behind the stop cannot affect the amount of light which has passed through. This, however, is not the case; the amount of light passing through the stop is constant, but the amount of work it has to do varies with the focal length of the lens. If one focal length be double the other, the one image will also be double the other lineally, that is, it is twice as long and twice as broad, and therefore four times the area. The amount of light being the same, but the image with the bigger lens four times the area of the other, the illumination of the larger image can only be one-quarter that of the smaller, and therefore four times the exposure must be given in order to enable it to complete its work upon the sensitive film.

To equalise the illumination, and consequently the exposure, four times the amount of light must be admitted, and to do this requires a stop twice the diameter. This means that a half-inch stop in a six-inch lens will give the same illumination and exposure as a one-inch stop in a twelve-inch lens.

It will be noticed that each of these stops is one-twelfth of the focal length of the lens to which it refers; hence, stops which bear the same proportion to the focal length, or, have the same angular aperture, give equal intensity of light and equal exposure. The usual way of expressing this proportion is *f*-8, *f*-16, *f*-32, &c., and *f*-8 in one lens will give equal exposure to *f*-8 in another lens, no matter what form or focal length that other lens may have.

J. H. HARORAVE.

(*To be continued.*)

TER'S VIEW OF THE PHOTOGRAPHIC SALON.*

II.

Forewords commences thus: "Among the monochrome arts, photography seems to hold a place nearer to the copper-plate processes than to any others. Like them, it is a negative process, a plate being produced, from which positive impressions are afterwards made. As in etching, the original plate is made by chemical means; as in mezzotint and aquatint, the drawing is in tones, not lines; but, unlike any other process, this drawing is accomplished by the action of light without the interposition of the hand." To say that, "in etching, the original plate is made by chemical means" is a perversion of well-known facts. An etching is made on a solid plate of copper (*opaque*, of course, whereas a photographic negative is made on a *transparent film*), which is prepared with a highly polished surface, it is then covered all over with the etching ground, chiefly composed of wax, which is evenly distributed by the dabber. It is next blackened all over by the flame of a candle or other means. The artist, having previously made a careful drawing of his subject in black and white, makes a tracing of it, which he reverses, and with red transfer paper he makes a red outline of the leading parts of his picture; then he takes his etching needles of various thicknesses, and on the black ground he draws his picture, which is reversed throughout. He can judge of his progress by the coloured lines of the copper, which are seen through the black ground wherever his needle has removed it in making the lines. If it is to be what is called a "dry-point" etching, the lines are drawn more firmly and deeply, on the pure copper, without any ground, then it is ready for printing a proof. This is most suitable for small, light, and delicate work. If it is to be an ordinary etching, the lines need not be drawn so deeply; it is sufficient if, in the lighter parts, the copper is only scratched. The great advantage in this is that the drawing can be made with almost as much feeling and artistic freedom of touch as with pen and ink. The artist next places his copper plate in a flat dish containing about equal parts of nitric acid and water, and allows it to remain about five or ten minutes, according to temperature. The action is that the acid attacks the copper where it has been exposed by the etching needles, and deepens the lines in proportion to their strength. The black parts of the plate which are untouched by the needle are preserved from the acid. The object of biting in with the acid is to avoid the necessity of drawing the lines more deeply by hand, with less freedom. The etcher then takes the plate out, cleans off the black ground, polishes, and takes a proof in the printing press. The light parts are generally deep enough, and are covered over again with the etching ground or a stopping-out varnish, which protects the copper from the further action of the acid. The plate is again immersed in the dish for the purpose of deepening the lines which require to be darker; it is again proved, and the process is repeated again and again until the desired effect is obtained. The parts which are too dark are hammered up from the back and scraped down even on the surface with flat scrapers; the dry point is also used for finishing up the finer shades in the light parts. The value of an etching depends very much upon the artistic skill and feeling of the printer, and the manner in which he may leave the delicate *nuance* or soft tone of a shade of ink on the plate in addition to the lines. So important is the printing that some of the best etchers print their own proofs and keep their own printer. Etching is distinctly a branch of fine art; it is the direct product of the human mind and hand. A fine and important etching sometimes requires months and even years to produce. The above is merely a crude, general outline of the process, but it is sufficient to show the palpable absurdity of attempting to establish an analogy between the production of such fine-art work as this and the making of a photographic negative and print.

Mezzotint engraving is another fine-art process, and is produced by drawing and scraping on a copper plate; it is frequently combined both with etching and stippling. No mention is made of the beautiful arts of lithography and wood engraving. These also, in their highest development, are branches of fine art, and they bear a closer resemblance in their results to photography than etching does, although the processes are entirely different; they also are the direct product of the hand and mind of man.

In the second paragraph of *Forewords* we arrive at what is perhaps intended to be the great joke of the "Sahlong." Here it is:—"Although not entirely limited by what is presented before it, the camera is not much used to show its power of invention, being employed, generally speaking, to reproduce, more or less accurately, what actually exists before it at one time." We know the pretty poetical fiction about Galatea, where the sculptor fell in love with the beautiful young female form he had created in the marble, and the gods forthwith endowed her with life, and flowing blood, and soul, and brains; but I cannot credit the suggestion, thus gravely put forward, that they have ever bestowed any such gifts on a photographic camera, be it "Kodak," "Acme," "Snap-shot," or any other sort, to enable it "to show its power of invention," and I don't believe they ever will—not in our time, at least. But as we are here distinctly given to understand that the camera *does* possess the *power of invention*, and can show it when required, the authors must know of some new and miraculous "power of invention," in which the intervention of human brains is dispensed with altogether. Perhaps Edison has given them the wrinkle, or perhaps—as is more likely—this is only one of their little jokes; they seem to be of a very jocular turn of mind, do some of these gentlemen. In the course of my walk round the room I suddenly encountered a mysterious *something* in a little frame—No. 196, jestingly denominated *The White Robe of Winter*. When I looked I nearly lost my senses, and began to wonder where I was. I seemed to see a lot of small photographs cut into strips, all jumping over the top of each other in having a game at photographic leap-frog. My head seemed to swim; needles and pins seemed flashing through my eyes as they got dimmer and dimmer. Before it was too late I had still sense enough left to stagger to the nearest chair, into which I sank exhausted, stuck my hat over my optical department, and gasped for breath. When I "came to" I saw other people hurriedly rushing from "the accursed spot" with expressions of utter amazement and consternation. This, then, after all, may have been "the greatest curse of photography," this abominable freak. I gave it a wide berth; I never looked at it a second time. I would not enter that Sahlong alone at midnight—no, not for untold wealth (at least, not for less than half a sovereign down). I should expect to see "the thing" phosphorescent, the leap-frog business still going on, and goodness knows what else besides. Seriously speaking, the presence of "the thing" constitutes a daring assault on the public. I did not go to Piccadilly to have my organs of vision assailed in that manner.

I suppose it has been placed here by the Fuzzyites as an intimation or note of warning to this effect:—"This is what we are coming to! away with your old-fashioned prejudices—look out!" Terrible fellows these Fuzzyites—not content with blurring their own beautiful photographs out of all reasonable resemblance to anything in Nature or in art, they have actually set about blurring and obfusticating the very eyes of the visitors who come to look at them. This new photo-wooly-graphic school *may* (?) have a right to extinguish the finest characteristic qualities of their own art in the unworthy attempt to make a *mechanical imitation* of the mere technique, the outward husk, of quite a different kind of art, which is not homogeneous to theirs, which they cannot assimilate, yet may burlesque; but they should leave the eyes of the public alone. No. 171 is another of these absurdities. It is a little bit of very coarse paper, on which an ink bottle seems to have been upset, making an inky streak in the middle and blotting over the lower part. It is a poor joke—a mere affectation of eccentricity. The best work in the gallery is, of course, produced by operators who endeavour to secure the reflections of Nature in the finished style in which it is the natural function of photography to present them, aided by their own taste in the selection of subjects and the artistic manner in which they treat them. On the other hand, the least satisfactory works are those of clever operators, also with good artistic taste and feeling, who have got tired of the perfect work of

* *Concluded from page* 720.

Nature as rendered by photography, and prefer to waste their talent in the imitation of the work of other men — scene-painters and the painters of unfinished pictures, called impressionists—in which spurious imitation the mechanical labour involved in this branch of photographic manufacture necessarily destroys the finest and most valuable qualities of pure photography, some of which cannot be rivalled by any branch of art. There are pictures here printed on canvas, and even on raw cloth, which are far inferior to work which could be printed from the same negatives on suitable paper. *Cui bono?* More than a quarter of a century ago I used to see photographs on canvas by various methods, much superior to anything exhibited here. Then a large proportion of the photographs are sadly depreciated by the use of very rough drawing paper, which is quite out of proportion for small work; the delicate tones, sky, atmosphere, distance, water, and all the light parts in landscape are destroyed by the obtrusive, coarse texture; and in portraits the subjects are made to look coarse, and deeply marked with small-pox. That texture which is excellent for the reception of colour in the free, bold handling of large work is fatal to photography. *Photogravure* gives the very boldest rendering of the texture of pictures on paper which is perfectly smooth. It would be ridiculous for a scene-painter to imitate the delicacy and detail of a photograph; it is equally ridiculous for a photographer to imitate the breadth and boldness of scene-painting. *Suum cuique tribuito.* These photographic aberrations are the result of a desire to appear artistic—they are art pretentiousness. The late C. R. Leslie, R.A., a most refined and accomplished painter, in his *Hand-book of Painting* enunciated half a dozen words which should never be forgotten: "Pretence is the essence of vulgarity." PALETTE.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

On Friday, November 10, a meeting of the National Association of Professional Photographers was held at Coleman's Hotel, Henrietta-street, Covent Garden. The proceedings began with a Council Meeting in the afternoon, and this was succeeded by a high tea, kindly given by the President (Mr. Thomas Fall), and to which between thirty and forty sat down. At the conclusion of the repast the Chevalier Lafosse (Vice-President) proposed a vote of thanks to the President for his hospitality. This was seconded by Mr. W. Gill (Colchester) and supported by Mr. T. Birtles (Warrington). The President, in acknowledging the vote, hoped that no one would try to put down the Association by saying that it was not succeeding. It had already gone through a lot of difficulties, and he was certain that if they persevered, the future of the Association would be all right.

In the evening the President again took the chair at a general meeting of the Association, the attendance being extremely good. Among those present were Messrs. H. J. Whitlock (Birmingham), James Martin (New Southgate), Warwick Brookes (Manchester), Warwick Brookes, jun., F. Turner (Barnsbury), E. Howard Farmer, S. J. Beckett, J. J. Elliott, Frost (Loughborough), Spink (Brighton), Harold Baker (Birmingham), W. Gill (Colchester), Crosby (Sheffield), G. V. Yates (Sheffield), Hollis, W. P. Marsh (Bognor), W. T. Coombes (Plymouth), J. Martyn (Southwold), W. Davey, G. Pendry (Nottingham), Chevalier Lafosse (Ilfracombe), C. Lafosse, jun., Hogg (Ryde), R. Keene, jun. (Plymouth), D. J. O'Neill (Secretary), Mr. and Mrs. Snowden Ward, Mr. Thomas Bedding, and many others.

The President delivered an address to the Members [see page 733], after which an informal discussion on the aims and objects of the Association took place.

Mr. W. Gill said the Association had started too ambitiously, and he confessed himself rather disappointed with it. They were, however, he thought, coming to a healthier state. They need not be too anxious to do anything; if they only kept together, something would come to them to be done. As to the subscription (10*s.* 6*d.* per annum), he considered it should be doubled. He would rather let people apply for membership, which should be an honour, than endeavour to get new members.

Mr. Jas. Martin said photographers had a grievance against themselves and the public. The public wanted them to render their services at too low a rate, and did not accord them a due amount of consideration. They looked upon them as mechanics, and ignored the more or less number of years of experience which were necessary to enable them to turn out the work which the public required from them at so low a rate. He thought the causes of the grievance could be removed by imitating the Pharmaceutical Society in the case of chemists and druggists, and granting diplomas to photographers.

Mr. T. Birtles said the last matter had already been under discussion. It had been said that the public under-valued photographers' work. Well, he thought the public took them at their own prices, and if photographers sold work at low prices they had only themselves to blame for it. What was wanted was more unity amongst photographers. Where were the London photographers that night? That room would have been filled three or four times over if the London men had only come forward as they should have done. Some of the country photographers there had travelled hundreds of miles to be present to work for the benefit of the whole of the profession.

Mr. Snowden Ward advised photographers to undertake process work as a means of improving their positions.

Mr. R. Keene asked where the demand for process work existed in small provincial towns?

Mr. Ward quoted the case of Colne (Lancashire), which in his experience was sending to London to have lantern slides made.

Mr. Crosby alluded to a professional photographer in a small provincial town who had recently returned from London with considerable orders for lantern slides, &c. He was sorry the Association had not fulfilled the anticipations that had been formed of it.

Mr. E. Howard Farmer said that he was practically "born in a dark room," both his father and mother having been photographers, while he himself started in the profession on Ramsgate sands. His object in speaking that night was to try and remove the prejudice which existed as to the photographic teaching given by the Polytechnic. The object of that institution was to educate young photographers, and it included a large number of classes. If there were not enough young professionals to start the classes, amateurs were admitted at slightly increased fees. Photography had been rendered almost too easy by the introduction of dry plates. He strongly advocated professionals undertaking processes giving results which the amateur could not approach, and seconded Mr. Ward's suggestion that photographers should take up process work. There was an idea that collotype and other processes were very difficult, but that was not the case. As to the demand for that kind of work in the country, were not local papers frequently producing half-tone blocks? Then, why should not the local photographer supply them? There was nothing to prevent him. He thought also that photographers should supply a sitter with his finished photographs the same day as the sitting, and not keep him waiting two months. There was nothing to prevent the prints being delivered the same day. This would improve the business of the professional. In reply to a general chorus of inquiry as to how this was to be done, Mr. Farmer said it was actually being done.

Mr. Whitlock pointed out that a cabinet head took two hours to retouch and not a quarter of an hour, as Mr. Farmer said, so that he failed entirely to see how the prints could be so quickly delivered. No doubt Mr. Farmer was speaking of some quick process, of which they would be glad to have information.

Mr. Farmer said that the prints could be made by the developed-out, collotype or bromide processes.

The meeting closed appropriately enough by a demonstration of the new Paget Print-out and Development Paper by Mr. S. H. Fry.

ON THE PHOTOGRAPHY OF THE LUMINOUS RAYS OF THE SHORTEST WAVE-LENGTHS.*

The Source of Light.

THE purpose of the photograph demands a source of light rich in energetic rays of the shortest wave-lengths.

Only the light of electric discharges fulfils this condition. Hence I had merely the choice between the arc light and the light of sparks. As the latter promised the better result, all my photographs have been produced with spark light. For its production there was used a Ruhmkorff inductorium arranged for a maximum spark length of twenty-five cm. The primary current was furnished by six Grove elements. A Leyden jar, of 500 square cm. of external coating, was inserted in the track of the secondary current. In some cases an additional jar was introduced, and even occasionally two more.

For the region of wave-lengths 198·8 $\mu\mu$ to 185·2 $\mu\mu$, only aluminium electrodes are available, according to the observations of Stokes (*Phil. Trans.*, clii. p. 606, fig. 1, 1862) and Cornu (*Archiv. des Sci. Phys. et Naturelles*, III. Période, t. ii. p. 125, 1879), and merely for the wave-lengths 230·0 $\mu\mu$ to 198·0 $\mu\mu$, which I could not leave unnoticed, I used electrodes of zinc and cadmium. Zinc and cadmium deserve to be preferred to other metals, on account of the uniform distribution and relatively powerful action of their most refrangible rays.

The Photographic Procedure.

I use dry gelatine plates of my own preparation. Commercial plates are less suitable for the photography of spectra. When it is important to support as far as possible the optical power of the photographic spectral apparatus, where the sharpness of the image is a main condition, and also where a strong contrast in the intensity of the images of the lines is needed (photometry), the commercial plate is inadequate. It does not work intensely enough to assist spectroscopy to the extent of the modern dry plate.

The gelatine plate of my own preparation gives an intense and finely granular image on a ground clear as glass. The emulsion is relatively rich in silver iodide, containing, to 100 parts by weight of silver bromide, four to five parts of silver iodide. Its preparation is effected exclusively on

* *Continued from page* 707.

Eder's method, with silver-oxide ammonia (J. M. Eder, *Ausf. Hand. d. Photographie*, Part III., pp. 208–211, 4th ed., Halle, 1890), which I have used for more than ten years.

For developing the plates I use the soda-pyrogallic developer, and for fixation sodium thiosulphate.

The Photographic Proof.

Before proceeding to treat of photographic proofs, it may be remarked that I have long occupied myself in a complete manner with the photography of the ultra-violet region. My chief object was then the development of the graphic portion of the proofs, the most refrangible rays being overlooked. Only now and then, in a transitory manner, I have attempted to photograph the most refrangible lines of aluminium, but without success.

More favourable, then, with aluminium were the conditions of the most refractive lines of zinc, which precede the above-named aluminium lines in the series of the most striking rays of the ultra-violet. But, though I did not here operate unsuccessfully, the image which I obtained was always pale and indecisive.

The most refrangible lines of cadmium, which are still less deflected than most refrangible zinc lines, appeared regularly after a short exposure to light. But in intensity they were decidedly inferior to the neighbouring lines of smaller wave-length of the same spectrum.

In general the wave-length of the cadmium line No. 24 (226·55) formed the limit of my earlier photographs of the ultra-violet.

The above-mentioned most refrangible lines of cadmium, zinc, and aluminium have been marked by Mascart and Soret with numbers, and generally in spectroscopy, where the wave-lengths are not necessary, this system has come into use. I shall use it in what follows. Here follows a list of these lines with the Mascart-Soret characterisation, the wave-lengths as determined by Cornu (*Archives des. Sci. Phys. et Nat.*, III. Période, t. ii. pp. 121–126, 1879), and a design (fig. 1) taken from my own photographs.

Cd, No. 23, 231·35; No. 24, 226·55; No. 25, 219·45; No. 26, 214·41. Zn, No. 27, 209·88; No. 58, 206·10; No. 29, 202·43. Al, No. 30, 198·81; No. 31, 193·35; No. 32, 185·22. No. 28, No. 31, and No. 32 are double lines.

The photography of the cadmium spectrum formed the beginning of my investigation.

VICTOR SCHUMANN.

(To be continued.)

Our Editorial Table.

DR. ANDRESEN'S FIXING SALT IN BARS AND CARTRIDGES.

Arthur Schwarz & Co., Dashwood House, E.C.

WE have before now spoken of the convenience of the fixing cartridges issued by Messrs. Schwarz & Co. The latest adaptation of the idea is to compress the salts into small bars, which are handy in more senses than one, being less bulky than the uncompressed salts. The bars dissolve readily, the four ounce in thirty-six ounces of water, and so on, and thus an acid fixing bath is easily formed which answers perfectly. These fixing bars and cartridges should be popular.

TYRER'S PATENT POSTAL TUBE.

The Government Postal Tube Company, 70, Long-lane, S.E.

DOUBTLESS this tube would be found useful for the transmission of photographs, &c. It consists of an ordinary cardboard, towards one extremity of which is a hole which so allows of the disposition of the fingers that the contents of the tube can be withdrawn without damage to them.

"PHOTOGRAPHY AT NIGHT."

By P. C. DUCHOCHOIS, New York.

WELL knowing Mr. Duchochois' thorough knowledge of all that appertains to photography, we invariably read his writings with more than common interest. In *Photography at Night* he compresses into its 108 pages everything that can be said on the subject, giving, as might be expected, a primary place to magnesium, and full directions as to its employment in portraiture, including the arranging of the sitter, the lamps, and the developers to be employed. Printing by contact on bromide paper, enlarging, making lantern slides, and, indeed, everything that can be done by artificial light fall under the category of topics treated. The work can be obtained from the Scovill & Adams Company, 423, Broome-street, New York.

News and Notes.

PHOTOGRAPHIC CLUB.—November 22, Smoking Concert.

LEWISHAM CAMERA CLUB.—November 17, Exhibition of Members' Work.

WEST LONDON PHOTOGRAPHIC SOCIETY.—November 28, *Tele-photography*, by Mr. T. R. Dallmeyer.

BRIXTON AND CLAPHAM CAMERA CLUB.—Next meeting, November 21, *Skies*, by Mr. W. Thomas.

WIDNES PHOTOGRAPHIC SOCIETY.—Next meeting, November 22, at Bedford Chambers. Members' Lantern Slides.

LEEDS CAMERA CLUB.—November 23, Demonstration, *Lantern-slide Making by Reduction*, by Mr. C. Grayson.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—November 23 Demonstration, *Carbon Printing*, by Mr. Birt Acres.

THE Manchester Amateur Photographic Society's Annual Exhibition of Members' Work takes place on December 12, 13, 14, 15, and 16, 1893. Particulars of the exhibition manager, Mr. E. Ashman, 5 Bine Boar-court, Market-place, City.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—November 23, *Paget Company's Printing-out Paper, Toning and Finishing;* also special remarks and practical demonstration on *Part Print-out and Part Development of Image*, by Mr. S. Herbert Fry.

DEATH OF MR. THOMAS MAYNE.—We learn with great regret of the death of Mr. Thomas S. Mayne, which occurred at his residence, St. Hilary Brow, Wallasey, on Thursday, November 9. He was an enthusiastic and very successful amateur photographer, and was prominently connected with the recent Liverpool Photographic Exhibition.

SOCIETY OF ARTS.—The new Session of the Society of Arts commenced on Wednesday, 15th inst., when the opening address was delivered by Sir Richard E. Webster, Q.C., M.P., Chairman of Council. Amongst the subjects before Christmas likely to interest photographers, are, November 22, *Conformation of the Horse from the Artistic Point of View*, by Capt. M. H. Hayes; and, December 6, *An Artist's View of Chicago and the World's Fair*, by Mr. Frederick Villiers. Mr. Henry Blackburn will deliver a course of Cantor lectures on *The Art of Book and Newspaper Illustration* on Monday evenings, November 27, December 4, and 11.

HALIFAX CAMERA CLUB'S CONVERSAZIONE AND MUSICAL EVENING.—A thoroughly enjoyable entertainment was provided in the Mechanics' Hall, on Thursday night, November 9, by the Halifax Camera Club. The Club's headquarters are in Crossley-street, where meetings are held and experiments conducted. As Mr. J. Ingham Learoyd, the active President, explained to the large company which assembled, the object of the gathering was twofold: to interest visitors in photography and so draw new members; and also to add to the funds of the Club. The members had contributed a most interesting collection of apparatus and work produced by themselves. Mr. Thomas Illingworth, of Crown-street, furnished a large number of well-furnished photographs, many of large size; and Messrs. Thomas Illingworth & Co., of London, had also sent some charming exhibits. These exhibits, together with examples of electro blocks, photogravure, &c., the most improved cameras, and hundreds of pictures done by members, were exhibited on tables placed along the sides and across the room; while the tables were lit with lamps and decorated with plants, giving altogether a very pleasant effect. Members were present to answer questions and give any information desired respecting any of the objects or the curious processes of photography; and, more than this, a dark room had been fitted in which the work of developing, fixing, &c., was practically demonstrated. During the evening two exhibitions of magic-lantern views, also done by the members, were given. The proceedings were varied with selections of instrumental music by Mr. E. J. Walker and a party of friends, and songs by Mr. J. C. Marchant and Mr. A. Munday. Mr. C. Thomas ably officiated as accompanist. Mr. H. Walsh, of Thornleigh, Halifax, is the Hon. Secretary.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

November 14, Ordinary Meeting, Mr. J. Spiller (Vice-President) in the chair.

The following were unanimously elected members of the Society:—Messrs. G. Ardaseer, Thomas Bedding, Mrs. C. W. Ward, Messrs. J. C. Burrow, E. R. Cox, jun., A. W. Dollond, C. Hipp; Staff-Surgeon Preston, and Mr. G. Stevens.

Photography in Coal Mines.

Mr. Herbert W. Hughes, F.G.S., A.R.S.M., gave an address on this subject, saying that he was anxious to obtain some ideas which would help him in tackling this difficult branch of photography. The first series of mining photographs ever taken were by Mr. Arthur Sopwith, of Walsall, where the seam was from six to seven feet thick. The methods that were perfectly successful with Mr. Sopwith were useless with him (Mr. Hughes), where the seam was thirty feet thick. The only other coal-mining photographs taken, that he knew of, were by a Pennsylvania photographer; the remainder were metal-mining views. He did not wish to disparage metal-mining photographs, but nearly twice as much light was required to get the same result in a coal mine as in a metal mine. The soft, sooty variety of coal so often met with absorbed the light instead of reflecting it, whereas in metal mines it was reflected with comparative brilliancy. Alluding to the views in Cornish mines, taken by Mr. Burrow, and shown at the Exhibition, he said his remarks applied equally to them, the only difference being in the lighting respectively employed by him and Mr. Burrow. The latter gentleman used a triple magnesium flash lamp; he (Mr. Hughes) a Platinotype Company's lamp, supplemented by an Optimus 1000 candle power lamp. As to lenses, Mr. Burrow and himself tried lenses of the rapid symmetrical and portrait type. Mr. Sopwith's pictures had been taken with a portrait lens, but they lacked distinctness in objects comparatively distaut from the lens, which should not be. Both he and Mr. Burrow finally used a lens of Zeiss, Series III., while for certain purposes, the Zeiss lens being of rather long focus, he had obtained most excellent results with the Concentric lens of Ross. By using this lens at *f*-22, he found that it did not require double the illumination that the Zeiss did at *f*-18, as, with a short-focus lens, one could get so much nearer the object, and the conditions of lighting were so totally different that the light is reflected back, so that one obtained more of it. In fact, with a short-focus lens and a small aperture, he would burn the same amount of magnesium as with a long-focus lens of larger aperture. In this kind of work the difficulties to be overcome were not many, but they were hard. Smoke from blasting, a moisture-laden atmosphere, water from the roof, supplemented in coal mines by the presence of coal dust, which thickened the atmosphere and deposited particles on the plate, were among the few he enumerated. Condensation of moisture on the lens was difficult to get rid of. He obviated it somewhat by always carrying his lenses in his pocket. The opening of a door in the mine was sometimes sufficient to send in a stream of cold air, which would condense moisture. It was impossible to properly compose the picture on the ground glass. He generally arranged a series of lights round the principal objects, and moved the camera about until he obtained the principal points on the ground glass. Focussing had to be guessed at. Sometimes one could burn a length of magnesium wire for that purpose, but in the majority of cases, where it was burnt, it was impossible to take a photograph that day. The air should pass from the object toward the lens. He had found the light given by the Platinotype Company's lamp more actinic than that of ordinary flash lamps. One scene he took had 270 grains of magnesium burnt on it, and the same picture, taken from the other side, had ninety grains; the latter negative was, if anything, the better exposed. The only instantaneous photograph he had got underground was obtained by accident, the lamp stopping, as it were, in its flash. The negative turned out one of the best he had taken. For developer, he succeeded best with pyro and ammonia. He never over-exposed, and usually took from two to three hours to develop, subsequent intensification being always necessary. To show the difficulties of the kind of work, seventy per cent. of the plates he exposed were failures, and of the remaining thirty per cent. one-half only were good. Mr. Burrow said that, of his exposures, seventeen per cent. were good. In his (Mr. Hughes's) case, nine hours' work underground only produced three negatives, which, on development were valueless.

A large number of slides, by Mr. Hughes, Mr. Burrow, and Mr. Sopwith, were shown, illustrative of the difficulties of coal and metal-mining photography, as well as of points in Mr. Hughes's paper. He pointed out that, in pictures where very dark shadows occurred, secondary lighting of them was necessary, but care was to be taken in preventing direct light from the magnesium entering the lens.

Mr. Brough, as a mining engineer, bore testimony to the value of the photographs, which, he said, was hardly to be over-estimated. In teaching mining engineering to ordinary students, diagrams conveyed but a very imperfect idea of the state of things that such students would meet with. Such pictures would also make teachers and lecturers' work more interesting. To the geologist the question was also a vital one. One of the most difficult problems was, that which related to the formation of ore deposits; here the mining engineer and the geologist had to work haud in hand.

Mr. Graves (also an expert) said the mining photographs had given people a wonderfully good idea of what underground workings were like.

The Chairman asked for an explanation of the fact that one of the photographs had been taken by magnesium light while one of the men had a Davy lamp in use.

Mr. Hughes said an artist's licence had been taken. Mr. Sopwith (who took the photograph) had satisfied himself that there was no gas present.

Mr. Debenham, in 1865, had taken photographs in a Cornish tin mine, using wet collodion. As to an oxy-magnesium lamp being more advantageous than other flash lamps, magnesium burnt in oxygen was known to give more light than the same quantity of magnesium burnt in air.

Mr. Wilmer suggested that possibly condensation of moisture in the lenses might be obviated by employing an oil or water jacket.

After other remarks, Mr. Hughes briefly replied; and a vote of thanks was passed to him.

The Hon. Secretary gave a brief *resumé* of a paper by Mr. W. K. Burton, *On the Range of Light Impinging on a Plate during Exposure in the Camera;* and the proceedings terminated.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 9,—Mr. J. S. Teape in the chair.

Attention was called to a statement in the *Standard* of a gas bottle having burst.

Mr. Hodd said he could not accouut for it; if it had been a drawn steel cylinder, it would not have burst.

Mr. R. R. Beard showed a new saturator called the "Gridiron." He had tried it in various ways, but could not get any back snap. The saturator was packed with asbestos. He thought a weak point in it was that there was no means of stopping the evaporation of the ether when not in use.

Being a Lantern Night, slides were shown by Messrs. Bayston, Steiumetz, Hodd, Austin, Joy, aud the Hon. Secretary.

Brixton and Clapham Camera Club.—November 7, the chair being occupied successively by Mr. R. G. F. Kidson (Treasurer), Dr. J. Reynolds (President), and Mr. F. Goldby (Vice-Presideut).—The Club settled details with respect to the forthcoming Club Exhibition, which will be held at the Clarence Rooms, Coldharbour Lane, Brixton, from Thursday, January 25, to Wednesday, January 31, 1894, both days inclusive. There will be no open class, and prints will not be divided into classes, as on former occasions. It was decided to invite Messrs. Pringle, Cembrano, Colonel Gale, and Mr. Warnerke to act as Judges, giving them full power to award or withhold medals as may seem best in their judgment, the only restriction in the matter being that not more thau two medals shall be awarded to any one exhibitor. Full particulars and tickets may be obtained from any member of the Club or of the Hon. Secretary, Mr. B. E. Pinder, 7, McDowall-road, Camberwell, S.E. Subsequently a paper was read and a demonstration on *Enlarging* given by Mr. Butler, one of the members. An enlargement 12×10 was successfully made from a half-plate negative, the enlargement (on Morgan & Kidd's bromide paper) being developed with the following formula:—Amidol, 2 grains; sulphite soda, 24 grains; bromide of potassium, 1 grain; water 1 ounce.

Hackney Photographic Society.—November 7, Mr. T. H. Smith in the chair.—The following work was shown by members: Mr. Gosling some hand-camera shots; negative and print by Mr. Farmer, and photographs of pen-and-ink sketches by Mr. Beckett on argentotype paper developed with amidol, showing what an intense black this developer will give with a freedom from stains. Mr. Hudson showed a frame for enlarging portion of a quarter-plate negative with four-inch condenser of optical lantern, which had springs for holding the negative perfectly vertical during exposure. Samples of Elliott & Sons', "Barnet" lantern plate were distributed amongst the members, reports to be lodged at a subsequent meeting. A discussion upon Exhibition matters brought the evening to a close.

Lantern Society.—November 13, Annual Meeting.—The report and balance-sheet having been adopted, and the officers for the ensuing year elected, the set of 100 slides received from America were shown. These slides, which are of excellent quality and interesting subjects, are available for the use of members until May next, application to be made to the Curator, who will book dates in advance.

North Middlesex Photographic Society.—November 13.—In the regretted absence through illness of Mr. Horsley Hinton, who was to have addressed this Society, a general discussion on various topics took place. Mr. AVERY raised the question whether it was allowable, or true in art, to put a cloud into a landscape which was photographed upon a day when there were no clouds but a clear blue sky, or whether such a sky should be simply toned down to represent a blue sky. Mr. MARCHANT thought it would be justifiable to put in any cloud that was suitable, but it *must be* suitable. He did not think a painter would stand at putting in a suitable cloud if it helped the picture, and why should not a photographer? Mr. MATTOCKS had seen many paintings with a cloudless blue sky, and if a photographer could convey the idea of blue sky he did not know why he should not do it. But it was admittedly difficult, and the next best thing was to put in a suitable cloud. Mr. GOLDING thought that a sky slightly toned down would, at any rate, in some cases, represent blue sky, and instanced Mr. Calland's picture in the Salon *Orchard in June*. Mr. COX thought a man must carry in his mind the ultimate effect desired, and might do anything which would help him to gain that effect. Mr. BEADLE thought that anything which would tend to make a photograph more picturesque was justifiable. Mr. MUMMERY said it did not matter two straws whether clouds were present when the landscape was photographed or not. Would any particular cloud improve the effect? That is where a man must use his judgment, and he would put a cloud in if he thought it would be an improvement. He thought it possible to get the exact tone value of a blue sky if it were required. Mr. Cox objected that you could not get the luminosity of the sky. Mr. MUMMERY said you could not get the luminosity of the setting sun, but you could get a tolerably correct representation of it by lowering the tone of the picture to correspond. The discussion was continued by Messrs. Forbes, Wall, Pither, Cherry, and others, the general opinion being, that if a cloud would help the picture it might be put in.

Woolwich Photographic Society.—November 9.—There was a big muster of members at St. John's Schools to see the lantern slides that had been sent in for criticism. About 160 were passed through the lantern, after which a set of sixty slides taken by members of the Manchester Camera Club were shown, and greatly applauded. It added very much to the interest centered in this set that Mr. W. H. Dawson, who acted as lanternist, was forced to announce that he was a Manchester man, and, as the slides were put through, gave the audience a lot of information respecting the spots chosen for illustration.

Brooklands (St. John's) Photographic and Scientific Society.—Ordinary Meeting held on Tuesday, November 7, Mr. F. J. Simpson in the chair.—Nine new members were elected. Mr. M. W. THOMPSTONE delivered a lecture on *Photographic Printing Processes*, in which he dealt with the methods of working the platinotype, carbon, Obernetter, Nikko, silver, and gelatine-chloride processes, exhibiting several prints done by each process. The growth of photography was traced from the year 1835 to the present day, the latest improvement, and most interesting part of the lecture, being the development of partially printed prints on printing-out paper. After briefly describing the process, the members were treated to practical illustrations of this new method of printing. Several prints were passed round, the image in some being just visible, the length of exposure being stated as one-tenth of the full printing time. It was satisfactorily shown that, however much under-printed the image might be, it could not be told from a fully printed one after development. The prints were immersed in a solution of potassium bromide, the recommended strength being potassium bromide, one ounce; water, half pint; and left in for two minutes. Having been thoroughly washed, they were put in the developer (as recommended by the Paget Company), when the image gradually increased in depth until it resembled an ordinary print, care being taken that the prints were removed from the developer just before fully out. It was pointed out that a thorough washing was then necessary, as, if this was neglected, development would continue and spoil the print. The prints were then toned in a sodium acetate bath, and, when fixed, resembled in every way a print done in the ordinary way on printing-out paper.

Gosport Photographic Society.—The ordinary meeting of this Society, held on November 8, was devoted to an exhibition of lantern slides. They were greatly appreciated, especially the architecture and flower studies. Next meeting November 22, at the Society's rooms, 46, High-street, Gosport.

Newcastle-on-Tyne and Northern Counties Photographic Association.—The monthly meeting was held on the 7th inst., Mr. J. P. Gibson, President, in the chair.—The Chairman opened a discussion on printing processes, which was continued by Messrs. Auty, Arnott, Brewis, Brown, Park, Parry and Watson, who exhibited specimens of almost every process. The details of the forthcoming Exhibition were discussed and decided upon. Next meeting, November 21, exhibition of prize slides.

Widnes Photographic Society.—November 8, the President (Mr. V. C. Driffield) in the chair.—Mr. PRIESTNALL gave a demonstration on *Flashlight Photography*, and took a photograph of a group of their members by means of magnesium light. He used an apparatus with twelve lamps, each burning three grains of magnesium powder. The exposure was made on a Marion half-plate, Hurter & Driffield actinograph speed No. 70, using a Ross rapid symmetrical lens, eight inches focus, working at *f*·8. The plate was developed with pyro and ammonia, fixed, and handed round for inspection. It turned out to be a good negative, and Mr. Priestnall promised to bring some prints of it to the next meeting. The following questions were discussed:—1: Do rapid plates take longer to fix than slow ones? If so, why? The general opinion was that the answer to this should be, No; and it was not at all safe to assume that fixation was complete immediately on the disappearance of colour from the back of the film; and it was advisable to allow plates to remain in the hypo at least fifteen minutes, in order to ensure all the silver salt being dissolved therefrom. 2: In developing plates out of the same box, some take longer to fix than others. Is this a sign of over or under-exposure? The answer to this was: Exposure does not affect the time in fixing; but some plates were more thickly coated than others, owing to the glass used not being perfectly level, and it took longer to dissolve the silver salt from those. It was agreed that next meeting be reserved for the exhibition of members' lantern slides.

Dundee and East of Scotland Photographic Association.—The second general monthly meeting of the Session was held in Lamb's Hotel, Dundee, on Thursday, the 9th inst., Mr. J. D. Cox (President) in the chair.—After routine business, Dr. J. K. TULLOCH read a paper entitled, *Remarks on Hand-camera Work and Hand Cameras* [see next number]. Mr. FEATHERS, curator of the Society's album, drew attention to his difficulty in procuring prints for the album from the members, and hoped that in future they would conform to the rule of contributing at least one print each. The prizes for the best pair of prints taken at the Association's excursions during the past season were awarded to—1st, V. C. Baird; 2nd, Rev. E. J. Gough; and, 3rd, J. Thow.

Photographic Society of Ireland.—November 10, Mr. MORGAN gave a demonstration on the new developers, *Amidol, Metol, and Glycin* (Hauff). Some negatives were developed, and proved very satisfactory. Mr. Morgan also exposed a few lantern slides in the presence of the members, and produced first-rate results by the use of both amidol and metol respectively. The demonstration excited a deal of interest, and terminated with a free discussion on the subject. Several new members were elected.

FORTHCOMING EXHIBITIONS.

1893.	
November 17–25.....	*Stanley Show (Photographic Section), Agricultural Hall. Manager, Walter D. Welford, 57 and 58, Chancery-lane, W.C.
,, 20–25.....	*Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, Rose Bank, South-west-road, Leytonstone.
December.....	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
,, 18–Jan. 22, 1894	*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE QUESTION OF COPYRIGHT.

To the EDITOR.

SIR,—I have lately heard that it is not necessary to register a photograph in order to secure the copyright. To state a case:—I ask a popular clergyman to give me a sitting for his portrait; he consents, and I only send, say, half a dozen cabinets for his acceptance. I am told that the copyright of such a portrait is vested in myself alone, and no one has any legal right to copy it without my consent. You will see no money passes between us, and the clergyman's coming to be photographed is tantamount to his consent. I shall be glad to know if this is absolutely correct.

I have also been informed that it is now the custom of many photographers in London to charge twenty-one shillings for granting permission to any publishing firm to reproduce any copyright photograph. Is this also correct? I hope it is, for the barefaced way one's photographs are reproduced without permission demands some kind of check, and the photographer is only within his rights to demand a fee. I have had scores of photographs copied, and they think they are very generous if they purchase a photograph at two-thirds the price and attach your name to the reproduction.

Some editors of papers are honourable enough to send a fee for photographs supplied, even unasked; I have met with two such instances lately. This is as it should be, and promotes a much more healthy feeling. Kindly reply in your next issue.—I am, yours, &c.,

London-road, Ipswich, November 12, 1893. W. VICK.

FILMS *VERSUS* PLATES.

To the EDITOR.

SIR,—I notice in the JOURNAL of the 10th inst. a letter by W. J. Stillman, and am not going into the question of "Films *versus* Plates," as your readers all know by this time I am in favour of films; but I must object to the *last few* lines of his letter, where he says, "But a photographer who depends on amidol for a rapid work can have only a *limited* knowledge of what can be done."

Now, I strongly object to these remarks, as I have written, said, and proved that amidol, when used by one who knows how to use it, is the best developer I know for rapid work, and I am sure both you and your readers have samples of really instantaneous work done by me and developed with amidol, that prove what I have said about that developer is right. As to whether I work it at the $\frac{1}{50}$ or the $\frac{1}{100}$ cannot matter a cent as long as I am able to catch the object moving so as to be sharp, and as to one having a limited knowledge of developing because he uses amidol, well, such a remark I call absurd.

I do not say that other developers are not as good in the hands of those who can use them, as every one has a right to have his own opinion about such matters; in fact, my opinion is, it is not the developer, but the man who uses it, as one used to development ought to be able to get good results with any developer. The only reason I have noticed these remarks are that I have written one or two articles for the papers and Year-books on amidol, and do not fancy being told that I have a limited knowledge of what can be done.

Mr. W. J. S. is quite right to use any developer he may fancy; but certainly he must give others that right without making such remarks.—I am, yours, &c., A. R. DRESSER,

Springfield, Bexley Heath, Kent, November 11, 1893.

THE BURSTING OF AN OXYGEN CYLINDER.

To the EDITOR.

SIR,—I notice in to-day's paper that another lamentable fatal accident has taken place with an oxygen cylinder, and I wait the arrival of a Bradford paper for fuller details. The report that the cylinder was of cast iron is surely a mistake; but, if a *steel* cylinder exploded with the shock of a fall of only two or three feet, it is high time that the Board of Trade, the oxygen companies, the merchants, and the users of cylinders defined the best and safest method of handling these dangerous goods. I called a meeting of my staff to discuss the matter to-day, and it was suggested the cylinders might be cased in leather, stout American cloth, or thick canvas sacking, and delivered home on a barrow instead of per bearer.

And yet our meeting was no sooner over than seven cylinders were delivered from a lorry at our goods entrance, and laid down naked upon the hard Whinstone kerb.

I maintain that the highest intelligence should be directed to the minimising of risk to those called upon to handle such goods, who, like the unfortunate messengers, carters, railway men, and others, may be quite ignorant of their dangerous nature. It would be interesting to know whether there have been more accidents since the introduction of compressed oxygen than with that made from a retort and filled into gas bags.—I am, yours, &c., ARTHUR SEET.

November 9, 1893.

MR. WOODBURY AND THE PAGET PROCESS.

To the EDITOR.

SIR,—In reply to Mr. Wilson's letter to you regarding my publication of the Paget method of developing printing-out papers, I hasten to set right the evident misunderstanding.

At the time the matter was divulged to me I was making experiments in the same line myself, and had already succeeded by a preliminary conversion of the free silver into chloride and iodide, using the Paget lantern-plate developer.

I was then informed of the method devised by Mr. Wilson using bromide of potassium. This I found superior to my own method, but was asked not to divulge same, nor have I ever done so until the publication of Mr. Wilson's method in a recent issue of your magazine, when I immediately wrote an article on the subject, which appears in the issue of the *Photographic Times* now in the press. I send you an advanced proof herewith, and you will see that I give the fullest credit both to Mr. Wilson and the Paget Prize Company.

In the formula I gave in the *Photographic Times*, and to which Mr. Wilson refers, an iodide is used. A similar process I tried nearly eight years ago, the only difference being that I substituted the Paget lantern-plate developer for an old ferrous-oxalate one. I am willing to give every credit to the Paget Company for the perfection of a simple and effective method of development, far superior to anything else I know.—I am, yours, &c., WALTER E. WOODBURY.

New York, October 28, 1893.

MR. H. P. ROBINSON AND EXHIBITIONS.

To the EDITOR.

SIR,—The letter from Mr. H. P. Robinson in the BRITISH JOURNAL OF PHOTOGRAPHY, of the 3rd inst., raises an important question relating to Exhibitions, and that is, the right he assumes for a small body of photographers to dictate to societies and exhibition committees throughout the country the rules and conditions under which their exhibitions should be conducted; coupled, too, with the suggestion concluding his letter, that those that are not arranged in conformity with the regulations that these men approve of for the time being, should be boycotted, that the ever-increasing army of photographers should be persuaded to prevent such exhibitions being successful by refusing to contribute to them.

Surely, it is time that those who have the management of Exhibitions, and, still more, the far larger class, those who contribute to them, should protest most strongly against the arrogance of a clique presuming to regulate in such an arbitary manner all competitions, and, if consenting to officiate as Judges, overriding at their own will the published conditions under which photographers have been induced to contribute.

Mr. Robinson's reference to the Photographic Society of Great Britain as an example to follow is, at the present time, singularly inopportune; its recent exploit in medal awarding could only be quoted as an instance of what photographic societies *should avoid at any cost* if they have any regard at all for the progress of photography, either pictorially or technically. What would Mr. Robinson, or other leading workers, have said if such a production as *Watching and Waiting* had been awarded a medal at any suburban or provincial society's exhibition, even had it been in a novices' class. In such an instance, instead of estimating work fairly on its merits, the "judging" seems to consist in the judges airing their eccentricities, and passing over meritorious work in order to favour that that is treated according to their peculiar prejudices. There are many men whose views are so warped and distorted by the extremes to which they carry their "fads," that it is an absolute impossibility for them to form a fair judgment on any work submitted to them.

Judging at exhibitions is a most difficult and delicate task, and no one is more anxious than the writer than awards should only be given for thoroughly good work; but how can Mr. Robinson expect photographers to respect the decisions and deliberations of these twenty-four when they marked by such glaring inconsistencies? What one will extol as the only true faith in matters artistic, others will consider rank heresy, and even the same man will not always hold the same opinion for twelve months at a time. There are many, who, if they are not so skilful as photographers, are still equally competent to arrange conditions and rules under which work shall be accepted for competition. The capricious awards and decisions of many of these twenty-four whom Mr. Robinson considers should lay down the law for all societies, *are far more in need of reform than the conditions and rules of the exhibitions that they condemn.*

The remark that "the hunt after medals is chief amusement for which recent exhibitions seem to be instituted,' might with greater propriety have been omitted from the letter of a man who has taken so many medals as Mr. Robinson has done; considered in conjunction with his view that the "best exhibitions are those that offer no medals," it would seem that they who have taken scores of medals in the past are those who would have medal awarding abolished, as they are unwilling that the coming generation of photograpers should share with them the honour and distinction that medals unquestionably give, although the conditions of success are increasingly difficult each year, by reason of the larger number of men producing throughly artistic work. Nothing teaches so much as to see our own work side by side with that of others. Without medals most suburban and provincial exhibitions would not attract the good work that they frequently receive, and many would never have the opportunity of seeing and learning from the productions of those who excel in pictorial photography.—I am, Sir, yours truly,

Dacre House, Arundel-street, Strand, W.C. HENRY W. BENNETT.

THE PHOTOGRAPHIC EXHIBITION.

To the EDITOR.

SIR,—Will you kindly allow me to say a few words in reference to a subject which has been treated in a strangely unjust manner? I allude to some of the awards in the late Photographic Society of Great Britain's Exhibition, and I particularly allude to Nos. 55 and 254.

To me it seems altogether strange that so many should get hopelessly fogged in reference to these awards, and that so many otherwise intelligent persons cannot see that the ordinary canons of photography are in these cases entirely inapplicable, and consequently improperly applied. The absurdity of some of their conclusions ought at least to make them pause and consider whether there is not some error in their premises, which, if true, would make the Judges of this Exhibition not only grossly incompetent, but simpletons and fools into the bargain. Dare these gentlemen draw such a corollary as this? I think not. Even the most reckless amongst them should certainly hesitate to apply such conclusions to men whose great merits have shed so distinct a lustre upon the profession. This being the case, it is certainly amusing to read the effusion over the *nom-de-plume* "Free Lance" in your last issue. This gentleman

simply justifies his assumed name, for he applies with singular felicity those principles to writing which governed the actions of that historically notorious personage. Free he most certainly is in reckless assertion, without the slightest attempt to justify it by legitimate criticism or a fair statement of facts. He certainly displays no modest diffidence in slashing at the adjudicators' feelings, or in passing his cock-sure judgment upon their decisions. Yes, certainly, photography would become a laughing stock for the whole world if its dignity and character depended upon such champions as this; but, thank fortune, there are too many good and true men in its ranks who can take good care of its well-being without the assistance of rant or the reckless display of ignorance of the fundamental principles of honest criticism.

Allow me also to make some remarks upon No. 254. I found it, to my surprise, a modest, unassuming, and refined picture, one in which the principles of art are as successfully carried out as the materials and controlling conditions will permit. I found neither dirtiness, ignorance, nor want of experience displayed in its manipulation. On the contrary, I found clearness of tint with knowledge in its lines, composition, and treatment of its light and shade, in short, a well-conceived and harmonious picture completely representing its title—

> "*Watching and Waiting*, weary and sad,
> Hope seems departing in dim twilight clad.
> Yet still she sits watching upon the cold stone,
> While moonbeams seem mocking that true heart so lone."

You can, therefore, infer from what I have already written that I approve the decisions of the Judges, and, in addition, I must also say that I admire the moral courage which can treat with disdain those critics whose ignorance and conceit are so much more conspicuous than their knowledge, discrimination, and taste.

In conclusion, let me congratulate those gentlemen who have inaugurated and carried to a successful termination the Salon Exhibition. They have demonstrated that art wedded to photography is now a recognised fact, with full certainty that no man can sunder them. Let me also advise those who have so thoughtlessly assailed some of the awards in the Photographic Society of Great Britain Exhibition to gain a little knowledge of that art. It will save them from such folly in the future, and will, to a considerable extent, atone for their injustice in the past.—I am, yours, &c., A. R. E.

November 13, 1893.

BRISTOL EXHIBITION.

To the EDITOR.

SIR,—Anybody who wants to improve the world, or contribute his little mite towards that doubtfully desirable object, should proceed very cautiously, or unlooked-for effects may be produced. In my desire to see some reformation brought about in provincial Exhibitions, I wrote what I thought was a very mild and innocent letter, explaining why I could not exhibit, to the Hon. Secretary of the Bristol Exhibition, and it seems to have sent that official into a "ten-knot gale of royal rage" at sight, and he appears to be so pleased with his reply that he not only sends what he apparently mistakes for an answer to the two papers in which my letter appeared, but also to another, whose readers must wonder what it is all about. He does not give me the least credit for honesty of purpose, but, "in anger insignificantly fierce," accuses me of animus, misrepresentations, and evident and petty desire to damage the Exhibition, also of discourtesy, a desire to coerce others, and to play "Sir Oracle." Brave words, but not convincing. They neither confute my letter, nor prove anything, except, perhaps, the ten-knot gale to which I have alluded. I still maintain that, if photography is to be advanced, the best work must be attracted to Exhibitions, and that will never be done while exhibitors find medals are so numerous and cheap as to afford no incentive to excel, and so easily won that no lasting value can be placed upon them. The ease and number attract mediocrity, and the diminished value produced by lack of rarity repels the best workers.

In a mysterious paragraph Mr. Bond refers to some correspondence at a former Exhibition, which he says I must remember. I am afraid he places more importance on this correspondence than I do, for I have only a dim recollection of something of the kind with somebody at Bristol, but I don't think it was Mr. F. B. Bond. On referring to my register of pictures sent to Exhibitions, I find I exhibited at Bristol ten years ago, and was awarded a medal for a *genre* picture for a landscape photograph. It is possible I may have called attention to the absurdity, just as I am now calling attention to the absurdity of offering a medal to about every other exhibitor.

I must admit I overlooked the part of a paragraph empowering the Judges to withhold medals for want of merit; in the prospectus it is mixed up in a paragraph about the Hanging Committee, and escaped my attention.

Mr. Bond accuses me of discourtesy in not intimating to him that I intended to publish my letter. I do not see the discourtesy (it was not *his* letter I was publishing without his permission), but I ought to have seen the necessity of calling his attention to it if I may infer, from a few words in a letter I received from him, which he must excuse me for quoting, that he never reads the photographic journals. He says, "I don't remember to have seen the document you refer to as drawn up by the Photographic Society of Great Britain." This was the "Rules and Recommendations" which appeared, and were commented upon, in every paper. Obvious moral: The photographer who neglects the photographic press is liable to get into trouble.—I am, yours, &c.,

Tunbridge Wells, November 10, 1893. H. P. ROBINSON.

To the EDITOR.

SIR,—Mr. H. P. Robinson's letter of the 3rd inst. is, to my mind, nothing more nor less than a direct and premeditated attack on the Bristol Photographic Society and its exhibition. Mr. Robinson's only reason for writing seems to be that, as the rules are framed, he cannot exhibit any of his unmedalled work, and therefore he wants to try and stop other workers from sending in exhibits.

To hide this reason, he makes the conference rules a cloak.

If Mr. Robinson had such great faith in the conference rules, why did he not further back them up by exhibiting some of his pictures at Pall Mall this year? Mr. Robinson must not forget that, in years gone by, he was just as eager to gain awards, and sent to quite as many exhibitions, as the so-called "*pot-hunter*" of the present day.

Possibly Mr. Robinson's "*bushel basket is full now*," and therefore he does not want any more.

Perhaps he would have been satisfied if they agreed to place his exhibits in the centre of a wall and surround them with the less fortunate workers, so that his work would have been shown to the disadvantage of others, as notice the late exhibition held at the Dudley Gallery.—I am, yours, &c.,

Central Photographic Club, Coleman's Hotel, Henrietta-street, Covent Garden, November 14, 1893. JOHN H. AVERY.

YELLOW STAINS ON P.O.P.

To the EDITOR.

SIR,—We gladly welcome Mr. Pentney's valuable contribution to our information on this subject, and, with his permission, we will give it the wide-spread circulation it desires by embodying it in the next edition of our pamphlet on the working of P.O.P.

We confirm Mr. Pentney's view that Mr. Bothamley was not asked to investigate the causes of staining after fixing. We limited the scope of Mr. Bothamley's inquiries into the matter, because all the correspondents who wrote on the subject had found the staining occur only in the earlier part of the manipulations.—We are, yours, &c.,

THE BRITANNIA WORKS COMPANY, LIMITED.

Ilford, London, E., November 10, 1893.

OPERATORS AND THEIR SPECIMENS.

To the EDITOR.

SIR,—With reference to a letter in last week's JOURNAL by an operator whose specimens have not been returned, I may say, as an employer, that on advertising some time back for a retoucher, I had some forty or fifty replies, and among them about four did not enclose specimens with their letters, but in a separate package by Book Post, with no name or indication of who the sender was. As several came from London, the post-mark was of no service as a guide, and I had nothing to do but guess at the handwriting. It is very possible that some of these went wrong, but I never heard. Assistants in want of a situation might do well to remember that a photograph of themselves with the word "self" marked at the corner does not convey all that is needed to identify their work from others.—I am, yours, &c., ERNST LAMBERT.

32 *Milson-street, Bath.*

THE ACTION OF A LENS SIMPLY EXPLAINED.

To the EDITOR.

SIR,—Were it not that Mr. Taylor's letter (published in your issue of October 20) is an unjust and ungentlemanly attack upon me, I should be inclined to smile at the ridiculousness of his statements.

I entirely deny having copied Mr. Taylor's article (the use of his diagram I have already explained), and challenge you to reprint the two articles in *full* in your magazine, and take the opinion of your readers. The idea of comparing a sentence here and there, and taking such ones as, "The angle of view of a lens is determined by the relation of its focal length to the measurement of the image it can best define," is absurd in the extreme. Does Mr. Taylor claim any originality for this statement? That my own sentence is almost the same can only be regarded as a coincidence—and not a very extraordinary one either, considering it is one of the fixed laws of photographic optics, explained in every work upon the subject.

Then, again, the sentence, "As sound is transmitted by a wavelike motion of this luminiferous ether." The comparison of sound and light-waves is surely not original with Mr. Taylor? He will find it in almost every elementary book or article on light.

With regard to the explanation of the reflection of light from opaque bodies, Mr. Taylor's comparison is, to say the least, very unfair. He takes half of one of my sentences and compares it with a whole one in his own article. The true comparison is as follows:—

Mr. Taylor's Article.	*Supposed Plagiarism.*
A surface capable of being seen must be, to some extent, rough. The roughness acts in this way: Waves of light meeting the surface and reflected from it are broken up by the rough particles. Each projecting particle becomes a centre, from which reflected waves of light spread out in all directions.	Waves of light meeting the surface of an object, provided it be to some extent rough, are broken up. Each particle becomes a centre, from which waves of light are reflected and spread out in all directions; each point becomes, as it were, the stone in the water, sending out waves of light which reach the eye, where they are brought together again, and condensed to a similar point on the retina; and in this way we see the object.

It will be seen that I am working on a different illustration altogether, having previously compared the light undulations with those produced on a still pond when a pebble is thrown in, an illustration by no means new. Your readers will, I hope, at once see the injustice of the comparisons.

I will not take up more of your space, but only ask you, in justice to myself, to print the two articles in parallel columns *in their entirety*, and let others judge of the truth of your or Mr. Taylor's accusations.

With regard to the language and epithets Mr. Taylor has thought to make use of, I will say nothing, but try, at least, to remain a gentleman.

—I am, yours, &c., WALTER E. WOODBURY.

New York, October 30, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange Watson's Premier 15×12 three double backs, for Watson's Acme 12×10 three double backs.—Address, H. L. MOREL, Market-place, Nottingham.

Wanted to exchange magic lantern by Newton & Co., with four-wick lamp and screen, also sixty slides—subject, Holy Land—and a few comic ones, for a whole-plate portrait lens by a good maker.—Address, D. G. THOMAS, 51, Hope-street, Wrexham

Will exchange quarter-plate camera, lens, double dark slide, and tripod for magic lantern with four-inch condenser.—Address, W. H. HEMING, East Cliff Studio, Whitby.

Dallmeyer rectilinear lens whole-plate, complete, list price, 6*l.* exchange for portrait lens half-plate or whole-plate by good maker. Address A. J. TILEY, 203, Newport-road, Middlesbrough.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

A. W. CARTER.—Messrs. Ross & Co. will shortly issue the Goerz lenses.

NON PLUS.—There are no plates made by Pettit in the market. The "Sandell" plate is probably what you require.

GEO. B. TURNER.—A parabolic reflector may be used for ordinary lantern exhibitions, but should never be employed for photographic enlarging.

PYRO.—The cause of the stains is that the prints were washed in water that was not clean, probably in a dish contaminated with hyposulphite of soda.

C. C. C.—In quoting the weight of cameras and slides, it is not usual for makers to include in the weight the plates they are to carry. If the apparatus weighs only what the catalogue states, there is no cause for complaint.

S. W. E.—We fear the N. A. P. P. will not assist you, as you are not a member. Even if you were, we doubt if it would be otherwise, as we have never heard of their taking proceedings against any one for infringement of copyright.

T. W. STILES.—Enamelled iron dishes may be used with safety for toning prints provided the enamelled surface is perfect. If it is not, the gold will be precipitated. Porcelain or earthenware dishes are far more reliable for gold solutions.

J. P.—The portraits are fairly good as portraits, but they are spoilt as pictures by the light background, which is about the same tint as the faces. They would have been better also if less front light had been used, so that they would have had greater rotundity.

T. W. C.—Although the orthographic lens is a very good one for many purposes, it has but a very small commercial value. If you advertise it at the price you suggest, it is very doubtful if you will obtain a purchaser. Indeed, it is doubtful if you would at half that price.

C. J. EMENY.—By removing the Steinheil lenses from their present mount, and setting them in one shorter by half an inch to an inch the area of illumination will be increased to the dimensions required. A small stop will have to be employed. Do not tamper with the original mount.

W. JENKINS.—All that has been published on chromo photo-mechanical printing has appeared in our pages from time to time. No work specially devoted to the subject has been published as yet, and we doubt if one will be at an early date, as most workers—that is, those who work commercially—treat the subject rather as a trade secret.

A ROGERS.—It would certainly be illegal to make lantern slides from music, although it may bear the intimation that the song may be sung in public without licence. This does not give permission to make copies of it; indeed, on most works it is stated that making copies will be an infringement of copyright, and will be dealt with as such.

H. T.—After starch has been made a few days, it becomes thin, so your experience is not unique. In that state it should not be used, for it has then lost much of its adhesive properties, and, furthermore, it is likely to act injuriously on the prints. Starch paste, when used for mounting photographs, should be made fresh the day it is used.

B. RENNIE.—If the steel plate of the rolling press is as rusty as described, we imagine that it will be better to obtain a new one. When rust has eaten very deeply into a plate, it will frequently cost quite as much to have it repolished as to purchase a new one. If, before the press was stored away, the plate and rollers had been coated with beeswax, they would not have been affected by the damp.

A. BENTON.—The best extemporary light for taking portraits at the fancy ball is either the magnesium or the aluminium flashlight. If the building is illumined by electric light, cannot you arrange to have an arc light at your service? With that, and one or two extemporised reflectors and screw, more satisfactory results could be obtained than with the flashlight, and the sitters would feel more at ease.

JOHN DICKIE.—1. Zinc plates ready for use may be had from such firms as Winstone & Co., Shoe-lane, E.C., or Hughes & Kimber, West Harding-street. 2. The former firm supply the paper. No cement is required to attach the transfer ink to the metal, the pressure alone is sufficient. 3. Fine plaster of Paris, suitable for the purpose, may be had from any of the stereotypers, and plumbago from those who supply electrotyping materials, or philosophical instrument sellers.

F. J. QUICK.—1. Ordinary sheet glass will suffice. Extra white glass may be had at an additional cost without corresponding advantage, and it is liable to change colour. 2. Yes, if the curtains be thick enough. 3. Quite a matter of convenience. 4. No. Much on the subject may, however, be found in the back volumes of the JOURNAL. 5. A very suitable material may be had from the tailors' trimming warehouses under the name, we think, of "casban." 6. Suitable red glass can be obtained from any of the dealers in photographic materials.

SUNLIGHT says: "Having a studio facing due south, I am anxious of obtaining a subdued light; in fact, it is absolutely necessary. I shall, therefore, esteem it a great favour if you will give me your advice as to the best material and means to obtain this end."—During the winter months thin muslin strained on light wooden frames, so that they are easily removed when the sun is not shining, will be the most convenient means. In summer the glass itself should be stippled over with starch paste, to which a little whiting has been added. This is readily cleaned off when the dull weather again approaches.

OMEGA writes: "I should be obliged if you would tell me whether I am right as to the quantity of acids used in converting a half-sovereign into chloride of gold. I am not sure, but I think it was one and a half ounces muriatic acid and half an ounce nitric acid with a small portion of water. 2. When dissolved, do I evaporate to dryness before diluting and neutralising?"—In reply: 1. Two and a half ounces of the former acid to one of the latter, with three ounces of water, is a better proportion, but a little more than a quarter of this quantity will suffice to dissolve the half-sovereign if assisted by gentle heat. 2. Theoretically, the solution should be evaporated, but in practice it is not necessary.

CURLED GELATINE FILM NEGATIVES.

We direct attention to an article by Mr. S. Bourne, on another page, in which this gentleman speaks of the inconvenience experienced by the tendency of thin celluloid film negatives to curl into a scroll when dried. This is a topic in which many, ourselves included, feel much interested. Every allowance can be made for feelings of irritation experienced by the individual who, having developed and washed his pellicular negatives, pins them up by one corner to dry, only to find next morning that each one has in course of drying curled itself up as if trying to rival the dimensions of a pencil case, and resisting with all its springy power every endeavour of the artist to get it opened out and laid flat.

Fortunately, it is not difficult to reason from the evil to its cause, and from that to the cure. While we write we have on the table beside us a number of negatives taken during the last Convention at Plymouth on that particular kind of Eastman rollable film made for the Kodak, in which instrument the exposures were made. These are all bright and clear, and, what is more to our purpose at present, they are all flat, in the sense of there being not the slightest indication of curling.

On the other hand, we have negatives taken on a portion of the *same* spool as those mentioned, and developed in the same way, but which are now curled up like a cedar pencil, in which state they were when dried. It is very evident that, all the other conditions being equal, there must have been something different in the subsequent treatment of the two sets of negatives, that is, their treatment after having been taken out of the washing tank. Such was really the case.

Every worker with gelatine knows that, after having been wet, it contracts with great force as it becomes dry, and certain industries, not related to photography, are based upon this property. When a thin film of celluloid has received a coating of gelatine, which, in course of treatment, is softened and surcharged with water, it naturally follows that, if during drying there be no counteracting agency, the contraction of the gelatine film must overcome the resistance of the celluloid, which does not undergo any contraction. If the celluloid film were thick and strong enough to remain unaffected by the shrinkage of the gelatine, then would the latter succumb, as it were, to the resistance it met with, and dry without shrinking.

The application of this principle to the flat drying of a rollable film negative is not difficult. On taking it from the washing trough, remove all the surface water by a cambric pad, as we described in an article recently on the quick-drying of negatives, and then allow the drying to be effected under conditions which will prevent the film negative from assuming other than a perfectly flat position. Among these may be mentioned placing it between the leaves of a folio, which must be kept closed under pressure, if necessary; cementing by the margins to a plate of glass, or anything flat and rigid; super-imposing upon it a thin and moderately heavy frame, which shall rest upon the margins only. By employing these or any like means for keeping the negative flat until complete desiccation has taken place, the negative will ever afterwards give no trouble in printing from any tendency it may have to curl.

When not in the printing frame, film negatives should be stored either between the leaves of a folio or between tw sheets of millboard or stout card, round which one or two Indiarubber bands have been passed.

What has been said applies to the prevention of curling. But it also effects a cure in the case of those that have already become curled. To this end it is only necessary that they be opened out perforce and soaked in water until the gelatine has absorbed as much as possible, when the treatment previously recommended for drying must be had recourse to.

We shall be pleased to hear the opinions of others relative to the flat drying of negatives taken on *thin* celluloid

PHOTOGRAPHIC PIRACY.

Complaints are frequently made that the existing law on copyright is in a very unsatisfactory state. But, unsatisfactory as it is, it is amply sufficient to reach a certain class of offenders when it is put into force. Last week, one Walter Perry, described as a picture dealer, was mulcted in penalties and costs amounting to a little short of three hundred pounds, with the alternative of fifty-six weeks' imprisonment, for infringing the copyright of several popular modern engravings and photogravures, the property of different well-known publishing firms. The negatives were also impounded. This exemplary sentence was, doubtless, partly due to the fact that the defendant had previously been fined for a similar offence some time back at Manchester, and in connexion with some of the pictures included in this prosecution. The works pirated included such pictures as the *Village Wedding*, *The Ruling Passion*, *The Day of Reckoning*, *The Roll Call*, &c., the prosecutors being Messrs. Agnew & Sons, Tooth, H. Graves, Arthur Lucas, Mendoza, the Berlin Photographic Society, and others.

It is exceedingly hard upon publishers who have possibly paid several hundreds of pounds for the copyright in a picture, and perhaps a similar sum for the engraving of a plate, to have the work pirated and its sale materially injured by un-

principled photographers. Although the piracies are often publicly sold, it is, we are told, exceedingly difficult to reach the real offenders—that is, those who actually produce them. Not very long ago we saw a number of photographs, including most of those enumerated, displayed against a hoarding close to one of the principal railway stations in London. The prints were about fifteen inches by twelve, were of excellent quality and neatly mounted, with large margins ready for framing. The price asked for them by the itinerant vendor was, if we remember rightly, four shillings or four and sixpence per pair. At that price, considering there must already have been one or more profits on them, one would have thought that it would not have been worth the risk incurred by the producer. In cases of piracy of this description, the prosecutors usually try and get at the principal delinquents—that is, those who make the negatives, although the vendors of the prints are equally liable to the penalties.

The law is just the same with regard to the copyright in photographs as it is with engravings, and the penalties for infringing it are the same in both cases; yet photographs are pirated daily, and we seldom hear of prosecutions in connexion with them.

Under the present law the owner of a copyright has two courses open to him upon its infringement. He can either proceed summarily before magistrates, as in the case just cited, or sue in a superior court for damages, injunction, and forfeiture. Not long ago a case of this kind was decided in the Queen's Bench Division. It was this: A firm of Continental fine-art publishers issued photographs of works in which they held the copyright. A London firm, who advertise on a very large scale, had one of these photographs reproduced by lithography, to be used in connexion with one of their advertisements. An action was instituted for damages, and an injunction to restrain farther use of the pictures, and forfeiture of all copies, stones, &c., asked for. In the result the plaintiffs obtained substantial damages and costs, an injunction restraining further issue of the copies, and forfeiture of all the prints in the defendants' possession, amounting, we were told, to some hundreds of thousands. These proceedings were taken under the International Copyright Act, which confers upon foreign artists the same rights in this country as they enjoy in their own.

Defective as the existing copyright law undoubtedly is in some respects, it is manifest that it is equal to protecting the general run of copyright works if put into force. This is, however, seldom done by photographers, though, as we have just mentioned, their works are being pirated right and left, particularly by some of the illustrated periodicals. The maximum penalty, according to the law, is ten pounds for every copy sold. This would be no slight matter in the case of a large circulation, if enforced.

A very flagrant example of the piracy of photographer's work is many of the cheap varnished lithographic views, bound up as albums, of holiday resorts, produced in Germany. In many instances these are direct piracies of the local photographer's productions, and from their being sold at such a cheap rate they must necessarily materially injure the sale of the originals. If proceedings were taken when this is the case, there is little doubt that substantial damages could be recovered. In the case of infringements by the illustrated press, it is doubtful if sueing for damages would be the best procedure, inasmuch as it might be difficult to prove that the sale of the photographic prints had been seriousiy damaged by the piracies of them in a periodical. Therefore, under these circumstances, the better way would probably be the summary, and less expensive, one before a magistrate.

It will be noticed that almost always, when proceedings are taken for infringing the copyright in engravings, publishers combine and work together in the prosecution. But this is rarely, if ever, the case with photographers. They appear to have very little unity amongst themselves, even when it would conduce to their mutual welfare.

PLEA FOR AN HISTORICAL MUSEUM.

VERY numerous indeed are the applications continually being made to us relative to whether this, that, or the other thing is new; and nearly equally numerous are the inquiries made as to where one can see apparatus, at one time well known, but which have now fallen into desuetude, having been supplanted by other and more improved forms of the same.

This implies the desirableness of establishing an historical museum, one in which can be seen a history of photographic advance from the earliest times up to the present moment. We know that historical collections in a more or less perfect form exist, or are being made in connexion with a few clubs and societies, and are to be found in the hands of private individuals; but, in the former, the examination of these is, in a large measure, restricted to such of their own members as have an archæological turn of mind, while the latter naturally may not feel inclined to throw open the doors of their private residences for the benefit of an inquiring public.

What we advocate is the establishment of a public museum, to which all interested might have ready access, whether they belonged to any photographic society or not, one which shall be open at all times, and be placed under the selective management of a small committee competent to deal with the matter, and who, as such, should not necessarily be connected with any photographic society.

It is possible that some of our public museums, *e.g.*, the South Kensington or Patent Museums, might be found to willingly allocate a corner of the space at their disposal for so worthy an object were proper representations made to the respective authorities, and we feel certain that, were this effected and confidence in the managing committee established, many of those who now possess such objects of historical interest as those we have in view would readily part with them, even for a terminable period, for such an object.

We have often thought it a pity to see, at auction sales of private scientific effects, objects replete with interest from an historical point of view sold for almost nothing. For example, a lens, guaranteed to be that by which Daguerre took many of his pictures, brought seven shillings and sixpence; a collection of prints, together with the paper negatives of the time of Fox Talbot, only about half of this sum; a Sutton's panoramic camera, complete in every respect, including a costly spherical lens for a dozen shillings; and so forth with regard to other articles which might fittingly stock a public museum, but which private individuals could not afford space for in their possibly already crowded shelves.

What an interesting collection might be made of cameras and lenses from the earliest period, of panoramic and pantascopic cameras, of stereoscopic cameras and stereoscopes, printing frames, stands, roll-holders, projecting lanterns, and the thousand other things that are for years suffered to accumulate on one's hands until by death or the removal into another house the fiat goes forth to clear them all away. If a well-

accredited public museum existed, many who now break up their apparatus, rather than send them to the auction room, where, as they say, they fetch only insulting prices, would gladly present them to such museum. We spoke with one of this class only quite lately, and he had actually broken up some apparatus and given it to his servants to use as fire-lighters for the reason given. As with apparatus so with books. Fortunately, the Free Library of the Patent Office, in Southampton-buildings, Holborn, contains a valuable collection of books relating to our art, more particularly those of recent and current date, and, as this is daily open to the public from ten o'clock in the morning till ten at night, and contains all the best works and serials devoted to photography, the necessity for any other library of a public nature does not appear, except this, that a museum would take charge of albums or portfolios of pictorial works of a by-past epoch which could not find a place in the Patent Office Library.

We throw out this plea for an historical museum of photography in the hope of some energetic and public-spirited individuals taking it up.

VARIATIONS IN WINTER DEVELOPMENT.

Two or three weeks back we referred to the necessity that arises at this time of year for the adoption of special precautions in order to ensure something like uniformity in the conditions of working in the dark room, our remarks then being mainly confined to the question of temperature. Although this forms the chief point of difference between summer and winter working, there are other circumstances that may be examined, in which, if temperature cannot be wholly excluded, it plays only an indirect part.

In our previous articles we alluded to the desirability of preserving a certain uniformity of temperature in the dark room, but more especially of the solutions themselves, and of course, if this matter were rigorously attended to, there would be little ground for further trouble. But, whatever may be the theoretical possibilities in this direction, it is absolutely impossible in practice, even in the most perfectly arranged establishments, to maintain a really uniform temperature throughout the year, or indeed, in view of the sudden climatic changes experienced at all seasons in this country, from day to day.

It may be found comparatively easy, in the manner we suggested, to secure a constant temperature of the developing and other solutions by the use of warm or tepid water in mixing them, and to thus ensure that their work is at least commenced under fixed conditions. But it is obviously impossible to keep the atmosphere of the developing room automatically or otherwise at the same normal temperature, and consequently, but especially in cold weather, the solutions exposed as they are in open dishes must tend constantly to change. It is in the cold season, when the outside temperature may be thirty, forty, or even fifty degrees below that selected as the normal, that the difficulty will be greatest, for under such circumstances, even if actually *hot* when poured into the dish, the developer will in a very few minutes have sunk far below the desirable point.

In well-equipped establishments—that is to say, in the professional laboratory, fairly well-heated and ventilated, and where work is constantly proceeding with regularity, the trouble will be at the minimum, and is easily met; but it is the amateur, who perhaps only has occasion to go to work at irregular intervals, and with inadequate means of securing the necessary conditions, who will be the greatest sufferer. Let him be as careful as he will, say, in warming his solutions as directed, he omits to take into account the rapid fall in temperature that goes on in the chill atmosphere of the unheated room; the developer acts too slowly, and, believing he has done what is necessary, he wrongly attributes the result to under-exposure, or to insufficiently energetic solution. He strengthens it up with alkali, and presently finds he has got all he can out of the plate, and that the result is far from satisfactory. Then he proceeds to increase his exposures, and so blunders on from bad to worse.

Now, under conditions such as these, although it may not be practicable to secure uniformity of temperature, it is possible, by other means, to minimise the trouble that arises from accidental variations. It is well known that developing solutions behave very differently as regards the proportions of their ingredients, but more especially the quantity of restrainer required, when the temperature is considerably altered. Thus a pyro solution may be used in winter with a proportion of bromide that would be altogether inadequate in even moderately warm or temperate weather, while some of the newer developers may safely, if not indeed beneficially, be employed without restrainer at all.

Some years ago we conducted a series of experiments with a view of testing the effect of temperature in development, pyro and ammonia being employed, and the solution being used at various temperatures artificially reduced to nearly the freezing point. The result showed that as the temperature was lowered the necessity for bromide was reduced, and *vice versâ*, and that the brightness and vigour of the image increased with the cold, while softness and a tendency to veil resulted from a warmer solution. At the same time, the lowered temperature greatly increased the time occupied in development, and almost necessitated a considerable reduction in the proportion of bromide, or a corresponding increase in the quantity of alkali, the former course proving the preferable one.

During the next three months or so we expect to hear many complaints of failure from under-exposure and insufficient density; but where such occur we would strongly counsel, not an increase of exposure, nor a strengthening up of the developer with alkali, but a reduction of the proportion of bromide, the temperature of the solution, it being always understood, being raised to 65° or 70° to commence with. Where pyro is used in conjunction with sodium sulphite the proportion of the latter may also be reduced to the lowest available point, as this too has, especially in cold weather, a retarding action in development.

Hydroquinone is scarcely the developer that would be selected for winter use—for negatives, at least; but, if it should be used, bromide must be altogether dispensed with, and sulphite seems scarcely needful at any time. With this developer, too, the temperature is of more importance than with any other, a very few degrees making all the difference between fairly rapid and altogether tedious development. For this reason alone hydroquinone is scarcely a suitable agent for winter use, particularly now that there are other equally clean and, at the same time, more rapid ones.

Para-amidophenol and its hydrochlorate may be used with advantage, without bromide, but the sodium sulphite in this case cannot be dispensed with, its function being apparently, as with amidol and metol, of equal importance with that of the alkali. The very low degree of solubility of these substances

especially the former, renders it necessary to see very carefully to the temperature of the solutions, otherwise much of the active agent may crystallise out.

With amidol and metol, which appear to promise best as winter developers, it is a question whether the bromide can be safely omitted altogether. With some plates, no doubt, it may, but with the majority it will be found safer to use it in moderation. Thus, where in summer weather we have used as much as one grain of bromide to the ounce of developing solution, when the very cold season comes we should not use more than one-tenth of that quantity, or even less where the plates are of a particularly clear character.

It follows, from what has been said regarding the increased effect of bromide in retarding development in cold weather, that at the present season the growing practice of using the developer repeatedly is not likely to prove as successful as during the summer months. It must be borne in mind that each film developed adds a very considerable proportion of bromide to the developer—a fact in itself sufficient to account for a good deal of want of uniformity—while, unless the temperature is attended to after each development, the gradual fall added to the increased restrainer will prove fatal.

For negative purposes, where ferrous oxalate is used, the bromide may be considerably reduced, if not altogether done away with; but for positive work both bromide and acid will be better retained in order to keep the whites clear.

A Prize Shutter.—The prize of 1000 francs has been awarded by the French Society for the Encouragement of Industry to M. Decaux for a new photographic shutter.

Solubility of "Insoluble Salts."—Herr A. F. Holleman has been investigating by an electrical method the extent to which certain salts, usually termed insoluble, are capable of being dissolved in water. Selecting from his lists those salts only which are of interest to photographers, we find that silver iodide is soluble in 1,074,040 and 420,260 parts of water at 28·4° and 40·4° temperature, respectively. For bromide of silver we have 1,971,650 and 775,400 at 20·2° and 38·4°, and chloride is set down at 715,800 and 384,100 at 13·8° and 26·5°.

Removal of Pyro Stains.—These stains are really more difficult of removal than silver from woven fabrics, and quite as difficult with the fingers. For the latter, perhaps, the best plan is to well wash or rub together with dilute acid—tartaric, oxalic, acetic, &c.—and then to well rinse under the tap. If the latter precaution be omitted, the stains will reappear when the hands are washed with soap. For linen, &c., the dye is too much fixed for this treatment, and other methods have recently been under discussion in our contemporary, the *English Mechanic*. The following method is one of those recommended:—Immerse the fabric in a saturated solution of oxalic acid, and leave it to steep for some little time. Next place the material, now impregnated with the acid solution, in a ten per cent. solution of bleaching powder (so-called "chloride of lime") till the stain disappears, and finally well wash in clear water. A little rubbing facilitates the removal of the stains. Another correspondent describes a simpler method, which he states to be superior. It consists in the use of a one-solution made by boiling together, in water, bleaching powder and carbonate of soda.

Photographing Sound.—This feat has actually been performed by Dr. Raps, as explained by him to the Berlin Physical Society. The method is based on the use of a Jamin's refractometer, which produces interference phenomena by means of reflection and refraction of a ray of light at the surfaces of two thin parallel glass plates. When the air between these two plates is transmitting sound waves, the interference bands are displaced, and, by means of a slip of sensitised paper, kept in motion on a drum and placed behind a slit, the aerial vibrations are recorded. The first experiments were made with a closed organ pipe, near whose end were two openings facing each other, but covered with glass. Upon varying the pressure of the wind blown through the pipe, photographs of different characters were obtained describing certain curves indicating this pressure. Open-pipe experiments were more difficult, but even with these successful photographs were obtained. Dr. Raps had also obtained photographs of the vibrations from the singing of vowel sounds, which exhibited several interesting relations of the component parts of the sound to one another. He also exhibited photographs of the vibrations produced by the sounding of a hunting horn.

Photo-chronographic Work in Paris.—*La Nature* has a long article on this topic, showing how it is now employed in what may be termed a State-recognised study. At the Saltpetrière Hospital in Paris a special open-air laboratory has been fitted up for conducting experiments, on a complete and extended scale, of the play of the various muscles and parts of the body during various phases of muscular exertion. The camera contains a dozen lenses, and is mounted either on a studio stand or a field tripod. The exposures are made by electricity, and aware of the fact that some control of the duration of exposure is needed, so as to obtain sufficient detail and not mere silhouttes, under varying lights and distance of object, every provision has been made for carrying out this requirement. With regard to accurate measurement of the time, though Foucalt's metronome is valuable, it cannot be used for very brief periods of time. Ultimately, a modification of Trouvé's interrupter was devised, and found to be excellent for the purpose. In the article in question will be found excellent illustrations of the whole arrangement, showing how very complete an installation has been carried out. One view in particular gives a very good idea of what the arrangement is capable of. It represents the apparatus at work taking a series of photographs of a workman stripped to the skin, striking an anvil with a heavy hammer. There cannot be a doubt that such photographs taken in half-tone will be of the greatest value in many physiological investigations.

PHOTOGRAPHY IN WARFARE.

The subject of photography applied to military purposes is one that is now receiving a little of the attention it merits. That photography may be made of valuable assistance in warfare is a self-evident proposition, but hitherto its applications have been limited in extent, and it is only the scientific branch of the army—the Royal Engineers—that has practised it. Much of the work done at the School of Military Engineering at Chatham is familiar to us, and it is here that many of the photo-mechanical processes have been worked out, or, it might even be said, have originated. The Ordnance Survey Maps are testimony to the perfection to which our "brave defenders" have attained in the photographic process by which they are produced. In the application of photography to the numerous uses to which it might be put in the field on a campaign, we seem, however, hardly to have kept pace with the times, and the paper recently read before the Photographic Society of Great Britain by Captain Mantell, R.E., entitled *Balloon Photography Applied to Military Purposes*, appears to support this view. It may be gathered from the paper that, until recently, there has been little done in experimenting in a direction which, it is evident, must be an important one in warfare—that of obtaining maps or, rather, bird's-eye views of the country at the seat of operations by means of a captive balloon. The difficulties to be overcome are not few. The effects of the motion of the balloon, even in moderately calm weather, are described as being very unpleasant, and, in anything like a wiud, as being far worse than those experienced on a vessel in the heaviest sea; so that, in addition to photographic and manipulatory difficulties, the nausea of sea sickness, or its equivalent, has to be contended against. The actual photographic work is not the plain sailing it might appear to be. The gyration of the balloon and its rolling motion render it exceedingly difficult to point the camera in the desired direction at the

moment of exposure, and, owing to the movement being in the camera itself, the duration of the exposure must necessarily be very brief to obtain a sufficiently sharp result, one-sixtieth of a second being about the maximum possible, even under favourable conditions. In a wind of the velocity of ten miles an hour, negatives could be obtained showing no appreciable amount of blurring, but when the wind attained a velocity of sixteen miles an hour, all work was found impossible. With a free balloon the work was much simpler, as, instead of tossing about, the balloon moved with the wind. It will be seen, from these few facts, that balloon photography is anything but play; but Captain Mantell may be trusted to advance matters if he has the opportunity afforded him. He certainly has that valuable qualification in an investigator, that he is not ashamed to admit his want of knowledge and to ask assistance.

Another aspect of military photography is the subject of an extremely able article in the *Pall Mall Gazette* of the 30th ult.—an unsigned article, but evidently from the pen of a practical photographer. The writer points out that, although photography has been hitherto entirely the province of the scientific branch of the army, the Royal Engineers, there is no reason why it should remain so. There are, in all branches of the service, officers who are excellent practical photographers, and whose attainments might be utilised in a way which the existing system does not recognise. A photographic contingent might be attached to every army corps, a body trained in the use of the camera for the purposes of reconnaisance and expert in map reproduction and all the branches of photography likely to be useful in active service. The material for such a contingent could be easily obtained from the non-commissioned officers and the rank and file, for modern developments have rendered previous scientific training comparatively unimportant, and the service would certainly be popular, owing to the great fascination of photographic work, whatever its application. The necessary technical training might be conducted under the supervision of the Royal Engineers, with the Chatham School of Photography as a centre, but with local centres at the various military stations throughout the country. The cost of this would be comparatively trifling, whereas, as a set off, there would be in a short time, in every corps throughout the army, at least one officer and two or three non-commissioned officers or men who could use the camera in a reconnaisance instead of, or in addition to, the pencil.

The idea commends itself at once to photographers as one quite capable of being carried out. It is obvious that, while photography remains the exclusive prerogative of one department of the forces, the extension of the uses to which it is applied is likely to be made but slowly, and, as Engineers are not ubiquitous, on many occasions when photography might be employed with advantage, it must necessarily be dispensed with, on account of the absence of operators. For military purposes in the field pictorial excellence is quite a minor consideration; the rapid production of prints is important, and of more importance still is certainty, that is, that every plate exposed shall result in a negative capable of giving prints good enough to tell the tale intended. The utmost portability and simplicity of apparatus are essential, but there is no reason to fear that a demand in this direction would remain long unsatisfied.

Before the authorities at headquarters are likely to consent to the "extension of the camera" in the direction indicated, they will have to be fully convinced that photography, as a means of graphic expression, is better than the pencil, that its employment need not entail any great addition to the provisions made for transport, and that the expense to be incurred will not be great. However, we have learned —happily from the experience of other nations—that success in warfare is largely dependent upon the advantage taken of arts which can be cultivated in times of peace, and, whatever may have been our errors in the past, we have every reason to believe that those to whom we have entrusted the duty of providing for the defence of our country are fully alive to the responsibility which rests on them, to neglect no means available for the purpose. A. Mackie.

STANLEY SHOW PHOTOGRAPHIC EXHIBITION.

The second annual Photographic Exhibition in connexion with the Stanley Show of Cycles at the Agricultural Hall, was opened on Friday, November 17, and will remain open until Saturday next, November 25. The Judges on this occasion were Messrs. Henry Sturmey, J. Traill Taylor, and E. J. Wall, and medals were placed at their disposal by the Committee with considerable lavishness. The management of the Exhibition was in the hands of Mr. W. D. Welford, who must be congratulated not only on the success of the show as a whole, but in particular of the hand-camera class, which was a particularly strong and good one. If rather weak in the champion class, other departments of the Exhibition sufficiently atone for it, and the total display was undoubtedly good and interesting. This year the pictures were wisely separated from the apparatus, the latter being arranged in the outer gallery. In the room devoted to the pictures we should have been pleased not to see the flags and streamers with which it was adorned, as to our thinking such garish attempts at decoration are best omitted from a display of photographs, which have nothing to gain from their presence.

In Class A (Champion), the gold medal went to Mr. C. S. Roe for his *Sedge Gatherers*, a crisp, forcible study of a man and two women engaged in that occupation—easy and natural in its arrangement. Mrs. Main, with her Alpine series, *Frost and Sunshine*, took the silver medal, and Mrs. Marriott (somewhat luckily, we think) the bronze medal for an Irish seashore view, carefully exposed and printed, but otherwise not very striking. Messrs. Mendelssohn, Byrne, and Pym exhibited good portrait work, which, to our fancy, deserved recognition, particularly the first-named two. Mr. Burrow's mining series were also passed over.

Class B (Landscape) was really so good all through that we are sure the Judges must have had a tough job in coming to their decision. The gold medal went to Mr. R. S. Webster for *When the Evening Sun is low*, a boat with two occupants near a rocky shore; the silver to Mr. Warneuke for one of his Pall Mall Landscapes; the bronze to Prince Barma for a pretty and painstaking view, *On the River at Tipperah, India*; and diplomas to Messrs. J. H. Anderson for *Winter's Morning*, a riverside study, effective from a realistic point of view, but not otherwise noteworthy; and J. Kidson Taylor for *A Snug Berth*, a capital bit portraying a ship at anchor in a small bay, like all Mr Taylor's work, sound in execution. A view of *The Tower Bridge*, by Mr. W. Howell; a bold *Sunset* and a tender *Eventide* by Mr. W. Norrie; a capital *Sunday Morning*, an old fellow escorted by a young woman emerging from a church, by E. S. Baker; and noticeable work by Messrs. J. Avery, Hartley Bros., E. Hankins (an excellent hoar-frost bit), E. Benson (a meritorious *Mountain Stream*), and others are included in the class.

Class D (Figure Studies, *Genre* portraiture) was also a remarkably good one; indeed, although small, we go so far as to say that it includes some of the cleverest work of its kind we have seen this season. The gold medal is well won by Mr. D. J. Scott for *Dividing the Spoil*, a humorous group of three schoolboys, one receiving a bite from an apple held by another, while a third, over his slate, is smiling unctuously. The youth holding the fruit has the attitude and the expression of "Don't take it all!" A very clever bit of work this. Prince Barma takes a silver medal for a figure study of a young girl, one of a series of princesses of the House of Ancient Tipperah; Messrs. Lutzel Bros., a similar award for a frame of delicate and refined portrait studies, chiefly of ladies and children. Mr. C. E. Wyrall the bronze for a large study, *Is oo Cross?* a little lady asking the question of a dog whom she has dressed up in fantastic garb; and Mr. Byrne, a diploma for a series of charming portraits in red carbon. Messrs. Werner, Terras, Treble, Count Gloeden, &c., also exhibited in the class, Messrs. Lutzel's and Byrne's other exhibits being particularly striking.

Class E (Hand-camera Studies) was, as we have said, particularly strong, the gold medal going to Mr. J. A. Sinclair for a frame of four of his now familiar Swiss and Italian excerpts, well chosen, beautifully defined, and technically admirable. Mr. Sinclair had three other frames all in his best (or Continental) style. Awards also went to Mr. J. Kidson Taylor (delightful land and waterscapes, quite worthy of a stand camera deliberately used), Charles Knight (shots at soldiers on the march), J. H. Gear (sheep in a farmyard), Charles Job (rustic studies). To this class, which we unreservedly salute as a tribute to the potentialities of the hand camera as capable of the highest artistic expression in photography, a great many other well-known workers contributed good examples of their skill.

In Class F (Beginners since 1890) Mr. J. H. Gear (who seems a very old "beginner") received the silver medal for a splendid interior of Whitchurch Church; Mr. Stewart Smith the bronze for an interior group of the Glasgow Art Club (very good); Mr. A. Kemp a bronze

for *My First Love* (portrait of a very old lady), and Mr. J. H. Anderson took a diploma. We have seen no better beginners' class than this: it was good in landscape, portraiture and interior work, and only the cruel exigencies of space prevent us from paying many of the competitors some pretty compliments.

Class G was for pictures taken with apparatus carried on cycles, and this contained some fairly good land and seascapes. Messrs. Barron (silver), W. B. Dart (bronze), and Harry Wade (diploma) were successful. In the Society Competition the Gosport, East London, Midland, and South London competed, and the last two secured awards, the South London being particularly strong in architecture and interiors. Take it all in all, the Exhibition was far above the average of its kind.

The show of apparatus was remarkably strong, and we can conceive that the casual visitor must have been greatly gratified at the display. Handsome stands were occupied by Messrs. Adams & Co. (hand cameras, changing boxes, lanterns, stands, &c., in profusion). R. & J. Beck (whereon the philosophy of the "Frena" was expounded in all its ramifications), Sands, Hunter & Co. (cameras, lenses, &c.), Cresco-fylma Company and Morgan & Kidd (with an effective display of enlargements in carbon, collotype, bromide, &c.), Wormald & Co., Morley & Cooper, Holmes & Watson, Platt & Witte, W. Wray, &c.

Now that so many photographers are cyclists, and *vice versâ*, we are sure that followers of both pursuits must have visited the joint Exhibition with considerable pleasure and as much profit.

CAMERAS AND FILMS.

Like your own, Mr. Editor, my photographic experience dates far back into the past, embracing a period of nearly forty years. Having passed through every phase of the art from the early days of collodion through the various so-called dry or preservative processes, I can only marvel at the wonderful developments of these later days, and the facilities now afforded for the practice of our old and favourite pastime. I compare the ready-made dry plates, their marvellous sensitiveness, the light, compact, and admirable cameras of to-day with the heavy cameras, cumbersome tent, the silver baths, bottles of chemicals, and all the bulk and weight of the paraphernalia required by the landscape photographer of the old days, and can only congratulate the latter-day followers of the art that their lines are cast in such pleasant places, and that they have so goodly a heritage.

One of the greatest strides that has been made, and one of the most useful practical steps of modern photography, has been the introduction of films to take the place of glass for negatives in landscape work. Even young men and strong, to say nothing of men whose growing years have not abated their ardour, can, on a hot summer day, appreciate the enormous advantage of a film-carrier containing thirty exposures on a spool only a few ounces in weight over the burden of six heavy plates in three double slides. But here, I am afraid, my record of progress in this direction must stop.

Much as has been done there is still something wanting, and the object of this communication is to call the attention of our camera-makers to a matter of much importance, and to urge them to exercise their ingenuity and inventive faculties a little farther, and make one more addition to our present appliances.

These rolled films are exceedingly light and easily developed, but after this our troubles begin. They are difficult to dry flat, soak them in glycerine as we may; but, when we come to print from them, then it is that one's temper gets ruffled, one's patience exhausted, and certain ejaculations hardly fit for ears polite are apt to escape us. No power that I am acquainted with can keep these films flat or prevent them rolling up to the size of a lead pencil, especially in a warm room. And the difficulty of unrolling them, adjusting the paper, and getting them into position in the printing frame, is tremendous, involving much loss of time and temper. This is owing to the films being so thin. With cut films the case is different; being thicker, they do not curl up in the same way. But with these cut films as used at present we lose one of the great advantages of films, viz., the command of a large number of exposures, with a minimum of weight and trouble in changing.

What is wanted, therefore, is an arrangement not much larger or heavier than the present roll-holders, which will carry, say, twenty-four cut films, each of which can be easily displaced after exposure, and another brought into position. But perhaps some one will say this has already been done, and I shall be referred to this or that hand camera for proof. This may be quite true, but I am not speaking of hand cameras, with which I am not much in love, but of ordinary sizes, say, up to whole-plate or 10×8.

Whoever will give us this boon will deserve and will receive the grateful thanks of thousands of amateurs, and will also, I doubt not, lay the foundation of a profitable business. If the problem has indeed been solved as regards hand cameras, it needs, one would think, very little ingenuity to adapt the principle to larger sizes. If the inclusion of as many as twenty-four films increases the difficulty, reduce the number to twelve, but twenty-four would be an advantage.

I have taken as many as twenty-four negatives in one day, notably once at the Lakes of Killarney, which I could not otherwise have got, and the last four exposures were amongst the finest things I have ever done. This was, of course, by means of a roll-holder, as there was no dark room handy for changing.

I commend this suggestion to our camera-makers as one most thoroughly practical and useful, and trust by next summer the piece of apparatus I am pleading for will be *un fait accompli*.

S. Bourne.

REMARKS ON HAND-CAMERA WORK AND HAND CAMERAS.

[Dundee and East of Scotland Photographic Association.]

I confess to having been for a long time a very great sceptic as to the possibility of doing even decent photography with a camera held in the hand. The excellent slides shown at some of our meetings from negatives said to have been done in hand cameras almost persuaded me that the thing could be done, however, and I immediately set about a mild kind of inquiry into two or three points which specially interested me.

Whether it be from use and wont, habit, prejudice, or what you like, I am a "stickler" for definition. I go in chiefly for lantern-slide work, and, however tolerable a 14×12 fuzzytype (as they have been jocularly called) may be, want of definition in a little picture three and a quarter inches square has always been singularly abhorrent to me.

For this reason it was a long time till I could bring myself to believe that a hand-camera negative need not necessarily be blunt. I have proved to my satisfaction now that a *high* degree of sharpness is attainable in a hand-camera negative. A good deal of the work done by the hand camera is not sharp, but it need not have this defect, and this was the first question I determined to test, "To what extent must one be prepared to sacrifice definition in taking to a hand camera?"

Andrew Pringle, in his classification of amateurs, has a class of *mechanical* amateurs. It seems that their hobby finds expression in the designing and making of hand cameras. I plead guilty to being of this class, and furthermore plead guilty to having made no fewer than four hand cameras this season. When I say I have made four hand cameras, I mean this in a certain restricted sense. For certain reasons which may appear later on, I soon decided in favour of dark slides as against a magazine arrangement, and it is to be understood that in my home-made hand cameras I did not make the dark slides. But, to begin at the beginning, when I first decided to take up hand-camera work, I sought to make a camera having the following conditions or qualifications. First, it must be small, light, and portable, strong, weather-proof, capable of carrying eight to twelve plates, easily changed. The shutter must be not over-fast, and not liable to get out of order. Lastly, but most important of all, it must be well within my power of construction.

I first of all sent to Mr. Wray, of London, for a simple stereoscopic lens of five inches focus. I decided upon a single lens for the following reasons. First, as I only wanted the lens to cover a lantern plate, a single lens of five inches focus is practically rectilinear even under trying conditions upon this size of plate. Secondly, a single lens gives a crisper and more brilliant image. Thirdly, this stereoscopic lens by Wray, working as it does magnificently at an aperture ratio of eleven, was abundantly fast for all ordinary purposes; and, lastly, a single lens even by a good maker is comparatively cheap, this lens by Wray, for instance, costing but twenty-five shillings.

To have gone in for a rectilinear I would have had the advantage only of working with a larger aperture, and this with the disadvantage of giving me less depth of focus, or requiring me to arrange some focussing arrangement on my camera before I could have taken advantage of the large aperture for near and far objects. By contenting myself with an aperture of f-11, I secured such depth of focus as to render any focussing arrangement on the camera unnecessary—a huge point, I think. A single lens has other points of

advantage which I need not advert to, such as the ease with which a shutter can be fitted on it, and so on.

The lens having been duly received, I set about the construction of camera No. 1 as followa:—A well-made pine plate-box with grooves for twenty-four plates was procured. This box was divided into two chambers or divisions by a thin partition of wood. The front half was the camera proper, the back half the magazine. The lens was placed on the end of the box, having upon it a shutter, which I need not describe, as it did not turn out satisfactorily. The hinges and hasp were blackened with chloride of copper, and the whole box covered with morocco leather. It had quite a respectable appearance. Although there had been no attempt made to disguise the true nature of the machine, if one carried it under the arm (and it was small enough for this), with the lens looking to behind you, not in front, people passed by, like the Levite of old, and took no notice.

The plates were changed in a simple and certain way. I had a small bag made of two thicknesses of black twill. The mouth of the bag was opened, the camera dropped in, and the bag tightened by means of a running string round the wrist. This done, the catch of the lid was turned, the lid opened, and the plate taken from the back half of the camera (where were a dozen plates in the grooves) and slipped down in front of the partition, where it was ready for exposure. I used this camera some half-dozen times, but soon found that it had two faults.

In the first place, while the plates were most easily and rapidly changed, the manœuvre was conspicuous and objectionable in streets and crowded places, where one would most naturally use a hand camera.

In the second place, the movement of the hand and arm to release the shutter caused the camera to move, and my pictures were blurred. At first I thought I had not set my lens to focus. I tested this by setting my camera on a stand, and exposing with a cap. The picture was sharp. I then thought the shutter vibrated the camera. I tested this by holding the camera myself and getting a friend to release the shutter. The picture was sharp. I therefore concluded that it was the movement of the hand and arm in the act of releasing the shutter that did the mischief. I may remark here that I am convinced that many of the blurred pictures got from hand cameras are brought about, not by vibration of the shutter, not by unsteadiness in holding in a general way, but from this special movement made unconsciously in the act of releasing the shutter. Later on I will describe some trials I made to determine how prolonged the exposure might be without blurring, this movement being eliminated.

Seeing that the mode of the changing of the plates was unsuitable, and the shutter difficult to release without movement, I determined to make another camera. I cannot show you this first camera, for the simple reason that I have used certain parts of it as material in the subsequent cameras. In thinking over the question of an easy release for a shutter, I remembered that I had a simple drop shutter, which was all that could be desired in this respect. I hunted it out. A simple unaccelerated drop shutter gives about the speed I like. It is not prone to stick or get out of order, but it is cumbrous; over and above this, it adds considerably to its size to have it on the camera in a set state. Still the drop shutter had so much to recommend it that I determined to adopt it and bring all other conditions to suit it. As I had no means of keeping the light from entering the camera while setting the shutter, I abandoned the idea of any magazine arrangement, and decided to have dark slides. Having little experience of magazine cameras, I can give no opinion upon them. All that I can say is, that the dark slides have given me unbounded satisfaction. You can carry one in this pocket, one in that, so that you never feel them about you. You can fill Nos. 1 and 2 with quick plates, and Nos. 3 and 4 with slow, and expose them how you like. You can slip down to the harbour with only a single plate or with eight, just as you like, and the changing is simple and rapid. I am a great believer in the dark-slide system. As dark slides are not child's play to make, I ordered four from Mr. Birnie, and meantime set about devising camera No. 2.

I thought myself almost to distraction as to how I could contrive to design a box with a drop shutter on the end of it to look tidy and unconspicuous. While busy over this question, I remembered that camera No. 1 had not proved weather-proof; indeed, I was convinced that it was not possible to make a hand camera weather-proof, and, if this were to be remedied by having a water-tight case of any kind for the camera to be carried in, seeing that the camera would be only exposed for a moment during the exposure of the plate, I might as well have the camera any handy shape I liked, independent of appearance altogether. This simplified matters hugely. I designed a simple box, of proper dimensions at the back to take the slides, but getting narrower towards the front, to allow my hand to lie naturally to the release of the shutter. The body of the camera I made of stout millboard, attached with brass screws to a mahogany front for the lens, and a mahogany frame behind for the dark slides to work in. The whole was covered with stout morocco leather, and, as you will see, is quite presentable. I thought I would require no finder, but placed a circular spirit level on the top. This camera I thought, at first, a great success. I got my saddler to make me a nice leather case to hold it and the dark slides, and thought I had come to my journey's end.

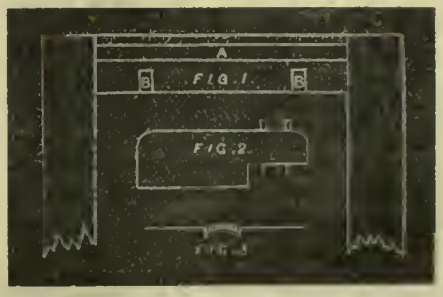
J. K. Tulloch, M.B.

(To be continued.)

A COMMON DEFECT IN PHOTOGRAPHIC DOUBLE DARK SLIDES, AND ITS REMEDY.

A very common defect in double dark slides of the ordinary book form is the admission of light between the shutter and the top rail of the slide framing when the shutter is drawn out to expose a plate. It is none the less dangerous that it may not show itself for some time. If the camera is kept carefully covered with the focussing cloth while the slide is withdrawn, all may be right, but some day the cloth may be blown off just at the critical moment, and the result may be one or two streaks of fog across an otherwise good negative. Having had some valuable negatives spoiled by this means, I speak from experience, and it is in order that my experience may be of use to others that I now explain the remedy, which is very simple.

It is in those dark slides where the shutter is prevented from coming completely out by two small screws that this defect is most



likely to occur. In order to permit of the entire surface of the plate being exposed in the camera, there are pieces, B B (fig. 1) checked out of the top part of the slide frame to receive these screws. This leaves only a small part of the frame to keep out the light, and it is seldom so well fitted as to be quite light-tight.

The remedy consists of a piece of narrow black velvet ribbon glued across the top of the frame, as shown at A (fig. 1). The shutter must be entirely withdrawn, first unscrewing the two small screws before referred to. If it is prevented from coming out by means of a narrow strip of veneer glued across near the bottom edge, which is also a very common plan, this strip of veneer must be carefully chiselled off.

If the shutter is a very loose fit, as is often the case, the ribbon may be glued right on the surface, but it generally requires a shallow groove cut to take up some of its thickness.

The velvet ribbon may be got in a draper's, and cotton back is to be preferred before silk; a quarter of an inch broad is sufficient, but broader may be used with advantage if there is room for it. Fig. 3 represents the ribbon and its groove in section.

If three dark slides are to be done, and it is an improvement even to the best, it will save both time and trouble to make the small tool shown at fig. 2. A piece of hard wood about four inches long, one and a half inches broad, and a quarter of an inch thick, has a check cut at one end; two small nails are driven in at suitable distances from the check and from each other, to form a gauge for cutting the sides of the groove; the points of these nails project about a sixteenth of an inch, and they are further sharpened by means of a file. By using this tool as a carpenter's gauge is used, the sides of the groove are neatly and easily cut. The groove is then cleaned out with a narrow chisel, leaving it higher in the centre than at the edges. The edges of the ribbon will thus be well under the surface of the wood, and, if properly glued in, will not be liable to be torn off by the shutter.

Kentigern.

LEYTONSTONE CAMERA CLUB EXHIBITION.

A big step in advance has been made by the Leytonstone Camera Club in the Exhibition, the second annual one, which was opened last Monday, and is to remain open all this week, not only in the quality of the pic

ures hung, but also in their arrangement and disposition. Last year we felt it our duty to pass a few strictures on certain features of the Exhibition, and we are happy to observe that they have been profited by, the result being a thoroughly representative collection of pictures illustrative of photographic art up to date, presented to the public in a praiseworthily careful manner, and one, moreover, which would do credit to much older photographic organizations than the Leytonstone Club. At the same time, we must temper our praise with one recommendation, and that is, while the Club does its best to avoid skying frames, it should also endeavour to abstain from "flooring" them. On this occasion, what we were informed the Judges considered one of the best photographs in the room the hanging authorities had hung on the floor, as the Irishman says, so that, in all probability, nineteen out of every twenty visitors would miss seeing it. The Judges were Colonel Gale, Mr. Cembrano, and Rev. F. C. Lambert.

Class A (Landscape and Seascapes—members of the Club) was not, as is generally the case with members' classes, too large. Mr. G. H. Cricks took the silver medal with *An Essex Swamp*, which we have previously noticed, and also showed *A Summer's Eve at Canvey*, a characteristic study on the Essex flats. Mr. D. G. Riddick was prominent in the class, securing the bronze medal with *Where Twines the Stream*—a soft, pleasing study of river, wood, and meadow, skilfully composed. He also showed *The Silent Brook* and *By Mead and Stream*—two similar subjects ably handled. Messrs. E. S. Coleman, H. E. Farmer, E. A. Golledge, H. H. Summers (bronze medal), F. W. Wates, and A. E. Bailey also showed excellent work. Class B (Architecture—members) was a small one, Messrs. H. E. Farmer and J. H. Gear being prominent, the latter gentleman taking the bronze medal for a technically good view of *The Choir, Westminster*. No awards were made in Class C (Portraiture and Figure Studies, including animals); Mr. Tom Symmons was perhaps most successful with a large picture of a young lady, *Que Voulez-vous, M'sieu*, offering fruit for sale. In Class D (Enlargements—members) Mr. Symmons received the silver medal for a fine enlargement, badly hung—*Winter*, and Mr. C. A. Russell the bronze for a study of a *Sunset*, treated in the diffused style. Mr. Gear showed *Whitchurch Church*, which was medalled at the Stanley Show. In the Members' Lantern-slide Class Messrs. A. E. Bailey (silver) and W. E. Farmer (bronze) were successful.

There were three open classes. In the Champion Mr. W. Thomas took a silver medal for a series of hand-camera river studies, and Mr. Wellington a similar award for *Eventide*. The class though small was good. In the open lantern slides a special silver medal was awarded to Mr. P. Martin for a series of imitation statuary, *Characters from London Streets*, full of humour and carefully made. Mr. Hankins also won a silver medal for a series of slides from hand-camera negatives. For Class G (prints of all kinds by any process) nearly 200 pictures were in competition, the silver medal going to Mr. Bhedwar for *The Voice of Silence* (which was shown at the Salon), and the bronze to Mr. J. H. Anderson for an *October Sunset*, a study of sky and water. This was undoubtedly a very fine class indeed. Messrs. West & Son (yachts), W. Thomas (hand-camera), Sandland (animals), S. B. Angle (a clever flashlight photograph of a dancing lady), Cadby, H. P. Robinson, Warneuke, Oakden, Howell, and Byrne (some remarkably good portraits) being among the prominent exhibitors. A loan collection of photographs, in which work by Messrs. Elliott & Son, Horsley Hinton, Ralph Robinson, the Autotype Company, Karl Greger, the Stereoscopic Company, Waterlow, and the Platinotype Company was shown, constituted a fine exhibition in itself.

Altogether the Leytonstone Club may congratulate itself on having organized a show of fine photographs which will surely not be beaten by any of what are known as the minor Exhibitions.

ON THE PHOTOGRAPHY OF THE LUMINOUS RAYS OF THE SHORTEST WAVE-LENGTHS.*

With a slit of the width of 0·020 mm., and an exposure of one minute the Leyden jar spark of cadmium gave all the main lines but the two most refrangible, No. 25 and No. 26, in contrast to the others, strikingly pale. As it might have been expected, this difference in intensity did not disappear, even on prolonged exposure, until solarisation became perceptible in the more intense lines. The difference in intensity which regularly followed on normal exposure would not have attracted my notice if I had not had at my disposal several cadmium proofs of extraneous origin—three original plates, for which I am indebted to the kindness of Mr. W. N. Hartley, of Dublin—which have also been taken upon silver bromide gelatine with a quartz prism and quartz lenses.

These proofs showed the difference in the intensity of the above-named lines decidedly less than my plates. They therefore justify the assumption that Hartley's experimental arrangement had in some manner relatively assisted the photographic action of the lines No. 25 and No. 26. I was confirmed in this conclusion by three other cadmium photographs by the same spectroscopist, good photographic reproductions of which accompany one of his treatises (*Scientific Transactions of the Royal Dublin Society*, "Photographs of the Spark Spectra of Twenty-one Elementary Substances," vol. i. series 2, pp. 231–238, 1882), and which, in contrast to the above-named original plates, are in harmony with my plates; whence, therefore, the difference among Hartley's proofs? This question was of essential import for the continuation of my work.

Hartley, on the ground of the plates of his two negatives above named, had marked with a diamond the date 1880; his treatise appeared in 1882 My investigation began in the year 1889. As regards the arrangement in taking Hartley's plates above mentioned, I merely know that an apparatus with quartz prisms had been employed. Hartley's treatise explained his arrangements in taking the other spectra. From reasons, the exposition of which would prove tedious, I have below, in the solution of the above question, kept myself exclusively to the proofs. This was admissible, since they display a difference palpable for the present case. The length of the spectra is different. If measured between the cadmium lines No. 9 and No. 26, it amounts in the plates to 82 mm., and in the figures to 157 mm. As both spectra show no appreciable difference in the re-solution of their crowded lines, it was permissible to assume that the dispersion of Hartley's spectral apparatus was the same, and that merely the focal distance of the lenses was different. Therefore the lengths of the aërial transit of the rays of both apparatus must have differed from each other approximately in the same proportion as the focal lengths. It has been already proved by Cornu (*D'Almedia J.*, x. pp. 5-17, 1881) that the transparency of the air decreases with the wave-lengths of the rays, especially in the ultra-violet, though certainly in strata of much greater thickness than those of Hartley's apparatus. Still, I have felt compelled to uphold the resistance of the air as the sole cause of the above-named difference in the intensity of the two most refrangible lines of cadmium. On the one hand, because Miller's proofs already showed that a stratum of air, even of moderate thickness, may prove an insuperable difficulty in the photography of the ultra-violet; and, on the other hand, because all further experiments which I instituted to detect other causes for this phenomenon proved fruitless. An experimental strengthening of this assumption, the necessity for which seemed more urgent on every new photograph, had to be postponed until the conclusion of the connected examination of the spectra of zinc and aluminium, on account of procuring the necessary instruments.

The zinc spectrum in its most refrangible part acted still more feebly than the cadmium spectrum. For instance, an exposure of three minutes was required for the appearance of the most refrangible line, No. 29. Like the efficacy, the intensity showed a further decrease. Of all the main lines of cadmium and zinc, none appeared so slightly as the zinc line No. 29. The combined spectrum of both metals showed better than any other that the intensity decreased with the wave-length as yielded by a spark springing over between these electrodes. (When employing three electrodes, I connect the pair of electrodes with the current circuit, whilst the single electrode of the other metal was introduced with its extreme end into the track of the spark, where it then took part in the discharge in a normal manner.) Few metals are here at all suitable like zinc and cadmium.

Contrasts in the intensity of adjacent ultra-violet lines are shown in the inflection spectrum better than in the refraction spectrum, since the deflection of the rays does not succeed progressively with the wave-length as with the prism, but proportionally. Hence the lines towards the more refrangible end are more and more crowded together, whilst in the refraction spectrum they recede further from each other. Proofs which I took with a concave grating revealed still better the decrease of the intensity and efficacy of the lines in question.

According to Cornu's hypothesis (*Comptes Rendus*, lxxxviii. pp. 1285–1290, 1879), a stratum of air of the thickness of ten metres suffices for the absorption of the rays of the wave-length 211·84 $\mu\mu$.

The rays Nos. 27, 28, and 29, the wave-lengths of which are smaller, are consequently absorbed by such a stratum of air in a still stronger degree.

I utilised this fact in order, even before the completion of the above-named new apparatus (see *ante*), to procure a more certain basis for the measurement of the absorption of the more refrangible rays in the air than was afforded by the former observations. To this end I execute

* Continued from page 739.

some proofs with the quartz apparatus, in which the sparks and the photographic plate were distant from each other, not ten, but seventeen metres. The light was conducted directly into the apparatus. Two quartz lenses placed at the focal distance of the rays arriving at the plate in front of the slit and the sparks co-axially with the collimator, collected these rays in the aperture of the slit of the collimator. After fifteen minutes' exposure all the zinc lines appeared, contrary to expectation, although very thin and devoid of expression, which, however, was this time unimportant. The important part of the result was the fact that the atmospheric air, as tested by brom-silver gelatine, is far more pervious to light than might have been expected according to Cornu. In addition, the thickness of the stratum of air employed by no means corresponded to the limit of transparency. According to my firm conviction, a much thicker stratum of air would have led to the same result. How did my assumption of the influence of the air upon the photographic efficacy of the most refrangible rays agree with this result? Little as I could bring them in harmony, the cadmium phenomena furnished ground enough to uphold them unaltered. That the numerical values which Cornu has given for the aërial absorption could no longer serve as a basis after they had been found doubtfully trustworthy in my photographs of the zinc spectrum need not surprise us. Cornu's statements are founded on the behaviour of the wet-collodion plate, whilst my proofs were taken only with the gelatine plate. The sensitiveness of both plates is fundamentally different, and in that part of the spectrum which exclusively concerns us it is totally unknown. How the sensitiveness of both plates may vary in the ultra-violet we have hitherto no observations to show.

I next proceeded to take the spectrum of aluminium. The first experiments were fruitless. Not until I had enlarged the slit to the unusual extent of 1½ mm. and had exposed for twenty minutes did I succeed for the first time in recognising on the fixed plate at least traces of the line No. 30, and the less refrangible components of the double line No. 31. The image of lines was certainly so faint that under ordinary circumstances it was visible neither by transmitted nor by reflected light. To perceive it distinctly especial precautions are required. In the same manner I subsequently obtained, after an exposure of forty-five minutes, the remaining aluminium lines. Thus I had arrived at the region of the smallest wave-lengths, but had by no means attained my purpose. My proofs certainly supplied evidence that the most refrangible aluminium rays after traversing a stratum of air of two metres in thickness could still exert upon silver-bromide gelatine an impression capable of development; but an application of such proofs in spectroscopy, at which I was aiming, was not to be thought of. The clearness of the lines was insufficient.

An attempt to obtain better results by elevating the energy of the rays failed completely. What I effected with an induction apparatus of unusual size, constructed by Keiser & Schmidt, of Berlin (length of sparks 50 cm.), expressly for these proofs, demonstrated merely that the object could not be approached in this direction.

More for the sake of completeness than with a hope of success I executed an aluminium proof with the above-mentioned grating apparatus. I never obtained even a trace of a line. The grating was well suited for taking the zinc lines, but with the aluminium lines of the shortest wave-length it failed entirely.

Nothing remained but to take a photograph with a thicker air stratum; After I had studied the behaviour of my plate in the aluminium light under normal conditions, the thickening of the stratum of air seemed a more suitable expedient for the direct demonstration of the influence of the air upon the photographic efficacy of the most refrangible rays than previously. I employed for this purpose the same experimental arrangement which I had used in taking the zinc spectrum. The track of the rays in the air up to the photographic plate measured consequently again seventeen metres.

Not a single exposure now left an impression upon the plate, not even when I exposed for an hour and a half with very energetic sparks. The thickening of the stratum of air had therefore caused all the light-rays, which in the former case had left an impression, to become enfeebled on their passage to the plate to complete inefficiency. Thus I had at last obtained experimentally the confirmation of my supposition on the aërial resistance in the most refrangible ultra-violet, and at the same time the certainty that, if with the resources of the present day a further advance is feasible, this can be effected only after sufficient diminution of the resistance of the air. No apparatus in my possession could be adapted to this condition. The continuance of the experiment was therefore effected chiefly with newly acquired instruments, mentioned under "Cadmium," the arrangement of which had been brought into accord with the experience collected in photographing the most refrangible rays.

B. With especial apparatus.

The leading idea in the design of the new spectral apparatus which my next photographs required was the utmost possible reduction of the resistance of the air. My reflections had led me to three different constructions, according to which the stratum of air was to be reduced, either diminishing the focal distance or by exhausting the tubes of the collimator and the camera, whilst retaining the original focal distance, or by exhausting the entire spectrum apparatus.

The entire removal of the air from the track of the rays in the apparatus would certainly ensure the most favourable result conceivable, if the desired object is attainable in this manner. But the difficulties of obtaining such a spectrum apparatus, exhausted of air in the manner of Geissler tubes, seemed so considerable, that I even renounced the less serious project of partial exhaustion, and decided on the diminution of the focal distance.

A very short focal distance yields, if a single quartz prism is employed, spectra of a minute length. Spectra rich in lines, such as that of the sun, are then no longer capable of resolution. For such photographs the apparatus is almost useless. This applies more to the visible spectrum than to the ultra-violet, and in the most refrangible part of the ultra-violet, where the lines, according to their wave-length, are relatively much more remote from each other than in the less refrangible part, the conditions are still more favourable. Here, therefore, as I show below, the resolution of densely crowded lines, which in such cases are decisive, can be effected with microscopical minuteness, even with a very small apparatus.

An increase of dispersion by means of a greater number of prisms cannot be admitted, on account of the loss of light involved. The result of the experiment depends, in the first place, upon preserving the energy of the rays.

In order that the proofs, in spite of their smallness, might meet the most severe demands, everything was done which could promote the sharpness and distinctness of the image, both in the construction of the apparatus and in the selection and arrangement of the auxiliary apparatus required for taking the photograph.

Concerning the measurement of the focal distance I have remained for a long time undecided, as all the data for the effects of a greater or less reduction of the length of the tube were wanting. The numerical values which Cornu has established for the absorption of the most refrangible rays in the air were here unsuitable, from the reason mentioned. So much only seemed certain, that a moderate decrease of the length of the tube would scarcely lead to a decisive result. Proceeding from the assumption that the greater energy of the rays, and in like manner the complete sharpness of the image, were connected with a smaller length of the tube, and that a small but sharply defined image was preferable to one large but less clear, I selected a lens of only 150 mm. focal distance.

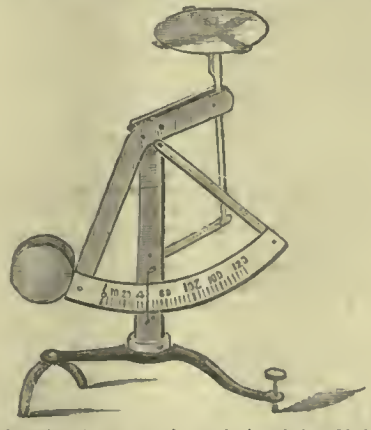
VICTOR SCHUMANN.

(To be continued.)

Our Editorial Table.

A PHOTOGRAPHER'S BALANCE.

THE cut shows a cheap balance just brought out, for weighing photographic chemicals, which it does with a surprising degree of accuracy. It has a glass pan which can be easily detached. The quadrant is



graduated to twelve drachms, apothecaries' weight (divided by scruples).

When we say that this really well-made balance can be obtained

from any dealer at a shilling, or possibly a very little over this sum, it will evoke wonder how it can be made to sell at the price.

The "Lucerna" Finder.

Under this pretty name Mr. J. R. Gotz, 150, Shaftesbury-avenue, W.C., has brought out an elegant and well-made finder, which is capable of being placed on the top of a hand camera to look down upon, or on a camera brought up to the level of the eye when the view is seen by looking through the finder. In either case the image is characterised by conditions of luminousness quite equalling those under which the view is seen by the eye. The principle of construction of the Lucerna is that of the conjunction of a plano-concave lens and a plane-silvered mirror which is capable of being erected at an angle, or allowed to fall flat against the bottom of the finder.

PATENTS COMPLETED.

Improvements in Plate or Film-holding Changing Backs or Slides for Photographic Cameras.

No. 23,229. Thomas Samuels, Monken Hadley, Middlesex.—*October* 21, 1893.

My invention relates to multiple plate or film-holding changing boxes, or dark slides of that kind, in which a number of sheathed plates or films are placed in front of one another in a box-like chamber, and are transferred in succession from one end of the series to the other through the medium of a flexible light-tight bag enclosing the open side or end of the said box, the plates or films either facing all one way or being placed back to back in double sheaths so as to form a double series facing in opposite directions, according as the box or holder has a shutter at the front only or at both front and back.

My present improvements relate particularly to the means whereby the transfer of the sheathed plates from one end to the other of the series is effected, and they have for their object to facilitate the operation of transferring the plate and admit of the flexible bag being so reduced in dimensions that it may be folded wholly within the open mouth of the changing box which it encloses, and be itself enclosed and protected when thus folded by a hinged lid. My improvements also have for object to guard against double exposures.

According to my present improvements, the lifter or frame, whereby a plate to be transferred is partially withdrawn and caused to project sufficiently into the bag to enable it to be seized by the fingers, is adapted to act, not only as a sliding lifter, but also (when it has fulfilled its purpose as a lifter) as a lever to transmit a backward pressure to the whole series of plates, in order to force them backwards sufficiently to make room in front of them for the plate which has just been brought from the other end of the series. This lifter is constructed of a U-shaped frame having cranked and inwardly projecting legs at the ends adapted to engage with the sheathed plate to be withdrawn, the side members of the lifter being guided by the sides of the plate chamber, and when the lifter is drawn out to its full extent working on fulcra thereon, or the side members of the lifter may be jointed and work on these joints as fulcra. The mouth of the flexible bag is affixed within the aperture of the plate-holding box, and the bag is attached at a suitable point to the cross member of the lifter, so that, when the lifter is drawn out and swung slightly backwards, the bag will be distended and brought to the proper position to enable the plate raised by the lifter to be seized through the bag, raised wholly within the latter, and transferred to the other end of the series, without shifting or relaxing the grip until the operation is completed.

The means whereby the swinging of the lifter in the forward direction is caused to transmit a backward pressure sufficient to cant the whole series of plates backwards to admit of the introduction of the plate to be transferred, comprise intermediate levers pivoted to the sides of the plate chamber on which the side members of the lifter act, and which levers, in turn, engage with, or terminate at, their opposite ends, in presser pieces, bearing against the front flanges of the foremost plate sheath, and presenting inclined surfaces to the incoming plate, so that, after having made room therefor, they, as well as the intermediate levers by which they are actuated, will be restored to normal position by the act of introducing said plate.

In order to guard against double exposure, especially in the case of a changing box or slide having a shutter at both front and back, and containing a double series of plates placed back to back in double sheaths as above mentioned, I provide an automatic or partly automatic locking device, whereby a shutter having been once drawn cannot be drawn a second time until the hinged door, which closes in the bag, has been opened, which, of course, is only done for the purpose of obtaining access to the bag and transferring an unexposed plate to position for exposure. This automatic fastening consists of a latch adapted to permit the withdrawal of the shutter a first time, but to oppose a second withdrawal of the shutter on the latter being closed, and to be itself locked or engaged by a latch or detent mounted on the inside of the door, and which may be in such operative connexion with the fastening of the door that the act of unfastening and opening the door restores the locking device to its initial condition of disengagement or freedom, so that it no longer obstructs the withdrawal of the shutter. Each shutter would be provided with such a locking device, both controlled in the same way and by the same or by independent means.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 16,—Mr. G. W. Atkins in the chair.

Mr. Everitt asked for information as to getting vigour in the carbon process. He said that he had difficulty in obtaining a good image with a good negative; he thought that his sample of potassium bichromate might be in fault.

Mr. Debenham had given up the process on account of this difficulty. Tissue varied much; as to strength of bichromate bath he considered three per cent. sufficient and squeegeed the surplus solution off the surface as well.

Mr. Mackie judged the time of sensitising by the limpness of the tissue.

Mr. Everitt explained that he had used three negatives of different character, and yet could not get results; he was using the Autotype Company's Sepia tissue, as he liked the tone.

Mr. Debenham suggested that he should try their engraving black tissue.

Mr. Child-Bayley said that Mr. Burton had obtained great brilliancy with the tissue at the point of insolubility.

Mr. Rawlings asked for members' experience of Hill Norris's collodion dry plates.

Mr. Everitt remarked that some samples gave weak images, and he preferred to do without intensification.

Mr. Child-Bayley said that the image lost in fixing.

Mr. Teape had found no difficulty in getting density, but the image was rather hard. He found that a medium negative required for exposure half an inch of magnesium at a distance of about seven feet; an ordinary lantern plate required the same amount at two feet distance.

Mr. Child-Bayley said a collodion dry plate wanted three seconds at eighteen inches distance from a gas-burner. Pyro-soda developer gave violet-black tones.

Mr. Debenham said that he preferred hydroquinone. In answer to a question, he stated that the reason of collodion emulsion setting into clots on the plate was the absorption of water. The remedy was to dry off the solvents and redissolve. The new methylated spirit was injurious, giving veiled shadows.

Mr. Parfitt asked how best to copy without showing the grain of the paper.

Mr. Debenham said it was essential that the light should be low down, short of getting reflections. Oblique illumination showed the grain, therefore it

should fall as nearly perpendicular as possible, and a light in the opposite direction was useful.

Mr. PARFITT had heard of a cone of tissue paper being used, and

Mr. TEAPE suggested a black screen with a hole for the lens through it.

Mr. Welford was thanked for the presentation of photographic literature to the Association.

Mr. Rawlings passed round a print which was obtained from an enlarged negative, a print from which was rephotographed and worked up with the air-brush, a second negative being then taken from it.

MANCHESTER PHOTOGRAPHIC SOCIETY.

NOVEMBER 9,—The President in the chair.

Mr. LAWES reported results of the trial of "Una," a new toning medium, the general conclusion being that it gave no advantages over the usual gold solutions, and, as no indication of its composition was supplied, any opinion as to the permanency of the tones could not be offered. It was certainly very simple in application, and this was perhaps its only merit.

Mr. F. EDWARDS contributed some notes on the use of "Nikko" paper as used by himself for enlarging, and he found that for this purpose it gave much superior pictures to the ordinary bromide papers, and with ferrous-oxalate development very pleasing tones. A liability to blister had to be guarded against, otherwise he had no fault to find with the working of this paper.

The PRESIDENT opened a discussion on the recently introduced "Hill Norris" collodion dry plates for lantern slides. Personally, he was quite satisfied with gelatine, but considered the collodion plates good. In the discussion, the advantages over gelatine named were freedom from stains and the ease of intensification, and thus control over wrong exposure. The drawbacks were a difficulty of judging the right development, and a reduction during fixing.

A fine collection of enlargements of photographs of microscopic objects, kindly lent by Mr. W. I. Chadwick, were shown during the evening; these were bromide enlargements from quarter-plate negatives produced by the microscope.

Ealing Photographic Society.—November 16, Mr. W. T. White (Vice-President) in the chair.—One new member was elected. Dr. GIBBONS read a paper by Mr. F. L. Pither, entitled *Notes on Landscape*. The author of the paper strongly condemned mere mechanical work, and urged that the subject should be carefully considered with the view of producing the most artistic result possible. The art of selection must be carefully studied, and too much must not be reproduced in a given area. Individuality should be striven for, and nature should be depicted, not in one phase only but in all her varying moods. Whilst aiming at individuality, certain simple first principles must not be neglected. No prominent line or feature should equally divide the picture; as a general rule, no continuous line should run parallel to either edge of the picture, and parallel lines should be avoided unless much broken up or counterbalanced. Two most important qualities were breadth and atmosphere, and, if these qualities were not produced by the actual exposure in the camera, they should be indicated by the judicious application of light washes of Indian ink to the negative. The paper provoked a lively discussion, and regret was expressed that Mr. Pither had not entered into greater detail regarding his methods of work. The rules drawn up by the Council for regulating the use of the dark room were read.

East London Photographic Society.—Nov. 14, Mr. M. A. Wilkinson in the chair.—After the preliminary business had been disposed of, the CHAIRMAN called upon Mr. S. HERBERT FRY for his lecturette and practical demonstration on *The Paget Prize Printing-out Paper*. The lecturer prefaced his remarks by eulogising the great advantage that this paper would confer on all those—amateur and professional alike—who had only a minimum of time to devote to their printing and showed a print as an example which had only received (approximately) one-tenth of the ordinary exposure. This print he proceeded to develop. He preferred to leave the print in the bromising solution at least *ten* minutes, although the printed instructions advocated *two* only, as he found that better and more sure results were obtained. The thorough washing of the print after this first stage in development was strongly advised, as the majority of the failures in using this paper were traceable to insufficient washing. If greater contrast were desired in the print, a soaking in the No. 3 solution before development (not omitting the use of the bromising solution as instructed) would give the required result. Any form of gold bath would tone the developed prints, but he preferred the following formula:—Hypo, 1 pound; acetate of lead, 1 ounce; common chalk, 1 ounce; add water to make bulk equal to 80 ounces, and, for every 5 ounces of solution, add one grain of gold chloride, allowing 1½ grains of gold to each sheet of paper. Use once only. In reply to a question from one of the members as to a good method of intensification for gelatine negatives, he said that after the usual blacking, the negative should be placed in a gold bath and then redeveloped. The usual courtesies were passed to Mr. Fry for the lucid and practical manner in which he had treated the subject. A sample of Beecham's patent spotting and retouching medium and transparent water colours was handed to one of the members to test and report thereon at the next meeting.

Hackney Photographic Society.—November 14, Mr. Robert Beckett in the chair.—Members' work was shown by Messrs. Roofe & Sodeau. Several members showed specimens of lantern slides printed upon the new Barnet plates. The results were very good, and included a great range and variety of tone. Mr. Roofe showed prints of printing-out Paget and P. O. P. papers, toned with one ounce and a quarter of an ounce acetate of lead respectively. There appeared to be no difference in results. The prints required a little deeper printing than for sulphocyanide toning. Mr. Sodeau showed a platinum print torn in four pieces, toned with uranium to warm tones, three quarters being toned one and a half, three, and twelve hours respectively. The tone that pleased most was that subjected to three hours' toning. Mr. SMITH asked if there was any remedy for reducing an over-printed P. O. P. print to a normal print. Farmer's reducer was recommended. Mr. BARKER asked how long Alpha paper would keep under ordinary circumstances. Mr. BECKETT stated he had used it five to six years old. Mr. ROBERTS said he found the edges turn yellow after keeping some time. Mr. H. M. SMITH, of Messrs. Eastman, then proceeded with a paper upon enlarging generally, and dealt with some very interesting points in connexion with same, illustrated by diagrams. A demonstration was then given, and some excellent results were obtained.

North London Photographic Society.—November 7, Annual General Meeting.—The report of the Council was received and approved, and the following officers elected for the ensuing year:—*President:* Mr. J. Traill Taylor.—*Council:* Messrs. W. Bishop, J. Brewer, J. Douglas, J. Oakley, and E. W. Parfitt.—*Curator:* Mr. W. Few.—*Hon. Secretary and Treasurer:* Mr. W. T. Coventon, 50, Highbury-park, N.

Putney Photographic Society.—November 16, Dr. J. F. Farrar in the chair.—Mr. S. HERBERT FRY, having been unable to prepare the necessary prints to illustrate his promised paper on *Unconventional Printing Methods*, was compelled to postpone that subject until a subsequent meeting, substituting a demonstration on *The Paget Prize Company's Print-out Papers and Lantern Plates*. Mr. FRY stated that, as the same emulsion was used for the paper and plates, and the treatment was so very similar in both cases, he would confine his remarks chiefly to the plates. These, he said, had many advantages over most others. Their chief qualities were, however, their great range of tones, the tolerable certainty of being able to get any tint (warm or cold), absolute purity in the high lights, and, however deeply printed, great translucency in the shadows; in fact, these slides were quite equal to the old collodion. The plates could be treated in two ways, either printed out fully and toned, and fixed, or, if preferred, they could be only partially printed out and the image developed to full depth, the subsequent toning and fixing being the same as when fully printed out. There might at first be some little difficulty in printing to the proper depth, but generally it would be found advisable to print rather fully, as the image could readily be reduced by immersion in a two to three grain solution of ferrocyanide of potassium. This bath would also have the additional advantage of clearing the plate. If under-printed, there was a tendency to force the plate and to veil the high lights. As the developer could be be modified, great power was given over the resulting image, so that by this method good and artistic slides could be made from practically any negative. The development presented no difficulties, and the chemicals were those usually found in any photographer's dark room; the formula for the paper was the same as for the plates. Having brought an exposed plate, Mr. Fry proceeded to show how it was developed. Without previous washing, he placed it in a ten per cent. solution of bromide of potassium, explaining that it should remain there at least three minutes, but that fifteen would not be too long. After having been well washed it was transferred to the developer. As the image gathered strength, he warned the members not to allow development to go as far as in the case of fully printed-out plates, as the developed image appeared to stop more light. After development the plate *must* be well washed—fifteen minutes at least in running water—for, should any developer be carried in the film to the toning bath, the gold would be precipitated, and intensification as well as uneven toning might take place. Development should on no account be forced. If carried on slowly, the result would be well under control, and also more satisfactory. Should the plate, after being toned in the separate bath (but, of course, before being fixed) it could be redeveloped and retoned. Mr. Fry strongly recommended that the instructions and formulæ issued with the plates should be strictly adhered to, as they had been thoroughly tested, and could be relied on to give good results. This was specially so with the developer; in the case of the toning bath greater latitude was permissible, and any bath which had been found satisfactory with print-out paper would do very well. A combined toning and fixing bath should never be used a second time. Just sufficient should be made up for the work to be toned, and, having been used, must be thrown away. Stock solutions could, of course, be kept separately for a long time. Toning should not be carried quite so far as is desired in the final result, as both the paper and plate dry of a somewhat colder tone. A good washing should be given between toning and fixing, and after fixing the washing must be very thorough, the result depending greatly on the thoroughness of the washing. A hearty vote of thanks terminated a pleasant evening.

West London Photographic Society.—November 14.—Mr. J. C. DOLLMAN delivered an address on *Figure in Landscape*. After stating that the disposition of figures in a picture is mainly a matter of feeling begotten of the occasion, Mr. Dollman proceeded to deal with the title subject under the three headings, "Why," "Where," and "How." *Why* have a figure at all the landscape may possess a charm apart from "human interest." If figures be admitted into the picture they should be of secondary interest, subordinate to the principal idea. The figure may assist in intensifying the meaning of the subject, as a man struggling before the storm conveys the idea of wind, or a figure or group may give balance or point to the subject. Turner is the source of the highest instruction on this point. *Where?*—Genius is often an instructive guide. In photography the relative value of the figure is sometimes miscalculated, and the focussing screen, giving the image upside down seriously handicaps the photographer. A suggestion put forward by the lecturer was that the landscape should be photographed first, and a print taken. The print could then be examined at leisure, and the question of where the figure should come thought out. Subsequently the scene could be rephotographed with the figure in the position decided upon. Though troublesome, this plan should prove efficient, and it would give photographers the opportunity of showing what art they possess. The best place for figures is in the space between the mid-distance and the near foreground of the landscape, though a figure quite in the distance may be the making of a picture if judiciously introduced. *How?*—In posing your models, don't overdo it. Learn the value of restrained power, simplicity, and suggestion. *Never do it all.* Leave something for the spectator to do. Provoke inquiry, curiosity, fascination, *and* gratify it. Avoid the commonplace. Seek for simple, unaffected occupation for your figures. Figures in motion should have more space before than

behind them. Study variety in posing your models. Rather let the models pose themselves at your instruction, and seek for grace in disposing them. If the *pose* is *easy*, it will be graceful. Shun the conventional. A sympathetic model is alone the kind to employ. The lecturer concluded with some humorous references to the conventional costume of the day, with especial reference to men's clothing and the absurd persistency of the top hat.

Woodford Photographic Society.—November 16.—Among the items of interest were some lantern slides, shown by Mr. Malby, which very strongly emphasised the influence of temperature on development. Two plates exposed by artificial light under ordinary conditions of working refused to develop satisfactorily, though development was prolonged for three-quarters of an hour. On testing, the temperature was found to be about 47°. Two more plates, similarly exposed, produced most satisfactory slides in a developer identical in composition, but at a temperature of 68°. The President showed a bottle of pyro solution (with sulphite of soda) mixed in April 1888, with some plates exposed under a Warnerke sensitometer, and developed with this solution and one freshly mixed respectively. When the temperature of development was 70°, no difference could be seen between the two; when at 55°, there was a slight difference in favour of the freshly mixed solution. A discussion on *The form that the work of a Photographic Society should take in order to be of the greatest assistance to its younger members* was opened by Mr. H. T. Malby, who said that the first few steps in photography presented the greatest difficulty; if initial difficulties were thoroughly mastered, a sure step had been taken on the road to success. In development, it was useless to lecture, and not of much value to criticise plates after they might be spoiled. In order to teach a young photographer how to develop a negative, it was necessary for a more advanced worker to take him patiently through the actual work. A beginner could never tell when to stop development, and it was impossible to teach this other than by practical demonstration. He offered to give such assistance to any of the members of the Society who desired it at Saturday evening meetings, specially arranged for that purpose, the same afternoons being utilised for outdoor work, when assistance in exposure, management of camera, composition, &c., could be given. Next meeting, December 7, Mr. H. T. Malby on *Copying*.

Birmingham Photographic Society.—November 14, Mr. G. F. Lyndon in the chair.—In continuance of the series of one-man exhibitions, Mr. J. T. Mousley showed a large number of photographs illustrating his methods of working. The prints, which were mostly of architectural subjects, showed great skill and care in selection, and were of splendid technique. They illustrated many methods of printing, some fine sepia tones on gelatine paper being especially admired. Mr. Mousley also gave hints as to mounting and framing, some novel frames being laid on the table.

Liverpool Amateur Photographic Association.—*Life in Tripoli.*—This was the title of a lecture delivered on Wednesday night, 15th inst., by Mr. G. E. Thompson in the City Hall, Eberle-street, under the auspices of the Liverpool Photographic Association. Mr. Paul Lange, in the absence of the President, occupied the chair. Mr. Thompson paid a visit to Tripoli, in Barbary, last April, and secured a large number of admirable photographs, about 140 of which were shown on the screen by the aid of Messrs. Archer & Son's fine limelight lantern. The lecturer gave an interesting account of a week spent in the sunny oasis of Tripoli, among the Arabs, negroes, camels, fruit gardens, and palm forests. His views of the desert, with its boundless stretches of sand, were most telling; here and there were seen camels coming in from distant oasis, laden with esparto grass. This is a staple trade of Tripoli. Views were shown of one of the chief grass yards, where one hundred negroes are employed. The processes were described up to its shipment off to England, where it is converted into paper. The homes of the negroes were visited, including the huts and groups of the people.

On Thursday evening, November 16, Mr. Bynoe gave a lecture on *Hand-camera Work*, with special reference to the "Frena" system; he illustrated all the working parts by diagrams on the screen, showing the improvements in No. 2, the principal being the size, quarter-plate, and the alteration in the shutter, also the use of magnifiers for near objects; he explained and illustrated the great use and simplicity of the swing back. After answering some questions, he exhibited some specimens of pictures taken with the camera.

Glasgow and West of Scotland Amateur Photographic Association.—November 20, Mr. W. J. B. Halley (President) in the chair.—Twenty-one new members were elected. Mr. Victor L. Alexander demonstrated printing on "Nikko" paper, and gave his experience as to time of exposure for printing and enlarging. He showed excellent enlargements made on this paper and finished with a matt surface. Mr. William Goodwin read a paper on *The Factors that Affect Exposure*, stating the limits within which these factors may be expected to vary, and showing how tables of exposure are constructed. An exhibition of members' lantern slides terminated the meeting.

Glasgow Photographic Association.—October 19.—The first popular meeting was held in the large hall of the Philosophical Society's Rooms, Mr. William Lang, jun., F.C.S. (President), in the chair. Mr. William Lamond Howie, F.C.S., delighted a large and appreciative audience with his lecture, *The Scottish Alps*, the descriptions being illustrated with a large series of views taken by the lecturer during his ascents of the more important highland bens. The pictures of mountain scenery taken from the plains and from the snow-clad summits were greatly admired. A number of views of the snow scenery on the summit of Ben Nevis, photographed last Easter, were then passed through, the great precipices from various points, the curious configuration of the surface snow, and views of the Observatory on the summit, 4406 feet above sea level. The observers were shown at work, and one of the most striking being the summit hotel and restaurant. One view showed Beu Aonach with two figures standing on the brink of the precipice, which drops 2000 feet into Glen Nevis. The lecturer's experiences amongst the mountains were told in a racy and interesting manner. In contrast to the many snow scenes were shown some excellent landscapes of highland scenery, and also a few fishing and deer stalking scenes. On the motion of Mr. John Stuart a very hearty vote of thanks was awarded Mr. Howie.

November 16, Mr. William Lang, jun., F.C.S. (President), in the chair.—The President delivered his retiring address, and then after office bearers for the ensuing year were elected, Mr. John Stuart succeeding Mr. Lang in the Presidentship, which he has held for eight years, a number of photographic novelties, including new printing-out and developing papers, apparatus, and a Dallmeyer focussing view finder for attachment to a camera were shown.

Munster Camera Club.—The opening meeting of the session of the Munster Camera Club was held last week in the lecture hall of the Crawford School of Science and Art, when Major Lysaght (late president of the Society) gave an address on the subject of his visit to the Photographic Convention recently held at Plymouth. Mr. John Day presided. Major Lysaght, in the course of his remarks, explained that the meeting at Plymouth was the eighth that had taken place, and next year the Convention would be held in Dublin. He then proceeded to exhibit many photographic views that he had taken during the cross-channel trip and of places of interest in and around Plymouth. A group of the members attending the Convention was photographed and put upon the screen. Numerous other slides of a miscellaneous series were also shown, and dealt with interesting subjects. At the conclusion of the discourse Dr. Rinorose Atkins proposed a vote of thanks to Major Lysaght, and referred to the services that he had afforded the Society during his presidency. He considered that now the Society, having been so well established, should continue, and its members should rally round their new President. The Chairman, in conveying the vote of thanks, said the members felt that they owned a deep debt of gratitude to Major Lysaght for the interest he had taken in the Society, and the committee considered that they could not allow their late president to leave Cork without presenting him with some token of their esteem. Therefore, in putting the vote of thanks, he had also to ask Major Lysaght to accept the illuminated address that had been prepared, and that it was the desire should be presented to him on behalf of the Society. Major Lysaght, in replying to the vote of thanks, assured the members of the Society that the gift which they presented him with on the occasion of his leaving the city would be always appreciated by him. Though he would not be able to be amongst them in the near future, still any assistance that he could render would be most cheerfully given in the way of providing photographic lantern slides for the entertainment of the members of the Society. His desire would be that the members should fall in with Dr. Atkins's suggestion, and to assist their new President for the advancement of the Club.

Photographic Society of Japan.—Oct. 6 Mr. C. D West in the chair. Mr. W. K. Burton showed comparative results of work done with lenses of "symmetrical" or "rectilinear" type, and the new Zeiss anastigmatic lenses. The most interesting comparison was between an aplanatic (rapid rectilinear or rapid symmetrical lens) of exceptionally good quality and an anastigmatic, Series II. The difference was remarkable. Briefly summed up, the anastigmatic was with full aperture twice as rapid as the aplanatic. It gave the same flatness of field with twice the angular aperture (four times the rapidity) and, with a small stop, it acted as a wide-angle lens. The absence of astigmatism in the anastigmatic lens was remarkable. Aplanatic lenses of the same rapidity, or even greater than the anastigmatic, were made, but, used stop for stop, the roundness of field was greater than that of the somewhat slow aplanat that has been used for the comparative experiment.

FORTHCOMING EXHIBITIONS.

1893.		
November 24, 25	...	*Stanley Show (Photographic Section), Agricultural Hall. Manager, Walter D. Welford, 57 and 58, Chancery-lane, W.C.
" 24, 25	...	*Leytonstone Camera Club. Hon. Secretary, A. E. Bailey, Rose Bank, South-west-road, Leytonstone.
December	.....	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
" 18–Jan. 22, 1894		*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

News and Notes.

Lewisham Camera Club.—December 1, *Modern Plate-making*, by Mr. H. O. Drake.

The Photographic Club.—November 29, *Lantern Matters*, Monthly Lantern Meeting.

Liverpool Amateur Photographic Association.—November 30, *Quiet Corners in France and Italy*, Lantern Lecture by Mr. W. P. Christian.

Bristol International Photographic Exhibition.—The Judges already appointed are Messrs. Valentine Blanchard, Payne Jennings, and S. P. Jackson (painter).

Dark Rooms at Venice.—Mr. W. J. Stillman writes: "For the convenience of amateurs of photography, who are working in Venice, I wish to say that they will find at the establishment of Celso Mantovani & Co., Merceria del Capitello, Nos. 4861-2-3, well-fitted and spacious dark rooms, with water supply and electric light, as well as the ordinary chemicals."

The Thirty-eighth Annual Exhibition of the Photographic Society, which closed at ten p.m. on Wednesday, the 15th inst., has been, judging by the support it has received from the paying public, by far the most successful

on record, no less than 11,376 having passed the turnstile (exclusive of the staff of those members and others who visited the Exhibition at times when it was not open to the public) as against 9931 last year, which was the largest total up to the present. The Exhibition has been visited as heretofore by many of the best-known artists of the day. The Lantern Evenings were even more favourably attended than was the case last year, the gallery, especially for the last few nights, being packed.

CROYDON CAMERA CLUB LANTERN SHOW.—A densely crowded audience assembled at the Braithwaite Hall on the 15th, when Mr. Charles W. Hastings showed and explained a collection of lantern slides. Following the above, the President of the Club, Mr. Hector Macleau, F.G.S., acted as *cicerone* in explaining the features of a large number of views contributed by members of the Club. The fifty cricketing snap-shot studies by George Corden produced much interest and laughter, especially *Puzzle*, *Find the Secretary*, and another, which exhibited Mr. Sydney Eldridge attitudinising at "the nets." A series by G. R. White, who worked the lantern, of views at Boyton's Water Show, also went well, and brought out prolonged applause. Other members to show slides were Mr. Frost, H. E. Holland (some capital views in Devon and Cornwall), and Mr. Ryan, this last gentleman's Norwegian series giving great satisfaction. Last on the list were the unusually fine set of Indian palaces and other interesting features, by Mr. C.F. Oakley.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

EXHIBITIONS AND MEDALS.

To the EDITOR.

SIR,—I am pleased to find that my letter to the Bristol Executive, which you kindly printed, has elicited some correspondence, and I wish we could see the question thoroughly thrashed out, and settled for a few years.

Mr. H. W. Bennett will, perhaps, be surprised to learn that I almost entirely agree with him, and I reply with pleasure.

To his first paragraph:—It is, I think, admitted all round, and supported by the press, that Exhibitions have been divided into too many classes, and too many medals have been offered and are usually awarded. It is a good sign, and some evidence that I am right, that the promoters of many Exhibitions are now reducing the number. Mr. Bennett questions the right of a small body to dictate, &c. But somebody must "bell the cat." I am not a small body, but perhaps I have as thick a skin as any, which enables me to endeavour to perform that disagreeable office.

Mr. Bennett refers me to the recent judging at Pall Mall. He has me there. I leave the defence of the Judges to "A. R. E.," who does so with singular skill in the letter which follows Mr. Bennett's.

What I take exception to most in your correspondent's letter is when he says that the objection to medals might have been omitted from the letter of "a man who has taken so many medals as Mr. Robinson has done." My opinion about medals has never changed.

The Salon, among its other successes, certainly showed that a large collection of photographs could be got together without the assistance of prizes, but I am in favour of medals judiciously offered. I owe much to medals, and am very proud of my collection, which was nearly all won before medals were spread broadcast for every daw to pick at. Medals have done a good deal towards extracting the best work out of me that was there to bring out. This was when the medal was really a prize and the work was done in competition for it.

Writing to you five years ago on this subject, I said, "There was a time when winning a medal was an event, when the wonderful news was flashed off to you by telegraph," and more to that effect. Are medals so valuable now? For many years that I competed, medal-giving Exhibitions were so few that you could seldom take more than three prizes in a year, if you took all that were possible, both British and foreign. One of these medals was worth a score of those of the present day, when half a dozen have been known to fall to one exhibitor at one time. Do they induce photographers now to take more than a languid interest, or to do special work for all they are worth? Certainly not. To compete in the many subdivided classes, photographers seldom take more trouble than to select from what they happen to have by them.

There is also a letter dated from the Central Photographic Club, signed "John H. Avery." As the tone of this letter seems to be intentionally offensive, I shall pursue my usual course, and take no further notice of it.—I am, yours, &c.,

H. P. ROBINSON.

Tunbridge Wells, November 17, 1893.

THE SMELL OF OIL LANTERNS.

To the EDITOR.

SIR,—Your remarks upon the offensive smell when using oil lanterns are so fully to the point that, whilst endorsing them entirely, I would supplement them by reminding your readers that, if they will take the trouble to pour off all the oil remaining in the reservoir when the lantern is done with, then relight the wicks and allow them to burn out, all the residue and the oil with which the wicks are saturated will be consumed, and the lamp consequently will be perfectly clean and free from stale oil, which, as you correctly say, is the cause of the offensive smell.

By no other means can you free the lamp and wicks. I have now been using this method for the last two years and find it most efficacious. It may appear to give additional trouble, but such is not really the case, as no perpetual wiping is needed, and the lamp is always ready for use. You may remember I notified you of this method some time ago. Of course the reservoir must not be recharged till the lantern is in position for another entertainment.—I am, yours, &c.,

FRANK HOWARD.

The Chilterns, Wallingford, November 18, 1893.

PLATES *VERSUS* FILMS.

To the EDITOR.

SIR,—I think Mr. Stillman's letter in your issue of the 10th inst. needs some answer on my part.

In Mr. Stillman's letter of October 15, he writes as to "the results of trials of films of various makers against plates," and winds up with the sweeping statement that, "for work requiring the highest rapidity, films, as now put on the market, without regard to their make, are no substitute for glass plates."

I ventured to give instances in my own experience to show that films were made equal in all respects to plates. Mr. Stillman now tells me that I "have a very vague idea of what constitutes a test," and it is suggested all my tests were made by guess with different developers on different days.

In his letter of the 15th, Mr. Stillman says the very rapid films fogged after two months, a statement apparently meant to apply to all the various rapid films he had used; he now says it applies to Mr. X's films. The most astonishing, to me of Mr. Stillman's experiences, however, is that even the very rapid films were less than one-fifth the rapidity of the rapid plates, the plates, he says, being fairly exposed in one-thousandth of a second, and the films breaking down with one-two-hundredth of a second.

The experiences I gave were, like those of Mr. Stillman, made in ordinary work. The following, however, may be of interest to some of your readers, although I would not suggest that they are as conclusive or as accurate as experiments Mr. Stillman may have made.

I obtained, more than a year since, samples of three makes of films, A, B, and C, and plates of the same make as A, and bearing the same speed number, 25 W. The B make was also marked 25 W, and C no speed number, but the most rapid of the maker.

One of each make of films and a plate were put in a dark slide, side by side, and exposed with a shutter, the exposure being made on the evenly lighted front of a house. They were all developed together, in the same dish, with ferrous oxalate. Result, none of them quite sufficiently exposed. Film B was the best. With the film and plate A, by the same maker, the plate was slightly the best. Film C was slightly the slowest of the lot.

The difference between all of them was less than I expected, and in the case of A and B no more than I should in any case expect between different plates bearing the same number, W. The same experiment was repeated with hydroquinons, with practically the same result, only the hydroquinone did not develop any of them quite so far, due to either the light having gone off between the two exposures, or showing it to be a less powerful developer.

If there is any retarding action due to celluloid, I can only imagine it is due to the camphor in the film. I put several lumps of camphor in water, and left it for several days; the water then smelt and tasted strongly of it. I took two plates of the same batch as used in the other experiments, and exposed them together; they were then soaked for an hour, one in plain water, the other in the camphor water, and developed together. Result, no apparent difference whatever.

I have sometimes thought a plate ought to appear more exposed than a film with the same exposure, due to the reflection of light from the back of the glass. If this were so, a *backed* plate should be slower than an unbacked one.

As to amidol, it is the most powerful developer I know for short exposures, although Mr. Stillman does not think much of it apparently.—I am, yours, &c.,

H. G. M. CONYBEARE.

FILMS: CAUSES OF THEIR DETERIORATION.

To the EDITOR.

SIR,—We have noticed remarks in the photographic press from time to time about the action of free camphor in the celluloid film on the sensitive emulsion. We think we can now offer the real solution of the troubles said to have arisen, and we desire to sound a note of warning.

The Continental films that have so far come under our notice, while we admit they are most attractive in appearance, we have found in every

case, that they are either acid, or have a tendency to become so, under certain conditions taking quite a long time to develop. This is the fault of nearly if not all material that we have ever seen made by parties other than ourselves, and took us quite a long time in experimenting and the expenditure of a great deal of money to overcome in our goods.

Its presence is fatal in photographic negatives. The cause of films being bad is simply an acid tendency in the film acting on the photographic emulsion.

As I have mentioned above, the sheets or films may not show any acid by the ordinary tests when freshly received; it is a peculiar property of the material, when made by ordinary methods, to gradually develop its own acid. It is to a very slight extent at first, although quite sufficient to chemically affect the photographic emulsion, but once started keeps on growing, until the material disintegrates and eventually takes fire by spontaneous combustion. If English plate makers use this material or in fact any material but such as ours, they will surely experience this result and ruin the reputation of their plates. As I say, they cannot detect it at first, except in isolated instances, but, long after the plates are made, they will commence to deteriorate and become ruined. The assurance that ours are not the same in this respect is the fact that they have been in use for six or seven years, and have shown by the only test which is safe, namely, the test of time, that they are free from it.

If your readers do not believe all the statements that we have made, there is a test which we can point out to them, although it is not an absolutely certain one, and the material may still stand the test, and yet contain the elements which will lead to the results referred to. Heat has somewhat the same effect in developing the acid quality as time, although in nothing like the same degree, and we feel satisfied, from our experience, that in almost every case, if you take a piece of any film but our own, and press it between plates heated to, say, about 210° to 240° Fahr., leaving it, say, fifteen minutes or so, and then scraping off with a knife some fine shavings from the surface, and have them tested by a competent chemist for nitrous acid (not nitric acid), that, if his tests are sufficiently delicate, he will find traces of it. The traces may be only slight, but, once started, they will progress as before stated.

We are, of course, aware that it will be said that our statements are coloured by our own interests, but the facts, as given above, and as confirmed by our own experience in a number of tests, are literally so.

As regards the appearance—that is, its clearness and transparency—there is no trouble in accomplishing that. We can make it just as good, and even better, in these respects than the Continental samples, but it is not safe to do so, and we have always refused to make this class of material. It is in trying to preserve this appearance that one of the greatest dangers in producing an acid tendency in the stock is occasioned.—We are, yours, &c., S. Guiterman & Co.,

35 *and* 36, *Aldermanbury, London, E.C., November* 21, 1893.

CAN THE GRADATIONS IN OUR NEGATIVES BE VARIED, AND CAN INCORRECT EXPOSURES BE CORRECTED BY VARIATIONS IN DEVELOPMENT?

To the Editor.

Sir,—Permit me, through the medium of your Journal, to call the attention of your readers (doubtless many of whom were present) to the deductions of Mr. Howard Farmer, as enunciated in his lecture at the Polytechnic on Tuesday, November 7, entitled as above, which attacks a universally accepted and foregone conclusion respecting which very few, if any, of us practical workers ever had a doubt. I have studied under Mr. Farmer, and take him to be a man of practical common sense; but I think that here he has made a serious blunder. He sought to show, and finally made the statement, that gradation *cannot* be altered by modification of developer; and what really appeared to be such was a more or less amount of fog present, according to treatment by a more or less concentrated developer; and that in some instances this fog was graduated over the film, this bringing us to the conclusion that it was variation in thegradation.

Never was I more surprised at any statement, and Mr. Farmer's reasoning at the time seemed logical enough; but it was not until a day or so afterwards, when thinking quietly over the lecture, that it occurred to me that Mr. Farmer, while arriving at his conclusion, had lost sight of one fact, which would doubtless have had a very different effect upon the final result of his reasoning. I refer to the fact that printing density in a negative is reached long before the extreme limit of the action of light is brought out by the developer.

Let us by a simple test explain. Take the case of an under-exposure—presuming we know this before commencing development—and that the subject is a lady wearing a white dress, with a background of heavy foliage. If we start this plate with about a quarter the normal amount of accelerator, the dress will first appear, and, the development going on slowly, it will gain in density, and probably get as dense as it should be in a sufficiently developed negative for printing purposes before more than a bare outline of the features or trace of the background is discernible. Now, let us take another negative of the same subject, similarly timed, but at the outset treat it with dilute ammonia (or other accelerator, according to developer), and, when it has penetrated the film, pour it off and replace by the developer containing the full amount of accelerator, and diluted with water to about twice its normal bulk, and with the least admissible amount of restraining bromide. With this treatment all the available detail in the negative will simultaneously flash out, and as development is prolonged the lights build up proportionately as the light has acted, and by the time printing density is reached we have a negative entirely different in quality to the previous one, the contrast being nothing nearly so marked, the face sufficiently dense, and a fair amount of detail in background—in fact, a very passable negative. Now, is this difference due to fog alone? I say most emphatically, No. Agreed, there is a certain amount of fog in the forced negative, but not anything like sufficient to account for the difference in quality and gradation. In the one case we have a negative of a white dress; in the other an average negative with the proper amount of gradation. According to Mr. Farmer's arguments, there is the same amount of detail in both, the difference being entirely due to graduated fog. Judge ye! With Mr. Farmer I could agree, provided that development in both instances was sufficiently prolonged to bring out the extreme limit of the action of light; then we might get two negatives, the only difference between them being due to fog. I speak from long and exceptional experience, having developed for several years in succession almost the whole of the negatives of the leading—or, at least, one of the three leading—portrait firms in the West, in addition to several years' experience previously and since in business for myself. Should this come under Mr. Farmer's notice, we trust that he will at once see his mistake. — I am, yours, &c.,

H. W. Busbridge.

41 *Vanbrugh-park, Blackheath, S.E., November* 14, 1893.

EXPERIENCE, JUDGMENT, AND THE CALCULATION OF EXPOSURES.

To the Editor.

Sir,—One of the provincial Societies has given to the world the dictum that "no exposure tables or meters at present in use will entirely supersede judgment and experience," and you have touched upon the subject in an editorial paragraph last week.

I, in common with probably all other practical photographers, entirely agree with this very evident fact; but the phrase seems to be written under the assumption that all such "aids to exposure" *do* attempt to entirely take the place of judgment and experience, and are therefore failures.

Naturally I speak of the methods carried out in the exposure meter invented by me, and I do most emphatically say that it in no way attempts to supersede judgment and experience, save in the matter of testing the actinic power of the light. On the contrary, the very essence of its principle is that it provides terms for recording the result of such judgment and experience, and utilises these records in subsequent exposures. And there is the advantage in such systematic records that beginners can have part of the experience (in the matter of exposure) of older photographers communicated to them.

It is true that there is one factor—the character of the subject to be photographed—which will always require the exercise of the judgment of the photographer, and in my system the user of the exposure meter is given full play in the exercise of such judgment, only this is kept distinct from the more constant factors of size of stop and the relative speed of plate.

In one detail I certainly attempt to supersede the usual method of exercising judgment. The human eye is a most inadequate instrument for estimating variations in the chemical force of the light, and in the amount of light reaching a given subject, and in this matter of estimating light I find the readings of an actinometer far more reliable than the judgment of even an experienced photographer.

When, in the brewing trade, the saccharometer and the thermometer were introduced to take the place of old rule-of-thumb methods of estimating the gravity and temperature of the liquors, the cry was, no doubt, raised that "nothing would take the place of experience." But brewers now know that these indispensable instruments aid them by accurately recording the methods of experience, and enabling the same results to be obtained time after time. And so it will be with the use of the actinometer for photographic exposures.

I find it continually assumed that an exposure meter is something especially designed for a beginner. I must confess that I seldom thought of the beginner in designing my instrument. My aim was to get an accurate and simple instrument for the use of photographers who feel the need of help, more especially in difficult subjects, such as interiors, and it is within my knowledge that a very fair proportion of my instruments sold are used by photographers of experience.

There is a very funny assumption in the editorial paragraph on the subject which I must refer to. It is presumed that when a man has estimated an exposure by tables or meter, and the light changes just before he makes the exposure, he is slavishly bound to give the exact exposure just calculated. Surely he is in exactly the same position as if he had estimated the exposure by his unaided judgment, and is perfectly free to alter the exposure on the moment in accordance with the altered

light. In my experience the use of an actinometer quickens rather than dulls a photographer's perception of the variations of light.—I am, yours, &c., ALFRED WATKINS.

Hereford, November 18, 1893.

MEDALS AND EXHIBITIONS.

To the EDITOR.

SIR,—Not being exhibitors, we should like our humble opinion to be considered impartial. We fail to see why the Bristol Committee cannot make what rules they like independent of medal-hunters; they have held successful exhibitions in the past, and, we hope, will again. It seems to have been the custom to give medal-receivers the best positions, and award another medal mainly on account of prestige thus obtained, not altogether the superiority of their productions, passing over those of less known but perhaps equal merit who do not send pictures all over the kingdom, with the chance of being hung out of sight. The custom of recent years to give the same picture several medals in the same year we consider, rightly or wrongly, most unjust to others. We have in mind an extensive photographic business boasting of being awarded over forty medals, many of them for two or three pictures that were produced entirely by the *employés* of the person whose name they bear. We see many suggestions from week to week for improving business; one by a teacher of photography, who evidently wants teaching, of sending home pictures same day as taken. No one so far seems to have seen that what has tended to lower the profession most in the public estimation, and make it a hard struggle for many good men in a small way of business, is the system known as canvassing, in many cases swindling, by which big firms have reaped fortunes from every town, to great injury to their smaller brethren.—We are, yours, &c., RUDD & Co.

Dudley.

MR. WOODBURY AND THE PAGET COMPANY.

To the EDITOR.

SIR,—In reply to Mr. Woodbury's letter, will you allow me to say that I frankly accept his explanation; but, at the same time, would like it to be clearly understood that I was not aware of his experiments, and therefore derived no hint or assistance of any kind from them. Nor have I since been able to succeed with iodide. The whole affair seems to have arisen from a series of curious accidental coincidences, combined with a little indiscretion on the part of Mr. Woodbury; but, as he has now so fully and handsomely admitted our claim to what I must still hold to be the only practicable method, I trust that no more need be said. For my part, I am quite content to bury the hatchet. R.I.P.

A somewhat injudicious friend of Mr. Woodbury, who has been making a little sensational "copy" out of the incident, sees no novelty in the process, because, in the year 1881, Dr. Eder described how gelatino-chloride paper for development (not printing out) might not only be made from a chloride emulsion, but also by the roundabout process of sensitising chlorised gelatine paper on a silver bath, and then washing out the surplus silver, or converting it into chloride by floating again on a bath of sodium chloride.

There may possibly be some connexion between this and the new process; but I am somehow tempted to think of Tenterden Steeple and the Goodwin Sands, or to wonder whether any modern shipbuilding patents might be upset by showing that one Moses, a good many years ago, published a description of how a gentleman named Noah built an ark.—I am, yours, &c., WM. J. WILSON.

Paget Works, Watford, November 20, 1893.

ELECTRICITY FOR STUDIOS.

To the EDITOR.

SIR,—In his article last week "Free Lance" alludes to an article which I wrote, and then goes on to say, "I do not know if he is the same writer who gives an interesting letter upon electric heating. If so, I am afraid his sanguine hopes about the economy of electricity will be doomed to disappointment. He had been informed that the cost of heat from electricity would be about the same as gas. This is moonshine." Now, I cannot see how the question of heating by electricity can be in any way affected by the question as to whether I did or did not write an article on a different subject. I am the same writer, but how could my hopes be doomed to disappointment when I wrote, "this is a *practical realisation* of electric heating which I have long hoped for?" I felt gratified, not about the "economy," but because electric heating had become an accomplished fact. I said that the cost would be about the same as gas, or, if it cost a little more, less heat would be required, as there is no waste. He says, "This is moonshine." Electric *heating* gives no shine at all, it is produced and works in pitch darkness. Electric lighting by a large and lofty arc lamp is the nearest approach to actual moonshine that the world has ever yet seen. Who can forget those delightful summer nights at the old Horticultural Gardens at South Kensington when the coloured fountains used to play, and all London had a chance of a few hours of healthful enjoyment, enlivened by the cheerful strains of finest music, and inspired by pleasant rambles in the grounds, lit up by the refulgence of perpetual moonshine from the electric globe, even when the nights were dark and starless, and Luna was not due?

"Free Lance" is very droll when he tells me to "turn on the electric lights in any apartment for an hour, and then, after ascertaining the increase of temperature, burn an ordinary gas burner, gas costing, say, less than one-fourth the electricity, and see which gives the greater increase." Turn on the electric *lights* to *heat* any apartment, and that to test the suitability of the electric *light* for *heating* a photographer's *dark* room! Why, it is one of the greatest advantages of the electric light that the amount of heat emitted is so slight as to be almost imperceptible. He is quite unaware of the fact that electric heating is produced on entirely different principles, and does its work in a state of absolute darkness. You can easily cook a dinner by electric heat, but you must have either electric, gas, or oil light to do it by. Extinguish the light, the cooking will go on all the same. You can smell it and hear it, but you cannot see it; there is not the slightest spark of light to be obtained from the electric heating apparatus. The polished bottoms of the saucepans, kettles, &c., remain quite as clean as the tops.

"Free Lance" announces that electricity "is a toy for heating when any ordinary comparison of cost is instituted. I should like 'Palette's' informant to tell him what it would cost to heat enough water for a hot bath, and then to ask Mr. Fletcher what he would do it for with gas." I called on my informant, Mr. H. J. Dowsing, Member of the Institute of Electric Engineers, &c., of the firm of Crompton & Co., the acknowledged pioneers of electric heating; while waiting to see him I observed upwards of a dozen full-size electric ovens for cooking a dinner, including large joints, &c., they were marked "Sold to the City of London Electric Supply Company." I was told they formed portion of a sample order for twenty to be let out on hire to their customers, and that other electric companies were following in the same track. I showed Mr. Dowsing the challenge, and asked him if he would prepare an estimate for heating a bath; he replied, "Certainly not, at the bidding of a correspondent of whom we know nothing, and who himself knows nothing of the subject, but who yet can propose a test the most unreasonable and unfair that could possibly be devised; we are far too busy and our time is too valuable to be wasted for the benefit of any rival firm. Electric heating is a comparatively new thing, and we have only been working it out practically during the last nine months; a bath has never yet been heated by electricity, but, if a *bonâ fide* application were made to us, we should set about making experiments and calculations, and prepare an estimate. A "Fletcher's Patent Water-heater" is a costly apparatus, specially contrived for that particular purpose only; the water passes over such an enormous heating surface of copper, that almost the whole of the heat is extracted from the gas before it passes into the flue; it could not, therefore, afford a fair average test of the use of gas for ordinary heating purposes. Mr. Dowsing recently completed a new and greatly enlarged edition of the *Electrical Engineer's Price Book*, an important work of 406 pages, published last August by Griffin & Co. He states in his preface that, although there has been an ample issue of scientific works, up to the present nothing appears to have been done in the way of general information on the commercial aspect of electrical work, which fact has convinced him of the absolute necessity of affording it. He lent me a copy to look over, and kindly gave me permission to extract any information which might be useful to your readers. He mentioned that Mr. W. H. Preece, F.R.S., Chief Electrician to the General Post Office, in addressing the Municipal Engineers lately, stated that 1 lb. pound of coal distilled into gas will give a light = 17 candles per hour; 1 lb. do. in electric energy = 48 candles incandescent, or 288 arc. In the event of continuous demand for electric supply day and night, he calculates that the current could be supplied for light at a price equivalent to 1½*d.* per 1000 cubic feet of gas, charged at present 3*s.* I have it, on the same high authority, that 4000 candles for one hour will require 1000 cubic feet of gas at a cost of 2*s.*; 4000 candles can be produced by the arc light at 8*d.*, and by incandescent lamp for 4*s.* Average price paid for burner for gas (at 3*s.* per 1000) is 9*s.* per annum; ditto, ditto, for electric lamps, 10*s.* ditto.

In the General Post Office the price paid per gas lamp is 18*s.*; ditto, ditto, electric lamp, 22*s.* In the Post Office Savings Bank, owing to the improved health of the 1500 people employed there, 300 extra days' work were secured from the staff, and the value of this time exceeded the cost of the electric light. All large employers have received the same benefit; it is indeed the sanitary aspect of electricity that is ensuring its rapid advance. It can now be supplied cheaper than gas; the Great Northern Telegraph Company, at Newcastle, say that electric lighting is only two-thirds of the former cost of gas, which is 1*s.* 10*d.* per 1000; electric energy 4½*d.* per unit. I am told that at Ottawa, Canada, it is only 1½*d.*; that must be owing to cheap water power. There is no difference between the practical cost of electricity and that of gas. Gas at 3*s.* per 1000 costs the same as electricity at 6*d.* per unit. I visited the St. Pancras Electric Works, which they are rapidly extending, they supply the current for light at 6*d.*, and for heating and cooking at 3*d.* per unit; they charge 10*s.* for laying on the electric supply. In the City of London the price for heating is 4*d.* per unit. In chapter 12 of Mr. Dowsing's book, on "electric smelting and welding," he says, "it is only now that electricity is made available

or heating purposes on a large scale. No other form of furnace can produce such enormous heat as that generated in the electric furnace." Other firms are now beginning to supply the fittings for electric heating; I saw one pint of water, the other day, boiled in a copper kettle on an electric heater, at Verity's, in eight minutes, at a cost of one farthing. The heating stoves do not seem as yet to give so much heat value as the ovens, &c. I think they would be too expensive at present for a large studio, but a dark room could probably be heated admirably for about 50 per cent. more than gas; even if it cost double, it would be practically cheaper, considering its many advantages. This must be my final communication on the subject.—I am, yours, &c.,

PALETTE,

November 17, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Six-inch or a twelve-inch burnisher, for a good rolling press.—Address, J. WEBBER, Photographer, Canterbury.

Wanted, retort and purifier for making oxygen; in exchange for Postage-stamp camera, nine lenses, or lantern slides.—Address, EARL, 47A, Broad-street, Worcester.

Photographic News, 1875 to 1888, unbound; exchange for (secondhand) 12×10 or 9×7 field camera, tripod, or leather cases; difference adjusted.—Address, F. WATSON, 33, Alfred-road, Acton, W.

Will exchange background, exterior, canvas in oils, good condition, by Marion, for clouded background or good interior.—Address, ALBERT DURN, The Studio, Wotton-under-edge, Gloucestershire.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

GOLD CHLORIDE.—There is no danger of forming an explosive compound with the mixture of nitro-hydrochloric acids you name.

SUUM CUIQUE.—We should be glad to insert a letter on the abstract question as to whether an operator has a right to a copy of the work he does.

MARY CAMPBELL.—What is meant is that to the stock toning solution sufficient gold should be added to make up for that used, say, one grain per sheet.

COL. SPENCER NICHOLL.—Dissolve the silver nitrate first, and then add the cyanide until the precipitate formed is redissolved. You reversed the process.

W. BLAKE.—White hard varnish must be diluted with spirit to make it suitable for negatives. If it has been used as purchased, no wonder that "it has proved a failure."

PYRO writes: "Would you kindly give me the address of photographic publishers of views in Paris (French scenery), and greatly oblige?"—Perhaps some reader will oblige.

A. BURRIDGE.—Communicate with the local police in all such cases; but, better still, do not part with your money until you have taken reasonable precautions to ascertain the *bona fides* of the advertisers.

W. T.—We do not think that photography is systematically employed at the London hospitals. We can only suggest that you write to the secretaries of those institutions, stating your qualifications and wishes.

G. R.—It is quite a fallacy to suppose that the copies of paintings to be seen in the shop window are made from monochromes painted for the purpose of reproduction by photography. They are made from the originals, which, more often than not, are in very brilliant colours, as most Continental paintings are.

A. W. X.—Time is too short yet to pass any opinion on the comparative permanence of albumen and gelatine prints. The former process has been on its trial for forty years or more, and many of the prints are still without change. The latter has only been on its trial for a few years, and some prints, like others on albumen, have shown a marked change in the time.

R. A. E.—The safest way to fill an ether saturator by artificial light is to do it outside a window at which a light is burning on the inside. In this way, no risk whatever is incurred. The saturator should never be recharged in the room before the audience should it become exhausted. Apart from the danger, the smell of ether is objectionable to those who are not familiar with it.

A. J. writes: "Would you kindly tell me what is the best system of marking and storing negatives for a small business where the expense of separate envelopes for each negative does not appear to be advisable?"—Simply write or scratch the name and number on the negative, and, if envelopes are too costly, wrap them in plain paper with the number written upon it on the outside.

C. THOMAS.—You must not rely too much upon what is said on photographic matters in the daily press, otherwise you may believe in a lot of nonsense. We did not see the announcement in question, but it must have carried absurdity on the face of it.

J. A., JUN.—Write to Messrs. Schmiers, Weruer, & Co., Leipsic. They will supply the necessary machines, &c. The cost of a medium-size machine is, we think, between two hundred and fifty and three hundred pounds. The other appliances are not costly. You must have been exceptionally unfortunate in your experience with collotype printers. Had the work been entrusted to a good house, you would not have to reject half the prints.

W. J. FARMER.—We could only answer your numerous questions after a long series of experiments, occupying a great deal of time, which you are probably better able to afford than we are, or why not try these experiments for yourself? We are always glad, where possible, to help our correspondents in their difficulties, but in your case nothing less than an exhaustive treatise is required. At this (and especially by post) we must beg you to let us draw the line.

STEPHEN WILSON.—The collotype process is far more applicable to that class of work than Woodburytype. With the latter process delicate vignettes are not to be successfully obtained when working on a commercial scale. Furthermore, collotypes can be as easily printed with white margins, so that mounting is unnecessary, as without. If price were an object, it is possible process blocks would answer, that is, if the number required is tolerably large; for small numbers, collotype is cheaper than "process work."

LONDON, W.C.—The price of copper plates, surfaced and polished, ready for etching, may appear somewhat high, but we believe they are not, if of good quality, to be had at less than the prices quoted. The rolled sheet copper of the metal warehouses would require a great deal of laborious and tedious work to be bestowed upon it before it could be made available for photogravure plates. We are not aware that the plates used for this purpose on the Continent are any better than those sold here, and we doubt if they are.

ROBERT W. CONCHIE.—1. Better not mix up the formulæ; rather make comparative trials of the two, and use that which works best in your hands. 2. If the bath were made with pure materials, and in chemically clean vessels, the gold should not, and would not, be deposited. As your experience has been so unfortunate, we advise you to make up only sufficient bath at a time to tone the prints desired. 3. Yes, though it will keep better in a strong solution. 4. Lithographic chalk, or the ink used by lithographic artists.

W. A. T.—1. Unless the prints be treated with alum, the coating will dissolve if immersed in warm solutions. Alum the prints, and then proceed as you have been doing. 2. The spots are touched out in the negative. Only experience is required to judge of the right amount of colour to apply. That, of course, must depend upon the density of the image. 3. The yellow screen is of little use with ordinary plates. 4. It may be applied by itself or mixed with a little dextrine. Plenty has been said on the subject during the last few months.

B.—The electric-lighting plant supplied by the firm named is very complete, and is used in many of the London studios. They would doubtless supply it with any other lamp if preferred. If you make the apparatus yourself, it will certainly cost you less if your time is not of great value. We see no reason why the gentleman you mention should not be a practical adviser; a knowledge of photography is not necessary to make an efficient appliance for lighting an object—the sitter in this case. Nothing on the subject is needed beyond what has already appeared in back volumes.

F. J. R.—1. To have about equal quantities of silver converted into chloride and citrate respectively, the quantity of citrate of potash should be fifteen grains. The proportion here given makes a softer picture, but eight and fifteen would print better from thin negatives. 2. Chloride of ammonium at boiling temperature would decompose borax, forming tetrametaborate of soda; but we do not think it should in the cold. It may have some effect on old bleached lac. Try potassium or sodium chloride. It answers nearly as well, though it is more trouble, to size the paper first and then salt.

W. RATCLIFFE.—The fault—the mottled appearance in the prints—is due to the paper being insufficiently sensitised. A much longer floating, on that strength of bath, was required on account of the hardness of the sizing as it was applied. If the lac were good, the whole of it should have dissolved. Probably the sample used had been bleached for a long time, and so had lost its solubility. If you read the article again, you will see the solution is to be applied with a brush, not the paper soaked in it for ten minutes. This, in itself, was quite enough to account for the appearance when the paper was printed.

CONTENTS.

capable of being exercised on the sensitised gelatine by the celluloid support, Messrs. Guiterman & Co. have shown us the result of an experiment made by one of the experts of the Celluloid Company, Newark, N. J., U.S.A., of which they are agents for this country. In order to anticipate the action of time, two squares of celluloid—one a German production, the other being the American make—were placed on a thick pad of blue blotting-paper, and, after being covered with a thin paper, a laundress's flat iron heated to a temperature of 240° or 250° Fahr. was left on for five minutes, with this result, that the German make had become disintegrated and given off enough nitrous acid to show a decided decolourising of the paper in immediate contact with it. The American sample remained unaffected. As is well known, there are various ways of making celluloid, no two manufactures being absolutely alike.

A Good Word for Rollable Films.—If celluloid, *per se*, has really any deleterious action upon gelatine emulsion, it certainly takes a long time to assert itself.. We have in our possession two prints, and very good ones they are, from negatives taken on Eastman roll-holder films by Mr. Edward J. Smith, of Halifax. One negative was taken the same week the spool was received, the other *four years* later. The former represents a deep dell showing the half-dried-up bed of a river, and received an exposure of three seconds; the latter, a portion of the same spool and exposed half a second with *f*-22 four years afterwards, represents a somewhat trying scene, a vast crowd taking part in some public inaugural meeting all under a roof and imperfectly lighted, but well and fully exposed. Most undoubtedly no deteriorating influence had been exerted by the one film upon the other in this case; and we are pleased to be able to say that the same methods of preparing films that were employed four years ago are in force at the present time. In Mr. Edward J. Smith's letter he says, speaking of the film in question, "The film has not been kept wrapped in tin foil or treated with any special care, but has been in the roll-holder all the time, and has travelled some thousands of miles by sea and land."

Picture Pirates in America.—In reference to the article in last week's issue on *Photographic Piracy*, and an allusion to a suit decided under the International Copyright law, a correspondent directs our attention to the wholesale piracy of English and Continental pictures in America, and makes some very strong comments on the subject. Complaints are, we know, loud and deep amongst English publishers of the piracy, in America, of the works they issue. But it is not against such pirates as that referred to last week, who simply make silver prints; it is against otherwise reputable publishers who reproduce the works by photo-mechanical methods. Not long ago we were told by the representative of a London firm that, no sooner than they had issued a photogravure print of a painting, the copyright for which they had paid a large sum, and gone to a great expense in the production of the plate, the print was pirated and issued as a coloured supplement in one of the American journals. Quite recently we were consulted by a Continental art publishing firm as to whether it would be possible to make some additions to the printing ink that would prevent the prints being successfully reproduced, as it was suffering so severely from the piracy of their productions in the States.

Spotty Prints.—For many years past we have noticed and called attention to the fact, that at this season complaints of minute spots on silver prints are more prevalent than at any other time. We are not alluding to spots that make their appearance months after the prints have been mounted, but to those small ones that are frequently met with before they are mounted, or within a very short time afterwards. This year is no exception, and we have already seen several examples that have greatly perplexed those who have produced the prints, and who, in the generality of cases, have attributed the evil to anything but the right cause, namely, dust. It often happens that, at the time the prints are taken out of the washing water, sweeping and dusting operations are going on. Now, the dust of photographic workrooms is of a very pernicious character, consisting as it does of particles of hypo, pyro, and numerous other equally deleterious matters, rendered by the artificial heating of the apartment. It will at once be admitted that, if any of such particles settled on a moist print, they would cause trouble. Apart from the floating particles of the chemicals employed, there are often others present that are equally as deleterious, the dust from coke stoves, for example. When the fire is poked or the ashes are raked out, a dust of a sulphurous nature is created, which, if any particles settle on a wet print, is almost certain to produce spots. On one occasion we placed some moist prints near a coke stove, and then stirred the fire so as to raise a dust, which was then allowed to settle. The result was that, after a day or two, the prints showed as prolific a crop of minute spots as could well be imagined.

YELLOW STAINS ON GELATINO-CHLORIDE PAPER.

While the subject of yellow stains upon gelatino-chloride printing-out paper is on the *tapis*, I should like to give my own experience, and suggest an apparently unsuspected cause. Hypo has received such a bad name in years gone by that, as Mr. Pentney remarked a week or two back, we were too prone to lay all the blame of yellow stains, without any further inquiry, to its credit. But what about sulphocyanide of ammonium? It is as much a sulphur compound as hypo, and, although the combinations it forms with silver chloride are perhaps not so unstable as the hypo compounds, they are still subject to similar decompositions.

In addition to this, the gold compounds, formed by the mixture of auric chloride with the soluble sulphocyanides, are of an equally, if not more, unstable character than those of silver, and, under present conditions of toning, these are, it seems to me, quite sufficient to account for many otherwise obscure cases of yellowing.

Mr. C. H. Bothamley, in his recent report on this subject, alludes to the appearance of yellow stains in the course of toning, and which he describes as an occasional, though very rare, occurrence. This is very far from being the case, in my own experience at least, when sulphocyanide of ammonium or potassium is employed. I am not speaking of only recent experience, but will go back seven or eight years with gelatino-chloride, and I have had a similar discolouration with albumen paper when using a combined toning and fixing bath containing sulphocyanide. In fact, although not a constant or regular occurrence, this yellowing of prints in the toning bath itself has been a pretty frequent trouble with me, ever since I began to use the mixed gold and sulphocyanide toning bath first recommended for gelatino-chloride paper.

The formulæ originally published for this purpose contained, it will be remembered, a minute trace of hypo, for what reason introduced I do not know; but it was natural to blame the yellowness on to that, and, as I found the bath toned just as well without it, the hypo was discarded. But still the yellowness occurred at intervals, and what was worse, or rather more to the point, in fixing the evil on to the toning bath itself, was the fact that a bottle of the stock toning solution (in concentrated form), after standing some months unused, was found to have deposited a dirty yellow granular powder, while the sides were coated with a thick layer of a similar character.

But it was not until comparatively recently that, having taken up the working of gelatino-chloride paper more regularly, I have felt the full force of the trouble, with the result that I have, for some months past, given up using sulphocyanide altogether, and so got rid of the discolouration in the toning bath completely. I am referring solely to that kind of yellowing, or such as occurs between toning and fixing, *in the absence of any possible chance of contact with hypo*. Under such conditions, I think it may be set down to the effect of sulphocyanide; but, when there is any doubt as to the presence of hypo, "honours may be divided."

When the yellowing does occur, it will be either when the attempt is made to tone too many prints in the same solution, or, more probably, when the bath has been put away after being once used, but not exhausted. The danger is not so great in the first instance, as few of us are foolish enough to try to tone a larger number of prints than we know there is gold for; but it is different

or heating purposes on a large scale. No other form of furnace can produce such enormous heat as that generated in the electric furnace." Other firms are now beginning to supply the fittings for electric heating; I saw one pint of water, the other day, boiled in a copper kettle on an electric heater, at Verity's, in eight minutes, at a cost of one farthing. The heating stoves do not seem as yet to give so much heat value as the ovens, &c. I think they would be too expensive at present for a large studio, but a dark room could probably be heated admirably for about 50 per cent. more than gas; even if it cost double, it would be practically cheaper, considering its many advantages. This must be my final communication on the subject.—I am, yours, &c., PALETTE,

November 17, 1893.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Six-inch or a twelve-inch burnisher, for a good rolling press.—Address, J. WEBBER, Photographer, Canterbury.

Wanted, retort and purifier for making oxygen; in exchange for Postage-stamp camera, nine lenses, or lantern slides.—Address, EARL, 47A, Broad-street, Worcester.

Photographic News, 1875 to 1888, unbound; exchange for (secondhand) 12×10 or 9×7 field camera, tripod, or leather cases; difference adjusted.—Address, F. WATSON, 33, Alfred-road, Acton, W.

Will exchange background, exterior, canvas in oils, good condition, by Marion, for clouded background or good interior.—Address, ALBERT DURN, The Studio, Wotton-under-edge, Gloucestershire.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

GOLD CHLORIDE.—There is no danger of forming an explosive compound with the mixture of nitro-hydrochloric acids you name.

SUUM CUIQUE.—We should be glad to insert a letter on the abstract question as to whether an operator has a right to a copy of the work he does.

MARY CAMPBELL.—What is meant is that to the stock toning solution sufficient gold should be added to make up for that used, say, one grain per sheet.

COL. SPENCER NICHOLL.—Dissolve the silver nitrate first, and then add the cyanide until the precipitate formed is redissolved. You reversed the process.

W. BLAKE.—White hard varnish must be diluted with spirit to make it suitable for negatives. If it has been used as purchased, no wonder that "it has proved a failure."

PYRO writes: "Would you kindly give me the address of photographic publishers of views in Paris (French scenery), and greatly oblige?"—Perhaps some reader will oblige.

A. BURRIDGE.—Communicate with the local police in all such cases; but, better still, do not part with your money until you have taken reasonable precautions to ascertain the *bona fides* of the advertisers.

W. T.—We do not think that photography is systematically employed at the London hospitals. We can only suggest that you write to the secretaries of those institutions, stating your qualifications and wishes.

G. R.—It is quite a fallacy to suppose that the copies of paintings to be seen in the shop window are made from monochromes painted for the purpose of reproduction by photography. They are made from the originals, which, more often than not, are in very brilliant colours, as most Continental paintings are.

A. W. X.—Time is too short yet to pass any opinion on the comparative permanence of albumen and gelatine prints. The former process has been on its trial for forty years or more, and many of the prints are still without change. The latter has only been on its trial for a few years, and some prints, like others on albumen, have shown a marked change in the time.

R. A. E.—The safest way to fill an ether saturator by artificial light is to do it outside a window at which a light is burning on the inside. In this way, no risk whatever is incurred. The saturator should never be recharged in the room before the audience should it become exhausted. Apart from the danger, the smell of ether is objectionable to those who are not familiar with it.

A. J. writes: "Would you kindly tell me what is the best system of marking and storing negatives for a small business where the expense of separate envelopes for each negative does not appear to be advisable?"—Simply write or scratch the name and number on the negative, and, if envelopes are too costly, wrap them in plain paper with the number written upon it on the outside.

C. THOMAS.—You must not rely too much upon what is said on photographic matters in the daily press, otherwise you may believe in a lot of nonsense. We did not see the announcement in question, but it must have carried absurdity on the face of it.

J. A., JUN.—Write to Messrs. Schmiers, Werner, & Co., Leipsic. They will supply the necessary machines, &c. The cost of a medium-size machine is, we think, between two hundred and fifty and three hundred pounds. The other appliances are not costly. You must have been exceptionally unfortunate in your experience with collotype printers. Had the work been entrusted to a good house, you would not have to reject half the prints.

W. J. FARMER.—We could only answer your numerous questions after a long series of experiments, occupying a great deal of time, which you are probably better able to afford than we are, or why not try these experiments for yourself? We are always glad, where possible, to help our correspondents in their difficulties, but in your case nothing less than an exhaustive treatise is required. At this (and especially by post) we must beg you to let us draw the line.

STEPHEN WILSON.—The collotype process is far more applicable to that class of work than Woodburytype. With the latter process delicate vignettes are not to be successfully obtained when working on a commercial scale. Furthermore, collotypes can be as easily printed with white margins, so that mounting is unnecessary, as without. If price were an object, it is possible process blocks would answer, that is, if the number required is tolerably large; for small numbers, collotype is cheaper than "process work."

LONDON, W.C.—The price of copper plates, surfaced and polished, ready for etching, may appear somewhat high, but we believe they are not, if of good quality, to be had at less than the prices quoted. The rolled sheet copper of the metal warehouses would require a great deal of laborious and tedious work to be bestowed upon it before it could be made available for photogravure plates. We are not aware that the plates used for this purpose on the Continent are any better than those sold here, and we doubt if they are.

ROBERT W. CONCHIE.—1. Better not mix up the formulæ; rather make comparative trials of the two, and use that which works best in your hands. 2. If the bath were made with pure materials, and in chemically clean vessels, the gold should not, and would not, be deposited. As your experience has been so unfortunate, we advise you to make up only sufficient bath at a time to tone the prints desired. 3. Yes, though it will keep better in a strong solution. 4. Lithographic chalk, or the ink used by lithographic artists.

W. A. T.—1. Unless the prints be treated with alum, the coating will dissolve if immersed in warm solutions. Alum the prints, and then proceed as you have been doing. 2. The spots are touched out in the negative. Only experience is required to judge of the right amount of colour to apply. That, of course, must depend upon the density of the image. 3. The yellow screen is of little use with ordinary plates. 4. It may be applied by itself or mixed with a little dextrine. Plenty has been said on the subject during the last few months.

B.—The electric-lighting plant supplied by the firm named is very complete, and is used in many of the London studios. They would doubtless supply it with any other lamp if preferred. If you make the apparatus yourself, it will certainly cost you less if your time is not of great value. We see no reason why the gentleman you mention should not be a practical adviser; a knowledge of photography is not necessary to make an efficient appliance for lighting an object—the sitter in this case. Nothing on the subject is needed beyond what has already appeared in back volumes.

F. J. R.—1. To have about equal quantities of silver converted into chloride and citrate respectively, the quantity of citrate of potash should be fifteen grains. The proportion here given makes a softer picture, but eight and fifteen would print better from thin negatives. 2. Chloride of ammonium at boiling temperature would decompose borax, forming tetrametaborate of soda; but we do not think it should in the cold. It may have some effect on old bleached lac. Try potassium or sodium chloride. It answers nearly as well, though it is more trouble, to size the paper first and then salt.

W. RATCLIFFE.—The fault—the mottled appearance in the prints—is due to the paper being insufficiently sensitised. A much longer floating, on that strength of bath, was required on account of the hardness of the sizing as it was applied. If the lac were good, the whole of it should have dissolved. Probably the sample used had been bleached for a long time, and so had lost its solubility. If you read the article again, you will see the solution is to be applied with a brush, not the paper soaked in it for ten minutes. This, in itself, was quite enough to account for the appearance when the paper was printed.

capable of being exercised on the sensitised gelatine by the celluloid support, Messrs. Guiterman & Co. have shown us the result of an experiment made by one of the experts of the Celluloid Company, Newark, N.J., U.S.A., of which they are agents for this country. In order to anticipate the action of time, two squares of celluloid—one a German production, the other being the American make—were placed on a thick pad of blue blotting-paper, and, after being covered with a thin paper, a laundress's flat iron heated to a temperature of 240° or 250° Fahr. was left on for five minutes, with this result, that the German make had become disintegrated and given off enough nitrous acid to show a decided decolourising of the paper in immediate contact with it. The American sample remained unaffected. As is well known, there are various ways of making celluloid, no two manufactures being absolutely alike.

A Good Word for Rollable Films.—If celluloid, *per se*, has really any deleterious action upon gelatine emulsion, it certainly takes a long time to assert itself. We have in our possession two prints, and very good ones they are, from negatives taken on Eastman roll-holder films by Mr. Edward J. Smith, of Halifax. One negative was taken the same week the spool was received, the other *four years* later. The former represents a deep dell showing the half-dried-up bed of a river, and received an exposure of three seconds; the latter, a portion of the same spool and exposed half a second with *f*-22 four years afterwards, represents a somewhat trying scene, a vast crowd taking part in some public inaugural meeting all under a roof and imperfectly lighted, but well and fully exposed. Most undoubtedly no deteriorating influence had been exerted by the one film upon the other in this case; and we are pleased to be able to say that the same methods of preparing films that were employed four years ago are in force at the present time. In Mr. Edward J. Smith's letter he says, speaking of the film in question, "The film has not been kept wrapped in tin foil or treated with any special care, but has been in the roll-holder all the time, and has travelled some thousands of miles by sea and land."

Picture Pirates in America.—In reference to the article in last week's issue on *Photographic Piracy*, and an allusion to a suit decided under the International Copyright law, a correspondent directs our attention to the wholesale piracy of English and Continental pictures in America, and makes some very strong comments on the subject. Complaints are, we know, loud and deep amongst English publishers of the piracy, in America, of the works they issue. But it is not against such pirates as that referred to last week, who simply make silver prints; it is against otherwise reputable publishers who reproduce the works by photo-mechanical methods. Not long ago we were told by the representative of a London firm that, no sooner than they had issued a photogravure print of a painting, the copyright for which they had paid a large sum, and gone to a great expense in the production of the plate, the print was pirated and issued as a coloured supplement in one of the American journals. Quite recently we were consulted by a Continental art publishing firm as to whether it would be possible to make some additions to the printing ink that would prevent the prints being successfully reproduced, as it was suffering so severely from the piracy of their productions in the States.

Spotty Prints.—For many years past we have noticed and called attention to the fact, that at this season complaints of minute spots on silver prints are more prevalent than at any other time. We are not alluding to spots that make their appearance months after the prints have been mounted, but to those small ones that are frequently met with before they are mounted, or within a very short time afterwards. This year is no exception, and we have already seen several examples that have greatly perplexed those who have produced the prints, and who, in the generality of cases, have attributed the evil to anything but the right cause, namely, dust. It often happens that, at the time the prints are taken out of the washing water, sweeping and dusting operations are going on. Now, the dust of photographic workrooms is of a very pernicious character, consisting as it does of particles of hypo, pyro, and numerous other equally deleterious matters, rendered by the artificial heating of the apartment. It will at once be admitted that, if any of such particles settled on a moist print, they would cause trouble. Apart from the floating particles of the chemicals employed, there are often others present that are equally as deleterious, the dust from coke stoves, for example. When the fire is poked or the ashes are raked out, a dust of a sulphurous nature is created, which, if any particles settle on a wet print, is almost certain to produce spots. On one occasion we placed some moist prints near a coke stove, and then stirred the fire so as to raise a dust, which was then allowed to settle. The result was that, after a day or two, the prints showed as prolific a crop of minute spots as could well be imagined.

YELLOW STAINS ON GELATINO-CHLORIDE PAPER.

While the subject of yellow stains upon gelatino-chloride printing-out paper is on the *tapis*, I should like to give my own experience, and suggest an apparently unsuspected cause. Hypo has received such a bad name in years gone by that, as Mr. Pentney remarked a week or two back, we were too prone to lay all the blame of yellow stains, without any further inquiry, to its credit. But what about sulphocyanide of ammonium? It is as much a sulphur compound as hypo, and, although the combinations it forms with silver chloride are perhaps not so unstable as the hypo compounds, they are still subject to similar decompositions.

In addition to this, the gold compounds, formed by the mixture of auric chloride with the soluble sulphocyanides, are of an equally, if not more, unstable character than those of silver, and, under present conditions of toning, these are, it seems to me, quite sufficient to account for many otherwise obscure cases of yellowing.

Mr. C. H. Bothamley, in his recent report on this subject, alludes to the appearance of yellow stains in the course of toning, and which he describes as an occasional, though very rare, occurrence. This is very far from being the case, in my own experience at least, when sulphocyanide of ammonium or potassium is employed. I am not speaking of only recent experience, but will go back seven or eight years with gelatino-chloride, and I have had a similar discolouration with albumen paper when using a combined toning and fixing bath containing sulphocyanide. In fact, although not a constant or regular occurrence, this yellowing of prints in the toning bath itself has been a pretty frequent trouble with me, ever since I began to use the mixed gold and sulphocyanide toning bath first recommended for gelatino-chloride paper.

The formulæ originally published for this purpose contained, it will be remembered, a minute trace of hypo, for what reason introduced I do not know; but it was natural to blame the yellowness on to that, and, as I found the bath toned just as well without it, the hypo was discarded. But still the yellowness occurred at intervals, and what was worse, or rather more to the point, in fixing the evil on to the toning bath itself, was the fact that a bottle of the stock toning solution (in concentrated form), after standing some months unused, was found to have deposited a dirty yellow granular powder, while the sides were coated with a thick layer of a similar character.

But it was not until comparatively recently that, having taken up the working of gelatino-chloride paper more regularly, I have felt the full force of the trouble, with the result that I have, for some months past, given up using sulphocyanide altogether, and so got rid of the discolouration in the toning bath completely. I am referring solely to that kind of yellowing, or such as occurs between toning and fixing, *in the absence of any possible chance of contact with hypo.* Under such conditions, I think it may be set down to the effect of sulphocyanide; but, when there is any doubt as to the presence of hypo, "honours may be divided."

When the yellowing does occur, it will be either when the attempt is made to tone too many prints in the same solution, or, more probably, when the bath has been put away after being once used, but not exhausted. The danger is not so great in the first instance, as few of us are foolish enough to try to tone a larger number of prints than we know there is gold for; but it is different

when an unexhausted bath is used a second time. Under such circumstances, although there may be ample gold present, and the solution itself may be uncoloured, the toning will be extremely slow, if, indeed, any change take place at all beyond a slight *reddening* of the image. More gold is added to hasten the matter, but this only makes matters worse in all probability, and, though with perseverance some sort of "tone" may be got in time, the whites of the print will be pervaded by a sickly yellowness, and the solution itself will acquire almost as decided a colouration as the plain solution of chloride of gold—that is to say, a rich, bright yellow. The precise composition of the bath does not appear to matter much, provided sulphocyanide be present; I have had equally pronounced colouration with plain sulphocyanide and with the mixed sulphocyanide and acetate bath.

Another circumstance that seems to lend strength to the suspicion of sulphocyanide is this: If a plain gold and acetate bath, that has been put away after use, but not exhausted, be used a second time, the toning will proceed much more slowly than when previously employed, and it may happen that it will refuse to tone at all, as already described. Here, again, the addition of fresh gold proves useless, or worse, only hastening the decomposition of the solution; but, in this case, the colour developed by the bath itself is the well-known pink, or purple, according to the degree of change, while the prints either remain white or take a delicate pink tint.

I am not inclined to blame the sulphocyanide altogether for being the cause of the decomposition of the bath and the arrest of toning, but it certainly seems to alter the character of the products. The original cause of the changes referred to is undoubtedly to be found in the paper itself, and the rapidity and extent of the decomposition will depend upon the care with which the prints are washed before being introduced into the gold bath. If free silver be left in the prints to any extent, it is converted into chloride at the expense of the gold and then dissolved by the sulphocyanide. The first effect is a weakening of the bath, and after that a process of sulphur toning is set up by the dissolved silver.

But scarcely any amount of ordinary washing can be expected to entirely remove the slightly soluble citrate of silver contained in the paper, and this will be as readily acted upon by the gold solution as any free nitrate that may be left. Therefore, unless the prints be treated with weak chloride of sodium before toning, as directed at page 699, there seems to be always a chance of a certain amount of sulphur toning occurring when sulphocyanide is used; and, if the bath be used to exhaustion, then the yellowing will occur. Where the sulphocyanide is absent, the effect is confined to a reduction of both silver and gold in the toning bath and the destruction of its toning powers.

W. B. Bolton.

REMARKS ON HAND-CAMERA WORK AND HAND CAMERAS.*

The first fault that I had to find with it was this: I had placed the lens centrally to the plate, and this gave me my horizontal line too high, I had too much foreground by far. I see from time to time writers in the journals crying out for a rising front for the hand camera; I have no desire for any such addition. Let the lens be so fixed as to give, with a level view, a horizontal line about one-third up the plate, and the cases must be few indeed requiring further elevation. That was the first fault; that I remedied by altering the position of the lens. Now, some one may be inclined to say, "If you had had a view finder you could have had the horizontal line just where you liked by tilting your camera." True, but in that case my architecture would have been, so to speak, "to the dogs" without a swing back, and who has time to stand in a crowded street arranging a swing back? No, I found, after the alteration of the lens, the camera was all that could be desired, as far as performance was concerned.

What, then, was fault No. 2? It was this. I said that I had got my saddler to make me a case. Now, a saddler makes a solid and substantial job, not, however, erring on the light side. Again, a case to hold a quarter-plate camera, which does not fold down, together with four double dark slides, must needs be of considerable bulk, and this was fault No. 2—the camera and slides made a too heavy and bulky parcel. If you slung the thing over your shoulder, it was big enough to be conspicuous; if you carried it in your hand, where were you to dispose of the case while you made an exposure. It was weather-proof, and fulfilled every other condition, but it was too bulky. Of the few dozens of plates which I exposed in this camera, not one showed the slightest blurring, but, on the contrary, seemed, to the naked eye at least, to be as sharp as any stand camera picture. Once or twice I carried the camera out without the case (it has a leather handle for the purpose), stowing the slides in my pockets, but I found that the brass mounting of the lens, the spirit level on the top, &c., attracted too much attention. It is, however, the most reliable hand camera I have, as far as performance goes.

* Continued from page 751.

Having the dark slides, and having other lenses in my possession, I determined (keeping No. 2 just as it was) to design and make up camera No. 3. The conditions which I set myself to fulfil were these more particularly: that the camera must be light and small, and quite inconspicuous in appearance, so that it could be carried through the streets without attracting attention.

By this time I had given up the idea of having the camera itself weather-proof, a condition which, as I stated before, I did not see how it was at all possible to fulfil; and, even with regard to a weather-proof case for it, I had come to this idea, that a square of India-rubber cloth, carried in the pocket for emergencies, was all that was actually required.

I had now only one difficulty, and that was, how to fit neatly and inconspicuously a drop shutter to the camera, so that the whole apparatus might have the appearance of one box.

Although I gave much consideration to this question, I found no solution to it. I finally abandoned the idea of a drop shutter (which I am extremely partial to) with great regret. One would imagine that there ought to be little difficulty in enclosing a drop in the end of the box somehow; but a patent difficulty is this, if the drop is kept at "set," you almost double the length of the shutter, which either sticks out awkwardly beyond the sides, or, if you make the body of the camera large enough to conceal it, makes a large camera. If you keep the shutter half way, no part projects; but the lens is now constantly exposed, and thereby liable to dirt or destruction. An easy way out of this difficulty would be to have a leather plug to place in the aperture of the shutter. This seemed to me to be makeshift and unsightly, for, by it, it entailed another movement, to be remembered and carried out at the moment of exposure.

Having abandoned the drop shutter, I cast about for a substitute. The conditions to be fulfilled were these: it must be small, so as to be enclosed as part of the camera; it must be constant in its speed, not over-fast; and, lastly, it must be easy of release and easy to make. All these conditions seemed to point to a pivoted quadrant of some kind, and this was the form I eventually adopted.

It will be easier to show you than describe camera No. 3. It is a plain mahogany box, covered with morocco, an oblong aperture at the back to take a dark slide, while the lens is carried on a false front, two inches from the actual front, and which two inches of space are taken up with the lens mount and shutter. The actual front fixes with a spring catch, so that I can easily get in to the diaphragm plate, while, at the same time, it gives facilities for the repair of the shutter, should such be needed.

The lens I use in this camera is a Wray 5 × 4 wide-angle landscape. When making the shutter, I arranged it so as to be actuated by an elastic band, and it worked smoothly and well. The speed was greater than I liked. It was getting well into October when this last camera was finished, and I found that the light was too poor to give me well-exposed pictures with this shutter. A trifling alteration made it, that I could drive the quadrant over by a touch of the finger, and this I found by experience to be an excellent idea. It was now possible to give exposures of almost half a second. It occurred to me, as it must occur to you, that, with an exposure so prolonged, definition was bound to go. To my surprise, I found this not to be the case. Once or twice I did get blurred pictures, but in general they were quite sharp. Thinking over the matter at home one day, and making a few experiments to determine the matter, I found that the blurred pictures were not due to tremor of the hand, but rather to the general sway of the body on the legs.

At my next outing with my camera, I found that it was almost always possible to get something to lean on while exposing the plate, and from that moment I had no more blurred pictures. Until one has experienced it, he can have no idea how opportunity favours him in the matter of "leans." In the short time I have had this camera I have exposed a few dozens of plates, not once have I been disappointed in a "lean." This is by no means only a matter for amusement—it has its important side. It simply means that throughout the year the hand camera need never be laid aside as useless. I may say, as a parting remark on camera No. 3, that it has proved in every way very satisfactory.

Being still possessed of the spirit of camera construction, and my

material not being quite used up, I determined on a fourth camera As in camera No. 3, I had sounded the depth, so to speak, of prolonged exposure, my aim now was towards very rapid exposures.

I have had in my possession for a good many years a diminutive portrait combination. The equivalent focus is about three inches, and it gives fine definition over a circle of about two and a quarter inches, with full aperture about an inch. This was manifestly the very lens.

I have no wish to dwell on the making of this camera. Artists and nations are said to have their periods of gradual ascension and decline—clearly I was following the same law. I had reached the high-water mark of construction in camera No. 3, and there came to me the fixed and rooted notion that No. 4 would be a botch.

To set out upon any enterprise in this frame of mind was to bespeak failure. At every turn some cursed thing turned up to annoy and disconcert me. A piece of wood, which a moment ago measured five inches, now, for some unaccountable reason, measured six, my solder refused to run, the glue got thick and burned in the pot. Reverses are supposed to do people good in the long run; my reverses raised the very devil in me, I got more determined every moment; once I very nearly knocked off a finger with my hammer, I forbore to utter a single sound, I sat dogged with my finger in my mouth, and thought of Arnley's fine verse,—

> "In the fell clutch of circumstance
> I have not winced, nor cried aloud
> Under the bludgeonings of chance;
> My head is bloody, but unbowed!"

It was under such circumstances as these that camera No. 4 was dragged into existence. The shutter, a modified roller blind, works fast enough, and, indeed, is the one redeeming point in the whole thing. Having no leather to cover the body, I used American cloth, and this turned out one of the biggest mistakes I made. American cloth is cold and clammy to the hand, and, being waterproof, the glue which fastens it on seems never to dry. I have exposed not more than a dozen of plates in camera No. 4, and, as was to be expected from such an ill-starred venture, every one, for some reason or another, turned out a failure. Only one good negative out of the lot, and the mark of Cain was upon it, in the shape of a running boy with legs in ridiculously preposterous positions.

Having now described my four cameras, this incident of the running boy suggests to me the remarks I have to make upon hand-camera work. In my reading up of the subject, I notice that both Mr. Dresser and Paul Lange recommend a swift shutter. I confess to not seeing the force of this.

If these gentlemen have light, and lenses, and plates requiring so short an exposure, I have nothing to say. If, on the contrary, a high speed is thought to be necessary, either to prevent the appearance of hand-shake in the picture or to take without signs of movement rapidly moving objects, then I part company from them here.

I have proved to my own satisfaction that a very prolonged exposure may be given without signs of hand-shake in the picture; and, as for the photographs of rapidly moving objects, is it not a great mistake to photograph them at all? Examine a photograph of a street scene. Let us say that it is such a scene as requires a very fast shutter, that is, where the moving objects are not far from the camera. Can any one seriously argue that the resulting pictures, with their novel, if not grotesque, posing, are things of beauty. Is it not rather the fact that, in a great many instances, the postures of both men and beasts suggest drunkenness or imbecility? The argument that the positions shown by instantaneous photography are the correct ones, and that the poses and positions painted by artists are conventional and erroneous, will not stand a moment's serious consideration. When an instantaneous photograph of a number of persons moving about is shown round, what is the very first thing that is noticed and remarked upon? Is it not the ridiculous position of the limbs, and the apparently impossible attitudes in which the individuals are discovered?

Why should these things appear so absurd and strange? Do we not all day long see people walking up and down in every-day life? How can any representation such as this be said to represent what we really see when nobody recognises the truth of it—nay, I go a step farther, when the great bulk of people even deny the possibility of its truth?

To say that we have all along been deceived by the artist, and that, when we have outgrown the bad lesson, we will see the truth of the photograph, is nonsense. How has it never occurred to mankind that he was being deceived before? He had all along his every-day experience and his eyesight to guide him. The truth is, photography renders outside nature *not* as we see it, but as it really is, a very different thing.

There is a wide sphere and a great future for the hand camera; but, in my opinion, the first lesson that must be learned is what the hand camera can *not* do.

J. K. Tulloch, M.B.

HOW LENSES ACT.*

We now come to a property of lenses which is comparatively little understood, viz., depth of focus, or the power of defining sharply at the same time objects both far and near, and while considering it shall assume our lenses to be free from defects, such as spherical aberration, &c. I must apologise for having to introduce mathematics here, but it will not be very much, and I could see no other way of showing what I want without their use.

Suppose we have two objects at different distances, A B, sending rays to a lens, rays from A coming to a focus at (*a*), and rays from B at (*b*). A screen at (*b*) would receive a sharp image of B, but not of A, for these rays have not come to a focus, and at (*b*) would form a circle of light.

Similarly, if the screen be placed at (*a*), A would be in sharp focus, but rays from B would have passed their focus, and be in turn represented by a circle of light.

If the screen be placed midway between (*a*) and (*b*), neither would be sharp; each would form a circle of light half the diameter, or a quarter the actual size of the circles of light at (*a*) or (*b*). These circles of light are called circles or discs of confusion.

Now, the human eye is not microscopic in power, and if an image is not really sharp, but nearly so, it appears sharp, and is so for all practical purposes, so that, if the disc of confusion be made sufficiently small, images formed at both (*a*) and (*b*) will be practically sharp on a screen placed midway between them.

Most authorities agree that a want of sharpness, or blurring, or disc of confusion to the extent of $\frac{1}{100}$″ is inappreciable, and no harm to the picture, although, of course, they would like less if possible.

Assuming $\frac{1}{100}$″ to be permissible (although I do not agree with it), it follows that, if this small distance be $\frac{1}{100}$″, images properly formed at (*a*) and (*b*) would be in sufficiently good focus on a screen placed midway. This means that both A and B would be sharp, and also any object between them, but any object nearer than A would not be sharp.

Suppose the lens to be working at *f*-8, xy = $\frac{1}{100}$ focal length stop = $\frac{1}{8}$, It will be observed that their lengths depend entirely upon the angle at which the rays meet, and, provided that the angle remains constant, the lens may be what it likes—single, rapid rectilinear, portable, symmetrical, wide-angle, &c.; and, as in all such lenses, the combinations of which are close together, the rays, with similar stops, do come in at the same angle, the distance, (*a*) (*b*), is the same for all of them. There may be, and probably is, some difference in the portrait lens, the combinations of which are often three or four inches apart.

This distance, (*a*) (*b*), remain constant also when the focal length varies, as with *f*-8 the rays come in at an angle of 1 in 8, no matter what the focal length may be, and ditto with the other stops.

What I want to impress upon you is that, with any particular stop, the length, (*a*) (*b*), is the same, no matter what the form of the lens or its focal length may be; and, assuming the disc of confusion to be $\frac{1}{100}$″, these lengths are, with *f*-8 $\frac{1}{8}$″, *f*-16 $\frac{1}{4}$″, *f*-32 $\frac{1}{2}$″.

It now becomes necessary to see what happens to A and B, and this is where the mathematics come in.

$$\frac{1}{D}+\frac{1}{d}=\frac{1}{f},\ df+Df=dD,\ df=D(d-f)\ D=\frac{df}{d-f}$$

$$d=f+ab,\ \text{and}\ ab\ \text{with}\ f\text{-}8=\tfrac{1}{8}$$

$$\therefore d\ \text{with}\ f\text{-}8=(f+\tfrac{1}{8}'')$$

$$\text{Substituting we get}\ D=\frac{(f+\frac{1}{8}'')+f}{(f+\frac{1}{8})-f}=\frac{f^2+f\cdot 6}{\frac{1}{8}}=(f^2+f\cdot 6)\times 6=6f^2+f$$

$$D=6f^2+f\ \text{for stop}\ f\text{-}8$$

$$\text{Similarly}\ D=3f^2+f\ \text{for stop}\ f\text{-}16$$

We see from this that halving the diameter of the stop nearly halves the value of D, which is the distance of B from the lens, and therefore the depth of focus increases as the stop diminishes.

An interesting practical point comes in here. Suppose we are on the pier at Kingston, and have a quarter-plate camera with two lenses 6″ × 12″ focal length. There is a yacht a couple of hundred yards out, some trawlers in the distance, and some rocks which would make a good foreground close to. We find everything can just be got sharp with the 6″ lens at *f*-8, but very small; now, with what stop can we get everything sharp with the 12″ lens? We have just seen that, if the focal length be doubled, the stop remains at *f*-8. We could only get the rocks sharp if they were four times as far away, say 73 : 0 instead of 18 ; 6″. To rectify this, we must use a smaller stop but we have also seen that, to reduce the distance to quarter, we must reduce the diameter of the stop to quarter, and the one quarter of *f*-8 is *f*-32; therefore, a 12″ lens, with *f*-32, will only give the same definition, to both rocks and distance, as a 6″ lens with *f*-8, and the loss in rapidity is as 8 is to 1. This

* Concluded from page 737.

shows the very great advantage of short-focus lenses for instantaneous work. In this case the *f*-8 stop of the 6″ lens is $\frac{3}{4}$″ diameter, and the stop *f*-32 of the 12″=$\frac{3}{8}$″ diameter, or $\frac{1}{2}$ the diameter of the stop used with the 6″ lens. It will be noticed, however, that this use of a 12″ lens is rather unfair to it, as both lenses are used on a quarter-plate, whereas, if a 6″ lens were used on a quarter-plate, a 12″ lens would, for the same view, be used on a quarter-plate, and, as I stated before, the disc of confusion for a large picture is permissibly greater than that for a small one. This would permit the stop of the large lens being somewhat increased, and in general practice it will be found that, if a $\frac{3}{4}$″ stop can be used with a 6″ lens for any view, the same size stop, viz. $\frac{3}{4}$″, is the largest which can be used *for the same view* with any lens, no matter what may be its focal length.

I stated before that a single lens, with a large aperture, gave what I called a false depth of focus. The upper half represents parallel rays, and the lower half rays from a near point. It can be seen that a screen at any position will receive a soft image of both objects, and of all objects between them. Using a stop would destroy the false depth of focus, but would increase the true depth of focus.

Curvature of Field.—Another fault in a lens is curvature of field, which is as shown. A stop cures this by increasing the depth of focus, and so enabling the oblique rays to form a sharp image on the screen. For ordinary landscape work, a little curvature of field is often of advantage, as the objects to one side are almost always near, such as foreground, hedges, &c., and, being near, their images would be behind the screen were it not for this curvature of field.

Stops.—I should like here to say a few more words upon stops. I have frequently been asked, What is the use of having a great big lens in heavy mount, when a small stop is always used, which only utilises the middle and best part of the lens? could not the surplus glass and mount be cut away, and so give us a more portable lens? Although a small stop be inserted, the whole of the lens is utilised. You will see this if you look through a camera from behind, turning and twisting it about while doing so. The very oblique rays pass through the extreme edge of the lens, while those in front pass the middle of the lens; the more oblique the rays, the nearer the edge of the lens. There is less aberration with a double lens than with a single one, and this means we can get a sharp image with a larger stop; hence this form of lens has great advantages for rapid work. It was found that by lengthening the distance between the combinations, both curvature of field and aberration could be improved, and thus allow of a still larger stop, with its consequent extra rapidity. Placing the lenses further apart greatly reduces the field of view, while placing them closer together increases it. For ordinary fast work there is little objection to curtailing the angle of view; it only means that the focal length of the lens used must be increased a little; but, for wide-angle work, a large field must be obtained at all costs, and therefore the combinations of such lenses are kept close together; this means that aberration and curvature of field are not so much reduced as they might be, and in actual work must be remedied by using a smaller stop. This explains why wide-angle lenses are short and stumpy, and work with a smaller stop than a rapid rectilinear lens.

A lens could be made, the combinations of which could be varied in position, either placed closer together or farther apart. Such a lens could be used for both wide-angle work and rapid work, although probably no great gain would ensue for the same size picture, for the focal length would only be very slight, affected by the change of position; but by such a change the rapid lens, suitable for a quarter-plate, might become a wide-angle lens suitable for a whole plate. Mr. Traill Taylor says on this point: "Hence, by adopting suitable precautions in the reparation, a doublet lens may be made to act either as a wide or narrow-angle objective. The expediency of adopting a mount of this kind is, however, open to question, as there might not be one out of ten who would know "how to use its power aright were it placed in their hands."

Achromatism.—We now come to the last and most beautiful thing about a lens, which everybody has heard of, but the meaning of which, like many terms connected with optics, they have rather shady ideas, I mean achromatism. In one of the first diagrams, I referred to the light passing through a prism as being bent or refracted. But something else also happens, it is split up into all the colours of the rainbow, technically it is dispersed.

Not only is it thus split up, but each of the coloured rays is sent out a different angle, as shown on diagram.

Suppose another prism to be placed underneath, and a ray of light be sent through it, it would be similarly dispersed. Now, if the prisms were rounded off into lens form so that all rays would come to a focus, we should have a focus for red rays, and consequently a red image, next a focus for yellow rays and a yellow image; and similarly green, blue, and violet images, and each of these coloured images would be in different positions.

The rays which give most light, in other words, those which most affect the human eye, are orange and yellow, while the actinic rays, or those which most affect the sensitive film, are in and beyond the blue.

Now, if we were to focus a picture with an uncorrected lens, we should place the screen somewhere about the focus of the yellow rays, as these are the chief light-giving ones. On developing the plate, however, we should find a very poor, blurred picture, because the plate was not in the correct focus for the chemically active rays.

Now, if we turn to our prism again, a ray of light is refracted and dispersed; but, if we place a second prism, inverted, behind the first, this second prism will just undo what the first has done, and our ray of light will pass on without refraction and without dispersion, just as if a bit of ordinary glass had been there.

Now, it was discovered by Dollond, the optician, or, at least, the knowledge was first applied by him, that different substances and different kinds of glass had different powers of refraction and dispersion.

Hence refraction can be obtained without dispersion. This means that, if our second prism be properly designed, we can get a ray of white light to emerge from the prisms *white*, but with some refraction.

By rounding the prism into lenses, Dollond had made a lens in which the negative or diverging lens gave the same dispersion as the positive or converging lens, and being equal, they neutralise each other; but, the refractions not balancing, enough was left to make the lens work properly. Such a lens is called an achromatic combination.

I said that the dispersions balanced and neutralised each other, but unfortunately they cannot yet be made to do so completely.

When making a telescopic lens, not only do they make the curves to suit the axial rays, as I mentioned before, but they also so arrange the achromatism so as to give the best visual image, which is probably done by making the orange and light green to coincide, while the blue and violet rays, being visually unimportant, are uncared for, and have foci all to themselves somewhere; hence such a lens is not suitable for photographic work. There is in the Queen's College, Cork, a very fine 8″ refracting telescope, by Sir Howard Grubb, and they wanted to take photographs of the moon with it, but they found that, the lens being only visually achromatised, they could only get blurred pictures by focussing in the ordinary way. But after many experiments, and probably calculations, they at last found the actinic focus, which was, I believe, nearly 3″ nearer the lens than the visual focus. Similarly, with all other lenses made for visual purposes, correction has to be made; but I understand that the use of isochromatic plates, which are sensitive to the yellow, are causing a change in this matter.

For photographic lenses the maker's endeavour is to make the actinic focus coincide with the chief light-giving focus, so that no after-adjustment has to be made. In conclusion, I should like to impress upon you the importance of the formulæ $\frac{1}{D}+\frac{1}{d}=\frac{1}{f}$, for with this, and remembering that the size of both image and object are proportional to their distances from the lens, almost any question that is likely to occur to the average photographer can be successfully worked out.

J. H. Harorave.

TELE-PHOTOGRAPHY.

[West London Photographic Society.]

The first thing that strikes one in using a tele-photographic lens is that it is different in construction from ordinary lenses, *i.e.*, all ordinary lenses are fixed systems, having one definite equivalent focus, and form an image in one definite plane, upon which the focus for parallel rays is received. This plane is invariably constant for parallel rays, and when the lens receives parallel rays the extension of camera is at the shortest possible. This plane is, however, farther and farther removed from the lens when focussed for nearer objects, obeying the well-known law of conjugate foci applied to any definite fixed system of known focal length. This focal length is measured from one of the nodal or Gauss points contained in the lens system to the principal focal plane. As a matter of fact, there are *two* such points and planes for every system, and for any *fixed* system their position is readily and accurately defined, and they are unalterable. With the tele-photographic lens, however, the position of the plane upon which the focus is received is quite undefined, in fact any position may be chosen at which to place the focussing screen, either in close proximity to the lens itself or at any distance whatever farther away, focussing being performed by a proper adjustment between the separation of the positive and negative lenses of which the system is composed. The two nodal points or planes of both positive and negative systems are in themselves fixed and definite, but, when used together, forming the tele-photographic lens system, the separation between the nodal points in the two systems for the time being will determine the two final nodal and principal focal points of the entire system. This element of separation is most important in regulating the positions of the particular nodal point of the whole system from which the focus is measured and the principal focal plane for the time being. This separation is a very delicate adjustment, and by very slight alterations the focus is obtained upon any chosen plane of the focussing screen or plate.

The second initial difference that is noticeable in the use of this type of lens is that for equal extension of camera the image given is very much larger than that of a fixed system of an ordinary character. This is explained by the fact that the particular nodal point from which the focus is measured in ordinary types of lenses is con-

tained within the lens mount, whereas in tele-photo systems the particular one of the nodal points which determines the focus for the time being is situated considerably outside and beyond it. It is determined, not only by separation of the individual lenses forming the system, but also upon the ratio of their foci, thicknesses, &c.

At the outset, I may state that the crux of the utility of such a system rests upon the comparison between enlargement from small images as against the direct enlarged image thus given. The example which I show you, that was exhibited at the late Photographic Society's Exhibition, is an undoubted proof of the incomparably better results obtained by the direct method. This result was obtained for me by Professor Burton, who wished to satisfy himself as to its utility, and he told me that he conducted the experiment with a view of testing the relative merits, being, if anything, prejudiced in favour of subsequent enlargement at the outset on account of its greater facility.

The elements necessary for the exact determination of the capabilities of a tele-photographic system are:—

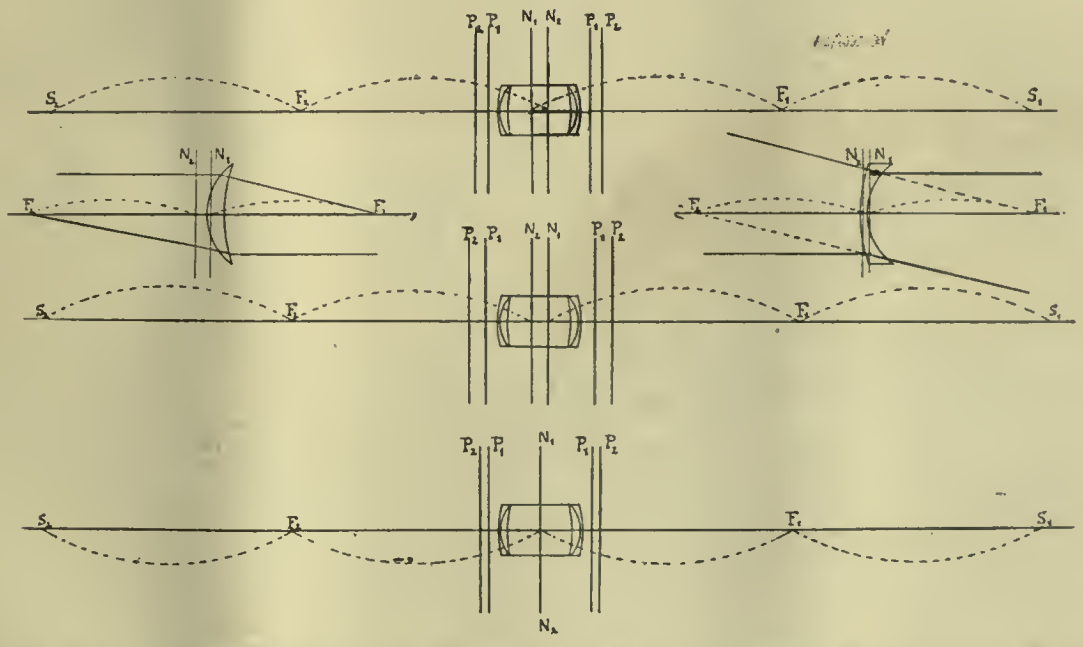
1. The focus of the positive system and the position of its nodal points or plane.
2. The focus of the negative system and the position of its nodal points.
3. The position of the nodal points of the entire system for a given separation of the above.
4. The intensity of the system for a given extension of camera.
5. The angle of view.
6. The plate that can be covered.

1. *The Focus of the Positive System.*—A great number of methods have been described from time to time, and none perhaps is simpler than choosing a known object sufficiently distant so that the rays may be considered parallel, and measuring the size of the image given, and comparing the size of the image with that given by a lens whose focus is known. The foci will then be proportional to the sizes of the images. If one has no lens of known focus to make such a comparison by, a very ready means is to obtain an image from a pinhole of a diameter calculated to give the best definition for an accurately measured extension of camera chosen. In practice I have found it useful to take an image given by a pinhole ten inches exactly from the plate as a gauge for all other measurements. The system ascribed to Grubb of measuring the focus by shifting the image, a distant object from one side of the plate to the other over a measured distance, and drawing lines by the side of the base on a clean sheet of paper, is also very readily done for systems in which the nodal point is contained in the mount; but this is hardly applicable for tele-photographic systems.

Another method very frequently used is simple in language but rather tedious in operation, namely, by obtaining an image exactly the same size as the object, and taking one quarter the distance between the plane of the object and the plane of the image (Fig. 1. This method has been considerably discounted of late, but really without good cause, inasmuch as the small error involved would be quite as small as compared with that by the Grubb method, and it is possible that there may be no error at all. The focus determined may be slightly too long, slightly too short, or it may be absolutely exact; this will depend upon the forms, thicknesses, and separation of the elements composing the system, whereby the nodal points may cross one another to a slight extent, in which case the focus would be slightly too short; they may be separated a little, giving as a result the focus a little longer than it really is; or they might very feasibly absolutely coincide, in which case the focus so determined would be exact.

Another method that I have recently employed is one that may interest you, and therefore I mention it because it is particularly applicable to the determination of the focus of tele-photographic systems. This method is dependent upon the earth's rotation, using the sun as a fixed object. A pinhole, or a lens of known focus, may be fixed upon the camera front by the side of a tele-photographic lens for the given extension at which the lens of known focus is in register (or in the case of the pinhole, if that be used, at any extension whatever). The tele-photographic lens for the chosen extension is then focussed upon the sun on the same plate. Simultaneous instantaneous exposures by both lenses are then made. If the pinhole is employed, it is exposed simultaneously with the exposure of the tele-photographic lens, and allowed to impinge upon the plate during the time the experiment is conducted. A convenient interval of time is allowed to elapse, when a second set of instantaneous exposures of the sun is made by the tele-photographic lens and the lens of known focus. In the case of the pinhole, which has been exposed during the whole period, the aperture is simultaneously closed. On development, the comparison of the distance travelled will give the proportion of the known focus to that of the lens which it is required to determine. I may mention here that the image given by a lens of 10″ focus will travel about an inch in twenty minutes. The experiment is preferably performed at equal intervals before and after the sun crosses the meridian. The image should also be at equal distances from—*i.e.*, similarly disposed about—the axis of the camera, this latter point being more important than the former.

Fig. I.



It is evident that the focus of a lens could be determined from the movement of the sun on the plate for a given interval of time without reference to another lens, but it would involve a knowledge of the declination of the sun (to be found in the Nautical Almanac) and would lead to a somewhat tedious calculation.

I shall mention one other system of finding the equivalent focus that may be readily conducted in an ordinary room on a winter's evening; this method too will lead up to the determination of the focus of a negative lens. It is dependent upon the different sizes of an image of a known object for differences of the conjugates: (1) Focus upon an object of known size and measure the size of the image given; (2) remove

the object of known size to a different distance, either nearer or farther from the lens, and measure the size of the image *then* given; also the distance traversed by the screen to the new position of focus. From these two sets of measurements the focus is then determined. Calling o the size of the object, i and i' the images given in the two cases, then $\frac{i}{o}=\frac{v}{f}-1$, $\frac{i'}{o}=1+\frac{v'}{f}$, v and v' being the distances from the nodal point from which the focus is measured to the screen and f the focus for parallel rays which we wish to determine, in other words, the equivalent focus of the lens. By subtracting one equation, from the other the uncertainty about the elements v and v' is eliminated, as their difference only is taken into account, and the focus, f, which we wish to obtain, is determined, $f=\frac{v'-v}{i'-i}\times o$.

The method that is ascribed to Dr. Schroeder of obtaining image and object of equal size, registering the position of the back, then focussing the lens upon parallel rays, and again registering the position of the back and measuring the distance between these two marks, will give very accurately the focal length of the system, and is a particular case of the general method just described, but involves more labour.

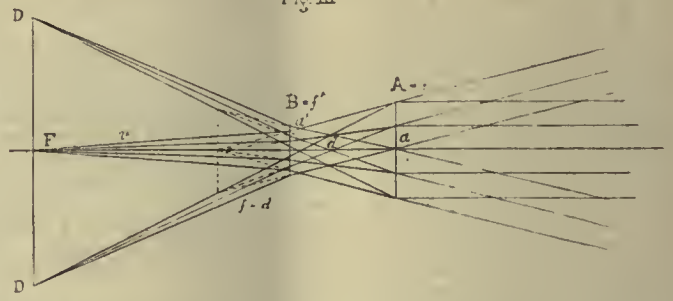
2. *The Focus of the Negative System.*—The only methods that have been described in this respect have been, firstly, the very rough-and-ready one of finding (by trial error) a positive system of known focus exactly equal to that of the negative, in other words placing two lenses in contact, so that no focus whatever is formed; and, secondly, by combining a more powerful positive with a negative, deducing from the difference of the focus of positive alone, and the focus of the positive combined with the negative, the focus of the negative lens system.

I propose to describe a method in which there are no elements of uncertainty, and this can be performed with the tele-photographic system in an ordinary room to determine the focus of its negative lens. First, focus upon an object, preferably an illuminated scale with definite markings, with the camera at a considerable extension. A piece of clear glass is placed in the plane of the image, and the size of the image read off by a micrometer. When this is noted, the second observation is to measure accurately the distance from the plane of the focus to some distinct point in the negative lens mount. Next rack the camera in a considerable amount, the more the better, and refocus the tele-photographic lens with the focussing screen in its new position, and a second time read off: first, the size of the image now given, using the micrometer; second, the distance from the plane upon which the image is now formed, and the definite mark upon the negative lens mount. The third operation consists in removing the negative lens entirely and focussing the positive element alone, and taking the measurement of its image with the micrometer. From these measurements one determines the focus of the negative lens. Calling o the measurement of the object given by the positive lens alone, v and v' the back foci as above, and i and i' the measurements of the image at these back foci respectively, the same formula as given before now obtains:—

$$f\text{ (the focus of the negative)}=\frac{v'-v}{i'-i}\times o.$$

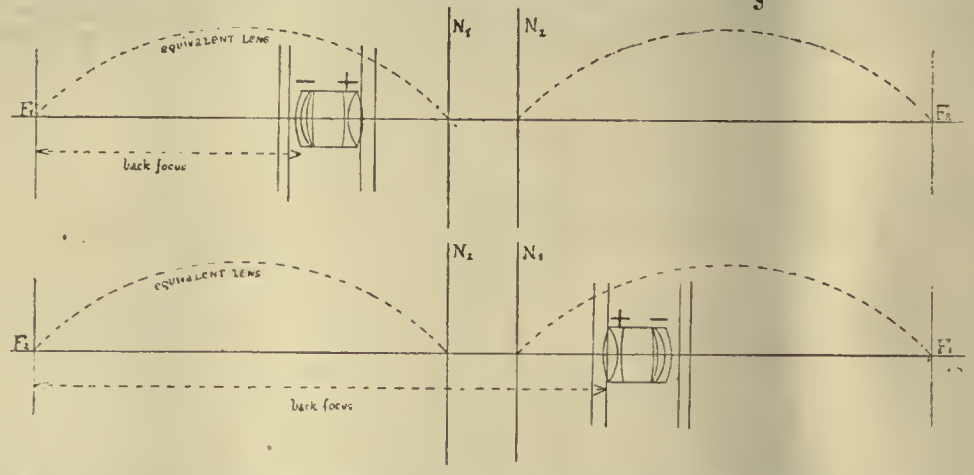
3. *The Position of the Nodal Points of the entire System for a given Separation.*—These, as I have already said, are determined by the foci of the positive and negative lenses employed in the system and the separation for the time being. For a given separation they are temporarily as fixed as in every lens system, whether positive, negative, or a combination of both. You have here (fig. 2) a diagram showing the

Fig. III



manner in which the nodal points, and planes passing through them, are thrown in front of the lens, and, in order to impress upon you the fact that they are fixed for the time being, I have a combination of a positive and negative lens, in which you will see how very widely the back foci of the system differ when the positive or negative lens is turned towards the object, but at the same time you will notice that the size of the image is identical in both cases; in other words, *the equivalent focus remains unchanged.* It is evident to you that, by turning the negative lens towards the object, the back focus is measured from the nodal plane a long way *inside* the camera, and to utilise a lens so constructed a very much longer camera would be necessary to obtain the same size of image as that given by an *ordinary* lens of the same back focus; in fact, it reverses the advantages of the tele-photographic system when used as it is intended to be used.

Fig. II



The methods of comparative sizes of a distant object between the tele-photographic lens and that of one of known focus, or the method in focussing upon the sun, are either of them applicable to determine the focus for any given extension of camera. I may mention here that perhaps the readiest method of obtaining the focus of a tele-photographic lens for a given extension has reference to the magnification of the complete system as compared with the positive alone. It is performed by dividing the back focus (*i.e.*, the measurement from the negative lens to the screen) by the focus of the negative lens and adding one. If the positive lens, then, have a certain known focus, the temporary focus for the extension taken will be given by the magnification produced by the tele-photographic system. If the magnification is n times, the corresponding focus of the lens will be n times that of the positive alone, and so on. It may be of interest to mention that with very long extensions of camera an approximate focus is arrived at by multiplying the camera extension by the focus of the positive divided by that of the negative.

It will be observed from this that with *short* extension there is an advantage on the score of portability, with greater corresponding magnification, than occurs at the "limit." Compare tele-photographic detective lens.

T. R. Dallmeyer, F.R.A.S.

(To be continued.)

ON THE PHOTOGRAPHY OF THE LUMINOUS RAYS OF THE SHORTEST WAVE-LENGTHS.*

The Photographic Spectrum Apparatus.

Its optical part consists of a double prism of 60°, with a square aperture of 30 mm., and of two plano-convex quartz lenses of 150 mm. focal distance (D, 589) and 26 mm. diameter.

The optician, Herr B. Halle, to whose kindness I am indebted for these lenses, has used the greatest care in the selection of the material and in its elaboration. How greatly this circumstance favoured the sharpness of the proofs I did not learn until I compared proofs taken with another pair of lenses of a different origin.

The two halves of the prism are joined together with a very thin layer of glycerine.

The mechanical part of the apparatus consists of a strong tripod fitted with levelling screws, which supports on a strong pillar a disc of 18 cm. in diameter, capable of revolving on its centre, upon which are fixed the collimator, the support of the prism, and the camera, so as to be capable of adjustment. The slide of the slit has cast-steel cheeks and a micrometer screw, the drum of which allows of readings down to 0·002 mm. It is connected with the collimator by means of a very accurately executed draw tube, with which also the plate is focussed. That this is effected with the collimator, and not also with the camera, is because the entire camera is built of glass, and is not adapted for drawing out. The support of the prism has adjustments necessary for levelling the prism (the Gauss eyepiece), and for adjustment to the minimum of deflection. A piece of velvet is suspended over the prism to exclude extraneous light.

The camera is the only peculiar feature in the apparatus. Except the case, it is built of mirror glass, and—with the exception of a small metal screw clamp, serving to secure the track of the case—there is in the entire camera not a single screw joint. The case can revolve on the medium line of the photographic plate, so that the plate can take any desired angle with the axis of the lens between 20° and 32°. The lens is secured directly to the glass body of the camera. Two openings, which the case, in consequence of its mobility, forms with the body of the camera, are closed with velvet. A glass junction, which I would here have used in preference, was impracticable. The oblique position of the plate can be read off on a roughly graduated arc. The body of the camera is of a parallel-epipedal shape, and is supported by an arm of strong mirror glass, prolonged at right angles on its long side. The prolongation of the arm effects the connexion of the camera with the rotatory disc of the apparatus, for which purpose the latter bears two powerful clamps.

The case is not distinguished in form and arrangement from the ordinary wooden cases. It has a slide and a cover like these, and it can also be displaced for the reception of spectra placed below each other in the direction of the spectral lines according to a scale applied laterally, so that a plate, with a sufficiently short slit aperture, may serve for a great number of proofs. The internal surfaces of the camera and of the cases, as the glass of which they are made is transparent, have a thin lining of a dead black colour. The outside is coated with black paper and shellac varnish. The size of the plates is 30 by 65 mm.

I have used glass for the camera in preference to wood, because, notwithstanding the requisite—and perhaps little trustworthy—paper coating, it is not greatly susceptible to the changes of atmospheric heat and moisture, and because wooden cases for such small plates can scarcely be made more accurately than those of glass. During use extending for months, the glass camera has never given occasion for dissatisfaction.

Setting up the Spectral Apparatus and the Auxiliary Plant.]

The source of light must be adjusted with the aid of a telescope. In order to keep the telescope and the collimator as much as possible coaxial during the duration of the entire experiment, a foundation was required as little sensitive as possible to atmospheric influences. For this purpose also I selected glass. A quadrilateral disc of mirror glass, with sides of 1 metre in length and 10 mm. in thickness, was fixed upon a very stable wooden foundation in such a manner that it was supported only in some few points. The position of the supports was selected so that the changes to which the wooden foundation was liable could be conveyed to the direction of the apparatus only in a very reduced proportion.

The apparatus directly concerned in obtaining the proofs was set up on the glass plate as follows, and, where practicable, it was specially secured against lateral displacement:—

Opposite to the spectroscope, and co-axially with the collimator, stood the reading telescope; between both, the spark support; and, close before the slit, a second stand with a slit-shaped screen of adjustable length. Between the spark stand and the screen there was placed, for a portion of the proofs, a condenser, of which more below. The screen came into use if the aperture of the slit was to be opened to the rays only for a part of its length. It could also be displaced along the slit by means of rack work in the support, so that the slit could be opened at any point to the length desired, and, if necessary, also in an uninterrupted succession at the transitions. The screen, as well as the sparks, required the reading telescope for accurate adjustment. This will be more intelligible if I add that the aperture of the slit length moved within very narrow limits, and often did not exceed the modest measure of 0·2 mm., and that, on the other hand, the sparks and the screen were generally at the distance of some centimetres.

The Source of Light.

The primary current was supplied by a chromic acid battery of four large immersion elements. Besides the inductorium (formerly used) of 25 cm. spark length, and the Leyden jars, there were also used this time a smaller inductorium for sparks of only 8 cm. in length. In some cases the inductorium was exchanged for an induction machine (four pairs of discs of 62 and 70 cm. diameter) connected with a Riess's jar battery (nine Leyden jars with an external coating of 1¼ metres).

As electrodes, there were again used, temporarily, cadminm and zinc: afterwards, permanently, aluminium, and finally, Ag, As, Au, Bi, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mo, Na, Ni, Pb, Pd, Pt, Sb, Si, Sn, Tl, W, all in the state of wire or short rods (Ca, K. Na, W), or crystals (Si), which were held in clamps of copper or platinum.

The Photographic Process.

This time also, when the utmost sharpness of design was needful, plates of my own preparation were used. But in general the photographs were obtained upon plates by Herrn E. Zettnow. In all cases I preferred them to my own plates, on account of their great sensitiveness and intensity, except where the utmost sharpness of the spectral lines was essential. Some spectra were taken upon Schleussner plates. The Schleussner plate works also clear, and is very sensitive, but its negatives betrayed the above-mentioned defect of all commercial plates—they were wanting in the intensity required for taking spectra. The developer and the fixing agent consisted as formerly, of pyro-soda and sodium thiosulphate.

The number of the negatives thus obtained is relatively large. The author's diary gives a conscientious account of the conditions under which each proof was taken. Every plate, even if a failure, is given in the order of time and with a progressive number, and the negative bases have the same number.

The Photographic Proof.

The commencement of my proofs fulfilled my expectations only to a very modest extent. My apparatus, indeed, as it was to be expected from the size of its aperture, was found very light-proof, but the two most refrangible rays of cadmium, Nos. 25 and 26, contrary to my anticipation, had gained little in intensity. It was not much better with the most refrangible lines of zinc, Nos. 27, 28, and 29. They certainly appeared earlier than previously, but their intensity still decreased decidedly with their wave-length. Hence it seemed as if the suspected action of the atmosphere might chiefly be reduced to a specific property of the lines concerned. But even this, as it appeared in the course of my subsequent researches, was in part correct; the main difficulty in my earlier proofs of the most refrangible rays lay in the imperviousness of the air to light. This resulted clearly from the proof of the aluminium spectrum which next followed. All the main lines appeared in a few minutes, and in greater intensity than heretofore. The most refrangible—the double line, No. 32—acted now always first, in contradistinction to former results, and its components were of equal strength, a circumstance which I emphasise merely because it acquired especial importance for certain subsequent proofs. Next to it there appeared the least refracted line, No. 30, and only some time after the intermediate line, No. 31, the least refracted component always first. On brief exposure, the more strongly refracted component did not appear at all, and even on prolonged exposure it remained far behind all the other lines.

This behaviour of the aluminium spectrum, with the new apparatus, ensued whether the proof was taken with or without a condenser, and with plates of high or low sensitiveness. In contrast to earlier observations, the lines, after an exposure of three minutes, displayed an intensity and distinctness quite sufficient for the purpose of measurement.

On more prolonged exposure, the more effective lines acquired the greatest intensity which the gelatine plate admits of. But, very remarkably, the action of light in this reagent is confined to these rays, whilst the less deflected portion of the ultra-violet is distinguished by an exactly

* Continued from page 753.

opposite phenomenon—the access of new lines, and their growth to a continuous band of the deepest blackness. Owing to this circumstance, the proofs have a peculiar appearance; they produce the impression as if the activity of their most refrangible half were still checked by some hindrance. We are compelled to this conclusion by the great intensity of lines No. 32, with which the effective band of the aluminium spark in the ultra-violet suddenly ends, and whereby, at the same time, the assumption of its prolongation towards the more refrangible side, where hitherto no action of light has been observed, receives a certain justification. It was this consideration which led my work from the path of reproductivity, on which it had hitherto mainly moved, towards new facts.

VICTOR SCHUMANN.

(To be continued.)

PRACTICAL REMARKS ON THE WORKING OF GELATINO-CHLORIDE PRINTING PAPER.

IN a previous article I referred to a few necessary precautions against damp when bringing gelatino-chloride printing paper into contact with a gelatine negative that was in any way liable to have absorbed moisture through being stowed away in a damp situation, and also referred to the suitability of this class of paper for printing negatives that were judged too weak or thin for yielding satisfactory results on albumenised paper.

As a rule, the chief error made when dealing with prints printed from thin negatives will be found in overwashing and overtoning them. In the case of gelatino-chloride, the toning in no way offers serious trouble when systematically gone about. For all round work perhaps there is no better toning bath to employ than the good old acetate bath, that has so steadily stood the test of time, and been such a good friend to professional and amateur alike. Here it is for the benefit of any who have never tried it, and the formula is of special value in respect of its being applicable for gelatino-chloride as well as albumen and plain silver paper alike, and is always ready at hand. When to be used in the case of gelatino-chloride, all that is necessary is to add a few crystals of sulpho cyanide of ammonium to a slightly weakened bath.

In 40 ounces of water dissolve 1 ounce acetate of soda, then break and add a 15 grain tube of chloride of gold. And this puts me in mind of about as funny a bit of photographic experience as ever fell to my lot. A few months ago, when asked by a novice about the toning of these prints, and having given him, as I thought, full particulars, I was buttonholed one day by him and submitted to a good all-round wigging, much after the following style:—"I say, Armstrong, what's the use of your humbugging a fellow in that way? I tried that toning formula of yours and found it no use. Can't get the prints to tone at all. It would be far better for you professional chaps to keep your information up your sleeve and refuse to give advice at all, rather than set a poor fellow all wrong!" This naturally made me curious to ascertain where the error had crept in, and so I asked him to bring along the stuff, as he termed it, for examination. Would the photographic public believe it, but the tube of gold had been inserted into the bottle without having been broken. All the satisfaction I got was, "Well, how was I to know to break the tube, thought it was a capsule. The instructions I read said just to add a 15-grain tube of gold, and I did it." Could ignorance go further?

And so I now, when giving this formula, always take care to add the word "break."

As I have said, this acetate bath is always ready for any class of paper, and when going to tone gelatino-chloride all that is necessary is to add one volume of water to three of stock solution, and then a few crystals of sulphocyanide of ammonium, and in a few minutes all is ready. A few words of advice to those having no experience in the way of working these admirable papers at this point may be of service. Before beginning to tone, have a full set of dishes, scrupulously clean, and ranged in order as follows: First, a dish not much larger than the size of print it is intended to tone (for I advise all beginners to tone one print at a time). Into this small dish place a reasonable quantity of toning bath made up as directed. On the right-hand side of this dish have a larger vessel, into which has been placed a hypo bath of one volume of a saturated solution of hypo to three of water, and let this be well filtered through a cambric handkerchief, and freshly made up. On the right hand side of the hypo have another large dish containing clean cold water, and on the right hand of this, again, a dish containing an alum bath, one volume of a saturated solution, free from all grit or sediment, to eight volumes of clean cold water; and, finally, a good-size dish, or basin, or tub, to wash the prints in. With such preparations made, the toning of any number of gelatino-chloride prints may proceed with the utmost certainty of success. The moment the print is taken from the frame, it is placed, with the left hand, into the small dish containing the toning bath, and quickly immersed, and turned face up and down. With a freshly made up bath the toning will proceed somewhat rapidly, and a little practice will be of value. The surface of the print will soon appear to assume a somewhat bluish tint, but the colour must not be judged by looking down upon the print; it must be held up to the window or light, and examined by looking through it. The moment a beginner does this, he will be struck with the marked difference between the surface colour as seen by looking down upon, as against the colour apparent by looking through it, and it is this looking through, or by, transmitted light that must guide the beginner in striking the proper tone.

As I have said, one of the common errors a beginner is most liable to make is the dealing with over-thin negatives and over-toning the prints from same. Therefore, any one commencing the use of this kind of paper should strive to get a good all-round printing negative, and one that will show deep shadows, and middle tints, and high lights when being toned and examined by transmitted light. With such a print from such a negative, contrasts and the colour of the deep shadows will easily guide an operator. As a rule, the deep shadows ought to have a little of what I call the rosy brown in them, whilst the middle tints and high lights will show a somewhat greyish appearance. The moment the deep shadows begin to lose this rosy appearance there must be no hesitation. The print must be passed from the left to the right hand, and quickly submerged in the hypo fixing bath. The colour will soon change, but after a few minutes the print will clear up nicely, and the fixing go on level for about fifteen minutes. Then with the right hand run the print quickly through the water bath on the right of the hypo dish. The washing at this stage should not be protracted; a mere rinse is all that is wanted, and then the print is placed for a good long time—twenty or thirty minutes—in the alum bath, and finally washed in several changes of water or running water for a couple of hours or so. Such is the routine, working always from left to right, the left hand alone touching the toning bath, and only one print at a time being dealt with, and this just as the print comes from the frame. The right hand must be carefully trained to refrain from touching the prints at any stage until it comes to the fixing bath.

I have said the prints are dealt with as soon as they are taken from the frames. Experience has taught me that the toning of gelatino-chloride paper is best not deferred for any great length of time after being taken from the negatives. When such is practised there is a distinct loss of brilliancy, and I know in this my experience tallies with that of other workers. Should the toning bath, after having treated a goodly number of prints, begin to tone too slowly, all that is necessary is to add a small quantity of the acetate bath from the stock solution and just an odd crystal or two of the sulphocyanide of ammonia. In a few minutes it will go on again with renewed vigour. The bath will be at about its best after a few prints have been passed through. In cases where a considerable number of prints have to be dealt with, it will be found convenient to have several toning dishes, say, three or four, into each of which one print at a time is placed; this permits of a good large batch being manipulated in a somewhat less period of time.

T. N. ARMSTRONG.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE North Middlesex is among the few Societies holding periodical exhibitions which can afford as it were to dispense with the assistance of outside photographers at its annual displays of members' work. That it is able year after year to bring together collections of photographs of high artistic and technical excellence without extraneous help, says much for the *esprit de corps* of the Society as a whole, as well as for the enthusiasm of its officers and individual members. This year's display is not one whit behind its immediate predecessor in point of average merit, although possibly any advance that may have been made on last year is at the best not easily discernible. Summing up the Exhibition as a whole, we should be disposed to say that while in landscape work a high degree of excellence was obtained, portraiture shows little, if any, advance.

In the last regard, the best thing shown was perhaps *A Girl's Head*, by Mr. C. Beadle, a pleasing, unaffected study which we noticed at the Pall Mall Exhibition. Mr. J. W. Marchant showed a capital study in platinotype, called *Evening*, the only thing wrong about it being its title, inasmuch as it might have represented mid-day as successfully as evening. It was a view across a river to some tree-studded meadows. The Judges awarded a certificate to Mr. Ernest Spencer for *Zingara*, a happily posed lady in characteristic garb, with her hands well placed behind her head.

The picture was in red tone, and was very successful. Mr. J. W. Marchant won a certificate with a delicate view, *The Footbridge*, crossing a stream, trees and bushes being utilised to make a harmonious piece of composition. The same gentleman showed an equally good view of a gentleman fly-fishing. Mr. A. J. Golding's river view, *Twilight*, was among the exhibits. To Mr. J. H. Avery went a certificate for *Reedy Waters*, a study of a commonplace reedy river and meadow, handled with the happiest effect. Mr. Ernest Spencer showed a portrait of General Booth, and Mr. Golding obtained a certificate for *Departing Day*, a pretty view across waters and meadows, as well as for a far larger view of sheep, *On the Marshes*.

A great many commonplace groups and portraits were hung. The awards for lantern slides went to Messrs. S. E. Wall and W. Taylor, and the first-named gentleman also showed some admirable landscapes. Of considerable utilitarian interest was a series by Mr. C. O. Gregory, illustrating the interior of a stationery manufactory. We are always glad to welcome the application of photography to this and similar uses.

The Judges were Colonel Gale and Mr. Cembrano. On the whole, while the North Middlesex gave an excellent display, we should scarcely be inclined to say that much of an advance had been made. But then the Society sets itself a high standard. The Exhibition was open for two nights instead of one, as formerly.

Our Editorial Table.

Messrs. Talbot & Eamer have sent for inspection their two hand cameras, the Talmer and Economic. They are both of the magazine

class, adapted for twelve pictures on glass plates, or twenty-four on cut celluloid films, in sheaths. The changing is effected by means of a soft leather bag, which, when not in use, folds neatly down over the recess in which the plates are stacked. The Talmer is fitted with one of Taylor & Hobson's rapid rectilinear lenses, the name being a sufficient guarantee for the excellence of this portion. The shutter has a rapidity varying from a fiftieth of a second to two seconds, although an exposure of any duration can also be given. It does not move with a gradual sliding motion, but with great velocity until the lens is uncovered, when it makes a halt for the period determined upon, after which it closes suddenly. The changing of the exposed plate automatically sets the shutter for the next; hence there is no danger of a plate being twice exposed. The number of plates exposed is shown by an indicator. The one shown to us has a fixed focus, but we observe from the price list of the firm that they are also made with adjustable focus and scale. Although small and compact, the Talmer has an unusually large finder. In the Economic, which is constructed on a simple system, the body is telescopic, adjusted by a rack and pinion, and is supplied either with or without a lens. It has a Thornton-Pickard time and instantaneous shutter. It is made in three sizes, and there is also a stereoscopic variety catalogued. The cuts give a good representation of each of the cameras mentioned.

"Una" Powder.

This powder, manufactured by G. Wright & Co., Hopwood, Lancashire, will prove to be the most formidable rival that gold, as a toning agent, has yet had to encounter; for, while all the tones obtainable by gold can also be got (on gelatine printing-out papers) by Una, this latter is immensely cheaper (a shilling bottle sufficing for a thousand quarter-plate prints), while it tones and fixes simultaneously with ease and certainty. It is claimed that the image is as permanent as if gold were employed, and, judging from such tests as we have applied, we think this claim may be substantiated. The method of using it is as follows:—

Dissolve two drachms of hyposulphite of soda in about seven ounces of water, and add thirty grains of Una. When the latter is dissolved, immerse the prints (without previous washing) face downwards, and keep moving for five to seven minutes. By this time they will have assumed an orange-brown to chocolate-brown tone, when they should be removed from the bath and the surface of the prints either sponged with a soft sponge charged with water, or the finger passed over the film, to remove any deposit that may be adhering, and then washed thoroughly for half an hour (at first in many changes of water). When dried, they will become a rich purple in tone, and can be afterwards glazed or matted if required. It is almost impossible to fail in getting the most beautiful results, but it is necessary to print rather heavily. If the print is too warm when dry, it can be easily retoned by again entering into the toning bath. It is better to let the water run a few minutes before making the solutions.

News and Notes.

Leeds Camera Club.—December 7, Paper, '*Beginners' Errors*, by Mr. C. C. Vevers.

The Photographic Club.—December 6, *Home-made Dry Plates*, by Mr. R. Child-Bayley.

West London Photographic Society.—December 5, Technical Social Meeting; *Lantern Slides*, by Mr. J. A. Hodges.

The address of the Hon. Secretary of the Glossopdale Photographic Society is now—F. W. Sharpe, Swan Inn, High-street, Glossop.

In the Open Class (G) of the Leytonstone Exhibition bronze medals were awarded to Messrs. R. S. Webster, J. H. Anderson, and L. C. Bensett.

Newcastle-on-Tyne & Northern Counties Photographic Association.—December 5, Lantern manipulation, with exhibition of novelties and demonstration, by John Watson. 19, Conversational Meeting.

Received.—Christmas number of *Detroit Free Press*, *The Gentlewoman*, *The Young Gentlewoman*, and *Figaro Illustré*. Also, *Photo-wastes, and How to Make the Best of Them*, from Robert Pringle & Co., London, with catalogues from F. W. Hart, Stoke Newington-road, N.; William Hume, Edinburgh; and Ross & Co., 111, New Bond-street, W.

Central Photographic Club.—The first "one-man" Exhibition is now open at the Club-rooms, Coleman's Hotel, Henrietta-street, Covent Garden. Mr. Thomas Fall's (Baker-street) pictures, which include some very fine dog studies, can be seen on production of visiting cards. The discussion on *Films versus Glass*, to be opened by Mr. H. M. Smith, has been postponed till December 15. Friday next (December 1) will, therefore, be an Open Night.

Liverpool Amateur Photographic Association.—Engagements for December:—December 6, Smoking Concert. Members willing to assist please communicate with the President. 12, Closing day Annual Competition. 14, Annual Meeting, Election of Officers, &c. Exhibition of Competition Prints and Slides. Mr. H. Simpson will exhibit and explain some ingenious and novel Improvements in the Working of the Lantern. 21, Lantern Lecture, *A Trip to Chicago*, by Mr. W. Harvey.

Mr. A. L. Henderson, who is at present residing at the Grand Hotel, Belvedere, Davos-Platz, Switzerland, writes as follows:—"When this reaches you, you may require artificial illumination to decipher these lines. Not so here. At this moment the light from the reflecting snow is dazzling. I arrived here three weeks since, and I have taken upwards of sixty negatives, all representing Davos in summer. Now the ground is thickly covered with snow, and we will see nothing green for several months. I am going to repeat the views in snow. The climate is something wonderful, so dry and cold. Consumptives sit out in the gardens day and night, the thermometer standing as low as 18° Fahr., many without bonnets or over-clothing. Plates of *medium rapidity* work with drop shutter *f*-64. We have many amateurs here. A magnificent dark room is attached to the hotel about 18 × 18 feet, water laid on, and heating apparatus so nicely arranged that my negatives dry in about thirty minutes. The hotel is thoroughly English; out of 200 visitors only about three per cent. of foreigners, so I have no difficulty on the score of language. I had no idea that Switzerland was so enjoyable in winter. I intend to remain all through the season. I will have pleasure in delivering a lantern lecture on my return, probably at the London and Provincial Photographic Association. I merely pen these few lines that, should occasion allow, you may intimate to your readers that, during the fearfully foggy English winter, lovely sunshine and magnificent views and photographic weather may be reached in about thirty hours from London. I will be pleased to describe some of my experiences at a near future." We shall be glad to hear again from Mr. Henderson, whose presence among the photographers in that quarter must prove quite inspiring.

Photographers' Benevolent Association.—Meeting of Committee at the rooms of the Photographic Society of Great Britain, 5A, Pall Mall East, on November 15, Mr. A. Mackie in the chair.—First application was one that had been received by one of the subscribers, and handed over to the Benevolent by

him. As the applicant had made two previous appeals to the Association, and both times been refused as unsuitable for assistance, the Secretary was instructed that nothing could be done. The second application was from a retoucher, who had been disabled for many months by a street accident, and whose case was partly considered on October 30. Secretary had already advanced, under instructions, 2*l.* Applicant now asked for 1*l.* 15*s.* to pay off his debts and sufficient money to live upon for five weeks, at the end of which time he would receive money from his friends to enable him to go out to South Africa. A loan of 1*l.* 15*s.* immediately, and 17*s.* 6*d.* for five weeks was granted. The third application, a collier, out of work through the coal strike, asked for means to obtain a whole-plate camera, as he was an amateur and could obtain enough work to keep him from starvation if he was able to photograph whole-plate groups. The Secretary was instructed that, as there was so much want amongst photographers, the Association could not assist amateurs to enter the ranks. Messrs. Charles Faulkner and Arthur Priestly, and Miss Edith M. Hardy were accepted as members. Donations were acknowledged with thanks from Sandell Exhibition, 9*l.* 14*s.* 3*d.*; Photographic Society of Great Britain, first instalment of benefit, 3*l.* 10*s.* 1*d.*; Hackney Society, collection, 1*l.* 13*s.* 6*d.*; Central Club, collection, 1*l.*; Photography Prize Competitions, balance, 18*s.* The Secretary reported that two applicants to whom loans had been made had commenced to repay them by small instalments.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
December 4	Camera Club	Charing Cross-road, W.C.
„ 4	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
„ 4	Peterborough	Museum, Minster Precincts.
„ 4	Richmond	Greyhound Hotel.
„ 4	South London	Hanover Hall, Hanover-park, S.E.
„ 4	Stereoscopic Club	Brooklands Hotel, Brooklands.
„ 5	Birmingham Photo. Society	Club Room, Colonnade Hotel.
„ 5	Bolton Photo. Society	10, Rushton-street, Bolton.
„ 5	Brixton and Clapham	376, Coldharbour-lane, Brixton.
„ 5	Exeter	City Chambers, Gandy-st., Exeter.
„ 5	Hackney	206, Mare-street, Hackney.
„ 5	Herefordshire	Mansion House, Hereford.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

November 28,—Technical Meeting,—Mr. Horace Wilmer in the chair.

The Assistant Secretary showed and explained the Thornton-Pickard Company's new tripod stand for tourists' cameras.

Manganese Printing.

Mr. R. Child-Bayley read a paper on this subject, which consisted of a synopsised account of Messrs. Lumière's experiments in printing with the salts of manganese. Briefly, the process consists of floating gelatinised paper on a solution of manganic lactate. When dry the sensitive surface is of a brown colour. Exposure is made behind a positive in the printing frame, the action of light being to bleach the paper and to form a faint positive image. The manganese salt is considerably less sensitive to light than albumen paper. Development is effected by a variety of organic compounds, the nature of which governs the colour of the image. No manganese is left in the developed print. If under-printed, the whites of the picture become discoloured. Mr. Child-Bayley followed the reading of the paper with a demonstration of the process, developing several exposed prints with aniline sulphate, acidified with hydrochloric acid, orthotoluidine sulphate, and para-amidophenol sulphate, blue, green, and brown pictures being obtainable. A large number of organic compounds may be used for development. The developing action cannot be stopped, but the stronger the developing solution the more vigorous are the prints. The addition of strong ammonia to the developing solution reddens the tone of the print.

A New Platinum Paper.

Mr. Leon Warnerke introduced Dr. Hesekiel to the meeting, and stated that he had just brought out a new platinum paper which gave black or brown images by printing out. While ordinary paper required a certain class of negative to give the best result—that is, very intense or very weak negatives—this paper would give good results from both. It was prepared on a special paper having a pyramidal kind of grain, produced by pressure, the effect of which was to give a great deal more intense blacks and whites. The paper would not deteriorate by moisture, and would thus keep longer than ordinary platinum paper. If the negative was a dense one, it was advisable to use the paper dry; if weak, the paper could be slightly damped by steaming. If under-printed, the image could be developed up with ferrous oxalate. Development gave a blue image. The prints are washed in solution of hydrochloric acid in the usual way.

A large number of specimens of prints on the new paper were on view, and Dr. Hesekiel and Mr. Warnerke received votes of thanks.

Messrs. Perken, Son, & Rayment's representative showed the firm's new three-wick oil lamp, which, on account of central and side air channels, gave a whiter and more powerful light than an ordinary oil lamp having four wicks, and therefore considerably more flame surface. Comparative discs were shown with the two lanterns, and slides projected, the advantage being much in favour of the new lamp.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 23,—Mr. R. Beckett in the chair.

The Carbon Process.

A demonstration of the carbon process, on behalf of Messrs. Elliott & Son, was given by Mr. Birt Acres, assisted in the practical department by Mr. Skelton. Mr. Acres said the process was a permanent and beautiful one, but, unfortunately, in its earlier days it had been hampered by patents. There were certain apparent difficulties that frightened the beginner. Any child could do albumen printing, as something was seen at once, whereas in exposing tissue no image was seen, and, if it were not carefully attended to, one would go on seeing nothing. Mr. Acres mentioned that Mr. Swan discovered the process by accident when using bichromated gelatine to produce an insoluble image for process work. It occurred to him to make the gelatine easier to handle by putting pigment with it. When it was transferred he found that he had got a carbon print. At a previous meeting of the Association the question of getting too soft results had been raised. This was one of the points that could be easily remedied in two ways, namely, by using an exceedingly weak bichromate solution, say, one-tenth of the ordinary strength, and the other way was by printing in direct sunlight, as the sun's rays would penetrate more deeply into the print to produce a more vigorous image. Results too soft for enlargement depended a good deal upon the kind of tissue used. The sepia gave a soft result, but blue or black gave more vigorous results. One of the strong points in favour of the process was the certainty of getting a good colour, which was not at all dependent upon the opacity of the negative. Having briefly given the *rationale* of the carbon process, and explained single and double transfer, Mr. Acres introduced Mr. Skelton as having worked with Mr. J. W. Swan, and the practical demonstration of the single transfer process was proceeded with. Mr. Acres said the tissue was of about the same sensitiveness as albumen paper. The preliminary soaking in water was most important; the tissue would first curl inwards and then outwards, when the print should be placed in contact with the support. It should not be allowed to absorb too much water. It should be well squeegeed down to prevent air bells; water left in would produce black spots. Development took on this occasion) in hot water two or three minutes, and the prints were then placed in cold water. Alum (said Mr. Acres) was used for fixing purposes. There was an advantage in making a print to develop at a future time, as, on account of the continuating action of light, a print exposed one day could be developed the next, gaining in intensity the meanwhile. Of course, properly exposed prints should always be developed right away; but, if the light was bad, it was an advantage to be able to put the print away for a short time. Answering a question, he said no aniline dyes were used in the pigment. He pointed out that exposure could be modified by using the developing water at different temperatures. Local development and restraining were also practicable by using hot water to get out high lights or save the shadows; thus there was a considerable amount of dodging by the process. For the double transfer process, the use of opal wherever possible was recommended, as by using it a much finer matt surface was obtainable than with a flexible support. The opal should be ground on one side, talced, and collodionised.

In answer to Mr. Barker, who asked whether the colour of the tissue affected the continuating action of light,

Mr. Skelton said perhaps there was a little preference in favour of the iron colours; anything which increased the solubility of the tissue increased the continuating action.

Proceeding, Mr. Acres explained the use of the safe edge, saying that it was immaterial whether it were placed on the film or glass side of the negative. After touching upon various points in connexion with the double transfer process (which Mr. Skelton was demonstrating), Mr. Acres explained that, in printing from a hard negative for transparencies, a tissue that gave a soft result should be used; if the negative were much too soft, a tissue that gave a vigorous result should be used. Again, a defect in the original negative could be worked on in the transparency before making the enlargement. The use of the actinometer in exposure was then explained, Mr. Acres concluding by re-

marking that with the single ransfer process much sharper images could be obtained than with the double, and it was, therefore, better to make a reversed negative to start with than to use double transfer.

The various processes of development, squeegeeing in contact with temporary supports, prepared opal, &c., strengthening flat images by means of water heightened in temperature, were shown by Mr. Skelton, a number of developed prints being passed round. Also there were on view in the room many carbon enlargements by Messrs. Elliott & Son.

By means of his lantern Mr. Acres then showed a varied collection of slides, illustrating the qualities of transparencies desirable for projection and reproduction purposes, the effects of intensification with permanganate, comparisons of carbon slides with gelatine, &c., and other points, and at the conclusion a vote of thanks was passed to him, and the meeting terminated.

MANCHESTER PHOTOGRAPHIC SOCIETY.

NOVEMBER 22.—The evening was devoted to a demonstration by Mr. S. Herbert Fry on *Paget Prize Lantern Slides*. He dealt with, principally, the characteristics of a good lantern slide, and he laid great stress on the importance of exposing correctly, and not, as some people try to do, by making the slide right in development. To secure uniformity of colour, it is no use making local applications. Of course, this is almost necessary in plates, but in lantern slides it cannot be done satisfactorily; when anything requires to be doctored, it must be done in the printing, and not by local application. Coming to the question of variation of colours, Mr. Fry had put through the lantern about a dozen slides all from one negative, but all of different exposures. Not one of the slides was of the same colour, all different, some being brick-red warm tones, purple-black, and others cold tones. Being all developed by the same solution, it proves what the lecturer said, that the gradation of colour is due to exposure, and not, as some say, development. One thing Mr. Fry impressed upon the meeting was that almost the same tone could be got either with the Paget slow or quick lantern plate; in fact, he seemed to think that even an expert could hardly tell the difference. This, of course, is a convenience when reducing in the camera, the rapid plate only taking about one-sixth of the time. Regarding developers for these slides, he thought the best were pyro and hydroquinone. Either of these, if mixed as per instructions of the Paget Company, would give splendid results. Coming to the new print-out lantern slide, he said these plates can be changed in the gaslight or dull daylight, and will not be damaged; they can either be partially printed, and then developed, and toned, and fixed, or printed right out, and toned, and fixed. Mr. Fry recommended the combined toning and fixing solution, the one he used being composed as follows:—

Hyposulphite of soda	1 pound.
Lead acetate	1 ounce.
Chalk	1 ,,
Water	80 ounces.

and to each 5 ounces of above solution he added 1 grain of gold. He calculated that each dozen plates would require about 1½ grains gold, that is, 7½ ounces of above solution. Regarding the printing of these slides, it is done in daylight, just the same way in which you do the printing-out paper. To obtain the best results in developing the slide, it must always be printed by daylight and not by gas.

Brixton and Clapham Camera Club.—November 21.—Mr. W. THOMAS read a paper on *Skies*, which, he said, could be produced in photography in one of two ways, either by photographing on separate plates for the landscape and sky respectively, or by securing the sky on the same plate as the landscape. He preferred the former method, one advantage being that it was easier to allow the correct exposure for the two portions of the picture. In exposing he uses a Tylar's shutter, and sets it for the landscape before stopping down the lens, exposing gradually for the foreground and quickly for the sky. Development should be carefully performed, since the sky must be not too dense. A large stock of negatives of skies should be kept, and the greatest care exercised in printing so that the lighting may be the same as for the landscape, the clouds occupying their correct position. Several specimen prints and negatives were submitted for inspection and generally admired. The methods of printing in clouds in prints, enlargements, and lantern slides were also fully explained, and several dodges described.

Central Photographic Club.—November 24.—A large and appreciative audience attended, causing the club-room to be filled to overflowing, to hear Mr. PAUL LANGE'S (Liverpool) lecture on *Norway*, which was accompanied by 130 lantern slides. The lecturer said most visitors attempted to see too much, but, owing to the enormous distances they travelled, they saw only the crust. To fully appreciate the beauties of that country, the traveller should arrange to cover only a limited portion of the country in the time at his disposal, travelling up the various valleys in the native conveyances. Personally he preferred "a carriage for two," the coachman sitting behind; but he could not understand a word the travellers might say. This method of driving was very enjoyable. The lecturer proved himself a good guide to the various fjords, valleys, and mountains which he himself visited, and his style was much appreciated. The technical and artistic excellence of the slides was a surprise to most of the audience. Some very fine sunrise and sunset effects in the German Ocean were shown, the colours on the screen approximating to those of nature, and were obtained by pure photography without the aid of pigments, by combining a number of lantern plates.

Croydon Microscopical and Natural History Club (Photographic Section).—November 22.—The twenty-fourth annual *soirée* of the Club took place in the Public Hall, when over 600 guests attended. In addition to the large collection of botanical, microscopical, and entomological objects of interest shown by the other sections of the Club, there was a fine display of work by the Photographic Section. Amongst those showing were Mr. Low-Sargeant, with several admirable enlargements; Mr. K. McKean, photographs of old lamps and pipes; Mr. Dodds, a series of Yorkshire views; Mr. Collyer and Mr. Rood, views of the excavations of the Roman encampment at Silchester; Mr. East, several fine views of Arundel Park; Mr. Epps, some charming little bits of Norway; Mr. Moss, Mr. Coldwells, &c. Particularly noticeable among the transparencies were Mr. Oakley's *Indian Palaces*, and a set of Norwegian studies by Mr. J. A. Carter.

Greenwich Photographic Society.—At the recent meeting of this Society, under the chairmanship of Mr. Charles Churchill, Mr. E. A. LEBLANC, on behalf of Messrs. Schwarz & Co., gave a most interesting demonstration of the use of their new developers and cartridges. A couple of Sandell films were successfully developed with metol, the extreme detail brought out by this energetic developer being much appreciated. Lantern slides, developed with glycin (which is apparently well adapted to this work), and bromide prints with amidol were also shown, the use of the "tone-fixing" cartridges being shown on untoned prints provided by the Hon. Secretary. Much interest was evinced also in the new fixing block produced by this firm, which, it would seem, is quite likely to supplant our old friend "unadulterated hypo." Mr. Leblanc received the cordial thanks of his somewhat small but appreciative audience. At the forthcoming meeting on December 6, Mr. S. Herbert Fry has arranged to visit us in connexion with the Paget Prize Plate Company's productions.

Hackney Photographic Society.—November 20th, Ladies' Night.—An entertainment was given by Mr. RENNIE, entitled *The Forth Bridge*, illustrated with lantern slides of a very instructive and scientific nature. The lecturer dwelt upon the subject from an engineering point of view, which was fully explained by the slides which were shown, illustrating the principles. The slides included the building of the bridge at various stages, launching of caissons, banquet, the Prince of Wales driving the last rivet, portraits of celebrities in connexion with same, &c. Many statistics were given in connexion with this gigantic bridge, which proved of great interest to several members. A further exhibition of members' slides was put through the lantern, and some excellent toned pictures were the result. The lantern was worked by the Hon. Secretary, Mr. W. Fenton-Jones. Members were specially asked to attend a meeting to be held on Tuesday, December 5, when a discussion upon the Society's outings will be brought forward.

Richmond Camera Club.—November 27, Mr. Cembrano in the chair.—Mr. C. H. DAVIS read a paper on *Films*, in which he drew attention to the advantages and disadvantages of celluloid as a substitute for glass, and gave his experience of the working of various makes of films. The subject was well discussed, and specimens of negatives and appliances were shown by the President and other members.

South London Photographic Society.—November 20, the President (Mr. F. W. Edwards) in the chair.—Thirteen new members were elected. Mr. A. LE BLANC gave a demonstration of developing, toning, and fixing with Dr. M. Andresen's cartridges. He first used a metol cartridge, dissolving it in about seven ounces of water. With this he developed an isochromatic plate, which had been previously exposed on a group of chrysanthemums. The gradation of the whites was perfectly rendered. For fixing, the demonstrator dissolved a bar of fixing salts in about forty ounces of water, which gave an acid fixing bath. The portability of the fixing bath was much admired. Lantern slides developed with cartridges were also shown. Development of paper prints with metol and amidol cartridges followed. The Hon. Secretary showed the Thornton-Pickard improved tripod. Samples of Barnet plates were distributed among the members for trial.

Woolwich Photographic Society.—November 23, Major Charles D. Davies in the chair.—The meeting was well attended. Some prints were handed up for inspection by Messrs. Dawson and Panting. During question-time, the old difficulty cropped up, *i.e.*, how to mount prints on gelatino-chloride papers. It would seem as though the Kent water is the cause of some of the trouble, leaving chalk deposits wherever the print is wetted. Further discussion, however, had to be deferred. The Chairman introduced Mr. ALBERT HILL, who then proceeded to give a practical demonstration on *Enlarging by Crescofylma*, in the course of which Mr. Hill said that the best results were obtained on films developed with hydroquinone or rodinal. Several films, both negative and positive, were removed from their original glass supports and steadily enlarged to about double the size, and then placed on their new support. The whole operation is remarkable for its simplicity.

Ashton-under-Lyne Photographic Society.—November 22.—Mr. WILLIAM MOSS gave a demonstration on *Microscopic Photography*. Dr. Hamilton, in introducing him to the meeting, said this was a new branch of photography, and, if it could be brought to perfection, it would be of immense service to the profession to which he belonged. Mr. Moss, in opening, explained the working of his camera, which he had had made specially for his own use. It combined long extension and ease of working with perfect rigidity. The lens tube was one made short, and it took the place of the ordinary tube on the microscope stand. The light used was the usual powerful paraffin lamp. Mr. Moss explained that the lenses were microscopic objectives, and were better if corrected for photographic purposes. They were three inches, one inch, and one-eighth inch focus, and with these the power of magnification ranged from three times to two hundred times. If a smaller enlargement were required, the ordinary photographic lens could be used. Exposures varied much, from two seconds to hours. A slide, representing a subject to which he had given much time and study, the tongue of the snail, was put in the microscope, and, after focussing on the ground glass, clear glass was substituted, and a compound focussing glass used to bring the object into perfect focus. The clearness of the image obtained by this method was evidently new to most of the audience, and was much appreciated.

Birmingham Photographic Society.—November 21, Mr. W. Jones in the chair.—The collection of slides, which were recently shown by invitation at

the Exhibition of the Photographic Society of Great Britain, were passed through the lantern. They were representative of the best slide work of the Society.

Cardiff Photographic Society.—The Eighth Annual Meeting was held at headquarters, Castle-arcade, on Friday, the President (Mr. C. F. Gooch, J.P.) in the chair.—The following officers were elected for the ensuing year.—*President:* Mr. S. W. Allen.—*Vice-Presidents:* Messrs. C. F. Gooch, J.P., Jonas Watson, J.P., Walter Iusole, P. Mansel Franklen, E. H. Bruton, Alex. Kellar, and H. Murrell.—*Hon. Treasurer:* Mr. G. H. Mills, jun.—*Hon. Secretaries:* Messrs. G. H. Bedford and T. H. Faulks.—*Council:* Messrs. W. H. Kitchin, F. Heitzman, W. Herbert, A. Freke, W. Foster, A. McKinnon, D. B. McCullum, W. Booth, W. J. Jenkins, Rev. A. T. Fryer, E. Hancock, jun., W. Cocks, and A. Montgomery.—The Secretaries made a report as to the prospective arrangements for the Winter Session, and it was decided to have a public exhibition of lantern slides on December 22.

Derby Photographic Society.—November 21, Mr. R. Keene presiding.—The election of officers resulted as follows:—*President:* Captain W. de W. Abney, R.E., C.B., F.R.S.—*Vice-President:* Mr. R. Keene.—*Committee:* Messrs. A. H. Bennett, C. Bourdin, C. B. Keene, T. Scotton, G. Walker, R. Woods.—*Treasurer:* Mr. A. B. Hamilton.—*Hon. Secretary:* Mr. T. A. Scotton, 9 Church-street, Derby.—Mr. S. H. Fry, of London, gave a lecture and demonstration on *Lantern-slide Making*. Mr. Fry very clearly explained the various methods of doing this—such as printing in contact with gaslight, printing out by daylight, partially printing out by daylight, and then converting the chloride of silver salts into bromide of silver and developing to the proper density by the ordinary methods, afterwards toning with gold in the usual way, and, lastly, by means of reduction in the camera. The demonstration throughout was excellent, and was watched with great interest by the large number of members present, and at its conclusion a general discussion took place.

Leeds Camera Club.—General Meeting, held Thursday last in the Club rooms, Mr. Irwin in the chair.—Forty-seven present. Lantern exhibition. Lantern manipulators, Dr. Thresh and Mr. Wigglesworth. Next meeting, December 7, paper, *Beginners' Errors*, by Mr. Vevers.

Leeds Photographic Society.—November 20, Members' Lantern Night.—A large number of slides representing summer outings were thrown upon the screen contributed by the following gentlemen:—Messrs. Atkinsons Reffits, Butterworth, Rodwell, Walker Denham, Burrell, Denison, Hampshire, Armstrong, Washington Teasdale, and Dr. Jacob. Criticisms were invited, and questions asked regarding the developers used, much useful information being elicited. Metol in the hands of Mr. Walker produced excellent results; exposure about one-half. Many very fine slides were shown, and a pleasing and interesting evening was spent. The Chairman (Mr. J. H. Walker, President) announced that, on December 7, Mr. Godfrey Bingley would give his lecture on his summer rambles with slide illustrations.

Liverpool Amateur Photographic Association.—November 23.—Mr. S. HERBERT FRY gave a practical demonstration on *The Paget Company's New Printing-out Paper*, the great advantage claimed being that it was only necessary to partially print out, the full image being developed by after-treatment. The process is very simple, it consists of taking the under-printed print, and immersing, without previous washing, in a ten per cent. solution of bromide potassium. The prints should remain in this bath for at least two minutes, and then well washed in running water for five minutes, then developed with hydroquinone, the formula for which is supplied by the Company, after which they should be again washed for ten minutes, and then toned and fixed in the ordinary way. The print-out opals and lantern slides can be treated in the same way as the paper. The opinion of most of the members present was that the partial development was most useful, especially in the case of opals, where great difficulty is experienced in examining them during printing. Some excellent prints were passed round to the audience, who found it a difficult matter to say whether they were partially printed out or not.

Midland Camera Club.—November 24, Dr. Hall Edwards in the chair.—The following are the officers for the ensuing year:—*President:* Mr. J. Hall Edwards, L.R.C.P.—*Vice-Presidents:* Prof. Allen, M.A., M.B., Messrs. H. R. Leech, M.R.C.S., J.P., S. G. Mason.—*Council:* Mrs. Welford, Messrs. F. H. Mason, F. Iles, T. H. Cox, A. H. Slade, J. W. Beanfort, T. Fletcher, A. J. Leeson.—*Librarian:* Mr. T. H. Cox.—*Hon. Secretaries:* Messrs. C. J. Fowler and R. J. Bailey. The PRESIDENT read a paper on *Dr. Hill Norris's Dry Collodion Lantern Slides*, remarking that Dr. Hill Norris was the inventor of the first dry plate, which he introduced thirty years ago. Lanternists are agreed that the finest results are to be obtained with collodion. One advantage claimed for the plate is the great saving of time as compared with gelatine. The lecturer exposed a plate, developed, fixed, washed slightly, dried, and placed it in the lantern, the whole time occupied being less than four minutes. It was stated that many amateurs fail to obtain density, the reason for which, the lecturer thought, was the low temperature of the baths used, recommending a temperature of at least 60° Fahr., and as high as 90° Fahr. may be used with advantage. Another point specially emphasised was that a bright light is necessary to obtain the highest results. The following extracts from a letter received from Dr. Hill Norris proved most interesting and useful:—"A few seem to have a difficulty in securing sufficient density. This, I think, is, in the main, attributable to over-exposure, or the use of the developer at too low a temperature; in other cases it may be the result of not continuing the developmental action sufficiently long. Again, when cyanide is used as the fixing agent, the plate may be allowed to remain in it long enough to attack the picture; in this respect hypo is safer, because, unlike cyanide, it is not a solvent of metallic silver (very strong cyanide will remove the image altogether). There is, however, another cause of feebleness of image, which is more fundamental, and not so likely to be observed by the occasional worker—I allude to the influence of the negatives. A brief exposure with a strong light is not the same thing as a prolonged exposure with a weak light; in other words, a strong, intense light acting for a brief period produces a far greater developmental effect on the silver bromide than a weak light acting for an equivalent length of time. With weak negatives, whether used for reduction or contact, the intensity of the light should be proportionate to the weakness of the negative—*i.e.*, the weaker the negative, the intenser the light should be. Pluck and vigour lie on the side of very slight under-exposure, softness and tameness on the side of over-exposure, perfection in correct exposure; but perfection in a slide implies also a perfect negative, and you, the photographers of the present and future, will be called on to decide whether this will be made on a gelatine or on a collodion plate." A number of collodion slides were passed through the lantern, some of which had been lent by Dr. Hill Norris.

Kilmarnock Amateur Photographic Society.—The Ordinary Meeting was held on November 15.—The President (Mr. FERGUSON) gave a highly successful demonstration on *The Making of Lantern Slides*. Mr. Ferguson uses hydroquinone at its normal strength for development. He has made a collection of over 200 slides illustrative of incidents and places in the life of Burns, Scotland's poet. Those who are competent to judge say that there is not a finer collection extant. It was agreed that in future the meetings be held on the third Friday of the month. Mr. Millar Banker is to give the next demonstration in the Oddfellows' Buildings, John Finnie-street, on Friday, December 15, at 7.30 p.m., subject, *Gelatino-chloride Paper (including the Paget Prize Paper) for Development*. A very interesting and instructive programme has been drawn up for this session, embracing such subjects as printing on Alpha paper, carbon and platinotype processes, enlarging, preparation of blocks for newspaper work, &c. The subscription is five shillings per annum. Secretary, Mr. William Paterson, 50, St. Andrew's-street.

CELLULOID FILMS.

To the EDITOR.

SIR,—As you invite correspondence on the drying of films, will you permit me to relate my experience of them? In the first week of May, I exposed in Belgium a spool of thirty, put in for me the week before by the Eastman Company. The light was splendid, and I found on developing one upon my return that the exposure had been correct. The remainder I cut up, and laying them one on top of the other, put them away in a cardboard plate box in a dry place. Circumstances prevented me from developing any more until last month. I then found that they had endeavoured to roll themselves up, but for lack of space for free movement had got no farther than forming a ridge down the centre and a curl at the edges. A preliminary soaking did not mend matters, and I had to proceed with the development under great difficulties, as it was impossible to keep the film flooded. Using my fingers for the purpose, portions of the film flaked off. Having in this way spoiled one or two pictures, I saw that it was useless to proceed, for neither during twelve hours' washing nor by several hours' immersion in glycerine and water was the cockling in the least reduced.

I then rolled them one by one round a cylindrical box—a most tedious and troublesome operation, as they were most refractory in bending in the opposite direction—and put them away for a fortnight. This device was successful in removing the curl; but, though I used tepid solutions, they then refused to develop in the shadows. With eikonogen and pyro-soda hardly any image appeared, whilst with pyro-ammonia they became silvered all over.

To remove this I tried various expedients, such as chlorinetted lime, cyanide of potash, and perchloride of iron, rubbing the film the while with a plug of cotton wool, but all without the least success. Finally, I used, in the same way, a very weak solution of hypo, with ferridcyanide of potash. This entirely removed the silvering, and left a negative of good printing quality wherever development had taken place. Perhaps this hint may be useful to those of your correspondents who have lately been complaining of the same trouble.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1753. Vol. XL.—DECEMBER 8, 1893.

THE PETZVAL PORTRAIT COMBINATION.

The increasing dulness of the weather suggests the employment of lenses of a type of the greatest rapidity possible. One of the greatest masterpieces of Professor Petzval is the portrait lens *par excellence*, and, as it is apt to be overlooked in the rush after something new, we purpose telling our more recent readers something concerning it.

Why is it *the* portrait lens? Simply because it gives sharp definition with an aperture greater than any other that has yet been produced. While we do not desire to introduce invidious distinctions between it and any other class of lens of the so-called "rapid" type, the latter cannot for a moment stand against the old Petzval portrait combination in respect of intensity of illumination and consequent rapidity of action. With the exceedingly sensitive plates now in use, and in bright summer weather, the special properties of the portrait combination are not in such request as when the brightness of the light diminishes. For obtaining portraits of children, or other fractious subjects, in dull weather the portrait lens is a necessity, seeing that most of them will, on an average, impress an image in one-fourth of the time required for a lens of the modern cemented class.

When working at full aperture, and in virtue of such a large aperture compared with its focus, while the principal plane on which the focus has been made is rendered with extreme sharpness, it cannot, of course, represent objects in the background with equal definition; but this is an advantage in an artistic point of view, as those possessed of any taste like to see everything subordinated to the figure which forms the portrait. The small angular or numerical apertures of the lenses in such common use at the present day have to answer for many sins of this nature.

The form of the Petzval portrait lens is essentially different from that of any other. Its front element is practically a plano-convex achromatic, the back being an achromatised biconvex of much longer focus than the front, and incapable of forming an image possessing sharpness on account of the excess of negative spherical aberration, a property which can only be obtained by the union of a positive and negative lens. This back lens lengthens out the oblique rays which fall upon it to a greater extent than it does the more axial ones, and thus flattens the field, while it also shortens the focus of the objective, and gives increased intensity.

We have said that the front lens is practically plano-convex. We have, however, objectives of this class in which the flatter surface is slightly convex, a peculiarity of all the extra-quick lenses issued many years ago by Voigtlander, as well as some by Andrew Ross. Many fine objectives by modern makers are absolutely flat; but in the great majority of cases the front lens has the flatter side slightly concave. The back lens, we have said, is biconvex, with an excess of negative aberration. Just here let us pause to again explain what we have many times previously explained, that a lens possessing negative aberration has its centre and its margin of different foci. The margin does not refract the rays so much as does the centre; in short, it possesses less magnifying power, whereas in a lens possessing *positive* sphericals the opposite condition prevails, for in it the margin refracts the light in a greater degree than does the centre.

In the olden times, when a lens of the greatest angular aperture was required, both front and back lenses were cemented. The front was composed of three elements, a double flint concave cemented between two crowns, the external form being double convex, although one side was comparatively flat as compared with the other. This was also the characteristic of the back lens, which differed from the former in that, owing to the depth of curvature of the flint-glass lens, the negative aberration was excessive. From a somewhat intimate acquaintance with this ultra-rapid form of lens, we have no hesitation in saying that it must prove inferior to that form composed of two elements only, flint and crown, much as now employed, in which the refinement of adjustment is effected by separating the lenses, more or less, by a ring. The precise amount of this separation forms a powerful factor in the determination of the flatness of field and marginal definition. The back lens is usually constructed of a concavo-convex flint lens and a crossed or unequally double crown lens, the curves being such as to leave an air space between when these were brought into contact at the margins. As a rule, the deeper the meniscus air space between them, the more pronounced will be the negative aberration. Andrew Ross, in his early lenses, recognised this, and turned the flattest side of the crossed crown lens towards the flint. This enabled him to obtain the required negative aberration with comparatively shallow curves. The tube, too, was shorter than usual, and as a consequence the covering power was unusually great, a whole-plate lens covering a 12×10 plate with ease. In the well-known stereoscopic portrait lenses of the late J. H. Dallmeyer, the crown of the back lens was not crossed, but of equal curvature. The great covering power of this lens is well known. Some back lenses of the late Dr. Monckhoven in our possession are characterised by the same peculiarity. These were made as portions of objectives for printing out by means of the solar camera.

Many years ago Voigtlander, as already mentioned, introduced a triple back lens, the surfaces of which were cemented. His object seemed to have been the securing of all the light possible by reducing the reflecting surfaces. We tried its efficacy as regards this property by substituting for the triple back lens a double one of the same focus, but uncemented in consequence of the inner curves being dissimilar; and the decision arrived at was that the double, separated lens was the better of the two. The maker must have arrived at the same conclusion, for it is more than thirty-five years since their manufacture was discontinued.

For lantern projections the Petzval lens will always hold its

own. This also applies to the production of enlargements, more especially when artificial light is employed and duration of exposure is a matter of consequence. The special form best adapted for both of these purposes is that which was introduced for *cartes-de-visite* in which flatness of field and marginal, as well as central, definition with full aperture were *desiderata*.

OBTAINING VIGOUR IN CARBON PRINTS.

Reference was made last week to some discussion on the above subject at a Society meeting as to the trouble one of its members had in getting a good image from a good negative, and another member saying he had to give up the process for the same reason. We are not going to enter into the question of what is a "good negative," which may mean anything or nothing, according to the use to which the negative is applied. One that may be worthless for one process may be the most suitable for another. In the case in question the trouble complained of was lack of vigour in the prints.

Since the carbon process was first introduced, now nearly thirty years ago, the general character of negatives has undergone a marked change. Those of the present day are of a far less vigorous type than those of former times—that is, there is now a shorter range of tones between the highest lights and the deepest shadows than there used to be when the collodion process was employed. But that is not all. Modern negatives are, as a rule, more or less veiled in the shadows, whereas in those of twenty years or more ago the deepest shadows were represented by perfectly clear glass. Now, it so happens that the effect obtained with bichromated gelatine by printing through a perfectly transparent medium is different from that obtained with a veiled one, however slight the veiling may be. It is for this reason that in all the photo-mechanical processes, based upon bichromated gelatine, collodion negatives are still employed almost exclusively.

Notwithstanding that the general type of negatives has undergone such a great change of late years, very little modification in the working of the carbon process has been made to meet it, as has been the case in most other processes. It is surprising that those who are supposed to be conversant with the subject have said so little in connexion with this point. It would be useless to suggest that negatives, like the vigorous ones of old, should be specially taken for printing from in carbon; therefore it will be of more value to point out the best way to obtain good results from such as those now in vogue. It may here be mentioned, in passing, that it is quite possible to obtain brilliant impressions in carbon from what may, even at the present time, be classed as feeble negatives, so feeble, indeed, that they will not yield good results on ordinary albumen paper, by adopting a suitable modification in the procedure.

It is well known to every experienced carbon printer that, the more highly sensitised a given tissue is, the softer or flatter will be the prints it will yield; whereas, with a weakly sensitised one, the contrasts will be stronger, and, if too weakly sensitised, the prints will have a decided tendency to hardness or bareness in the lights. Tissue that is used shortly after it is sensitised prints, all things being equal, with less contrast than one that has acquired a certain degree of insolubility—or perhaps it would, in this instance, be more correct to say, has lost some of its original solubility by keeping. Hence a great advantage, when extra-feeble negatives have to be dealt with, will be gained by keeping the tissue until it is on the verge of insolubility, even if extra hot water is necessary for its development. Prints made by printing in a subdued light possess, from a given negative, stronger contrasts than those printed in a bright one. Again, impressions that have only been partially printed by the light, and completed by the so-called "continuating action," possess a greater vigour than those printed direct out by light. Furthermore, greater contrasts are also obtained by printing deeply and then developing with water at a high temperature. There is yet another point to be mentioned, namely, that tissue which is sensitised in the making gives, as a rule, softer prints than one that is sensitised afterwards.

From the above it will be seen that the experienced carbon printer has ample opportunity of adapting and does adapt the process to every class of negative that can possibly be classed as a "good negative," and to many that do not come under that classification. To obtain the maximum degree of vigour from very feeble negatives, the tissue should be lightly sensitised. The strength of the bichromate bath and the time of immersion must, of course, be governed by the temperature, and whether the superfluous solution be removed by squeegeeing or not. If it is to be, a two per cent. solution will be weak enough. The tissue should then be kept for several days, or until it has lost a considerable degree of its solubility, before it is used. The printing should be conducted in the shade, until the impression is but about half done, then it should be put away for the continuating action to render it dark enough, or, preferably, rather overdo it. Then the print will require tolerably hot water for its development, which will add still further to its vigour when completed.

In here pointing out how the greatest vigour is to be obtained from a given negative, we have supposed an extreme case indeed such a one as we were challenged upon a little while ago, namely, to obtain a brilliant print in carbon from an abnormally feeble negative with veiled shadows that it was impossible to get even a passable print from on albumenised paper. But, in quoting it, the method is indicated as to how the process may be modified, in the hands of a thoughtful worker, to suit almost every possible requirement.

Photography and Astronomy.—In his Presidential address to the Astronomy, Mathematics, and Physics Section, at a recent meeting of the Australasian Association for the Advancement of Science, Mr. H. C. Russell gave a most interesting *résumé* of the connexion between photography and astronomy. We cannot do better than quote *verbatim* from the opening sentences of his address. He said: "The observer must stand aside while photography takes his place, and works with a power of which he is not capable, and I feel sure that in a very few years the observer will be displaced altogether, while his duty will be done by a new sensitive being—a being not subject to east winds, to temper, and to bias, but one above all these weaknesses, calm and unruffled, with all the world shut out, and living only to catch the fleeting rays of light and tell their story."

A New Weighing Apparatus.—A balance without beam has recently been described by M. Antoine de Saporta, which can easily be constructed by any of our readers though possessed of little mechanical dexterity. It consists in the utilisation of an ordinary hydrometer, placed in either simple distilled water or some lighter or heavier fluid. The method is simple, and, for quantities not weighing more than twenty or thirty grains, is capable of considerable delicacy of indication. All that is necessary is to make a short tube of paper or cardboard, and attach to the upper end of the hydrometer (which can be bought for a shilling or two), and then attach a fine

cardboard or stiff paper disc to this tube. An hydrometer with a fine stem is better for the purpose than one of thicker bore. To use it, the instrument is first placed, with its disc attached, in a jar of water, and an observation made as to the number on the scale indicating the floating point. Then a weight, say twenty grains, is placed on what we may term the scale pan, and a fresh reading taken. The rest is obvious; it is only needful to observe how many of the scale degrees, whatever their appellation — be they specific gravity, Beaumé, or other—are included between the two points already observed, and, calculating the proportion they bear to the twenty grains employed, to read at a glance the weight of any object (less than that number) placed upon the pan and causing the greater or less immersion of the hydrometer to give a different reading for each weight. To ensure the utmost exactitude, a process of experiment with a series of different weights, and observing and recording the level at each, would be necessary; but, by assuming that the extent of the immersion of the tube is in direct proportion to the weight, no great error would be made.

The Value of Photography in Exact Science.—It is not alone in astronomy that our science has made itself a power, scarcely a subject in the range of the physical sciences but is indebted more or less largely to photography and its power of recording exactly, and entirely free from bias, as Mr. Russell observes, phenomena of a most complicated character, occupying periods of time of extraordinarily short duration. Those of our readers who would wish to have some idea a little beyond what is termed "popular" knowledge cannot do better than read in the number of *Nature* for last week a report of a lecture delivered before the Physics Section of the American Association for the Advancement of Science, the title being "Phenomena of Time; Infinitesimal." We would, however, point more especially to one portion of the address where he shows what photography has done in the past compared with its present record. It cannot be doubted that, in this particular branch of science, as in astronomy also, the work, executed under laborious conditions and surrounded by difficulties that the present workers in scientific photography have no conception of, is greatly undervalued by almost all modern writers on this particular topic. Let us repeat Professor E. L. Nichols' words in this connexion: "We are apt, at the present day, to look to the introduction of the dry plate as the step necessary to the application of photography to the study of fleeting phenomena; but certainly" (he is here speaking of the work of Feddersen, done in 1862) "the results obtained by this early investigator, who used the ordinary wet-collodion process of his time, are not inferior, in definition or in detail, to any which have been published in recent years. Feddersen's researches are, indeed, worthy of all admiration." We will not quote more of his words, but, in asking our readers to dip into, if not read, this paper, we assure them they may possibly be astonished to see what photography can do as an aid in rigid scientific investigation.

THE PRACTICAL TESTING OF PHOTOGRAPHIC OBJECTIVES.

[Photographic Congress.]

Though it is of great interest to the optician to obtain an exact knowledge of all the properties and faults of any photographic system by numerical calculation, it is generally sufficient for the photographer, whether professional or amateur, to form a rougher idea of the capability of any photographic objective. The following is intended to aid the amateur to determine by comparison, without any particular apparatus, the capabilities of lenses, and it may be mentioned at once that this examination is just as exact (and much more comprehensible with regard to its results) as the measurements obtained by the use of the so-called testing apparatus.

For all examinations of photographic lenses the maxim must be laid down, that only lenses of exactly the same character may be compared together, and that, above all, their constants must be decided. We take it for granted that the amateur knows the simple methods employed for ascertaining the focal length and the working aperture, and thereby the intensity of the instrument. We therefore have only the following questions to decide:—

1. Which instrument with a given aperture not too small for instantaneous photography, gives the largest area of sharpness?
2. Which instrument gives the most even illumination of the field within this area of sharp definition?
3. Which instrument gives negatives with the greatest absence of fog?
4. Which instrument gives with the largest stop the largest area of sharpness?

All other questions which may be proposed in comparing objectives are useless; for instance, it is often said that this or that instrument possesses a greater depth of definition than another. We know, however, that this depends solely on the strength of lighting—at least, in so far as concerns the centre of the field.

Our first question must therefore be settled, because upon the utilisation of the sharpness with the largest aperture depends the applicability of the instrument for instantaneous work. The test is very simple. Supposing two lenses are to be compared, one with the greatest illuminating power of *f*-8, the other of *f*-7·3, we should commence our work by stopping down the lens of *f*-7·3 to *f*-8, in order to equalise the conditions under which both lenses work. If a suitable stop were not supplied with the lens, it could be easily made of blackened cardboard or tin. We now screw the lens to the fixed apparatus, which must be reliable as to keeping the surface of the screen and of the sensitive plate vertical to the axis of the lens. We then focus a distant object perfectly sharp, for which purpose it is best to use an achromatic magnifying glass placed upon the centre of the focussing screen. The best object for this purpose is a so-called test screen (a flat wall about ten feet square would do), which is completely covered with a net of lines, printed pages, geometrical designs, silhouettes, &c. The objective must not be too near this screen, the distance must be at least fifty times that of the focal length. Care must be taken that the apparatus is so placed that the axis of the lens is directed as perpendicular as possible to the surface of the test-screen. Should the focussing not result in an absolute sharpness at the middle of the field with the stop employed, it is necessary, by introducing other stops, to find out the largest aperture which will give perfect sharpness, and to insert a corresponding stop in the other objective. When in this way we have focussed the centre with the greatest possible accuracy, we proceed with the exposure. For this purpose it is best to use a plate of very fine grain, such as a transparency plate, and to expose for as short a time as will suffice. This done, we fix the other objective without changing the position of the camera, and take a second photograph with the same length of exposure and relative aperture. It is important that both exposures are of exactly equal duration, and that the plates are developed together in the same tray. From the plates so obtained various things can be ascertained by examining them on a retouching desk with a magnifying glass, starting from the centre, and marking those points where sharpness is just appreciably beginning to fall off. That objective which gives the larger part of the image in sharp definition is the more perfect one, because the object was photographed under the same angle in both cases. But a further examination of the plates gives us at once an answer to our second question, viz., which of the two objectives gives the more even illumination of the field. It is easy to notice, especially if the exposure was a comparatively short one, that the density of both negatives decreases from the centre to the edges of the plates. The more rapid this decrease is the less suitable is the lens for instantaneous work.

If we now repeat this comparison test of the two objectives with a very small stop, say of *f*-40, we can form an idea of the capability of the lenses for all such cases in which it becomes necessary to employ a small stop, whether to obtain depth of definition, to improve the definition at the edges of the field, or to prolong the exposure.

It will frequently be found that the proportionate advantage of one instrument over the other in the first trial proves to be the reverse in the second. So it may happen that an objective which with a full aperture shows poor definition at the edge of the plate and which for this reason would be declared to be inferior to the other, may, if worked with a small aperture, prove vastly superior to its rival. In estimating the values of the competitive lenses it is therefore necessary to consider for which special purpose they are intended to be used. For instantaneous photography the preference will always be given to the lens which, with a full aperture, gives the largest area of good definition; while that lens is the best for landscape photography which with a rather small stop gives sufficient sharpness over a wide angle, with a fairly even illumination of the picture.

An important test which is rarely resorted to, though it can be carried out with very little trouble, is the one referred to by question 3, viz., the examination as to the absence of fog, that is, the brilliancy of the picture produced by the lens.

There is formed in each lens by the repeated reflections from its polished surfaces, a certain amount of false light, which under certain circumstances may cause more or less fogging of the plate and a conspicuous flatness of the picture. The test as to this property of the lens is very simple. Fix on to the centre of the focussing screen a piece of tinfoil or black paper of about the size of a pea, focus the objective sharply upon the horizon, and then step out with the camera into the sunshine. The lens must then be directed towards the sun, so that its image falls exactly upon the tinfoil or paper spot. Now move the camera a little to and fro, and you will observe a number of luminous circles of various diameters, arranged in a straight line, which change their size and position according to the motion of the apparatus. These luminous circles are nothing else than conical pencils of rays of false light thrown by the lens upon the flat surface of the screen, and their size gives a clue as to the amount and harmfulness of the false light peculiar to the lens. If the size of the stop used for this purpose is taken as a unit, that objective must be declared superior in this matter of which the largest luminous circle is in proportion to this unit of the greatest diameter. Besides this, that objective is generally the superior one of which the number of the visible luminous circles is the smallest and the increase of the diameters the quickest.

The ordinary photographic lenses of the aplanatic type generally show three or four, sometimes even six such luminous circles, if the operator covers his head with a focussing cloth in order to shut out as far as possible all extraneous light. Experience has shown that under unfavourable conditions the objective gives also a distinct spot of light, if the smallest of the luminous circles is of about six times the diameter of the stop. The objective of which the smallest luminous circle is about ten or fifteen times the diameter of the stop would be considered a very good one, and such lenses give very clear negatives.

The necessity for ascertaining by personal tests the values of the many types of objectives has lately become a very urgent one. The great variety of new types of objectives lately introduced by English and German opticians makes it very difficult for the photographer to determine which he will select. The modern anastigmats and the somewhat similar Concentric lens of Schroeder have raised the standard of perfection which may be reasonably required of an ordinary photographic system, to a very considerable extent, and it would therefore be useless to compare such instruments with older ones, such as aplanatic and symmetrical lenses at all; they are very much superior to them. But it is not so easy to decide the question as to which of all these new systems should be preferred. In Germany it is chiefly Zeiss and Goerz who claim to have produced the most perfect objective. Until lately the palm has been given to the Zeiss anastigmat *f*-6·3 as the undeniably best objective extant for instantaneous photographs; this position it has now, in our opinion, lost, as it is much surpassed by the new double anastigmat of Goerz, and in all cases where the illuminating power of this instrument is sufficient (*f*-7·7) it may deservedly be called the best of all existing objectives.

Quite recently, however, the firm of Zeiss have endeavoured to produce an objective, in the form of their new anastigmat *f*-8, to be equal in value to that of Goerz. It is perhaps not yet decided in how far the makers have succeeded. Certain it is that the new anastigmat of Zeiss *f*-8 is superior to the former Zeiss objectives, and only careful comparative tests will reveal whether it is equal or superior to Goerz's instrument. In any case, this much can be said that photographic optics have in the last five years made advances which before that period perhaps nobody would ever have imagined. A further essential improvement is, one might say, scarcely necessary. All the new instruments allow with an aperture of *f*-8, which is sufficient for nearly all purposes of instantaneous photography, the reproduction of a sharply defined picture with its greatest dimensions at least equal to the focal length of the lens. The old aplanats, however, remain very much behind this; they cover, according to circumstances, a plate of hardly two-fifths of their focal length with absolute sharpness.

DR. AD. MIETHE.

CONTINENTAL NOTES AND NEWS.

A Remedy for Discoloured Albumen Paper.—The *Photographic Courier* says that when albumen paper has been kept for a long time, or, for any other reason, has acquired a yellow tint, the defect may be obviated in the following way:—Print slightly less deeply than usual, wash and tone, but commence fixation with such a mixture of hypo and red prussiate of potash (as is used for reducing negatives; this will remove the yellowness. Conclude fixation in the ordinary way. Query: Would this be applicable to gelatino-chloride papers?

Developing Aristotypes.—Feebly printed proofs may be developed, says the *Dilettante di Fotografia*, in the following solution:—

Metol	2 grammes.
Neutral oxalate of potash	10 „
Citric acid	2 „
Water	235 cc.

After washing, fix and tone as usual.

Death of Dr. A. Steinheil.—We have to announce the death, on the 4th ult., of Dr. Adolph Steinheil, a member of the well-known firm of opticians in Munich. He assumed the direction of the house in 1862, thus succeeding his father. Astronomical optics engaged his particular attention, while he will ever be associated in photographic history with the aplanats and antiplanats bearing his name.

New Method of Toning Gelatino-Chloride Prints.—In *Science Illustré* M. Bulher proposes the following plan, which is said to give tones resembling those of crayon pictures. The printed picture is first of all immersed in a litre of water acidulated with two or three drops of acetic acid. After washing in several changes of water it is toned. The toning bath (used at 30° C.) is made up as follows:—

A.

Distilled water	1000 grammes.
Gold chloride	2 „

After the gold is dissolved—

Strontium chloride	200 grammes

is added, and the solution heated to ebullition.

B.

Distilled water	1000 grammes.
Ammonium sulphocyanide	200 to 250 „

This is added little by little to A, the combined solution being agitated, allowed to cool, and filtered, 40 cc. of distilled water being added. The stock solution is preserved in well-stoppered bottles. The bath is made up of—

Water	1000 cc.
Stock solution as above	50 to 70 „

The toning is finished when the half-tones by transmitted light look of a greenish colour. After washing, the prints are fixed in hypo, again well washed, and then immersed in a filtered solution consisting of—

Distilled water	1000 cc.
Ammonia alum	50 „
Ammonia liquor	50 to 75 drops.

It is left in this for a quarter of an hour, and finally washed.

Aluminium Powder.—The following mixture is recommended for the aluminium flashlight:—

Powdered aluminium	21·7 parts by weight.
Antimony sulphide	13·8 „ „ „
Chlorate of potash	64·5 „ „ „

The three substances should be powdered separately, and the admixture made by shaking well in, say, a paper bag. Grinding the mixture with chlorate of potash is said to cause a violent explosion. The above burns in about $\frac{1}{17}$th of a second. A mixture burning less rapidly is composed of—

Powdered aluminium	30 parts.
Chlorate of potash	70 „

This burns in the fifth of a second.

International Exhibition at Milan.—An International Photographic Exhibition will be held at Milan from May to October, 1894. A list of patrons, consisting of the most renowned photographic scientists, has been organized. The offices of the Committee are at Via Principe Umberto, 30, Milan, where entry forms and all other particulars can be obtained.

Herr Valenta on Thiosinamine.—Herr Valenta has experimented with thiosinamine as a fixing agent. He finds that silver chloride dissolves in a 1 : 10 solution of thiosinamine as easily as in hyposulphite, silver bromide dissolves less readily, and iodide scarcely at all. The new solvent, therefore, can only be employed for chloride papers.

Boric Acid in the Combined Toning and Fixing Bath.—Herr Gaedicke, having experimented with eighty-four different kinds of toning and fixing baths, recommends one containing boric acid. The addition of a lead salt is necessary. The following is the formula:—

Distilled water	1000 cc.
Hypo	200 grammes.
Boric acid	30 „
Nitrate of lead solution 1 : 15	15 „
Ammonium sulphocyanide	20 „
Gold chloride solution 1 : 20	60 cc.

The paper, if acid, should be washed in water to which a trace of ammonia or sodium carbonate has been added. After washing, place in above solution. The tone is of a reddish colour, but it dries darker.

Treatment of Gelatine Prints in Hot Weather.—If in hot weather the gelatine has a tendency to leave the support, *Der Amateur Photograph* recommends a preliminary immersion of the prints for five minutes in—

Potash alum	5 grammes.
Water	100 „

Wash, and tone in—

Aluminium sulphocyanide	15 cc.
Water	100 „
Gold chloride solution 1 : 10	10 „

Fixation and washing as usual. The aluminium sulphocyanide is a liquid.

PRACTICAL HINTS ON WORKING THE ILFORD PRINTING-OUT PAPER IN INDIA.*

I HAVE chosen the above subject for my contribution this year, which will, no doubt, prove a benefit to the many readers of this valuable annual who work the paper in this country, where the climate has a great deal to do with the manipulation of the same.

I have used several tubes of the paper and worked it throughout the year, in the hot and cold seasons and the monsoons—with the result that I found it worked excellently through the two latter seasons, but it became troublesome in the former, especially in the months of April and May, and up to the middle of June.

I was one of the first to try the paper out here, having secured a sample tube that was sent out to a dealer in Bombay about eighteen months ago. I did not meet with much success at first, but I was so taken up with the tone and general appearance of the print that I determined to give it a fair trial. I did not use the alum bath at first, which, no doubt, accounted for the film being injured, which happened while I was manipulating it. When another consignment arrived, I sent for a tube. It was just as the monsoons were finishing, and from the course I now adopt in using it (detailed further on) I may safely say that the tone which I obtain is better than any I have as yet seen—even to the sample prints that are being sent out by the makers, and one would naturally think that they were the best that could be obtained. I have now adopted this paper, and abandoned the albumenised paper altogether. The following is the process I adopt:—

In cutting up the paper care must be taken not to let your fingers touch the sensitive side, as it is sure to leave a mark, which is very conspicuous when the print is finished. I cut the paper to the sizes I require for the day's printing, and keep the pieces in a large tube, the one that the six sheets are packed in. After they are printed, I put them into another similar tube, and so they remain till they are required for toning, &c. I think the above is a very good way to store the paper, besides making use of the old tubes, which saves the necessity of getting specially constructed boxes. I print in the shade, and I get a very soft picture. The printing does not take long, as the paper is much more sensitive than the ready-sensitised albumenised paper that can be procured in the market. I generally wait till I have printed three or more sheets, and then tone altogether. It may happen that they are printed a week or more before I am able to tone them, but it does not make any difference, as I find the keeping qualities of the paper are excellent, especially in a climate like India. It will be found necessary to print a little darker than what is required for the finished print, as the loss is not much during the toning and fixing operations. This can only be found out by practice under negatives of various densities.

In dry weather, when the paper will be perfectly dry, the image will be of a purple colour; whereas in damp weather it will be of a reddish brown. A purple-coloured print must be carried further than a print with a reddish brown aspect, as the former loses depth greatly in the subsequent operations. The prints are first washed in eight changes of cold water, by transferring them from one dish to another, which generally occupies from fifteen to twenty minutes. By the time you have passed them through the sixth washing, the milkiness in the water will have disappeared. (Do not be tempted to add salt or carbonate of soda to the last washing water, as I consider there is no advantage gained by it.) They are then put in an alum bath of the following strength:—

Alum	3 ounces,
Water	30 „

and kept there for five to ten minutes, when they are taken out and washed in five or six changes of water, after which they are ready for being toned.

In the months of April, May, and June, it is absolutely necessary to use ice. I have tried to do without it, but I find I cannot, for, with every possible care bestowed upon them, the film is sure to be scratched or injured in some way by the time they are finished. I do not find ice necessary during the other parts of the year, as the alum is sufficient to harden the film. The alum bath should never be omitted, as it renders the film less liable to injury. The following is the strength of my toning bath:—

Sulphocyanide of ammonium	100 grains.
Chloride of gold (Johnson's)	10 „
Water	60 ounces.

The most convenient way in which to measure the gold is to dissolve a 15 grain tube in 15 drachms of water, thus keeping the strength of 1 grain of gold to 1 drachm of water. The above bath is stronger than the one recommended by the makers, but I have found it necessary to increase it, on account of my always using the alum. In the event of the latter not being used, the bath will be found too strong, and will require diluting. The prints tone in this bath in from six to ten minutes. The action of the bath is rather peculiar. As soon as the prints have been immersed they turn to an orange colour, losing their vigour considerably; they soon recover strength, and darken as the toning proceeds, passing through various shades of red and brown till they become purple. On the surface they will appear to be perfectly toned, but the tone must be judged by transmitted light. Continue the toning until the brown shade has disappeared, except from the deepest shadows. On the surface they will appear to be considerably overtoned, but this alters in the fixing. Do not over-tone them, or they will have a very slaty appearance. The prints do not look so bright when dry as they do when wet, and this we generally find in all cases, the dry print always looking much colder. For warm-toned pictures the prints must be withdrawn from the toning bath at an early stage, the colour being judged by looking through them.

I never add gold to an exhausted bath, but prefer making an entirely new one, as I find that by so doing, and allowing it to stand for forty-eight hours, I obtain far better results. Above all things, never be tempted to warm your toning bath, but use it about the same temperature as the washing water.

* Received too late for the ALMANAC.

As regards the fixing, the following is the strength of the bath I generally use:—

Hyposulphite of soda	6 ounces.
Water	40 ,,

Keep the prints in the bath from fifteen to twenty minutes, after which they will be ready for being washed, which must be thorough, but not prolonged.

The prints must be kept on the move through all the various baths, or unequal toning or fixing is sure to result, which would spoil the picture in time.

I first wash the prints in several changes of water, and then keep them for two hours in a running stream, changing their position every five or ten minutes; they are then hung up to dry over lengths of string stretched from one end of the room to the other.

The trimming and mounting is done in the usual way. For a mountant I always use starch (Glenfield), with the exception of the enamelled prints, when I use a very thin glue. Starch, in my opinion, is about the best mountant a photographer could use. I mount the prints dry. After they have been trimmed they are laid face downwards on a piece of glass, and the mountant is put on them. The print is placed in proper position on the mount, a piece of cloth is laid over it, and a roller squeegee passed over the whole. I remove the cloth, and with a piece of soft muslin or sponge, which has been previously moistened with water, I gently rub the face of the print, which is then put aside to dry. Be sure not to rub the print with a piece of cloth after you have placed it on the mount, but use a roller squeegee, or you will injure the surface.

The enamelling is done the same as recommended by the makers. I have enamelled a few, but for ordinary purposes I prefer the surface as it is when they are finished in the ordinary way.

The paper is made in three colours, namely, pink, white, and mauve. I prefer the white, as it is suitable for anything, and, in my opinion, looks better.

In detailing the several processes in the foregoing, I have endeavoured to be as concise and clear as possible, so as to make it readily understood by all, and, in conclusion, I must place on record my firm belief, judging from the results of my own experience, "that the Ilford P.O.P. will be the standard of the future." JOHN T. FRY.

PRINTING FROM GELATINE NEGATIVES, INTENSIFICATION, COPYING, AND HALATION.*

GELATINE negatives may be printed from without being varnished. This has been frequently mentioned, and I quite agree with it if you only want a few copies, and the negative is of no farther value; but, to print in silver with any negative required for future use, no greater mistake can be made. Sooner or later the results are disastrous and utter ruin to the negative. Gelatine is so affected by moisture, and the silver paper may be apparently dry, but the backs of the frames, the blotting or backing which is frequently in many months of the year not always bone dry, the temperature not always at summer heat, renders it imperative, if you wish to preserve any negative, that it should be protected. In my own practice I always, when the negative is thoroughly dry, coat it with plain collodion. This resists the damp to an enormous extent, and is very effectual. They may then be used without much fear of future loss, but where many copies are required it is necessary to varnish on the gelatine film, and then very little chances of loss of negative. I wrote some months since in THE BRITISH JOURNAL OF PHOTOGRAPHY, stating I had made what I believed to be a very valuable discovery, and offered to remove the silver stains from any unvarnished negative sent me. This had the result of my receiving over one thousand negatives from all parts. With few exceptions I succeeded, but in some instances the silver had eaten through the film in holes. To remove this you may as well try and remove the small-pox marks from a man's face. If you have occasion to print immediately from a negative of any value, cover it with a piece of talc; and I may say this is a very excellent plan even if the negative has been varnished if numbers are required. I have some of Elliott's and Silvester's stereoscopic groups, taken over thirty years ago, covered in this way, and the plates are very little the worse for wear. Prevention is better than cure.

INTENSIFICATION.

Gelatine negatives in a great many instances require intensification. I know of no better than the following:—1st, A saturated solution of bichlorlde of mercury, well wash, and then take your No. 1 hydroquinone developer—say, hydroquinone, 320 grains; sulphite of soda, 4 ounces; bromide of potassium, 80 grains; citric acid, 120 grains; water, 40 ounces. Take 1 ounce of this stock solution to 4 of water, and you will get a negative vastly improved, and of a beautiful brown tone that will give excellent results.

HALATION AND COPYING.

Collodion, for which I have a very great weakness, and its result, nothing can excel. In the early days of photography I made a large number of negatives of copies of paintings and engravings (in, I think, 1853 or 1854). Wet collodion is very extensively used, and nothing can equal it for copying, &c. One difficulty I found in copying, and for interiors especially, was to get sufficient density without intensification; this I succeeded in overcoming by coating the plate with an old blood-red collodion which would without the slightest difficulty bring many a tear from the eye. Then, as soon as set, reverse the position of the plate, and coat with a newly iodised collodion; the results were all that was required. I have many negatives taken twenty-five years ago of Westminster Abbey interiors, and, on comparing these with those of the present day, the results, as far as halation is concerned, are vastly superior; one difficulty only I found, the film had a very great tendency to split on drying. This I got over by pouring on a solution of gum arabic and water. If the results in other hands equal mine, the reader won't grumble at the moments he has spent on the hints given.

HORATIO NELSON KING.

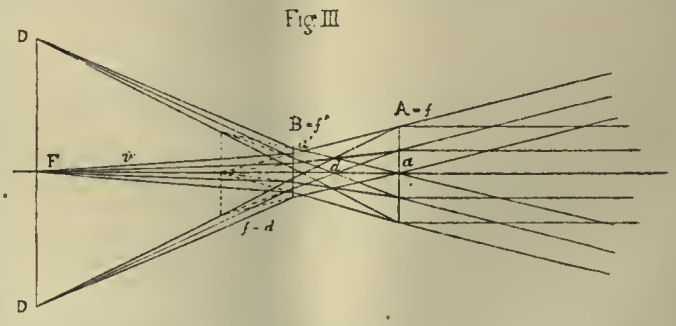
* Received too late for the ALMANAC.

TELE-PHOTOGRAPHY.*

4. *The Intensity of the System for a given Extension of Camera.*—You are all aware that the intensity of a lens is dependent upon the ratio existing between the available or working aperture of a lens and its focus. We have seen that the focus of a tele-photographic system for a given extension of camera may be taken either as an absolute measurement, or the focus may be considered in the sense of the magnification obtained as against that of the positive lens forming part of the system. The intensity, then, may be arrived at by reference to either of these two considerations. In the first place, if the absolute measurement of the focus be written down, the intensity is arrived at by dividing it into the diameter of the aperture employed in the positive lens, or the diameter of any diaphragm that is employed in the positive lens when making the exposure. The second method is perhaps the simpler, for, in this case, whatever intensity be employed in the positive lens, it is only necessary to divide that fraction by the magnification, and you have forthwith the intensity of the tele-photographic system.

5, 6. *The Angle of View and Plate covered.*—These are dependent upon the foci and diameters of both positive and negative elements contained in the system. Referring to fig. 3, the diameter of the circle beyond which no light can pass being called D, apertures of the

Fig III



positive and negative elements, a and a' and the foci f and f' respectively, the formula for obtaining the diameter is as follows:—

$$D=(v+f')\left\{\frac{avf+a'f(v+r')}{f'[v(f-f')+ff']}\right\}$$

and the angular diameter of the field of view is—

$$=\tan^{-1}\frac{v(a'f+af')+a'ff'}{f[v(f-f'(+ff']}$$

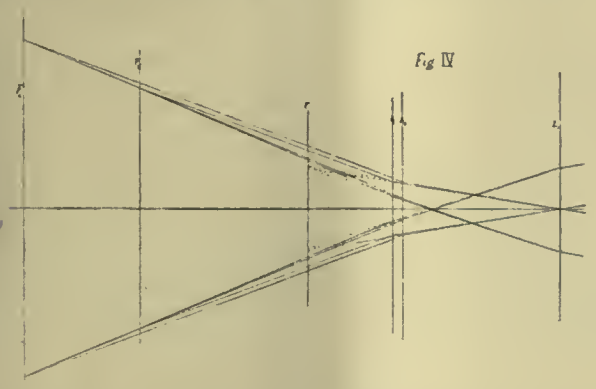
$$=\tan^{-1}\frac{a'f+af}{f(f-f')} \text{ approximately.}$$

The first of these formulæ only requires a knowledge of arithmetic

Concluded from page 768.

to readily determine the diameter of the circle covered, and the second is similarly interpreted by a reference to a table of natural tangents to obtain the angular measurement. It will be observed that, although the angle is nearly a constant, this does not imply that for various extensions of camera the angle included upon one of the same plate will be the same. This, of course, is not the case, and is in itself a very valuable feature of the instrument, in that it is not infrequently found that a portion only of some subject composes pictorially, and that its surroundings, if included, may mar the effect. By the use of this lens, a camera extension may be chosen to include only just so much as may be desired, and allowing this to occupy the whole plate (see fig. 4).

We have now examined all the elements necessary for the exact determination of the capabilities of any tele-photographic system. It



is evident to you that any positive lens, no matter whether of the portrait, rapid rectilinear, or slower types of lenses, can be converted into a tele-photographic system.

If the focus of a negative lens be chosen one-half that of the positive, you know in the limit that for any extension of camera the tele-photographic lens will give double the magnification of any positive of the same camera extension. If the negative lens be a third of the focus of the positive, the size of image will be three times that of the extension of camera chosen, and so on.

Hence, in making a choice of a suitable negative lens to combine with any positive lens, attention must be paid to the object to which the lens will be put. Weaker negatives will, of course, not give so much magnification as stronger ones, but score on the points of greater rapidity and greater covering power.

It is evident that, to avoid too much loss in intensity where high magnification is required, a rapid portrait lens of high intensity is best selected for the positive element. Such a positive element will naturally also score on the question of rapidity equally if a weak negative be employed with it; but any one who would propose to convert a slow lens into a tele-photographic system must bear in mind the necessity of choosing a weak negative to employ with it, or the rapidity of the entire instrument will become too much reduced to be of any value in any but timed exposures.

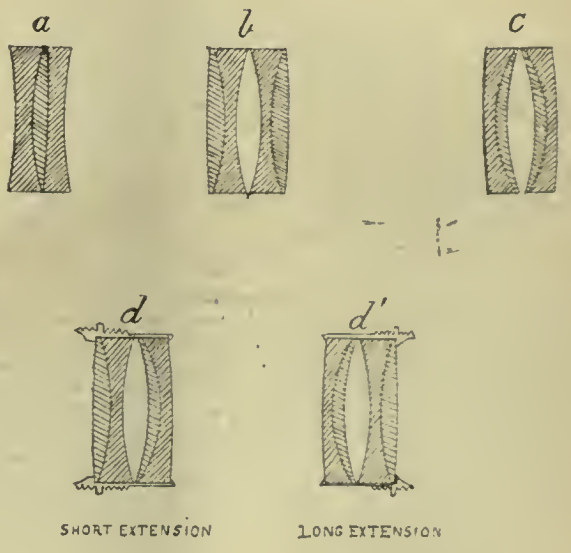
For instantaneous work I recommend a negative of half the focus of the positive, and that the positive should have an aperture of at least *f*-4. With this weaker magnification it is hardly necessary to employ the special form of portrait lens invented by my late father, although it is preferable, and, as I have before stated, if a high magnification is given, that adjustment for the correction of spherical aberration contained in it becomes essential.

For slower lenses I do not recommend a higher magnification than that suggested for instantaneous work, namely, with a negative one-half the focus of the positive. Such a lens may perform rapid work in bright light if the positive has an intensity *f*-8, provided too long an extension of camera be not chosen. When slower types of lenses are employed as positive elements, similar magnification can, of course, be obtained, but at the sacrifice of rapidity. In a word, a rapid positive lens must be chosen to construct a rapid tele-photographic system; but, if only moderate intensity obtains in the positive system, moderate magnification only can be expected consistent with adequate rapidity.

I will now call your attention to the most recent form of negative system that I have adopted. You will probably remember that the original form which I show you consisted of a single cemented positive and a single cemented negative. This I discarded within a few months of bringing it out, on account of the difficulty in overcoming very violent chromatic error in other than central pencils; also from the fact that a single system constructed on these lines does not enable one to correct the errors of spherical aberration for other than one definite camera extension; and, furthermore, it was impossible to eliminate the very violent pincushion distortion. The next step was to employ as a positive element a system corrected throughout its field, and to construct a negative which should enable the entire tele-photographic system to be properly corrected throughout the field, with the means of correcting the aberrations of spherical and chromatic order, and reducing distortion to a minimum. The form adopted consisted of a symmetrical form with exterior convexities as opposed to the single triple cemented form with exterior concavities (see *a* and *b*, fig. 5). Later on I adopted another symmetrical form for use with lenses of low initial intensity, still maintaining the exterior convexities (see *c*, fig. 5). This form I found useful in reducing the astigmatic error contained in the older types of cemented doublets, and from its form enabling weaker negative lenses to be made larger in diameter than was formerly possible, tending to greater quality of illumination and greater covering power.

On the occasion of a lecture I gave in March of this year at the Society of Arts, I described a form of unsymmetrical negative, and explained that it had an advantage over a symmetrical form, in that, by using it with one surface of the combination towards the positive lens or reversing it, I was enabled to obtain two *planes* for the reception of the image, one somewhat near the lens and the other at a considerable distance from it, in each of which there was perfect flatness of field (see *d*, fig. 5). You will observe the manner in which the lenses are mounted, and the right position in which to use them is

Fig V



conveyed by the manner of mounting. The projecting cell projects inside the camera for a small extension of camera, when the positive lens is more separated from the negative, and the cell is reversed and projects into the lens mount for a greater extension of camera, when positive and negative lenses are nearer together, thus assisting portability.

Now, with any fixed system, there is only one plane or definite camera extension in which there is a perfectly flat field. For an extension shorter than this the field is curved towards the lens, and for a greater extension the field is curved in a reverse direction. Now, by the form which you see figured at *d*, there are two such planes of perfect flatness, as already stated; and, furthermore, by the unsymmetrical form adopted, the eccentrical pencil is admirably corrected for both positions. In the case of the shorter extension, with the two concave contacts towards the lens, the pencils leaving the positive lens become lengthened, as it were, and give a flat field at a suitable distance for producing instantaneous work. If the negative were kept in the same position for a considerable extension of camera, the field would have a large amount of reversed curvature of field and a badly corrected eccentrical pencil. By reversing the negative element in the cell, the field becomes perfectly flat, and the eccentrical pencil perfectly corrected; in this case, as you will observe, the two convex contacts being presented towards the rays

leaving the positive element assisting in correcting the residual astigmatic error of the positive system. It has been in the effort of producing greater rapidity in tele-photographic systems, when it is only possible to employ moderate camera extension, that decided me to develop this form of negative to its present state of utility. When tele-photographic lenses were first employed, the general desire was high magnification only, and in that case I found the symmetrical form answer its purpose adequately, as it was constructed with a definite object in view, and not so much for varied applications.

I have to add now a few words on the necessity of avoiding tremor when photographing with lenses of this type. You have observed that the nodal point from which the focus is measured lies outside of the lens mount, so that, in giving any movement to the camera, one is producing a magnified error of tremor upon the ground glass in a similar manner to that in which the long end of a lever will move a greater distance than the shorter arm of an equal amount of angular deflection.

Another matter to which I wish to direct your attention is the necessity of very accurate focussing. This is performed with the rack and pinion, which separates the two elements, and it will be noticed that a very slight movement here will bring about a very rapid alteration in the focus. With the necessity for very accurate registration of the focus in view, I have recently turned my attention to constructing what I believe are two new focus-finders, which I will briefly describe.

In fig. 6 a mirror, *m*, is placed outside the top of the camera, parallel (preferably) to the plane of the plate where the image is

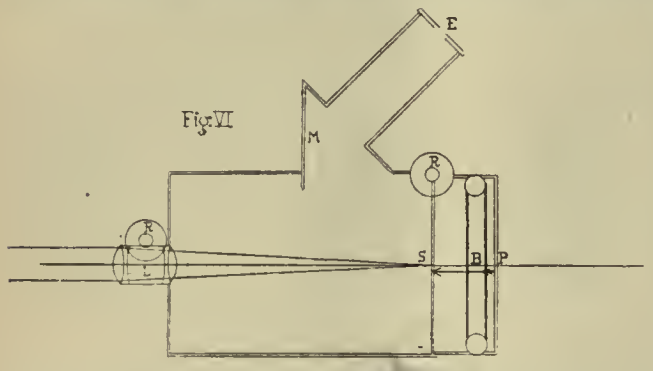


Fig VI

eventually received. At a convenient angle to the mirror a removable tube, or other enclosed dark chamber, is attached. If the mirror be perpendicular, the angle will be forty-five degrees. On looking down the tube, the image is seen upon a whitened screen, and this is actuated by a lever to remove it out of the way when exposure takes place. Behind this screen is a blind shutter. In removing the screen by the lever, the shutter, with the plate just behind it, brings the register of the latter into focus, and releases the shutter at the same time. I have to thank Mr. Newman, of Messrs. Newman & Guardia, for the accurate and intelligent manner in which he has carried out the mechanical portion of the work in this piece of apparatus, as well as in the mechanical details of the second form, which I will now describe. The principle of its construction rests on the fact, that the photographic lens, which forms the image upon the screen or sensitive plate, is itself also the object-glass of a telescope, through which the object photographed is also seen. You will observe in fig. 7 that a mirror is placed at an angle of forty-five degrees behind the back lens of the photographic ob-

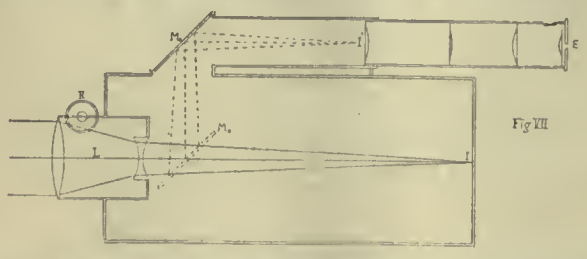

Fig VII

jective. This mirror is properly enclosed, so that no light shall reach the sensitive plate. A second mirror, parallel to this, is placed on the top of the camera, and behind the second mirror is fixed a tube carrying an ordinary terrestrial eyepiece. The whole being arranged so that no light enters the camera. For any individual observer the instrument is made to perform absolute registration of focus, once and for all, in the following manner: The mirror behind the lens is temporarily removed, and some known object is focussed upon the screen. The mirror is then placed into position, and the terrestrial eyepiece is then adjusted, so that the same object is sharply defined. The terrestrial eyepiece must be then fixed, or its position registered for the individual observer. It will then be found that, whatever object is in focus (made by the rack and pinion on the lens mount) seen through the telescope eyepiece will be absolutely in focus upon the screen or sensitive plate. I have discussed one or two methods of removing the mirror behind the lens to expose the plate with Mr. Newman, and we decided upon the form I show you as being very convenient. The spring which turns the mirror out of the way releases a small roller-blind shutter at the same instant. I first proposed to make this mirror revolve upon a diagonal axis, but do not think the same amount of light would be received upon the plate.

I half promised our friends, Mr. Winter and the Honorary Secretary, to bring you some results in tele-photography from the Norfolk Broads, but I regret to say that my main object was to try for living subjects, and the instrument was not ready in time. I took comparison proofs of an ordinary technical subject with moderate power negative attached to an ordinary rapid rectilinear lens. Mr. Hepworth has been kind enough to make lantern slides for me, and I have also to thank Mr. Rice for other comparison slides which he has taken for me, using in every case the same extension of camera. These I will now place upon the screen, but, before concluding, must thank you for the patient hearing you have given to a subject the importance of which I dare to hope is acknowledged by every photographer.

T. R. Dallmeyer, F.R.A.S.

EDINBURGH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

Our Edinburgh correspondent writes: With the advent of winter this Society has again its exhibition and medalling of the best work of the members during the past year. The examples shown are about equal in number to those exhibited in previous years, but, it must be stated, far superior in quality, especially so in the feeling of artistic as opposed to mere photographic excellence. It is a pity that, in an art-loving and practising centre such as Edinburgh, with quite free admission, there should be such a paucity of visitors. During my visit, in the best part of a brilliantly fine, if cold, day, the entire number of visitors were seven ladies and one young man, a presman, whose only mission was to find if there was to be any formal closing, which he desired to report. He was absolutely guileless of any knowledge of pictures or photography, but he could write so many words a minute.

One of the questions put by him was, "What do the various Classes II. to V. embrace" (I. was not visible)? a question also put by one of the ladies. Explanations in the room there were none, catalogues ditto, names, *noms-de-plume*, and non-competitives were there, titles occasionally, but anything giving any idea explanatory of such facts as one would wish to know and remember were generally absent.

In all the most important subjects the seer was left to guesswork. Now, in a painters' Exhibition the *habitué* soon gets to know, without a catalogue, the style, the mannerisms, the hand work of the artist if seen for several times; this is also visible with some photographers, where even the accessories and properties tell what the *nom-de-plume* is meant to hide, and doubtless to many more skilled than I they tell who their producers are, as handwriting often does without opening the letter. Is not this a mistake? Should there not be in every such Exhibition the fullest publicity given to all that may interest visitors? How often has a cleverly devised, or even a hastily well-chosen, title immortalised a subject, as well in prose or verse as in representative art, and the time seems now come when we may class all efforts at representation of what *is*, as art fine or otherwise, just as there are grades in poetry and prose, &c. Of course, with all imaginative subjects of depiction a different code of reasoning must be adopted.

I looked in vain for lantern slides, or any proofs on glass, although there is excellent accommodation for their display, without in the slightest degree deteriorating the lighting of the other pictures in the rather-difficult-to-light Exhibition room. They would, I presume, be too precious to be displayed to vulgar eyes without the necessary lantern, but yet they might have been removed for judgment or something else on the day of my visit. Examination of the slide itself, as well as its effect when projected on the screen, has a distinct educational effect—one of the principal purposes of an Exhibition.

Looking at the show as a whole, there is, undoubtedly, marked progress, especially in the picture-making department. It is true that painter, draughtsman, and etcher have had hundreds of years' start of the photographer in attempting to depicture external nature, and so have led, trained, or warped our ideas of how such things should be represented; but they have also, by example, shown what to do by their successes, and what to avoid by their mistakes, which are many. It may,

indeed, be said that the analytic art critic has done more, educationally, than the artist himself, so progress to the utmost perfection must not be looked for yet a while. The true artist being so by nature will show himself, no matter the medium through which he chooses to display his skill.

The decisions as to the most meritorious exhibits were announced on the closing evening of the Exhibition :—

I. Lantern Slides.—There being none of outstanding merit, the silver medal was withheld, and two bronze ones were awarded, one to H. J. Blanc, A.R.S.A., and one to William Mitchell.

II. Pictures taken during the Saturday Rambles.—The silver medal to James Roddick, bronze to T. Barclay, Secretary.

III. *Genre* Pictures.—Withheld in the mean time.

IV. Best General Work during the Season.—Silver medal to J. B. Johnstone, and a bronze each to Dr. Drinkwater (President) and G. L. M'Gibbon.

V. Enlargements.—Silver medal to James Patrick, bronze medal to R. S. Webster.

All the slides on exhibition were shown during the evening.

THE SPEED OF PLATES: A CRITICISM AND A REPLY.

[Paper read on Thursday, November 23, at the Camera Club. Communicated by the Author.]

A good many attempts have been made at various times to measure and set out numerically the speed of a photographic dry plate. Some have been more, some less, scientific; some have been based on a study of the nature of a plate and the action of light upon it, and others have been purely arbitrary. They all, however, seem to suffer from one defect, viz., that no one has ever yet given a sound definition of the "speed of a plate," and, consequently, in these methods of speed determination the quantity found and investigated depends not only upon the nature of the plate, but upon the method of investigation; and the "speed" is explicitly or implicitly defined to be some quantity that has cropped up in the course of the investigation rather than a constant of the plate itself.

This being so, it seems to be worth while to try whether some sound definition cannot be given of the term "speed of a plate," and whether this quantity can be expressed in definite numerical terms.

The most natural definition of "speed" that can be given would run something like the following :—

One plate may be said to be twice as fast as another when, the two being exposed under the same conditions, the slower plate requires twice the exposure of the faster, in order that, when the negatives are complete, they may be identical.

The first objection to this definition is the tacit assumption that it is possible to make two exactly similar negatives on two different plates. It is certain that this cannot always be done. To take an extreme case, it is absurd to suppose that, if a slow plate, thickly coated and rich in silver, so exposed as to give a round and sparkling negative, be taken for one, and a thin foggy plate, poor in silver, for the other, a negative as rich, and round, and sparkling can be produced on it as on the slow plate. Our definition, therefore, fails from the nature of things at the outset. And this leads us to consider whether the quality "speed" is really a property of the plate alone. In a certain sense no doubt it is, for it is clearly impossible to expose a slow plate with a rapid shutter in a dull light and get results, although, if a quick plate be substituted, a good negative may be obtained under otherwise identical circumstances.

The fact is, that the quantity we are accustomed to think of as speed is a highly complex quantity, and depends on the nature and make of the plate, the circumstances under which it is to be used, and the treatment to which it is to be subjected; more even than this, too, it depends on the result which it is desired to obtain; in fact, paradoxical as it may sound, the speed of a plate depends on its future history as well as on its past. For a long time since, a terrific wordy war has raged over the question whether the "speed of a plate" is dependent on the development or not, although possibly Messrs. Hurter & Driffield, whose position has been attacked, would never have affirmed that it was not. But now it may probably be said that they have withdrawn from the position that they did take up, viz., that the ratio of gradation in a negative cannot be affected by development.

The only rational definition of "speed" that depends solely on the nature of the plate, and not on any hypotheis that can be given, having been shown to fail, the question arises, What can be done to give the photographer some idea as to the relative exposures required by different plates? It is required to choose some property of a plate that can be expressed numerically which will give the user some rough idea as to whether, if Plate A requires five seconds under given circumstances to give a good resulting negative, Plate B will require seven, or ten, or thirty. It is impossible, as has already been shown, to give more than a rough idea, and this will appear still more plainly in what follows. Let us first consider the result that it is required to obtain, viz., the finished positive print or transparency.

Now, it has been held by the combatants in this discussion, and especially by Messrs. Hurter & Driffield, that the scale or gradation of the finished result is required to be the same as that of the scene portrayed. When this desideratum is attained, the print, they say, is photographically true, and the result is perfect. Surely this is contrary to all our knowledge up to the present time. Except for special purposes, such a print would be flat, stale, and unprofitable. It must be remembered that in working on paper or canvas we are not working between anything like such wide limits of darkness and light as occur in nature, but between the relatively narrow limits of black and white. Yet in these limits it is required to give the impression of darkness and light. How is this done? Ask any artist, and he will say that in working on canvas he consciously exaggerates his contrasts. A bit of yellow paint, dull and without lustre of itself, shines and glistens with the lustre of a gold ring when cleverly backed with a heavy shadow. How does Turner gain the effect of glorious glowing sunshine in his pictures? Not by the intrinsic luminosity of his colours, but by his skill in contrasting them. The mind is susceptible to the effect of contrast, and has been trained to appreciate it and translate it, till the mental effect is identical, or at least of the same order, with the mental effect of the light and shade of the scene itself. How does the photographer obtain this effect? By making his prints slightly harder than they would be if they were in an exactly proportional scale; by intentionally, though perhaps unconsciously, exaggerating his contrasts. In fact, by utilising that portion of the scale wrongly termed by Hurter & Driffield the "period of under-exposure."

Let us now examine the effect on a plate of a series of graduated exposures. A large number of measurements of the transparencies of plates exposed in a graduated manner in Spurge's sensitometer, and in other ways, have been published by Captain Abney, and Messrs. Hurter & Driffield, and others, any one of which will do for our present purpose.

We will take a plate exposed by Abney, and measured both by him and the writer. It is one that has been frequently spoken of at the Camera Club, and is typical of all the others. We will plot two curves from the measurements of this plate. In one, the logarithms of the exposures are set off horizontally as abscissæ, and the corresponding transparencies are measured vertically as ordinates. This is the method of plotting used by Abney in his method of speed determination. In the other, Hurter & Driffield's method is used, and the difference is that the *logarithms* of the transparencies, or "densities" as they are termed by those authors, are plotted vertically as ordinates.

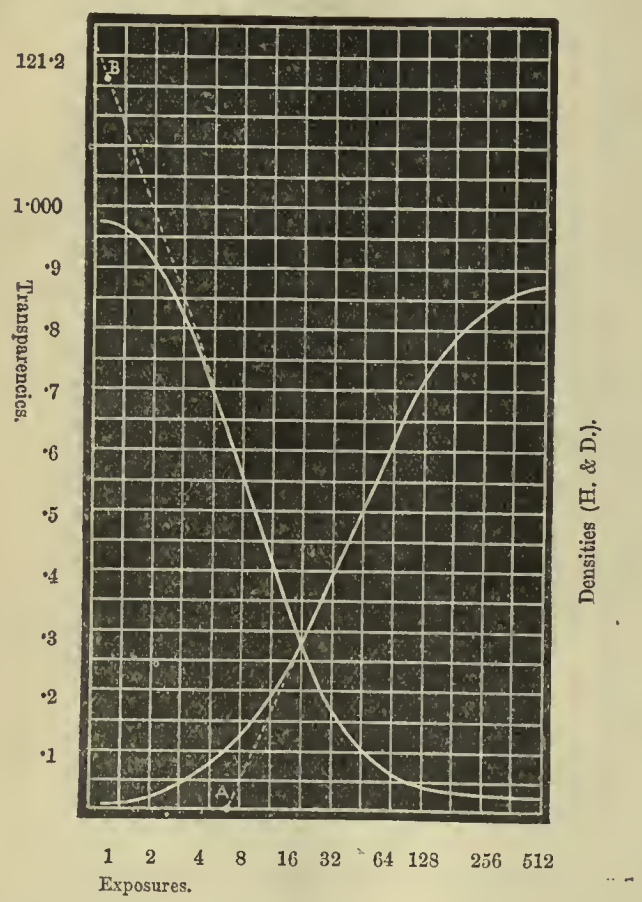
Let us compare the methods of speed determination of these two authors. It will be seen from fig. 1 that the speed of the plate is given by the points marked A and B in the diagram, according to Hurter & Driffield and Abney's methods.

According to the former, the *slowness* of the plate is proportional to 6·5, about, in some arbitrary units; according to the latter it is proportional to about 1 in some *other* arbitrary units. There is no reason at first sight why these should not both be true. That point will be considered later. The thing to be noticed, however, in this diagram is the part of the curve from which the number representing the slowness of the plate is deduced. By Abney's method it is deduced from the part lying between the exposures 2 and 32 in the arbitrary units we are considering. By Hurter & Driffield's method it is deduced from the part of the curve lying between the exposures 20 and 101. We will lay no stress on the fact that, in this particular case, as in fact in all, the figure is deduced from a more extended set of exposures by Abney's methods than by Hurter & Driffield's. But it is most important to notice that, by Abney's method, the figure roughly representing the speed is deduced from a set of exposures that give densities on the negative that are practically useful to the photographer, while, by Hurter & Driffield's method, it is deduced from a part of the curve in which the transparencies are of hardly any printing value. Abney's figure is deduced from a negative with transparencies ranging from 94 per cent. to 16½ per cent., while Hurter & Driffield's is deduced from a negative with transparencies ranging from 26½ per cent. to 4½ per cent. Surely no further illustration is needed of the comparative futility of Hurter & Driffield's method, for which they have claimed so much.

Again, let us look a little more closely into the printing values of the two types of negative. In the case of the negative used by Abney, the speed of the plate is deduced from a series of exposures, such that

the resulting transparency of any part of the negative relative to another part, that is to say, the printing value of that part of the negative, is inversely proportional to the exposure of that part. This

Fig. 1.



is Hurter & Driffield's criterion for a perfect negative. (See *Photo-Chemical Investigations*, p. 1.)

But, in the case of the negative given by the series of exposures utilised by Hurter & Driffield, it is quite easy to show, by an algebraical transformation of their approximate equation, that the printing value is inversely proportional to some power of the exposure; so that, while Abney's avowedly empirical formula gives approximately the required perfect negative, as defined by Hurter & Driffield, their own formula, which is put forward as an approximation to a formula not empiric, does nothing of the sort. In fact, their formula and whole method of speed determination is based on a misconception.* The quantity found no doubt does roughly represent the speed of the plate in a certain way, when exposed and treated in a particular manner; but it is of no use, because this particular manner is one in which no ordinary photographer would think of treating a plate,

* The printing value of a negative depends on the differences of the transparencies of the various parts, so that we may fairly take $\frac{dT}{dI}$, the differential of the transparency, for its measure. Since the curve of a plate, as plotted by Abney, or by Hurter & Driffield, always contains a point of inflexion, for parts near this point we may substitute the equation of a straight line for that of the curve, and this is what Hurter & Driffield have done to get their approximate equation. The equation of the straight line, in the case of Abney's curve, is

$$T = A - B \log I,$$

where A and B are constants, whence $\frac{dT}{dI} = -\frac{B}{I}$, and the printing value is inversely proportional to the exposure. But the equation of Hurter & Driffield's line is

$$\log T = \frac{B^1 \log I - A^1}{B^1 - 1}$$

whence $\frac{dT}{dI} = \frac{T}{I} B^1 = \kappa I$, where κ is some constant, and this expression in no way coincides with the required criterion.

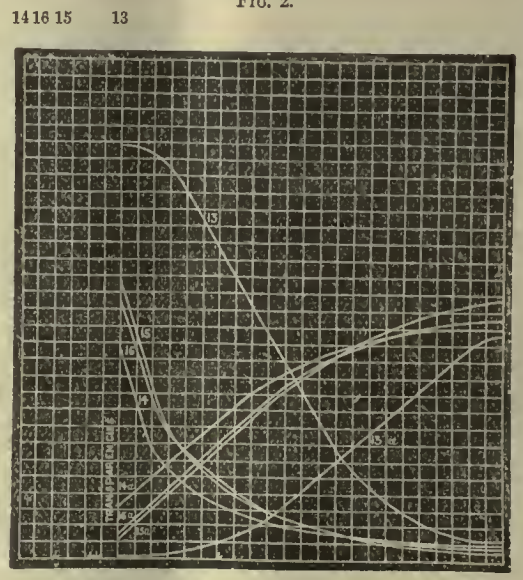
whereas Abney's method gives a quantity which does not pretend to give more than a rough idea of the speed under normal treatment. From the nature of things it can do no more than this. And its value consists in the fact that the series of transparencies from which it is derived is just that series that the average photographer utilises in his ordinary work.

It remains for us now to see what relation there is between the speeds derived by means of Abney's method, and by Hurter & Driffield's. It may easily happen that the relative speed of two plates will come out the same when determined by either method, but it may equally easily happen that this is far from being the case. In fact, a glance at fig. 1 will show that it is only the case when the range of the two plates is about the same—that is to say, when the range in which the printing values are nearly inversely proportional to the exposures is the same in both.

The best method of examining this point will be to take several plates and plot their curves according to the two methods, on the same scale, and then examine the results. In order to be absolutely impartial, we will take two plates referred to in Abney's paper at the Camera Club Conference, four plates measured by the writer, and three measured by Hurter & Driffield. The two plates referred to in Abney's paper are a wet plate and a "lantern" plate. *A priori*, if the lantern plate is a good one, we should expect it to give a negative approximating in gradation to that on the wet plate, since this "wet-plate" quality is usually desired in lantern plates; that is to say, the scales and ranges of the two plates would be expected to be similar, and the relative speed, as has already been pointed out, should be nearly the same when measured by either method. It is hard to apply Hurter & Driffield's method in this case, since the plates have not been measured through a long enough range; but, so far as can be judged, it appears, on plotting the requisite curves, that the relative speeds of the two are nearly identical, and the lantern plate comes out about 2·7 times as fast as the wet plate, by whichever method it is measured.

The four plates measured by the writer are numbered 13, 14, 15, 16 (*see* fig. 2.). No. 13 is a very slow plate, of well-known make; No. 14 one of the fastest plates in the market; Nos. 15 and 16 are re-

Fig. 2.



spectively a slow and a rapid plate, by the same makers, and are also well-known plates. These were all exposed for the same time in a Spurge's sensitometer, and developed in the same bath, a ferrous-oxalate developer being used, so that the experiments are strictly comparable. The relative speeds, as measured by the two methods, are given in the following table:—

	Plate.			
	13	14	15	16
Abney.....	1	3½	2½	3
Hurter & Driffield.....	1	9¾	5½	6

In this table the slowest plate is taken to have a speed of unity, and the others are compared with it. Thus, if an exposure of ten seconds is the least which will produce a negative with Plate No. 13, according to Captain Abney's method, three is the minimum exposure with Plate No. 14, and, according to Messrs. Hurter & Driffield, one only will be required.

It should be noted that, in the field, a slow plate is apt to appear much slower than it really is, since there is so great latitude of exposure with it. It has been said of plates of the same make as No. 13 that it is impossible by any reasonable exposure to over-expose them. Now, the writer has never compared Plates Nos. 13 and 14 in the field, but he has often used No. 13 and another plate very similar to No. 14, and of about the same speed, together, and it has been his habit to give No. 13 about five or six times the exposure of the faster one. Allowing for the tendency to fully expose a slow plate, it will be seen that, for practical purposes, Abney's number is probably nearer the mark than Hurter & Driffield's. This is not, however, convincing evidence, and must be taken for what it is worth. The curves of these plates are shown in fig. 2. The curves marked 13, &c., are plotted by Abney's method, those marked 13, *a*, &c., by Hurter & Driffield's. The numbers and arrows at the top of the plate show the position of the slowness points by Abney's method, those at the bottom the corresponding points by that of Hurter & Driffield.

The three plates measured by Messrs. Hurter & Driffield are Experiments 21 and 22 in their paper, and the chloro-bromide plate mentioned by Dr. Hurter in his criticism on Captain Abney's paper, made at the Camera Club, and reported in the Club *Journal* for July, 1893. Taking the speed of the chloro-bromide plate as unity, we get the following table of speeds:—

	Chloro-brom. Plate.	Expt. 21.	Expt. 22.
Abney	1	5·7	9·1
Hurter & Driffield	1	2	1·6

Here is a remarkable thing! Experiment 22 is a denser and apparently more fully exposed plate than Experiment 21 throughout the first few exposures of the series, and Abney's method brings it out the faster. Yet Hurter & Driffield's method inverts this order, although each of the whole series of densities in Experiment 22 is greater than the nearest corresponding density in Experiment 21.

One curious instance of a plate exposed and developed by Abney may be cited. This plate was cut in half after exposure, and the halves developed with different developers, viz., an eikonogen developer and one made up of ferrous citro-oxalate. On plotting Abney's measurements it is found that, while according to his method of estimating the speed the eikonogen-developed half was faster than the other in the ratio of 1·8 to 1, according to the other method the ratio became 1·25 to 1. This case, however, was affected by the same difficulty as was the case of the lantern plate and wet plate, since the measurements were not carried far enough, and did not include parts of sufficient opacity to draw the whole of the nearly straight portion of Hurter & Driffield's curve.

Sufficient has already been said to show that it is impossible to give in one term a number representing the sensitiveness of a photographic plate with any degree of accuracy, but that for rough purposes the method propounded by Abney supplies a number that more nearly represents this quantity, as required in the practice of most photographers, than that of Hurter & Driffield. It now remains to take up in detail some of the criticisms and strictures passed by Dr. Hurter at the Camera Club on this method, and see with what justice they were applied.

In the first place, Dr. Hurter proceeded to defend the assumption on which his larger formula was based. It has, however, been pointed out, by the writer and others, that this assumption depended on an experiment that was, to say the least, equivocal, and certainly not one on which to base so far-reaching a theory.* H. M. Elder.

(*To be continued.*)

* The experiment is described at p. 11 of Hurter & Driffield's *Photo-Chemical Investigations* in the following words:—"The co-efficient of absorption, κ has been assumed by us to have the same value both for the altered and the unaltered silver bromide. We have, however, experimentally ascertained that this is a fact. It can easily be proved photographically. If behind a plate, one portion of which has been already exposed so as to yield maximum density, the other portion having received no exposure at all, a very sensitive plate is placed, and if now a suitable exposure be given, it will, on development, be found that the shielded plate has uniform density all over." This is certainly an interesting observation, and, if true, at first sight seems to bear out the assumption based upon it by Hurter & Driffield. Still, it is open to many objections. In the first place it proves absolutely nothing about the light absorbed by the altered and unaltered silver bromide, for, assuming this to be opaque, no alteration in composition, or constitution, or colour, would affect the light transmitted by it, the co-efficient of reflection might alone be altered to compensate for the alteration in the co-efficient of absorption. Again, if it be not absolutely opaque, there is no reason to suppose that the transparency is necessarily altered by the effect of the light upon it. Even if it be altered, the alteration is certainly small, and, since the unexposed portion is necessarily exposed during the experiment, the difference in the effect of the light transmitted by the two halves may very easily be so small as to elude notice, even when careful measurements are made. In fact, the experiment can in no sense be called a crucial one.

FOURTEEN YEARS AGO.

Fourteen years ago a cart, drawn by a pair of bullocks, used to carry my photographic kit for outdoor work. The erection of the dark tent, within which I worked, occupied half an hour, and the providing of the water supply, the cleansing of plates, and the setting of other arrangements for collodion work took an hour more. For one success I had several failures, through chemical defects, plates drying with peculiar marks, films splitting and slipping, subjects moving, and once I remember working two days to get a satisfactory group of children. Only last month, as I was passing along the road, I stopped my carriage opposite a Hindu temple, and in a few seconds, with the clip of the shutter of my trusty Loman's hand camera, obtained a fine little picture of a group of idol cars, with worshippers in their various attitudes, from which I have since produced an enlargement. In 1879 my nearest neighbouring owner of a camera lived 200 miles away, and now, in this remote Hindu district of the island of Ceylon, there is a firm supplying photographic goods. The modern dry plate, which, through its simplicity and cleanness of working, gave the strong impetus to the popularisation of the photographic art, was only becoming talked about in 1878, and such an able artist as H. P. Robinson writes, in an 1880 Almanac, in his account of "A Cruise with Dry Plates," of commencing "last July" the use of these plates. "with the strict impartiality of a novice who knows nothing." Recently, I had to mount, in chronological order, a series of photographs, taken on collodion and gelatine, a comparison of which showed me the remarkable fact that, notwithstanding all the modern improvements, the old collodion possessed a marked superiority in the peculiar softness and brilliancy it rendered. I could not say whether it was due to any inherent qualities in the two vehicles, or to the necessity with collodion of developing at the time, which admitted of always correcting errors in development by fresh trials; but the old process shows a distinct superiority in the rendering of tones.

Photography had its field greatly widened in another direction during the last fourteen years. In 1880 "the mechanically accurate and practicable method of half-tone block-making" was being introduced to the notice of printers and publishers, and now almost every illustrated newspaper bears reproductions of photographs that enable those at a distance to realise events and scenes in a way never expected before photography came to the aid of the engraver. S. Kanagaratnampillai.

Jaffna, Ceylon.

HALATION: A COUNTERBLAST.*

It was early summer at Kennaquhairlo, and I found myself watching the scene an hour before sunset. The sun was descending in a cloudless sky, but some tall and fairly well-clad trees intervened. You all know the effect I witnessed; the leaves, twigs, branches, nay, the very trunks of the trees that attempted to block out old Helios were, or seemed to have been, quite obliterated by his overpowering beams, and this influence extended over so large an area as to give warrant to a belief that the sun was at least six times larger than we know him actually to be, as shown by measurement through our telescopes.

How, O ye naturalistics, must I represent the scene described? Am I to employ anti-halation plates and a diaphragm of the dimensions of a fractional part of a pinhole?

This, you will observe, lands me in a difficulty. If I represent Old Sol, as I know him scientifically to be, in relation to the trees, I set at defiance all truth as displayed to our unaided visual orbs, and if, on the contrary, I represent the scene just as I see it, I run counter to actuality, for we know that the trees are there, although the camera, which, of course, never can, and never does (?), lie, shows them to be absent, and very conspicuous by their absence.

Again, I transport myself to the interior of a cathedral, or, for that matter, to any church, and I find the large and well-lighted window in the end surrounded by a halo.

It is, I am told, the perfection of photography to photograph this interior without showing a trace of this halo, which, however, is part and parcel of the scene as witnessed from the interior. Suppose I succeed in doing so, would such scene, think you, be natural? I trow not.

* Received too late for the Almanac.

The famous trotting and running horses of Muybridge come handily in here to illustrate what, by this time, ought to rank as a truism, viz., that reality is not necessarily truth, for no eye ever saw the legs of these animals as depicted by him, although we know that he depicted nothing that was not there before his camera, and yet it is not truth according to the impressions conveyed to the brain by any sound pair of eyes.

If, then, as artists, we are to depose Muybridge's scientifically accurate limning of the quadrupedal limbs when in rapid motion in favour of those which are impressed on the retina, on what principle are we, by scientific means, to obliterate and leave unrecorded that halation which forms an effective item in a scene?

GEORGE MARKHAM, M.D.

THE KEEPING QUALITIES OF CELLULOID FILMS.*

THESE films are more and more appreciated in consequence of their great convenience as substitutes for glass plates, whether used flat on thick films or thin on the rollers. Being comparatively of recent introduction, it is difficult to express decided opinion as to their keeping qualities. It has transpired, however, here and there, that films kept some time before exposure do not give such satisfactory results as when used fresh. Emulsion on the glass plates is practically not affected by keeping when ordinary care is taken in storing. There is, however, the strong supposition that sensitive celluloid films lose their sensitiveness and become foggy with time. Observing that the packet, or rolls, of these films, by a very strong smell, betray constant elimination of the camphor and the solvent used (amyl acetate), naturally there is a suspicion that, if something has a deleterious effect on the sensitive gelatine surface, most likely it is these ingredients, so conspicuous by the smell, and situated in such intimate contact with the sensitive film. The object of my present communication is to invite persons interested in the matter to institute a series of mutual experiments in order to settle the question of the influence of the celluloid on the sensitive emulsion on the following lines:—Take an ordinary glass plate, apply with a squeegee and water in the middle of the plate a sheet (diamond-shaped) of celluloid, to be tested, having a surface equal to about one-fourth or one-fifth of the glass plate. Coat the whole plate with emulsion. Of twelve plates prepared in this manner, and carefully kept, one is to be exposed every month in the camera. When the image is developed, the central part of the negative will show the difference as compared with the rest if there is suspected action of the celluloid on the emulsion. If the negatives are dated, it will be easy to determine how soon the deterioration, if any, takes place. Different qualities of celluloid and of emulsion may produce the variation in the result, and for this reason it is desirable to have the experiences of different persons working independently.

L. WARNERKE.

News and Notes.

PHOTOGRAPHIC CLUB.—December 13, Members' Open Night; Exhibition of Members' Work.

WEST LONDON PHOTOGRAPHIC SOCIETY.—December 12, Lantern—Mr. J. A. Hodges on *Enlarging*.

WOOLWICH PHOTOGRAPHIC SOCIETY.—December 14, at St. John's Schools, Woolwich, *Isochromatic Photography*, by Mr. W. H. Barnes.

CENTRAL PHOTOGRAPHIC CLUB.—To-night, Friday, December 8, Mr. Brooker's Slides. 15, Mr. Howson will show the new Ilford matt paper.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—December 14, Lantern Slides of Mr. Burrow's negatives, *'Mongst Mines and Miners*.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—December 12, Ordinary Meeting. *The Distribution of the Image in Multiple Films*, by Mr. S. Herbert Fry; *Observations on the Lumière-Lippmann Colour Photographs*, by Mr. F. E. Ives.

HOLBORN CAMERA CLUB.—On Saturday last the Club held its fifth annual supper at Anderton's Hotel. Mr. D. R. Lowe presided over a representative gathering of the members, and the event proved to be one of the most successful gatherings of the sort.

WE are informed that several experimentalists are endeavouring to duplicate the results in colour photography obtained by M. Lumière on Lippmann's plan. We hope that the results will be shown at the meeting of the Photographic Society of Great Britain on December 12, when Mr. F. E. Ives is to make a communication on the subject.

* Received too late for the ALMANAC.

ASHTON-UNDER-LYNE PHOTOGRAPHIC SOCIETY.—December 14. This is the last day for receiving slides for the Society's competition. Demonstration and lecture on *The Chemistry of Photography*, by Mr. S. Sharp. Chairman, Mr. James Grierson. 20, Exhibition of Lantern Slides, and the awards given in the Society's Competition. Chairman; Dr. Hamilton.

MR. HORATIO NELSON KING has recently submitted to H.R.H. the Duke of Saxe-Coburg and Gotha, at Clarence House, his series of photographs of the private and state apartments of Clarence House. His Royal Highness congratulated him on the excellent series he had produced, and has since, by royal warrant, appointed Mr. King landscape and architectural photographer to his Royal Highness.

BRISTOL INTERNATIONAL EXHIBITION.—The following is a complete list of the jury at the forthcoming Bristol Exhibition, namely, Messrs. Bernard Altieri, Valentine Blanchard, S. P. Jackson, Payne Jennings, and the President of the Bristol and West of England Amateur Photographic Association, Mr. H. A. Hood Daniel. In response to a number of requests, the latest date for receiving exhibits has been extended to December 8.

WOOLWICH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—The second annual Exhibition of photographs and photographic apparatus will be held by this Society, in the large hall, Woolwich Polytechnic, on Thursday, Friday, and Saturday, February 8. 9, and 10, 1894. The Judges will be Messrs. F. P. Cembrano, Basil Bradley, and Rev. F. C. Lambert. The following are the classes:—For members only: 1. Prints, 8 × 10 and over, any process; 2. Prints, 8½ × 6½ and under, by any process; 3. Lantern slides, best set of six. Open: 4. Prints, any subject, any process, open to all; 5. Lantern slides, set of six (amateurs only). The Hon. Secretary is Mr. W. Dawes, 145, Chesnut-road, Plumstead, Woolwich, of whom particulars and entry forms can be obtained.

CROYDON CAMERA CLUB.—December 8, Special Meeting to try slides for Lantern Display on 13. 13, Second Lantern Display at Braithwaite Hall. *South Africa and the Cape;* musical interlude (see bills); *Good-bye to Old Croydon*, by Messrs. Corden and J. Smith. 20, *Various Methods of Slide-making*, by Mr. John H. Gear. January 3, 1894, *How to Use a Lens*, by Mr. G. R. White. 17, Third Lantern Display at Braithwaite Hall, by Mr. John A. Hodges and by members of the Club. Council Meetings, December 6 and 27, and January 10 and 24. Tickets for Lantern Display on December 13, sixpence each, or 5*s*. per dozen. A few reserved seats, 1*s*. Members are asked to make the display known to their friends and acquaintances. Those who can show window bills are requested to apply to the Secretaries.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—Meeting of the Committee, November 30, 1893, in the rooms of the Photographic Society of Great Britain, Mr. A. Mackie in the chair. First application was from an assistant out of employment, who asked for 3*l*. as a loan for temporary relief. Satisfactory testimonials had been received; but, as he had been nine months out of employment, the Committee thought there was little prospect of the grant asked for being a permanent benefit. An immediate grant of 10*s*. was made, and the Secretary instructed to ask for further particulars. Second application was from a member of the Association, an assistant, who asked for 30*l*., to enable him to start in business for himself. The Committee decided that this was not a form of loan that they could grant. The Secretary reported that three of the applicants who had been helped during the summer had commenced to repay the loans by small instalments, and that another, to whom a camera was supplied a month ago, had reported that he was succeeding very well, and, on receipt of payment for work which would be finished shortly, he hoped to repay the whole loan of between 4*l*. and 5*l*. Messrs. M. Howell, H. L. Morel, George Carter, and Roland C. Whiting were accepted as subscribers. Donations were acknowledged from Messrs. Marion & Co., 3*l*. 3*s*.; George Mansfield, 2*l*. 2*s*.; Captain Abney, 1*l*.; Mawson & Swan, 1*l*. 1*s*.; Jonathan Fallowfield, 1*l*. 1*s*.; Watson & Sons, 1*l*. 1*s*.; F. W. Verel & Co. 10*s*. 6*d*.; Richard Keene, 10*s*. 6*d*.; George Nelson, Dale, & Co., 1*l*. 1*s*.; H. G. Yatman, 10*s*.

Our Editorial Table.

AMERICAN ANNUALS.

THE INTERNATIONAL ANNUAL OF ANTHONY'S PHOTOGRAPHIC BULLETIN.

London: W. E. Peck & Co.

THE AMERICAN ANNUAL OF PHOTOGRAPHY AND PHOTOGRAPHIC TIMES ALMANAC.

London: J. Fallowfield.

WE observe that the former of these welcome Annuals has this year increased its dimensions to those of the latter, and in style and type both are now similar. Both have quite a number of illustrations, the respective frontispieces being, in the case of the former, a pretty studio portrait, by Dana, of Pittsburg, printed on American "Aristo" paper; while that of the latter is a reproduction from a stuffed parrot, printed in three colours, by the Coloritype Company. There are, in both, the usual reference tables, and contributed articles on miscellaneous photographic topics; and, above all, both are printed in large easily readable type. Their prices are two shillings each in paper covers.

Ilford Matt Printing-out Paper.

The Ilford Britannia Works Company have brought out a printing-out paper with a matt surface, which we think much of. Although it is quite devoid of gloss, yet it gives prints which are brilliant, and have no appearance of being sunk in, which is a characteristic of all matt surfaces obtained by being sensitised by flotation on a silver bath. It prints quickly, and can be toned on any toning bath. We predict a large demand for it.

Christia.

This is a new ruby material for dark-room illumination, introduced by Messrs. Thomas Christy & Co., 25, Lime-street, E.C. It is very soft and pliant, and folds without cracking. It is a safe colour, and seems to be just the kind of thing one would like to have with him when out on a tour.

Mr. William Tylar, of Birmingham, has sent us a sample of a gummed textile fabric he has prepared as a substitute for the black paper strips in general use for binding lantern slides. The great advantage of this fabric is that, unlike paper binding, it will not tear.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 30,—Mr. P. Everitt in the chair.

Mr. C. W. Canfield (U.S.A.) was present as a visitor. Receipt of a presentation copy of The British Journal Photographic Almanac for 1894 was acknowledged.

Mr. W. T. Wilkinson passed round a gelatino-chloride print developed according to the Paget Company's formula.

Compared with a printed-out picture, Mr. Debenham thought the developed showed better gradation.

Mr. J. E. Hodd showed a lantern slide made on a chloride plate. The image was rather dense, and there was a whitish surface deposit. Ammonium carbonate had been used in the developer.

Mr. Debenham suggested that the density was due to too long development, and said that hydrochloric acid solution would probably remove the whitish deposit. The correctness of the latter view was substantiated by experiment.

Mr. Wilkinson showed comparative results on Sandell plates and orthochromatic plates, the latter used with a screen prepared with methyl orange dissolved in collodion coated on patent plate. Mr. Wilkinson also showed three prints from negatives taken with discriminating screens, to be used in the preparation of three-colour pictures.

The Carbon Process.

The discussion on this subject, adjourned from the last meeting, was resumed.

Mr. Debenham said, at the previous meeting Mr. Acres had said that the speed of tissue was about the same as that of albumenised paper. That did not apply to tissue generally. He had found that a tissue sensitised on a three-to five per cent. bath was from three to four times as rapid as albumen paper.

Mr. Skelton (of Messrs. Elliott & Son) said the statement applied to tissue sensitised from the beginning, not to that sensitised by immersion.

The Chairman asked why such tissue should be slower than floated tissue?

Mr. Skelton replied that it contained much less bichromate.

In reference to imparting a matt surface to the prints, the Chairman mentioned that the Autotype Company recommended celluloid for the purpose.

Mr. Hodd said that if the celluloid contained scratches they would appear in the finished print. He asked what was the cause of the reticulation of the film? He had found it with freshly sensitised tissue.

Mr. Skelton said it was caused if the film was too soluble. The less time the film was soaked in water the better. In reference to a remark that in some prints shown the safe edge had printed through, he said it was not the proper thing. It had been caused by accidental exposure to light. If the negative gave a hard result, the surface could be sunned down, but clear edges were always obtained in the ordinary way.

Answering Mr. Teape, he said alcohol in the sensitising bath was not now used for preventing reticulation. Ice, however, was used, but, if the water were cool enough, it was not necessary to use anything.

After other discussion the meeting adjourned.

Croydon Camera Club.—November 29.—Mr. Leblanc gave a demonstration and explanation of *Modern Developers* to a good attendance. A snap-shot on a Wratten plate was satisfactorily developed with metol, and a lively fire of questions ably answered.

Croydon Microscopical and Natural History Club (Photographic Section).—December 1, Mr. Low Sarjeant in the chair.—A good muster of members attended to witness an exposition of the carbon process, which was ably given by Messrs. Braham and Burton, of the Autotype Company. After a brief description of the principles of the process, the method of printing was very clearly explained, together with the use of the actinometer, of which several varieties were shown. Reference was made to the continuing action which took place after the print was removed from the printing frame, and means of utilising this action were detailed. The print, in the single-transfer process, could be finished on paper of any surface; but the double transfer could only be satisfactorily finished on a smooth paper. The practical working of the single and double-transfer processes was then shown in the production of paper prints, opals, and transparencies, the treatment being the same in each case, only the final support to which the tissue was transferred differing. The tissue, after a short soaking in water, was well squeegeed on to the final support in the single transfer, all the water removed, and, after being blotted, placed in the developing bath of hot water. In a few minutes the portions unacted on by light were dissolved away. The print was then placed in cold water containing a little alum, and, after a rinse in clean water, hung up to dry—a finished print. In the double transfer, a temporary support of waxed paper—or opal for matt effects—was first used. The print was then similarly treated, dried, soaked again, and squeegeed on to the final support, the waxed paper being peeled off when dry.

East London Photographic Society.—November 28, Mr. C. Tylee in the chair.—Mr. L. E. Bennett, of 43, Mitchell-street, Bartholomew-square, was elected Hon. Assistant Secretary. Mr. M. A. Wilkinson, in a few but effective words, drew the members' attention to the great distinction which the Society had, through one of their members, achieved at the Stanley Show; he referred to Mr. C. Tylee, who had been the winner of the medal for the best individual picture in the Society's competition.

Richmond Camera Club.—Members were compensated for recent disappointments by a very enjoyable Lantern Evening on Monday, the 4th inst. A "Roberts" hand camera, an established favourite with several members, with latest improvements, including Thornton-Pickard shutter, was shown. A few members' slides were then shown: Views of the river, by Mr. Childs; Lakeland, by Mr. Neville; the Rhine, by Mr. Gibson; Spain, by Mr. Purcell; and Switzerland, by Mr. Davis.

Birmingham Photographic Society.—November 28, Mr. J. J. Bulton in the chair.—Mr. Underwood gave a demonstration on the working of gelatino-chloride papers, carrying out all the manipulations before the meeting, from the time the print is taken from the frame till it is in position with a matt surface upon its mount, including toning with platinum as well as the various gold baths.

Halifax Camera Club.—November 29.—Mr. S. H. Fry gave a demonstration on *Paget Prize Print-out Papers and Lantern Plates.* The lecturer, in a

lucid and interesting way, dealt with the characteristics of a good lantern slide *firstly*, and laid great stress on the importance of exposing correctly, and not, as some people try to do, by making the slide right in development. Coming to the question of variation of colours, Mr. Fry requested Mr. Priestley, the manipulator of the lantern, to show about twenty slides, all from one negative, but all of different exposnres. Not one of the slides was of the same colour, all different, some being brick-red, warm tones, purple-black and other cold tones. Being all developed by the same solution, it proves what the lecturer said, that the gradation of colour is due to exposure, and not, as some say, development. One thing Mr. Fry impressed upon the meeting was, that almost the same tone could be got either with the Paget slow or quick lantern plate; in fact, he seemed to think that even an expert could hardly tell the difference. Mr. Fry then developed an under-printed print. The process is very simple; it consists of taking the print and immersing, without previous washing in a ten per cent. solution of bromide of potassium. The prints should remain in this bath for ten minutes, and then be well washed in running water for five minutes; then developed with hydroquinone, the formula for which is supplied by the Company, after which they should be again washed for ten minutes, and then toned and fixed in the ordinary way. The print-out opals can be treated in the same way as the paper. The opinion of most of the members present was that the partial development was most useful. Some excellent prints were shown to the audience, which were much admired.

Cape Town Photographic Club.—Annual Meeting, Mr. F. Ayres presiding.—The first business was the reading of the Council's report for the past year, which was as follows:—The Council had much pleasure in presenting their third annual report for the year just ended. The balance-sheet showed a balance brought forward of 18*s.* 9*d.*; receipts during the year, 40*l.* 19*s.*; total, 41*l.* 17*s.* 9*d.*; disbursements during the year, 41*l.* 12*s.* 7*d.*; leaving a balance in hand of 5*s.* 2*d.* The number of members at the beginning of the year was forty-five; there were thirty-two new members admitted during the year, six had removed and resigned, leaving the present number of members seventy-one. The monthly meetings had kept up their interest, and had been well attended, the average attendance of members and visitors being twenty-two. Besides the ordinary meetings, the Club had organized and carried through the following entertainments:—On February 2, a lantern entertainment at which over 200 slides made by Club members were exhibited. These slides were now being circulated amongst the English societies. On May 10, a limelight entertainment was given, entitled *Round and About Lucerne*, with descriptive lecture by Mr. Charles Steytler, a member of the Club, the slides being from his own negatives. On August 17, a *conversazione* was held, to which some 250 guests were invited, including members. Over 1000 exhibits were shown. The ontings of the Club had been always enjoyable but not so well attended as may have been expected. The places visited were Table Mountain, Cape Town, Rondebosch, Constantia and Houts Bay, Sea Point, the Kloof, &c. The following subjects were introduced during the session:—*Pinhole Photography*, by Mr. C. Ray Woods; *Bellows-making*, Mr. C. von Bonde; *Stereoscopic Photography*, Mr. A. J. Fuller; *Wet-plate Process*, Mr. E. W. Allis; *Print-out Papers*, Mr. R. T. Pett; *Enlarging by Cresco-fylma*, Mr. A. J. Fuller; *Print-out Opals*, Mr. A. J. Fuller; *Polarisation of Light*, Mr. C. Ray Woods. The CHAIRMAN said they all knew that the present flourishing condition of the Club was mainly due to the energy and exertions of their Secretary, and he had now the pleasure, on behalf of the members, of presenting him with an illuminated address, together with a "Chadwick" hand camera, which he believed the Secretary had a special affection for. The election of Officers then took place. *President:* Mr. David Gill.—*Vice-President:* Mr. T. W. Cairncross.—*Council:* Messrs. E. J. Steer, C. Ray Woods, F. Ayres, J. R. Wignall, G. N. Lindup, A. Gracie, R. T. Pett, D. C. Andrew.—*Secretary and Treasurer:* Mr. A. J. Fuller. Two new members were elected, and the evening closed with an exhibition of members' slides. The limelight lantern was manipulated by Mr. Wignall with a new Lawson saturator, just imported by him, which worked very satisfactorily.

FORTHCOMING EXHIBITIONS.

1893.	
December.....	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.

* Signifies that there are open classes.

Correspondence.

GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—There is a flood of scribbling in your plethoric ALMANAC on the subject of gelatino-chloride paper. This is only what was to be expected from the immense growth in public favour of this class of paper. Of this scribbling there is a portion that is readable and instructive: more that is instructive, but, being simply a *resumé* of our own and other makers' formulæ and pamphlets, is unnecessary; whilst there is much more that is distinctly misleading, and apparently *ex parte*. Against this latter we desire most emphatically to protest.

First, it has been said that gelatino-chloride paper is much more expensive than albumen, but, in reckoning the cost of the latter, the writer of the article ingennously (ought we to say ingeniously?) omitted entirely the cost of labour, plant, and time, and also ignored the possibility of waste. To practical men we need not point out what a mistaken paradise the gentleman in question had created for himself. Another error that he made was to assume that gelatino-chloride paper consumed more than double the quantity of gold that albumen does. This is absolutely a false statement (unwitting, of course, on our friend's part, but nevertheless quite untrue).

Again, he writes of yellow prints and double tones as a necessary consequence of the use of the paper, and not as the result of careless or ignorant working. No one knows better than you, Mr. Editor, how far removed from truth such an accusation is.

Another gentleman writes that gelatino-chloride paper is much given to frilling, and, whilst we cannot answer for other makers' goods, we will say definitely that not one instance of such a thing has ever been brought to our notice during the year 1893, which he mentions, and we challenge the writer of the article to produce authentic evidence that such a case ever occurred.

History repeats itself, even in details, and we shall see the flowing tide of gelatino-chloride paper roll on unharmed by these puny efforts to stop its progress, just as the tide of gelatine plates flowed on in the past, unhindered by similar writers, who, from interested motives, or a desire to write something that should be a little out of the ordinary course, opposed or detracted from their advantages.

Gelatino-chloride papers necessitate a little unlearning of what the old-fashioned photographer knew in the past, a little use of common sense, and that is all: and this, we are glad to say, is usually met with. The photographic world, professional and amateur, will continue to use this paper as it has in the past, only to a greatly increasing extent. There was never any change in the photographic procedure which gained so ready and so firm a hold on the photographic public in such a short time, and such a hold could not have been gained unless the article had intrinsic merits of the highest class.

We apologise for taking up so much of your space, but think that the subject deserves the fullest consideration, and that misstatements, as we have indicated, should not go uncontradicted.—We are, yours, &c.,

THE BRITANNIA WORKS COMPANY, LTD.

Ilford, London, E., December 1, 1893.

BURSTING OF AN OXYGEN CYLINDER AT BRADFORD.

To the EDITOR.

SIR,—There is only one conclusion that can be come to in reference to Mr. G. R. Baker's remarks in your issue of the 1st instant relative to the reannealing of cylinders.

It is, either that they have been sent out by the makers unannealed, or that, after being tested to one and a half tons, and filled four times—as was according to the evidence the cylinder which burst—they require reannealing.

If the latter is the correct conclusion, it is a very alarming one, seeing the great number of cylinders that have been in use for years without, so far as can be learned, any reannealing, and it is to be hoped that the matter will not be allowed to drop until we have some authoritative statement on the subject. Professor Goodman's opinion on the question would be of value.—I am, yours, &c., R. G. M.

December 4, 1893.

To the EDITOR.

SIR,—I was glad to see so much correspondence in this week's BRITISH JOURNAL OF PHOTOGRAPHY respecting the recent cylinder explosion, and now that our fears are again aroused, we ought not to let the matter rest until the question of reliable tests of these cylinders are placed in the hands of disinterested parties. I urged the same thing several years ago (after the Glasgow accident) in your JOURNAL, but it was not supported, and the matter died away. I quite agree with Mr. W. I. Chadwick that we ought not to let this matter rest until these cylinders are under Government inspection and supervision, as in Germany. It is of vital importance, not only for the individual users, but from a public safety point of view, and the time has arrived when some action should be taken, to attain which I suggest that *all* Secretaries of the various photographic and lantern societies memorialise the Board of Trade to take the matter up. We shall never have safety without, as the so-called tests are not reliable, as was conclusively proved by the fatal cylinder being filled. I trust, Mr. Editor, that you will assist lanternists in this matter.—I am, yours, &c. J. R. GREATOREX.

Mytton Hall, Shrewsbury.

To the EDITOR.

SIR,—I was pleased to read Mr. Chadwick's remarks about the above, and I fully endorse his suggestions. I have been giving exhibitions for about twenty years, but, in consequence of this uncertainty in bottles, I have almost ceased exhibiting, with the exception of showing slides at our Society. Now, if Mr. Chadwick's suggestions were thoroughly ventilated, something might be done which would restore confidence.—I am, yours, &c., W. B. WOOD.

Urmston, December 2, 1893.

"FREE LANCE" AND HIS CRITICS.

To the EDITOR.

SIR,—May I be permitted to say a few words in reply to "Free Lance" in your last issue. I am glad he is so candid as to admit that he spoke unfeelingly of what he terms the absurdities on the walls at Pall Mall. I am invited to express my opinions upon "The Proud Turk." I must decline to do so, as I am not sufficiently acquainted with that picture to do it with justice or propriety. That reason, of course, cannot weigh much with him, but still I must give it for not appearing more courteous. I do not understand his criticism; his remarks are founded on different principles to those that govern my opinions. I certainly like his pose on the artistic standpoint, it is charmingly funny if not very dignified, and I should think that even "The Proud Turk" himself would smile at such a furious, feeble assault. The reasons given for denying all merit to this picture are so singular that they seem like a bad joke, yet I must traverse them in order to show their felicitous applicability.

"Free Lance" says, "The effect of light is neither moonshine, sunshine, nor haze." Is the gentleman serious here? Surely he must know there are other lights quite as legitimate to use as those he has named. Perhaps his twilights have been spent in such interesting company that they seemed all haze to him. According to my limited knowledge of the principles of art, violent contrasts are inimical to breadth and repose. While true lights are suppressed, gradations changed, and transparency destroyed by great artists in order to secure the necessary effects, I cannot understand a purely photographic standpoint; but as an artist photographer I am free to confess that I rather like underdone negatives. Some of them print rare effects with just a little cooking.

I must thank "Free Lance" for the information about the judging, although it is not quite news to me, having had a little experience in the matter myself. Having now to the best of my ability answered the gentleman, I hope he will pardon my liberty if I should ask one or two questions in return. Has he got and read the ALMANAC yet?—if not, let him do so as soon as possible, and study, ponder over, and digest it. He will become wiser, and next year he will be able to write an inteligible article on the Exhibition. Let him kindly read the "Plea for a Higher Criticism," by John A. Hodges; it is well-timed, sensible, and appropriate, and I hope it will tend to draw more attention to this important master. He recommends a painter as an art critic.

In conclusion, allow me to appeal to you, Mr. Editor, and all those who hold the profession in respect and have a glimpse of the coming light, to use the strongest endeavours to clearly classify the pictures which are now presented to our exhibitions. Broadly speaking, there are now three distinct classes. In the first, ordinary photography, of course, holds the principal position; in the second, photography controlled more or less and modified by the canons of art; while, in the third, photography becomes entirely subordinate to the requirements of art and disappears in the picture. This is inevitable, as in all true pictorial art materials and mechanism are so hidden that they are practically unseen. This will be the character of the best work of the future, and the sooner we recognise that fact the sooner we shall apply the correct rules of criticism to each of the classes already mentioned. Then each class of our art can have free play in its own sphere without encroaching upon the rights and prerogatives of the others, enabling them to work for the common good in the most efficient manner possible.—Yours, &c., A. R. E.

December 4, 1893.

CELLULOID FILMS.

To the EDITOR.

SIR,—We are not anxious to start a controversy as to the merits of our celluloid film over that of our competitors; the fact that they use our name to sell it under is evidence of their acknowledgment of our superiority; but we are most anxious that the photographing public should be thoroughly aware that there is more than one film now on the market.

Notwithstanding your able article of the 1st inst., we do not see that we can change the opinions we expressed in our letter to you. Some three months since, we had a small fire on our premises at Newark, N.J., that was distinctly traceable to a box of pipe-stems made by one of our competitors. They were of transparent material and practically solid film as used for negatives. It may be that, when in thin sheets with layers of gelatine between, the films are not so liable to ignition, but of that we have had no experience. This we know, that no material ever made by us has exploded or spontaneously ignited, that there has been no complaint against our film destroying the emulsion's sensitiveness since the mechanical difficulties of coating it have been overcome by the plate-makers.

We shall be very pleased to send, to any one desiring it, a small sample of celluloid of our own manufacture, that he may compare it with any plates he may buy or have on hand. We have found, as we showed you last week, that no film at present on the market besides celluloid will withstand heat, and that, when applied by means of a flat iron, that is as hot as possible without being so hot as to scorch paper, the imitation celluloid will crumble to yellow powder, while the genuine film is only damaged in the finish and loses its polish. Such an experiment is easy to make, care being taken only to keep a thin piece o paper between the iron and the celluloid and a pad of blotting-paper under all, to keep in the heat. It will often happen that sufficient acid will be given off to mark ordinary litmus paper, but, if it is desired to test for nitrous aid, the operater will need be more than a photographer and possessed of considerable expert knowledge of chemistry.

Thanking you in advance for your kind insertion of the above, we are, yours, &c., S. GUTTERMAN & Co.,

For the Celluloid Company, New York.

35 *and* 36, *Aldermanbury, London, E.C., December* 5, 1893.

ELECTRICAL HEATING.

To the EDITOR.

SIR,—In the letter from your correspondent "Palette," are some statements which need correction. The fact that the water heater referred to as mine is an "elaborate apparatus" has nothing at all to do with the cost of electrically heated bath heaters, which, except for the bedding of the conductors, can be made at a small cost to give quite as high a proportionate duty, for the power consumed, as can be obtained from gas; but the cost of the current for bath heating is at present much too heavy to admit of its being used in practice, although it may not be so when Mr. Preece's figures of the future are realised. Another mistake your correspondent makes is by bringing in figures as regards comparative cost which will not bear investigation. Mr. Preece, of the General Post Office, is made to state that "one pound of coal distilled into gas will give a light of seventeen candles for one hour." Neither Mr. Preece, nor the General Post Office, nor both combined, could distil "one pound of coal into gas." The statement as given is simple nonsense. It is not at all likely that Mr. Preece ever made such a silly assertion.—I am, yours, &c., THOS. FLETCHER, F.C.S.

Warrington, December 1, 1893.

PHOTOGRAPHIC PIRACY.

To the EDITOR.

SIR,—The following may be of interest:—(1) A smart young man came round our district with the photographs you mention, Luke Fildes's *Village Wedding*, &c., called upon business people, and disposed of a good many copies. He offered them to me at 5*s.* each, then 4*s.*, and finally my choice for 3*s.* 6*d.* A friend purchased two for 6*s.* His canvass of the district seemed very thorough. (2) A publisher called upon the stationers in the various small towns around, proposing to get up local albums; one stationer was prevailed upon to write one of our large publishing firms, asking permission to use one or two of their views; permission was at once granted, whereupon several others wrote, and "the cat being out," permission was promptly and properly refused. Eventually the local booklet was produced, but was so indifferent that I do not think it has interfered with the sale of legitimate photographs. (3) How the amateur is pirated: I was a guest recently at a wedding, and as time hung heavy until the light fantastic could be tripped, I proposed to photograph the party; this I did, and produced an excellent whole-plate negative (I did *not* pirate, there was no professional within ten miles). I offered to do one or two for the family, but declined to supply the party (about thirty). "Oh! hand the negative to a professional," said the bride's father, "I want a lot." So I sent the negative through to my dealer, had a dozen printed, nicely mounted on good cards, and handed them over, stating the dealer's price. Now I find that they are being forwarded to those interested, fifty per cent. profit added, and the guests are being allowed to believe that *I am selling them at that price.*

Resolved: That in future I devote myself to pure landscape.—I am, yours, &c., "FIXED."

November 28, 1893.

AMATEURS AND PROFESSIONALS.

To the EDITOR.

SIR,—Some time ago an article appeared in your paper referring to Amateur *versus* Professional, showing how the one might affect the other, &c. The following is an experience novel in itself, and, I think, worthy of an expression of opinion from you, Mr. Editor; and, perhaps, you might find space in the JOURNAL for the thoughts of a member of the profession. It is this:—

I am a photographer in Glasgow, and had occasion the other week to quote price for an outside group of fifty; and as it was pointed out to me that, in the event of a good picture, fifty copies, at least, would be required, I made up my mind instantly to have that order. I therefore offered to produce a 15 × 12 enamel in cut-out mount at 3*s.* 6*d.* each. Well, Sir, a meeting of those interested—viz., members of a choir—was held in due course, and my price, along with price from another photographer equally capable, was submitted; and I am told I received most votes, and just as the matter was about to be fixed, up jumps an amateur (a member of the choir) and offered to do the job for 3*s.* 3*d.* each. The Chairman thereupon suggested, as their friend and member the amateur

offered to do it at three pennies less, he ought to get it—and did get it accordingly. "Talk about the living wage!" Whew! This same amateur, I am told, holds a fair appointment on the staff of one of our *leading* evening papers.—I am, yours, &c., WHAT DO YOU THINK?

December 4, 1893.

HOW LENSES ACT.

To the EDITOR.

SIR,—Assuming that Mr. Hargrave has been correctly reported, I beg to offer a few remarks on his results.

1. Mr. Hargrave says that the distance, which he denotes by $a\,b$, is constant, with the same focal value of stop for all lenses. This, though approximately true, is not absolutely so, either for the same lens at different distances or for different lenses. If D_1 = distance from the lens in inches of the point sharply focussed, the stop, *f*-8, and the *diameter* of the disc of confusion $=\frac{1}{100}$", we have $\frac{1}{a\,b}=\left(1-\frac{f}{D_1}\right)\left(\frac{100}{8}-\frac{1}{f}\right)$ showing that $a\,b$ depends on D_1 and *f*.

2. If $\frac{f}{D_1}$ is small, $\frac{1}{a\,b}=\frac{100}{8}-\frac{1}{f}=12\frac{1}{2}-\frac{1}{f}$, and hence, approximately, $a\,b=\frac{1}{12\frac{1}{2}}$ for all such cases.

Perhaps Mr. Hargrave took the *radius* of the disc as $\frac{1}{100}$", but this is not the usual assumption.

3. To find D with the above value of $a\,b$, we have, as usual, $a\,b=\frac{f^2}{D-f}$, or $\frac{1}{a\,b}=\frac{D}{f^2}-\frac{1}{f}$,

$$\text{hence } \tfrac{100}{8}=\frac{D}{f^2} \text{ and } D=\tfrac{100}{8}\,.\,f^2.$$

This agrees with the usual formula—

$$D=100\,.\,\frac{d}{f}\,.\,f^2 \ (d=\text{diameter of stop}),$$

for the distance from the lens, beyond which everything is in focus at the same time as the extreme distance.—I am, yours, &c.,

CLIFFORD E. F. NASH.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

WM. GOODWIN.—Received; thanks.

J. F. HAMMOND.—Sorry we are unable to avail ourselves of your offer; thanks all the same.

NENN LAT.—The sunken, flat appearance of the print is probably caused by over-exposure.

J. S. asks: "Is it possible to restore platinotype paper which has been kept six months and gone wrong?"—No.

DORMOUSE.—Send us your name and address, in accordance with our rules, and we will endeavour to answer questions.

J. P. G.—There is no other brand of dry ferrotype plates than the one you name. Sorry we cannot help you in the matter.

"49."—It will be easy to arrive at a definite conclusion on the subject by shading one-half of the paper from the ruby light while the enlargement is exposing.

PYRO.—The working of the "tintype" process is similar to that of the wet-collodion process, only one is taken on blackened tin plate, whereas in the other glass plate is used.

ZENO.—1. Yes; if the gelatine be of a suitable character. 2. The paper can be sketched, and held secure, in the same apparatus as it is intended to be used for its ordinary purpose.

PLANTER.—1. We have heard of instances where gelatino-chloride papers have been taken to the tropics and brought home again, printed, and found to be in perfect condition. 2. Take the developer in cartridge form.

D. THOMASON.—We have not ascertained the price of Mr. Duchochois' book, nor have we heard of its being procurable in this country. Several hints on photographing by magnesium light will be found scattered throughout our recent volumes.

E. F. MULLER.—1. Undoubtedly excellent doublet lenses to cover half-plate can be obtained for 5*l.* 5*s.*, but you must make your own selection. It is not our practice to recommend one make in preference to another. 2. Write Mr. Alfred Watkins, Hereford.

S. R. B.—There is certainly nothing in the atmosphere or the light of Germany that will account for the asserted superiority of the photo-mechanical work produced there. Whatever excellence there may be is entirely due to the workers and not to climatic conditions.

T. O'BRIAN.—Thanks for your high opinion of our knowledge; but we must be excused from expressing any opinion on the validity of the patent for the shutter referred to, and also as to the validity of the patent you propose to take for another one. Better consult a respectable patent agent.

J. DORMER.—We have had no experience with the material in question, and know nothing whatever of its composition. It being a trade article, the makers, of course, do not publish of what it is compounded, so we can give no opinion as to whether it would act injuriously on bromide enlargements or not.

HUNTINGDON.—There is no reason to surmise that even the worst possible mounts to be found in the market would have any injurious action whatever on a carbon print. Certainly we have never seen or heard of an instance of such a thing. With regard to the alleged difficulty of the carbon process yielding good prints from good negatives, see article on another page.

B. A. MORRIS.—The difficulty in obtaining sufficient contrast in the negatives for photo-lithography is fully accounted for by the fact of extra-rapid plates being used. These are the very worst that could be employed for the work. Try either the plates made specially for the purpose, or adopt the collodion process.

FOG.—If the current is obtainable from the mains, by all means have it from that source; it will be far more economical than having your own installation for its generation. Most London portraitists, who went to considerable cost for engines and dynamos, have retired them since they have been able to obtain the current from the mains.

T. M. WILLIAMS asks how English prices for portraits compare with those on the Continent—whether they are taken at a less price than they are here?—We presume portraits are taken at a low price on the Continent, the same as they are here, but it is pretty clear that they cannot be taken for much less. So far as our own knowledge goes, cheaper portraits of fair quality are to be had here than abroad.

ROWSE asks if there is any process by which the features in a profile portrait are raised from the background, after the style of a cameo.—In reply: This effect cannot be produced by any photographic process, but is the result of artistic work on the portrait. About thirty years since, some exquisite cameo profiles in white wax were produced by Mr. Brewster, an Edinburgh artist, and at a more recent period a Parisian artist, whose name was unknown to us, produced pictures in relief, which were believed to have been done by pressing the print up from behind. The late J. Solomon, of Red Lion-square, was the agent for getting this work done, and specimens are still in existence, but the secret of making them was never divulged.

F. J. Q. asks: "Can you tell me of a Photographic Society convenient to Charing Cross, not too high in subscription—say, 1*l.* 1*s.* or 2*l.* 2*s.*—where one could see the photographic papers, American as well as English, hear the latest photographic news, and see demonstrations of new processes? Camera Club too expensive, and concerns itself mostly with high mathematics and art."—The Photographic Society of Great Britain, 50, Great Russell-street (subscription, 1*l.* 1*s.* per annum); the Photographic Club, Anderton's Hotel, Fleet-street (1*l.* 1*s.* yearly); the Central Photographic Club, Coleman's Hotel, Covent Garden, W.C. (1*l.* 1*s.*). Join all three, and you will get just about as much photographic pabulum as you can desire.

A. B. asks: "Can some one inform me how to clean an old oil-painting? It has got very dry-looking and indistinct. Can the cracks in paint be filled up?"

J. W. writes:—"Can you tell me the surest means of stripping collodion negatives when they are taken on plates prepared with French chalk—I mean stripping them for the purpose of placing them on another glass reversed?"—Two methods are open. One is to take a sheet of gelatine, such as that supplied by the dealers in lithographic materials, and soften it in water, and squeegee it on the negative and allow it to dry. The other is to place the negative on a levelling stand, and pour on a warm solution of gelatine, and allow that to dry. When the gelatine is dry, the negative can be taken from the glass and used as it is. If it be desired to mount the stripped negative on to another glass, a plate should be coated with gelatine, which should be allowed to thoroughly set. It is then immersed in cold water, and the stripped negative brought in contact with it while under water, then removed, gently squeegeed, and allowed to dry.

*** Several answers to correspondents and other communications unavoidably held over.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1754. Vol. XL.—DECEMBER 15, 1893.

OUR 1894 ALMANAC.

The British Journal Photographic Almanac for 1894 was published on December 1. The volume is the largest yet issued; it comprises 1336 pages, an increase of exactly a hundred pages on last year.

"Stereo-micrography" forms the subject of the editorial article, and among the contributors are Captain Abney, Professor W. K. Burton, Mr. Andrew Pringle, Dr. R. L. Maddox, Mr. R. H. Bow, C.E., Mr. Thomas Bolas, Mr. C. H. Bothamley, Mr. John Anderton, Mr. G. Watmough Webster, Mr. E. W. Foxlee, Mr. Thomas Bedding, Mr. John Howson, Mr. George Mason, Mr. Birt Acres, Mr. Redmond Barrett, Mr. Valentine Blanchard, Mr. William Brooks, Mr. James Martin, Rev. F. C. Lambert, Mr. W. J. Stillman, Mr. F. York, Mr. A. L. Henderson, and many others.

The frontispiece is a collotype portrait of Captain Abney by Messrs. Morgan & Kidd, and among many other illustrations will be found an example of Messrs. Waterlow's half-tone process, and illustrations showing comparative results on orthochromatic and ordinary plates by Mr. B. J. Edwards, and collotype reproductions of hand-camera work by Mr. H. C. Beck. The publishers inform us that 15,000 copies of the edition have already been disposed of.

THE WET-COLLODION PROCESS.

The fact of the wet-collodion process being now so extensively employed in various departments of photography, more especially in photo-mechanical and lantern-slide processes, and the further fact that we are in constant receipt of letters of inquiry relating to one or other phase of this subject, induces us to write a few articles relating to its chemistry and practice.

The collodion process was introduced through the medium of the *Chemist* in 1851 by Frederick Scott Archer and seems to have been originally intended by him to produce pellicular negatives—that is, the films after being developed were not primarily intended to remain on the glass plates, but to be removed therefrom and kept between the leaves of a folio when not in use in the printing frame. It was subsequently found by himself and others that the balance of advantages lay in the retention of the films on the glass plates on which they were formed, unless in such cases as necessitated a reversed print. Methods of stripping the film from the plate will be given subsequently. The process was introduced as a negative one, but it was soon discovered that by modifying the developer very fine direct positives could also be obtained in the camera, and it was this that led to the downfall of the Daguerreotype process; for, while collodion positives, when skilfully made, possessed equal, or almost equal, merits with even the finest Daguerreotypes, they could be produced with much greater simplicity, with less expense, and a shorter exposure in the camera, while their permanence is undoubted.

The collodion process is a very simple one, and when care is taken to keep the chemicals in good working order it is a very sensitive one, and one by which negatives of a singular degree of excellence may be obtained. Indeed, the productions by this process have long been held up as standards of excellence to which to attain by gelatine-workers.

The collodion is the first thing to claim attention. Its mechanical property of flowing with oil-like smoothness over a plate of glass—no matter how large—and forming a bright film of uniform thickness, which sets firm in a few seconds, indicated its great advantages as a vehicle for holding the haloid body which, when united with the silver solution, in which it had afterwards to be immersed, formed the sensitive surface.

Collodion, happily, is very easy of preparation, although it will prove more advantageous to purchase it ready-prepared from those who make a speciality of it. It is procurable in various kinds, some better adapted for positives, some for lantern slides, and some giving dense images for negatives and pen-and-ink line work. The quality of the soluble cotton of which the collodion is made has much to do with inducing the various properties named, although the iodising solution also forms an important factor in determining its suitability for special purposes. There is one among the innumerable iodisers that have been proposed which, after many trials of others, we determined upon adopting, and which makes what we would term a good all-round collodion, suitable for every purpose. This we will describe in a succeeding number.

Whether the photographer elects to make his own collodion or not, we should certainly recommend him to purchase his soluble cotton ready prepared, for, although there is no difficulty in making it, yet is there a certain amount of messiness with it, and this is the more objectionable when it is considered that the messiness arises from very strong acid mixtures. Besides, experienced makers are familiar with the properties induced by varying the specific gravity of the acids employed in conjunction with a variation of temperature, and such experience counts for very much. In what follows, we shall, however, and with a view to making these articles complete, give such directions as will enable any one to make his own pyroxiline without failure.

PHOTOGRAPHING ICE-CRYSTALS.

At a time when every photographer is on the *qui vive* for something new, it will not be unacceptable if we draw attention to a class of phenomena which, when successfully photographed, would make some exquisitively beautiful negative, interesting to every one, and especially so to scientific students. If any reader will refer to the first volume of that invaluable series of scientific works, *The International Scientific Series*, he will note that it is by the great physical investigator whose loss we have all so recently deplored—Professor Tyndall—and, turning over its pages, he will be struck with a set of illustrations depicting a few of the beautiful geometric forms which water when converted into snow so frequently assumes. These particular figures are from originals drawn by hand; but, if photography and the microscope were pressed into use, an endless variety of shapes could be reproduced with facility and fidelity, and a record as unique as beautiful obtained.

It is possible that there are many of our readers who have never seen a snow crystal: to all such we say, do not lose another opportunity of making acquaintance with some of the most beautiful objects to be seen in inanimate nature. We should here say that it is not in all snow showers that the crystals can be readily distinguished. Those downfalls in which large flakes descend in the semblance of feathers, though exhibiting traces of crystalline form, are useless for the purpose; but, when the air is very cold and less moist than usual, and the first snow makes its appearance as a coarse dust, we are certain to meet with the objects of our quest. Let a few of the small flakes fall upon a piece of dark-coloured cloth—nothing is better than holding out one's arm to receive the particles on the coat-sleeve—and then let them be closely examined. The tiny flakes will be found to consist of most beautifully shaped flat tablets of ice crystals all formed upon an hexagonal basis, but varying in a wonderful way, from a simple geometrical form to an intricate feather upon feather with six-rayed radiations.

It is not possible to describe them; they must be sought and admired, and of course in the cold, for it is scarcely needful to say their stability is as slight as their beauty is great when brought into a temperature above freezing. It will at once be said, How is the photographing to be carried out? Fortunately a reply can be given, for we read that a Russian professional photographer, Mr. A. Sigson, has already been in the field, and, in the *Journal of Russian Physico-Chemical Society* described his method of procedure. Naturally the first difficulty would be the placing of the crystals to be photographed in the field of the microscope, and this Mr. Sigson performs in a very ingenious manner. He makes an aperture in a piece of cardboard, and across it places a slight network of silk fibre, just as taken from the cocoon. This forms the "bed" for the crystals which are placed upon it, after being first collected on a piece of rough cloth. The apparatus used is a Zeiss microscope, fitted with an apochromatic lens, and connected with a long-focus camera. The card was placed as the stage of the microscope, illuminated in such a way that half the field was uniformly illuminated and the other half shaded off. Of course the stage of the microscope at least would need to be kept cold—no difficulty in Russia, but needing some little contriving in the proximity of dwelling-houses in this country. Mr. Sigson, however, had to make provision against failure through the heat of his breath melting the crystal; this he did by breaking through a pipe bent away from the microscope while he was adjusting the apparatus. The exposure needed for an enlargement of fifteen diameters was from two to five seconds only, his microscope being placed in an attic window at a strong inclination to the horizon.

It is quite evident that with one single crystal considerable variety of effect would be obtainable by varying the mode of illumination—light transmitted or reflected at various angles. We should like to suggest that, if a suitable power of objective were chosen, it would not be impossible to obtain stereoscopic photo-micrographs following the indications in our article referring to that subject in the pages of The British Journal Photographic Almanac [p. 597, *et seq.*]. It is true the crystals are mainly flat; but they possess some measurable thickness, and seen stereoscopically they would present an absolutely novel aspect such as no human eye had ever before seen. Such a mode of photographing them would give interesting and pretty pictures from clusters of partially formed or broken crystals, for, rendered in stereoscopic projection, every minute ray or particle would assist the charm though taken non-stereoscopically, and as a flat object, the absolute precision of a complete geometrical structure, though in fairylike forms, would be needful. In conclusion, we may say that, if any of our readers follow out the suggestion we have made, we trust that they will send us prints of their reproductions of what we confidently assert are some of the most fascinatingly beautiful objects to be found in inanimate nature.

THE IMPROVEMENT OF NEGATIVES.

There are many of our readers who take a sufficiently lively interest in the quality of their work to travel beyond the ordinary every-day routine, if by so doing there appears to be a chance of securing an adequate return; and in no direction, perhaps, is there a better opportunity of effecting this than in the modification and improvement of hand-camera negatives.

Such negatives as a class are only too frequently, from the very nature of the conditions under which they are taken, defective both in definition and gradation: in the first respect, either by reason of too great a strain having been put upon the capabilities of the lens, or in consequence of the movement of some of the objects depicted; and, in the second, from insufficiency of exposure. From one or all of these causes it may be said that the vast majority of hand-camera negatives suffer; and, such being the case, they cannot fail to raise feelings of regret in the mind of the ordinary careful worker who is capable of better things when the circumstances are more favourable.

But nothing is easier than to remedy this state of affairs by the expenditure of a moderate amount of trouble and some little skill. In applying the latter term, we do not refer to the trained technical skill of the artist or retoucher, though these, of course, will add greatly to the final effect attained, but simply to the exhibition of a little common sense and such manipulative dexterity as the most ordinarily gifted amongst us may possess.

Some years ago there appeared, at several of the Exhibitions, a series of instantaneous pictures of small size, but of such technical excellence, and, above all, perfect sharpness, although depicting objects in very rapid motion, that general attention was attracted to them; and, on inquiry, the information was elicited, although it was never distinctly acknowledged, that the result was due to a peculiar method of improvement

applied to the original negatives, or, more correctly speaking, to their reproduction in an improved form.

From the originals a series of slightly enlarged positives were first made, and, after these had been carefully worked up, in this case by a skilful artist, they were rephotographed on the original scale, with the result, as has been stated, that they attracted general attention. Only recently we were shown a number of hand-camera pictures which owed their remarkable quality to very similar treatment, and these were the sole work of an amateur who is utterly devoid of any trained manipulative skill with either brush or pencil.

It is needless to say that we should not consider such sophisticated work as eligible for exhibition in competition with pure photography. But that is not the present question. We are not advising this course of treatment to the army of exhibitors and medal-hunters, who, by the way, would be only too ready to "drop upon" any such cases of "faking," to use the vulgar term; but where, for his own satisfaction, the amateur desires to obtain the best possible results that are within his power, we hold that the end justifies the means, and no injustice is done to anybody.

At the present day every facility is afforded for the ready execution of this kind of work, the only materials required beyond those found in every amateur's regular stock being a few sheets of bromide paper, and some simple means of enlarging up to two, or, at most, three diameters. This is perhaps the most important point in connexion with the process, namely, the small degree of enlargement. What is required is just such an amplification as will permit of the easy touching in of details, without raising the necessity for work on an extensive scale. For the purpose, in fact, of quarter-plates, the degree of enlargement need not be more than two diameters; or, in other words, up to the whole plate, or, at the very outside, the ordinary $12\frac{1}{2} \times 10\frac{1}{2}$ size should not be exceeded.

So far as the process of enlargement itself is concerned, it is to be borne in mind that the expectation is not to obtain a perfect enlargement as such, but to obtain as good as possible a basis upon which to work with pencil, brush, crayon, scraper, or whatever means may be selected or may be most suitable. Under these circumstances, no very elaborate arrangement is necessary; indeed, the simpler it is, perhaps the better, and, to illustrate how exceedingly simple it may be, we cannot do better than describe the plan adopted by the amateur to whose work we have alluded.

The enlarging camera consisted of an empty box or packing-case, in conjunction with which was used a small quarter-plate sliding body portrait camera, carrying a five-inch focus single lens. The packing-case was fixed on end on a solid baseboard, with the lid at the back, and a hole cut in the centre of the bottom, through which the enlarging lens was pointed. The sides of the box were cut down until the lid, which was to carry the sensitive paper, was about ten inches from the aperture. A short shelf or bracket was placed outside the aperture upon which to stand the small camera, with its lens pointing into the box, a sleeve of black calico serving to shut out any extraneous light. The focussing glass was removed from its frame, which then became the negative-holder.

Before removing the focussing glass, however, a sheet of printed paper was pinned on to the lid of the larger box in the position to be occupied by the sensitive paper, and, a candle being shut up in the box, by its light the printed paper was focussed upon the ground glass, which was thus made to occupy the position in which the negative would be in correct focus, and, this point having been found, the camera was fixed in that position, as no necessity existed for varying it.

The enlargements were made by artificial light, a couple of duplex paraffin lamps being used, the light reflected from a screen of white cardboard. The sensitive paper was pinned in position before lighting up, the box closed, and the negative holder covered with an opaque cloth, until the lamps and screen were in position, when the exposure was made by simply lifting the cloth for the necessary time.

With this simple contrivance every requirement was perfectly fulfilled, and, given a more suitable lens for enlarging, the same arrangement would answer equally well as a permanent enlarging camera where no other exists.

The size of the enlarged positives was whole-plate, a smooth-surfaced paper being selected. The development was effected with hydroquinone, as giving a blacker tone and one more easily matched in the deep shadows with Indian ink, and in the lighter shades with crayon and lead pencil respectively, according to the depth required.

Speaking of this part of the business, it would seem that the services of an artist would be indispensable; but, as we have already stated, the "artist" in this case was entirely untrained, and, as he himself described it, "could not draw a man's hat to save his life." But the work required is not, after all, of a very difficult description. It consists chiefly in strengthening or filling in weak or defective outlines, adding to the depth of weak shadows, or, it may be, lightening those which are too heavy. The last proves the most difficult, the mere tracing in of outlines with pencil or crayon requiring little skill beyond that represented by carefulness. Deepening the shadows was done sometimes with washes of Indian ink, but preferably with black crayon, and the reverse was effected by the simple process of rubbing down with "ink-eraser," assisted with white chalk.

The methods adopted were certainly crude and primitive, but the result showed what could be effected even by one whose artistic capabilities do not extend beyond the exercise of a little common sense. In the hands of a trained, or even partially trained, artist the results obtainable would be proportionately better, and, when the "game is worth the candle," the labour is not ill-spent.

When the enlarged positive has been completed, it should be examined critically to see that none of the additions exhibit too strong contrast, either in depth of colour or sharpness. It is not quite easy to judge at first by the eye alone, and the photographer will often show up defects in this respect that have not previously been detected. However they are easily modified when recognised, and only cost another quarter-plate. Particular care must be given to the direction of the light used in rephotographing the enlargement, owing to the different surfaces displayed by the various media employed; but, if this be seen to, and proper harmony exist between the additions, the reproduced negative will not be distinguishable from one taken direct.

There are many instances where it is impossible to otherwise reproduce a defective negative in which this process will prove useful.

Portrait Clubs and Agents.—In an evening contemporary that devotes a column to "Notes and Queries," one of its correspondents says he joined a portrait club, and paid the amount (12*s.* 6*d.*) by weekly instalments of one shilling, completing the payments in

July, 1890. He now complains that he can get neither his portrait nor the money back, the photographers telling him that he must settle it with the agent, while the latter keeps putting him off. He wants to know how to act. Is this kind of thing at all common in portrait clubs? We have certainly heard of such cases before. It is this sort of thing that has tended, during the past few years, to lower the status of photography in the eyes of the public.

Popularising Art.—If one thing more than another conduces to popularise art among the masses, it is the bringing it before them in a recreative form. Just now, at one of the London Theatres of Varieties, a most attractive feature of the entertainment is a series of "Tableaux Vivants" depicting pictures by well-known artists. The works selected for the purpose are principally those with which the public have become so familiar through the photographs of them to be seen in the shop windows and in their own collections of "scrap' pictures. Seeing the favour with which these depictions of modern works of art are received, one cannot help surmising that, if lantern slides of the same subjects and of the same excellence were obtainable, they would command a ready sale, and would be extensively utilised in lantern entertainments. One reason why they are not in the market probably is, that on the Continent, where the larger proportion of these fine reproductions are made, the lantern has not obtained the same status and popularity that it has here. Amateur photography has mainly made the lantern what it is here, and amateur photography is not so much practised abroad as it is at home. "So much the better," remarks a professional friend.

Chromo-photography and Fugitive Pigments.—The specimen presentation prints of some of the illustrated papers, with their Christmas numbers, that are being shown at strongly lighted railway book stalls and in shop windows, again call prominently to mind, what we have before alluded to, that fugitive pigments are still frequently employed in the printing. In order to get effects that will please the general public, brilliant colours have to be introduced, and it so happens that those which are most suitable, on account of price and facility in working, are of an evanescent character when exposed to a strong light. Hence the marked change that some of these prints have undergone during the short time they have been exhibited. Just now a great deal of attention is being given to chromo-photography, in which transparent colours are necessary, and it is to be hoped that their permanency will receive consideration We are quite aware that it is much easier and less costly to make one or two of the tints required with fugitive pigments than with permanent ones. But that should not weigh with a new process, particularly when it is likely to prove of real commercial value.

Defective Colour Vision.—The annual report of the Marine Department, Board of Trade, on Examination in Colours for the year ended May 31, 1893, has just been issued. It shows that, although the number presenting themselves for examination for master and mates' certificates was less than last year, the number rejected for their inability to distinguish colours was greater. Pink, green, bottle-green, and drab seem to have been the most difficult for the candidates. With the cards, drab was in twenty-seven cases, out of the thirty-five persons rejected, mistaken for green, and seventeen mistook pink for green also. For some time past dissatisfaction has been expressed as to the system of testing, and in the report for last year it was mentioned that the Board of Trade had under consideration the important recommendations contained in the report of the Committee of the Royal Society on Colour Vision. This year it is announced that the Board have the matter still under consideration, and will establish "an entirely new system of examination as soon as the necessary arrangements can be completed." Defective colour vision is not unknown amongst photographers, and some suffer from it without being aware of the fact. This may account for the circumstance that some people cannot possibly tone a batch of prints all to the same colour.

Residues.—At the time when silver was nearly double the price it is now, and residues contained twice as much, or more, of the precious metals than they do at the present time photographers took very little heed of their wastes. They sent them to the refiner at odd times and were generally content with the return made. Now the residues—probably the depression in trade has something to do with it—are considered an important item, notwithstanding the depreciation in the value of silver and the fact that, however carefully collected, they cannot possibly be anything like half as rich in silver as they were when the paper was sensitised at home on strong solutions. In anticipation of the annual Christmas collection, we have already had several inquiries from correspondents as to the proportionate amount they ought to expect from the residues of gelatino-chloride printing-out paper as compared with those from albumen paper; some evidently expecting more. Now, it is quite impossible to answer such a question, inasmuch as the different gelatine papers in the market do not all contain the same amount of silver and neither do albumen papers. The only way to arrive at the correct value of the wastes is to burn the papers, and dry the other residues, then reduce the whole to a fine powder and pass through a coarse sieve. It can then be easily assayed, or, if sent to a respectable refiner, its full value may be ensured. No correct or even a rough estimate of the value of residues can be formed when they are sent away in the state they frequently are, and an unscrupulous refiner would be aware of that fact.

IS CELLULOID TRUSTWORTHY?

In your leading article two weeks ago you dealt with the question as to whether celluloid must necessarily deteriorate, and apparently come to the conclusion that it does not. But I think we may go further, and assert that, so far from deteriorating, it actually improves with age, and that Messrs. Guiterman's cry of alarm deals with a purely imaginary danger.

You point out in your article that pyroxyline naturally gives off nitrous fumes, more especially if confined in air-tight vessels—stoppered bottles, for instance—in which case, in the course of a few months, it will entirely alter its character, and eventually arrive at a semi-plastic condition, but I have never known it show any signs of "spontaneous combustion." If kept loosely in paper, the vapours escape as they are formed, and, though the wrapping-paper may be rotted, the pyroxyline itself does not appear to undergo any change.

That is the case with pyroxyline in the "raw" state; but what about collodion films—that is to say, pyroxyline after it has been dissolved and dried? It does not seem that the tendency to acidity is nearly as great under those circumstances, if, indeed, it exist at all at ordinary temperatures. No evidence exists, that I am aware of, that our negative films give off any acid emanations, nor, in the case of collodionised prints, are we accustomed to expect any such behaviour. A film of collodion, spread upon the surface of an albumen print, is supposed to add to its permanency; but surely, if that collodion film was constantly giving off dangerous nitrous fumes, the reverse would be the case.

But a very remarkable instance came under my notice a few weeks' ago of the permanency of thin collodion films, and, now that the question has arisen, an apparent proof of the absence of any evolution of nitrous fumes. I found accidentally, between the pages of a book, where it had lain since very shortly after the publication of the specification in 1864, a piece of carbon "tissue," made according to Swan's original process, and consisting, as some at least of my readers are aware, of a film of pigmented gelatine, supported on one of collodion.

Now, although that morsel of tissue has been for nine-and-twenty years pressed closely in contact with the pages of that book, there is not the slightest symptom of any rotting action, such as occurs when raw pyroxyline remains for any length of time in contact with paper. I have purposely turned up the page to re-examine; but, beyond a faint stain of bichromate, the paper is quite unchanged.

I forget the precise details of the mode of preparation of that tissue, whether, in fact, the collodion film was washed previous to

applying the gelatine, or simply dried, but I rather think the former, in which case the pyroxyline might be supposed to be left in a purer condition than before solution; still that provides no reason for any diminution in the tendency to decomposition, unless we imagine, as some of the early experimentalists into the composition of gun-cotton have done, that in the process of solution, to form collodion, and more particularly in washing or precipitation, it forms compounds, notably a hydrate, that are more stable than the original substance itself.

In another instance I shall mention there is every reason to believe that some such change, accompanied by a decided diminution in the tendency to give off acid, does occur. In 1877 the French Photographic Society awarded a prize to M. Chardon for a washed collodion emulsion process, one of the principal points in connexion with which was the employment of pyroxyline that had been already converted into collodion and reprecipitated with water. This precipitated "cotton" was of two kinds, called by M. Chardon "pulverulent" and "resistant" respectively, the one being thrown down with hot, the other with cold, water, and both presenting the appearance of fine flocks or coarse powder, and resembling, except in feel, pure tapioca.

For many years I had, amongst other samples of pyroxyline and papyroxyline, several packets of these precipitated products, some of my own preparation and two forwarded to me from Paris. The peculiarity I wish to notice is that when, some four or five years ago, I came to overhaul these old specimens, the only ones that did not necessitate repacking, owing to the rotting of the wrapping-papers, were those that had been precipitated, and which might, therefore, be presumed to have undergone a change.

On the other hand, I have often noticed in connexion with collodion pellicle in the dry state—that is to say, the mixture of pyroxyline and bromide of silver freed from soluble matter by washing—not only strong evidence of corrosive action, but also a palpable smell which might be bromine or nitrous acid, or both, showing that in this instance washing does not remove the tendency to change; nor, indeed, does it in the case of dry-collodion films when spread upon glass, as is shown by the gradual destruction of the undeveloped image by time. To counteract this, Mr. Warnerke proposed to impregnate the film with an alkali in order to neutralise the acid given off.

What is true of collodion films seems to be equally so of celluloid, for, so far as I can see in connexion with any samples that I have had access to, whether in the shape of films or the more solid form, there appears to be no appreciable acidity. The experiment with the hot iron quoted by Messrs. Guiterman & Co. serves only to demonstrate some slight difference between two samples of different manufacture, but has no practical importance, since, as a matter of fact, we do not habitually heat our negatives to 240° or 250° Fahr., and it is open to very serious question whether such treatment is equivalent to an "anticipation of the action of time."

I have not tried the experiment with blue blotting-paper, either at the normal or higher temperature, but I have in my possession negatives taken on some of the earliest celluloid films sent out four or five years ago, as well as samples of the uncoated films. These have all been kept, with the exception of a few cut stripe which have been loose in a box between the leaves of a book; but there is yet no symptom of any acid reaction, and, if the films will keep perfectly for that period, they are as likely as not to keep indefinitely.

I suggested at the outset of this article that celluloid films most probably improve with age, and I base this supposition partly on the fact that, whereas when these samples first came into my hands they were freely soluble in methylated spirit at the ordinary temperature, they are now insoluble even when heated. This is equally the case with the portions that have been kept loose and those preserved in a book, but the former have entirely lost their original odour of camphor, and the latter nearly so, so that, as the camphor volatilises with time, the celluloid actually becomes more permanent.

It is, perhaps, not straining a point too far to suppose that a similar result would accrue from the gradual evolution of nitrous acid, for, as is well known, gun-cotton in any form loses its solubility as it becomes de-nitrated, and, consequently, in the form of a film less liable to injury. That the presence of acid in excess is not a desirable adjunct is quite true, but that it is so serious a danger as Messrs Guiterman would have us believe I cannot think. In the free state it is easily dealt with, while that held in combination is given off so gradually, that if the films be properly stored it need cause no trouble or uneasiness. The very process of development, in fact, tends to aid in the de-nitration, and, judging from the action of alkalis upon pyroxyline and collodion, I do not imagine it would be difficult to eliminate the last traces of acid, and render the films quite insoluble if so desired.

In conclusion, if my most valuable negatives were on celluloid instead of glass, I should stand in no further doubt of their permanency than I do at present.

W. B. Bolton.

JOTTINGS.

There should be "cakes and ale" in York-street just now, for I see that the 1894 Almanac has reached the prodigious size of 1336 pages. My best congratulations to Editor and publishers. Apart from its great value to all connected with photography, in either a commercial or a manipulative sense, I can conceive that the Almanac may have other uses just as interesting, if scarcely so peaceful. "Bill, who's that bloke?" "Stranger." "Then heave (half) a brick at him." The Almanac would form a capital substitute for the Black Countryman's missile of endearment.

Mention of the Almanac reminds me that I have attained the overpowering honour of being "named" in its pages. I am accused of unfair criticism. Here are the circumstances. On August 18 last I remarked, *àpropos* of the Photographic Convention, the Photographic Congress, the Camera Club Conference, &c., and the diffuseness and verbosity of individuals studying photography in its scientific aspects, that there was too much "talkee-talkee" in photography. Four months afterwards Mr. Snowden Ward publishes in the Almanac (at page 655) an account of an International Bureau of Photography, of which he is chairman, and of the existence of which I was ignorant until reading his article. In the course of this he says: "We want all the helpful criticism and all the suggestions possible, but we protest against the unfair criticism that is found, in one of its mild forms, in the recent writings of 'Cosmos.' He condemns us for talking and not working." I invite Mr. Ward to explain how, on August 18, I could unfairly criticise and condemn a scheme which, so far as I knew or cared, was not then in existence.

Mr. Ward's article, like most of Mr. Ward's writings, is well worth reading, if only on account of the refreshing optimism pervading it. In the last regard he is an object of my sincerest envy. I am myself an incurable pessimist, and therefore, am constitutionally unable to look upon men and things through rose-tinted spectacles. It is not my fault; I was born like it. The objects of the International Bureau are (1) "To secure the official recognition of photography by the governments, local as well as central, of all civilised nations." If official recognition of photography by the Government will better the lot of the individual photographer, and ensure plenty of auriferous deposit in his Button Park, I extend my benediction to Object I; but I fail to see how it will. Object 2 "is to secure the establishment of national depositories for the receptions and care of photographs, and especially negatives, of literary, historical, or scientific value," and I hope it may, but shall be agreeably surprised if it does. Object 3 "is to establish an International Bureau for the exchange of prints and other reproductions of negatives in the national depositories, and to enable colleges, museums, and students to obtain photographic records from every land," which is a charming dream, and in all probability will never crystallise into a solid reality. There is no harm in sighing for the millennium; but some of us, even at the risk of being scolded for not joining in the chorus, may reasonably be allowed to doubt whether such a thing will ever take place while human nature remains what it is.

The battle of the printing papers is waging with apparently as much vigour as in the old days when platinum *versus* bromide was the

question of the hour. I observe that two matt-surface print-out papers and a print-out platinum paper are on the point of introduction. With these and developed platinum bromide, carbon, albumen, and the new school of rough surfaces, there is something to suit all tastes and styles. The more tastes and the more styles there are the better, say I. They certainly relieve positive printing of the danger of monotony, at any rate.

Some plain truths were uttered at the meeting of the National Association of Professional Photographers on November 10, and reported at page 738. The profession is admittedly in a bad way, but the fault, as was pointed out, rests chiefly with photographers themselves. Mr. T. Birtles, of Warrington, hit the right nail on the head with plain common-sense directness seldom encountered at meetings of this sort. "It had been said" (he remarked) "that the public undervalued photographers' work. Well, he thought the public took them at their own prices, and if photographers sold work at low prices they had only themselves to blame." True for you, brother Birtles; would that there were more of your stamp in the profession. Upon my word, professional photography would appear to be a last refuge for men whose business capacity is of the very lowest order. At the meeting in question photographers were urged to take up process work as a means of improving business. I echo the advice. The fact is, at the present moment there is a large amount of photographic work of many kinds being done all over the country by people who are not photographers, and the profession, as a whole, is at the loss. The more's the pity.

Friends, Rum'uns, Countrymen, and Brothers, A Merry Christmas to you all. To those of you who are professionals I will also say, May your shadows never grow less. You know the kind of shadows I mean, of course. To those of you who are amateurs, I say, Go forth and multiply. To all those in photography whom it may concern, I wish whatever they may wish themselves! [N.B. Please pack all hampers carefully, address them legibly, and prepay carriage.]

COSMOS.

THE LUMIÈRE-LIPPMANN COLOUR PHOTOGRAPHY.

[Photographic Society of Philadelphia.]

IN the spring of 1882 there were exhibited in the Photographic Exhibition in the Champs de Mars, in Paris, photographs by the Lippmann process of a parrot, a branch of holly, pieces of coloured glass, &c., which Alphonse Berget and others declared were true reproductions of the colours of the objects. I could see in these photographs only the colours of thin films, metallic and changeable as such colours usually are, and, in some instances, not even confined to the coloured objects themselves, but spreading over objects that were uncoloured in the original. These pictures were also devoid of either whites or blacks, the high lights of the objects being rendered more like black than the shadows. Others, notably Mr. Cameron Swan, who wrote a letter on the subject to the *Times*, noticed the same defects in these photographs, and Captain Abney, who had experimented with the process, found that, by varying the time of exposure, he was able to make a blue photograph with red light, and *vice versâ*, and coloured photographs with white light. It was generally admitted that the results obtained by Professor Lippmann did not sustain the claims made for the process, and when it was announced this year that the brothers Lumière had succeeded in so far improving upon Lippmann's method as to obtain really satisfactory colour photographs of natural landscapes, people who had seen the photographs for which such extravagant and inaccurate claims were made a year before were naturally, and very justly, sceptical.

Now, however, the Lumière photographs have been shown in public in London, and, although there is still a certain amount of mystery surrounding them, it is possible to form a truer estimate of their character and importance, and to make an intelligent comparison with another and more successful method, based upon quite different scientific principles.

The Lumière photographs are about three inches square, and by light reflected from their surface at most angles they have much the same appearance as the French albumen process lantern positives, the high lights of the picture looking like clear glass, and the shadows having the appearance of an albumen or gelatine film filled up with a dense, dark-coloured deposit of silver. It is said that by transparency they are negative images, but those shown are sealed up so that they cannot be examined by transmitted light.

Unlike Lippmann's photographs, these examples show colour only when the light is reflected from the surface at one particular angle, and for that reason the colours are not "changeable." This in itself is really a very important improvement, although it carries us farther away from, instead of nearer to, the popularly desired conditions in colour photography. It is, indeed, a significant fact that real and undoubted improvement intensifies instead of lessening a characteristic defect of the original Lippmann photographs, which some writers have not hesitated to say would "undoubtedly" be overcome—namely, the inability to see the colours at all angles.

If the pictures were uncovered the critical angle would, undoubtedly, be perpendicular to the surface of the plate, but it would then be necessary to provide some means for illumination and vision in precisely the same direction. It is also necessary that the source of light be large enough to illuminate the entire surface of the photograph equally with parallel rays, and it should be seen by parallel rays coming from it. A rough approximation to these conditions is secured by covering the picture with a shallow prism, and then examining it by the reflected light of a sufficient expanse of even white or grey sky, holding the picture at nearly arm's length from the eye. More satisfactory results could doubtless be obtained by means of a special device, which could be used like the stereoscope or the photo-chromoscope. It would be quite easy in this way to exactly fulfil the theoretical requirements for illumination and vision, and, at the same time, to magnify the picture, which must now be made to occupy only a very small angle of vision in order to be seen all at once.

The pictures are also projected upon a screen by means of the megascope or aphengescope lantern, and, in the absence of a special device for examining them by daylight, this is the only really satisfactory way of seeing them. It is, however, necessary to employ a powerful electric arc light in order to project them with satisfactory brilliancy up to even two feet diameter, as compared with ten feet, or twenty-five times greater area, for the photo-chromoscope pictures with the same light.

Seven pictures were shown at the Photographic Congress and at the Camera Club; four landscapes, two portraits with accessories, and one reproduction of a chromo-lithograph—a rather poor result, the original of which was not shown. Unlike Lippmann's photographs, they rendered the deepest shadows black and the high lights white, and showed many delicate shades of colour, which impressed the spectators as being something more than the ordinary colours of thin films. One of the landscapes was beautiful, although the foliage appeared to be that of autumn, while it was understood that the photograph had been made in early summer. In parts of some the chlorophyll green was fairly well represented, but in others, where autumn foliage was not suggested, the green was raw and metallic. The red of a tile roof looked dull and faded, the blues of the skies were criticised by some of the spectators, and the flesh in the portraits had an unnatural purplish hue; but, in my opinion, these defects are only such as one ought to expect from the manner in which the process was carried out, even assuming that it be really capable of making accurate colour reproductions if carried out in a thoroughly rational manner. From a theoretical point of view (and it follows, from a practical point of view), it is not reasonable to expect that a mixed colour like chlorophyll green will be accurately reproduced on a plate not sensitive into the red of the spectrum below the first absorption band of chlorophyll, or which is disproportionately sensitive to that red as compared to the sensitiveness to green. In the first place, the green rays only would act in producing the picture, resulting in a raw, metallic colour, and, in the other case, the red rays would act too much or the green too little, and result in a brown or red hue suggestive of autumn tints. Flesh colour, if the plate is disproportionately sensitive to blue, and not sufficiently corrected by yellow screen, must take on a purplish hue; or, if over corrected by yellow screen, a yellow hue must result. It follows that the plates must not only be sensitive to all colours, but the sensitiveness must be properly distributed along the spectrum, or, what amounts to the same thing, must be modified by the use of a quantitatively selective colour screen made up and adjusted by experiment in photographing the spectrum itself, just as I have for years made selective colour screens for carrying out the photo-chromoscope process and for orthochromatic photography, until the spectrum photographs correspond to the spectrum itself in the relative visual intensity of the different colours. Until this is done, it is not reasonable to expect that delicate shades of compound colours will be accurately reproduced by any process. It would appear from this that by no evident possibility can this method ever possess any advantage over

the photo-chromoscope process in the matter of accuracy, because in both cases it depends (admitting every possibility for the Lumière-Lippmann process) upon the relation of sensitive plates and colour screens, which must be regulated in the same way for both processes.

One of the most remarkable things about this Lumière process is its rendering of blacks and whites. According to Lippmann's theory, the blacks would be rendered by clear glass, and the whites by a film filled up with laminæ of deposit which would reflect light of every wave-length. In short, the greatest amount of deposit and opacity would be in the whites, and the smallest amount in the blacks of the picture, as in an ordinary photographic negative. I have already observed that the Lumière photographs, when seen by ordinary reflection, resemble a positive instead of a negative. It is further remarkable that the greatest amount of light reflected from these photographs comes from the parts which look like clear glass, and that even this amount, which makes the whites of the picture, is only equal to the reflection from a black glass, or the surface of the gelatine film itself. The shadows appear black, not because there is no deposit there (in which case the deepest shadows of the picture would be as "white" as the high lights in the examples shown), but because the glass is obscured by a deposit so thick and matt that it scatters the light striking upon it, instead of reflecting it straight back at the critical angle. In other words, we appear to have a positive where we are told that there is a negative; if this be true, is the positive the result of a "reversal" of the image by the long exposure; and, if so, is this reversal one of the conditions of success?

Does not this image, built up by photographic action upon the sensitive plate, act by a process of subtraction from the white light, which would otherwise be reflected from all parts of its surface alike, instead of by reflection from internal laminæ in the manner assumed by Lippmann?

Lippmann's theory, as I understand it, calls for a different series of lamiuæ within the film for every wave-length of light, amounting, where white light acts, to over 30,000 laminæ in a film no thicker than a single wave-length of red light! Would not such a series of laminæ in a film reflect a great deal of light instead of adding nothing whatever to the normal reflection from its surface, which is all we appear to have in the examples shown? Cannot every colour actually shown in the Lumière photographs be reproduced by means of a single interference film of varying thickness, backed up or broken by a granular deposit of varying density? Have we anything more than this in the Lumière photographs?

It seems reasonable to suppose that the long exposure given to these pictures would produce a reversal of the image. The dense deposit in the shadows might result from the action of scattered light in the camera, or to preliminary exposure, or to the use of a too active developer, or to any or all of these causes combined. May we not be given an opportunity to learn the truth, in order either to prove Lippmann's theory, or to formulate a new and more rational one?

At first glance it might appear that an examination of the Lumière photographs by transmitted light, might yield an answer to all of my questions, by showing that the image is really a negative one; but it is not even necessary, in order to explain the "whites" of these pictures, to assume that the image is positive throughout, but only that there is a superficial reversal, just sufficient to prevent the production, in development, of a deposit superficial enough to obscure the normal surface reflection of the gelatine film.

I have some hesitation in putting forth views which a more thorough examination of the Lumière photographs might lead me to modify; but since such examination is forbidden, I can only hope that the questions which I raise may help to bring about such a thorough investigation of the subject as its importance demands.

In conclusion, it is worthy of note that the Lumière-Lippmann process, whatever its capabilities as to accuracy may prove to be, when it is carried out according to theoretical requirements, is necessarily subject to limitations similar to, and in some respects greater, than the already successful photo-chromoscope process, which is carried out with commercial sensitive plates and ordinary development. Knowledge of this fact, which cannot be gainsaid, will doubtless lead many people to take an active interest in the friendly rivalry which promises to attend the further development and application of the two methods.

F. E. Ives.

THE SPEED OF PLATES: A CRITICISM AND A REPLY.*

He then proceeds to fall foul of the "law of error" formula, and here it would seem that Dr. Hurter misses the whole point and use of an approximate formula. It is claimed for the law of error formula that it gives an expression which fits the curve actually drawn from measurements on the plate, through that range of transparencies which is of use to the photographer. Dr. Hurter complains that, plotted according to his method, the law of error formula gives a parabola. This is certainly no valid objection, for can a parabola or a straight line be drawn through the greater number of fixed points? If, as is acknowledged, the parabola, is it not true that a parabola can be made to fit closer to a given curve than a straight line? Dr. Hurter's straight line gives a point in the diagram which, according to him, fixes the speed of a plate. Abney's parabola also gives a point (its vertex) which depends solely on the plate and its treatment, and may be made just as well as, and probably better than, any other to represent the speed of the plate. It has already been shown that Abney's curve deduces the number representing the speed from a practically useful set of exposures, while Hurter & Driffield's does not. It is only necessary to draw the curves to see that Abney's calculated curve fits that drawn from observation far closer than Hurter & Driffield's. In fact, this is shown in the diagram produced by Dr. Hurter at the discussion of Abney's paper, although the case is an unfavourable one for the latter author's method.

Having once started, however, on the discussion of Dr. Hurter's arguments in reply to Abney's paper, one could go on refuting them almost to eternity. No one would accuse the doctor of intentional unfairness, yet many of his arguments are unfair in the extreme, For example, in one place he asserts that, it being allowed that, plotted in a certain way, the law of error gives rise to a parabola. Captain Abney proceeds to prove that this curve does not differ much, from a straight line. Surely no unbiassed person would deduce this from Abney's paper. What he does in effect say is, that, as plotted by his method, the curve of transparencies has a point of inflexion, and it is known to every tyro in mathematics that in the neighbourhood of a point of inflexion a curve does not differ appreciably from a straight line.

There is no need to discuss Dr. Hurter's demonstration of the conditions of photographic truth. These may be discovered more easily without the use of any elaborate functional equation. It may, however, be noted in passing that, unless the printer has maligned him, Dr. Hurter's solution of the functional equation is, to say the least, incomplete. Besides, it has been pointed out above that Dr. Hurter's own method of speed determination is far less in accord with the conditions for photographic truth, as laid down by him, than the law of error formula. It is necessary to point out that the equation for density thus derived is not in accordance with the equation called "the approximate equation" in the paper entitled *Photo-chemical Investigations*. There is a factor required, which is of importance, since the equation is a logarithmic one.

It would be too wearisome to hunt down the whole of the errors and confusions in Dr. Hurter's criticism to the bitter end. He looks on Abney's method with a jaundiced eye, and is consequently unable to see any good in it. One great point in the method is that the measurement of speed depends solely on observation, and not on any assumption of the law of error or any other law, though the full interpretation of the number obtained, no doubt, requires such an assumption. Yet Dr. Hurter says, "We, therefore, depend entirely upon the law of error. If that be true, the rapidity by means of it may be true also. If it be false, the rapidity may be erroneous." Surely this is prejudice pure and simple!

Dr. Hurter does not in the least seem to realise what is meant by "determination of speed." As has already been shown, a rough number only can be assigned, and this cannot be an absolute quantity, since it depends on the unit of speed chosen. All that can be done is to roughly decide the relative speed of two plates. We have no absolute unit of photographic speed to work in, but we can easily say that a rapid dry plate is about thirty times as fast as a certain wet plate. It is as if we had no measure of length. Then we should be unable to say that A could walk four miles an hour, because there would be no miles; but there would be no difficulty in deciding that B could run just twice as fast as A could walk.

It appears from his criticism that Dr. Hurter thinks that both his number and Abney's are numbers representing the speed of a plate in absolute units, and he gives much trouble to the task of showing that the numbers obtained by the two methods are so different that Abney's method makes a certain plate out eleven times as fast as Hurter & Driffield's. All this is, of course, a pure misconception. All that the law of error does is to give a method of roughly comparing the speed of two plates under similar circumstances, and all that Hurter & Driffield's method does is exactly the same thing, with the difference that the quantities compared do not necessarily in the least represent the speed of the plate as used in practice.

There is yet another fact, however, which has a serious bearing

* Concluded from page 787.

upon all the work that has been done in the matter of speed determination. In a paper presented to the Royal Society in the early part of the present year, Capt. Abney proved that the assumption hitherto made by all photographers, himself among the number, was untrue, viz., the assumption that the effective exposure was proportional to the intensity of the light multiplied by the time of exposure. If this were true, we should find that, if two patches on a plate were exposed, one at 1 foot from a candle for $\frac{1}{10}$ of a second, and one at 10 feet from the same candle for 10 seconds, they would be indistinguishable on development. This, however, is very far from being the case, and this discovery seriously affects the accuracy of all Hurter & Driffield's work, since they made their exposures by means of a standard candle, the distance of which from the plate was varied as well as the time of exposure. The discovery no doubt affects Abney's measurements and those of the writer. But, so far as those made by means of a Spurge's sensitometer are concerned—that is to say, by varying the brightness of the light from point to point of the plate, but keeping time of exposure the same for every point—they are at least comparable among themselves. The number of varying factors in the problem is certainly reduced by one so far as each plate is concerned. It is true that, at p. 9 of *Photo-chemical Investigations*, Hurter & Driffield say that they have satisfied themselves that an exposure of $\frac{1}{4}$-candle meter for 40 seconds produces the same effect as 1-candle meter for 10 seconds. But it is apparent from this that the experiments with which they were satisfied must have been quite untrustworthy, as the most casual glance at Abney's paper in the *Proceedings of the Royal Society* will show, for it is shown there that, by an experiment of the simplest nature, it is easy to prove that this is not the case. It is, perhaps, a fair argument from this that, if these authors were so readily satisfied in one case, they were probably equally easily deceived in others, and there is considerable doubt thrown on their whole series of experiments by this consideration.

To sum up, let us now review and try to assign its true position to Hurter & Driffield's work. All must admire their energy, ingenuity, and perseverance, and, in fact, their whole work, viewed as a "serious attempt" to solve the vexed question of the rapidity of plates. But they certainly cannot be credited with any real progress. No sooner was their paper published than Captain Abney, than whom there is no higher authority on the subject, pointed out, and proved to demonstration, that their method of measurement was wrong in principle, and was affected by a considerable systematic error, viz., that it could take no proper account of the large proportion of light scattered by the deposit on a negative. It now appears that they themselves have retired from the position they took up in their paper, that "ratio of gradation," and therefore also "rapidity," is independent of the developer. At least this seems to be the fair interpretation of the second paragraph in the preface to the reprint of their *Photo-chemical Investigations*, published by Messrs. Cadett & Neall, in their *Dry Plates* for June, 1893.. Here they acknowledge that "extreme modifications in the developer" may bring about some alteration in density ratios, but go on to say that this fact is of no practical use, and all photographers should "scrupulously avoid" taking advantage of it; in fact, that no one ought to use anything but a ferrous-oxalate developer! This strongly reminds one of Du Maurier's Professor of Music, in *Punch*—"You have a pleasing voice, my young friend, but you do not use it in a legitimate way." "Perhaps, if I did, it would no longer please." "Ah, what does that matter? You should always produce your voice in a legitimate way, whether it pleases or not." Anyhow, whether they have reconsidered this matter or not, it has again and again been shown that, especially with the new developers, modification in the development may produce great modifications in the resulting negative. In fact, the writer has some plates which show that visible reversal may be produced or not at pleasure on similar and similarly exposed plates by varying the development.

In the original paper the main formula, which purported to be deduced from theoretical considerations, was abandoned in favour of an approximate empirical formula, and one object of the present paper has been to show that even this approximate formula, and the whole method of speed determination, of which it is the groundwork, is based on a misconception, and is practically useless, as it applies to a portion of the plate; that is to say, some of the highest lights of the negative, that is not, as a rule, utilised by the photographer. In fact, it may be said that Messrs. Hurter & Driffield's paper is a monument of painstaking, but misapplied, ingenuity.

H. M. ELDER.

"MATT P.O.P."

It is curious to note that the growth in favour of gelatino-chloride paper for printing-out purposes, which has been such a marked characteristic of photographic progress during the last two years or so, has, for a considerable time, been linked with an increasing taste for matt-surface effects. At the first glance, this statement may appear slightly contradictory, since the manifest advantages of gelatine paper are, in a measure, discounted by stripping the prints from a granulated surface. Public taste, however, appears to have decided that a great many subjects suffer no technical loss while acquiring an augmented artistic effect by a suppression of the glacé surface of the paper, so that the "matting" of gelatine prints has become very general. Such a fact was bound to arrest the attention of the manufacturers, and thus, as we briefly announced last week, the Britannia Works Company have introduced a printing-out paper which has a matt surface *per se*, and consequently, at one stroke, relieves the photographer of an operation which was not always assured of success, even when carefully performed.

At this time of the year photographic printing by sunlight is fraught with much difficulty; hence, last week, we were only able, as the result of a compulsorily slight practical acquaintance with the paper, to outline its leading points. Since then, we have had further opportunities of printing with it, and this, coupled with the interest always attaching to the latest printing surface, justifies us in returning to the subject. The paper support, which we understand has been specially prepared, is a very light one, having a smooth surface. The quantity of gelatine upon it is apparently small and the sensitive coating being without gloss, even in the light, until the silver commences to discolour, "which side is which" is not obvious. We are inclined to think the paper extremely rapid, as, in a poor light, we found some fairly dense negatives fully printed in about half an hour. The colour of the prints as they leave the frame is a peculiarly agreeable dark purple—quite unlike anything of the kind obtained with other papers. The surface of the paper is homogeneous, so that the fine details of the image are preserved, while the gradations in the negative are well rendered.

We may with advantage here quote the essential points of the makers' instructions for the use of the paper. They recommend printing to be done in the shade, unless the negatives are specially strong in contrast. The image loses little depth in toning, &c. The prints should be washed in several changes of water for fifteen minutes. Separate toning and fixing are recommended, the bath for the former being the sulphocyanide one. The prints dry darker and colder in tone than they appear when wet. For warm brown tones, the bath should be diluted. After toning five minutes washing in several changes is advised, and two hours in running water, or many changes, after fixing.

Our own experiments were made with a combined bath. With this we found it necessary to print considerably darker than the ultimate print was desired to be. Toning took place readily, and by arresting or prolonging the action we were enabled to obtain a range varying from warm brown to deep purple black. While wet the prints appear like ordinary gelatine prints, but when dry the resemblance disappears. Their lack of surface renders such a degree of care in subsequent handling, mounting, &c., as is the case with the highly surfaced prints, needless.

The results yielded by the new paper are not only artistically pleasing, but, looked at from the purely technical point of view, the fineness of detail, softness, fidelity of gradation throughout, especially in the half-tones, and all freedom from "double colour" should render Matt P.O.P. a great favourite. Above all, it is a simple paper to work, and, as it is capable of giving the most charming effects in the way of tones, it should do much to keep silver printing popular among all classes of photographers.

Mr. Howson last week showed us a selection of prints from negatives by Frank Sutcliffe, Crooke, Hodges and other clever photographers on the paper, and it was impossible to be otherwise than delighted with them.

PHOTO-ZINCO IN HALF-TONE.

[London and Provincial Photographic Association.]

NEARLY all beginners at photographic process work commence by making their negatives on dry plates, and, although I have at various times, whilst not exactly advocating their use, certainly encouraged it, now having learnt wisdom from experience, I cannot find compensating advantage accruing from their use. The chief argument in favour of dry plates put forward by most, is the old one of the fickleness of the silver bath; that, I take it, is a notion left over from the time when the wet-collodion process was in general use, and when it was so necessary, in order to obtain the utmost sensitiveness, to work the bath in such condition that even a variation of temperature would cause fog. For photo-zinco this is all changed, a large amount of acid being requisite to ensure clearness of lines

gives the desired stability to the bath, and consequently freedom from fog and uncertainty.

This being so it is possible to make three negatives finished and ready for printing in less time than one dry-plate negative can be done, so the sooner experimentalists abandon dry plates and try the wet process the better for results, certainty, and economy.

The grained screen.—This is a very important piece of apparatus, and I have here, by favour of Messrs. Penrose, four specimens of Levy's ruled screen, and from Percy Lund & Co. a specimen of Wolfe's reproduced screen; as far as results go, each is as good as the other, although some operators insist that the Levy is best, and others, again, that Wolfe's is; so for my own part I would say, if you have either you can go confidently to work and laugh at any one who says the other (*i.e.*, the one you have *not* got) is the best.

From the thickness of the screens it is obvious that some provision must be made in the dark slide for them; in all dark slides now made for the work this is managed by making the dark slide extra thick, leaving a space of from three-eighths to five-eighths in front of the sensitive plate and behind sliding shutter, and in this recess placing a carrier to hold the screen.

Printing on the Zinc.—The next step to take will be to make a print on the zinc, this being usually done either in bichromated albumen or in bitumen, the albumen process requiring a less exposure to light than the bitumen; but it has the drawback in requiring rolling up with ink before etching, and this is an operation requiring very great skill and care; this can, to some extent, be got over by dusting over with resin and warming the plate, which gives a resist as hard as bitumen.

Bitumen is best dissolved in chloroform, and the zinc plate sent round will show you just about the proper thickness the film of bitumen must be, if at all thicker there will be a difficulty in getting sufficient exposure to penetrate the film to the metal, hence it will float away under the turpentine used for development.

Specimens of straight polished zinc as used for line work, and of round polished zinc as necessary for half-tone prints, are sent round for comparison.

I have also here specimens of the rollers used, viz., a nap roller and a glazed one; the nap roller is the ordinary lithographic roller, the grain of the leather being outside; the preparation of such a roller is very important, as, unless it is properly done, the roller will be useless; a roller in the condition now shown you (*i.e.*, quite new) is worth 15*s.*, but if it was in really good working order would be cheap at 25*s.*

This roller is a glazed one, and is used to ink up the surface of the plate, only, as you see, the surface being hard and smooth.

Etching a half-tone block requires great skill and care, and calls for ability to use the brush in order to get the best effects, and unskilful use of the brush will quickly spoil what would otherwise be a good block.

The use of albumen and bitumen for printing on the zinc is now threatened with supersession, a process called Enameline—of which I now pass round a specimen—bidding fair to be better adapted than either for the purpose.

The process is a secret one (being of American origin), so I cannot presume to even make a guess at it, but I will pass round another specimen done by a process of my own, which has a very similar appearance to the other, and is done with a mixture of isinglass, white of egg, and bichromate.

The process is in itself very simple; a zinc plate grained in a weak bath of nitric acid is coated and whirled, then dried, exposed to light under the negative for from three to five tints of a Johnson actinometer; on removal, the image can be seen quite bright; it is next immersed in cold water to remove the bichromate and unaltered albumen, and dried. It is now carefully examined under a powerful glass, and if the whole of the grain can be seen sharp and without any rottenness in any part, the plate is ready for burning in, an operation done on a hot plate or in a Bunsen flame; here the image gradually develops until a beautiful blue black is attained, when it is ready for the etching bath without any rolling up of any kind, and, when the etching is complete, the plate is mounted and printed from with the enamel image on it intact. This method is only used for half-tone blocks, as the ordinary albumen process gives all that is necessary for line work.

W. T. Wilkinson.

MANIPULATIONS OF THE OPTICAL LANTERN.

[North London Photographic Society.]

In the paper which I am about to read I have no intention of going into lantern manipulation in general, but propose only to deal with the single lantern and blow-through jet, describing the manner of working them for the benefit of those members who wish to improve upon the results obtained from the paraffin lamp for home lantern work, enlarging, reducing, &c. I think the principal reason which prevents many from using the limelight is the exaggerated and almost unfounded idea of the danger attending the use of it. This idea is erroneous. With such ordinary care and attention as amateur photographers usually bestow upon the manipulation of their instruments and work, they can use the limelight with as much confidence as a paraffin lamp. For my own part I have more anxiety when using a paraffin lamp in a lantern than when using a blow-through limelight jet. A highly inflammable and explosive substance like paraffin used in a lantern, the interior of which becomes very highly heated (sufficiently so with me to have broken my condensers on two occasions) inspires me with much more trepidation than does the limelight. The few accidents which have occurred since high-pressure gas cylinders came into use have, I believe, been traced to carelessness or ill usage, and now that oxygen and hydrogen cylinders are respectively fitted with right and left-hand screw threads, thus compelling the gas compressors to fill the cylinders only with the gases for which they are intended, and the users to use their fittings in like manner, the prime cause of danger is eliminated, and, if only drawn steel cylinders are used, one may rest satisfied that the probability of an accident is very remote.

A few words describing how steel cylinders are made may interest you. A disc of steel is, by various machines, pressed into the form of a cap, and finally forced through a hole in a die by a plunger, the outside diameter of which is equal to the internal diameter of the cylinder. The cylinder is then in the shape of a test tube. The open end is heated and cupped over, and the neck formed by special tools. A hole is bored in the neck and threaded, and the valve is screwed and soldered in. The cylinders are tested by hydraulic pressure to more than double the greatest pressure to which they will be eventually charged, which is 1800 pounds on the square inch. They are made in sizes to contain from six feet to 100 feet of gas. I think a twenty-feet cylinder the most useful and economical for an ordinary worker. A lever key is best for regulating the flow of gas, but, for turning off the valve, an ordinary key is better, because, the lever operating with so much more power, one is apt to screw up too hard with it, and thus injure the valve seating.

Now, with respect to regulating the flow of gas to the jet, it is quite possible to do without a regulator, but even experienced hands find it difficult to manage the light without the aid of one when the cylinder is full, for, the pressure being so great, the slightest turning of the valve is sometimes quite sufficient to blow out the light, and make a great hissing. When the cylinder is three parts empty the regulator can be dispensed with, perhaps with advantage, and, when nearly empty, to get all the gas out of the cylinder, the regulator must be put aside, as the pressure is not sufficient to work the valve of the regulator, which thus stops the passage of the gas. I am referring to Beard's regulator, which I think is the best and most generally used. When using gas from the cylinder without a regulator, the tap at the jet must be opened full, and the rubber tube must not be tied on to the connexion, as otherwise the pressure will accumulate in the tube and burst it, but when using a regulator the tap at the jet must be turned off, the valve of the cylinder then opened with the key, and the tap of the jet used to adjust the light. If the tap at the jet be not turned off first, the regulator does not act, but the gas passes from the cylinder to the jet, as though no regulator was there. With regard to the jet, a screw-down tap to the oxygen is an improvement on the ordinary tap, as the flow of gas can be much more nicely adjusted.

I think that the ordinary tap for the hydrogen is the best when house gas is used, because the house gas, being at low pressure, the passage way of the tap must be large in proportion to allow sufficient gas to pass, and the screw-down taps that I have seen do not possess a gas way large enough for the purpose. The nipples of the jet are of prime importance, and there are several forms of these. I think that form is best in which the oxygen nipple is sunk below and inside that of the house gas to the extent of one-eighth of an inch, the house-gas nipple having an orifice smaller than its interior diameter at the position of the oxygen nipple, thus mixing the gases better, and concentrating them on to a smaller area on the lime producing a better light, and improving the definition of the picture, as the smaller spot of light forming the illuminant the finer is the definition.

The limes are an important consideration. Soft limes give the best light, but hard limes are more enduring, and so more economical. Some are only moderately hard, and they come half way between the soft and hard variety, and, I think, are the most satisfactory for general use. Mr. Lewis Wright recommends that the pin to which attached should be slightly tilted forward (*i.e.*, towards the the jet is condenser), and I think that a slight improvement in the light is thereby gained, the nozzle of the jet sometimes cutting off from the condensers some portion of the rays proceeding from the incandescent lime.

I have found the ordinary double plano-convex condensers answer every purpose; they should be mounted in the lantern as close up to the slide stage as possible, and the objective used to form the image should have the lenses, which form its back combination (*i.e.*, those nearest to the condenser), as large a size as possible consistent with the optical considerations involved, because, if these lenses are too small, they cut off some of the cone of rays proceeding from the condenser, and so enfeeble the light. I will proceed to describe what I consider the best way to get a good light and to obtain an evenly illuminated disc on the screen. After the regulator has been screwed into the neck of the cylinder, make the

connexion by the rubber tubes, the oxygen to the tap on the right of the jet, the house gas to the left; turn off the oxygen tap at the jet, and turn on the oxygen at the cylinder by the lever key, light up the house gas and let it warm the lime for a minute, now turn the house-gas flame down to about an inch in height, and very gently open the oxygen tap till the oxygen at the nipple of the jet is carrying all the house gas forward on to the lime; turn on a little more house gas, then a little more oxygen, and so on, gradnally adjnsting the two taps until the best light is obtained. When this is done turn the lime round several times, slowly, in order to thoroughly heat it. Look through the back door of the lantern at the reflection of the lime on the condenser, and, having loosened the screw which bolts the lime-turning arrangements to the tubes of the jet, adjust the lime thus horizontally until the small black spot, which is observed in the centre of the illnminated portion, jnst disappears, and, when this is done, tighten the screw. Now draw the jet a little distance back from the condenser, adjust the jet on the pin, vertically and horizontally, until the spot of brighter light on the screen is in the centre of the disc, put a slide in the stage and focus it; take it ont again, and then slide the tray and jet towards the condenser, nntil, on observing the screen, you notice it as nearly as possible eqnally illuminated. If there appears a want of light or a slight blue shadow at the top of the screen, the jet must be lowered; if at the bottom, it must be raised; if it is on the right side of the screen, the jet mnst be slightly swerved to the left; if it is on the left, it must be shifted to the right—of course I am referring to the lime end of the jet.

What I have said, I know, will be very stale to some of you, but I have made an effort to describe the elements of the manipulation of the lime-light for the gnidance of those who know nothing about it, and not in order to bring forward anything new which might appeal to the experienced.

E. W. Parfitt.

Our Editorial Table.

The "Rocket" Plate.

Elliott & Son, Barnet.

There is no doubt of this new plate of Messrs. Elliott & Son being remarkably quick. We submitted a sample to trial during the dull weather we have lately been experiencing, and under conditions best calculated to test for rapidity, and succeeded in getting fully exposed negatives. The "Rocket" plate develops easily and cleanly, and is possessed of great technical excellence.

A View by Moonlight.

By William Brown, Paisley.

A view of the village of Lamlash, Arran, which was shown at a recent meeting of the Glasgow Photographic Society, has been sent to us by Mr. Brown. It was taken on August 28 last, the day after full moon, and was exposed from 10.30 p.m. to 12 with a Ross's half-plate rapid symmetrical lens. During the first half-hour a No. 3 stop was employed, and during the remaining hour the lens was worked without any stop. The plate was a "Verel's Matchless," developed with pyro and ammonia. The moon must have been very bright and the atmosphere exceptionally clear to have enabled such an excellent picture to have been obtained.

News and Notes.

Lewisham Camera Club.—December 15, Lantern Evening; Prize Slides.

Leeds Camera Club.—December 21, Grand Lantern Evening, for members and friends, in the Large Room, New York-street.

West London Photographic Society.—December 17, Technical Social Meeting. *Carbon Printing*, Mr. L. Selby.

Photographic Club.—December 20, *Soda* versus *Ammonia as an Alkali in the Developer.*

Messrs. Arthur Schwarz & Co. inform us that they have been appointed sole wholesale agents by Dr. Hesekiel, for his Grain Platina Paper (matt surface).

"The Photogram" is the title of a new monthly magazine devoted to photographic and photo-mechanical work, to be issued under the editorship of Mr. Snowden Ward and Mrs. Weed Ward.

Messrs. Perken, Son, & Rayment inform us that the "Optimus" 100 Guinea Photographic Competition closes on December 31, after which no further prints can be received. A copy of the rules and list of prizes may be obtained of the firm, 99, Hatton-garden.

Central Photographic Club.—Friday, December 15, instead of the discussion, *Films* versus *Glass*, Mr. John Howson will give his first demonstration of *The Working of the New Ilford Matt-surface Paper*, at the Club-rooms, Coleman's Hotel, Henrietta-street, Covent Garden, W.C.

Liverpool Amateur Photographic Association.—Thursday, December 21, Lantern Lecture, by Mr. W. Harvey, *A Trip to Chicago.* Auction of Photographic Goods, the property of members, January 11, 1894. All articles intended for sale should be left with the Attendant, with full description, also reserve price. A few copies of spare presentation prints will also be put up to auction.

At the Central Photographic Club, Coleman's Hotel, Covent Garden, there is on view, till December 21, a "one man" collection of photographs, by Mr. Thomas Fall. It includes examples of portraiture, group, landscape, and animal study work. Small though the collection is, it is well worth a visit, as it shows Mr. Fall's powers to advantage. Visitors are admitted on presentation of card.

Munster Camera Club.—December 20, *Amidol as a Developer*, by A. Roche. 1894: January 3, *Retouching* (illustrated), by J. O'Connell. 17, *On Lens Stops and Exposures*, by H. Lund. 31, Discussion on *Printing Papers*, opened by K. B. Williams. February 14, *A Ramble in the Highlands*, by A. Newsom. 28, *The Stereoscopic Camera*, by R. Foley. March 7, *Photographic Dodges*, by J. Day. 21, Members' Slides. April 4, Annual Exhibition.

The Photo-Autocopyist.—The photo-autocopyist is an apparatus for easily obtaining a number of reproductions of a photograph by collotypy. A bichromated gelatine film is printed in the usual way, developed, placed on a stretcher, inked, and a print taken by pressure. The apparatus is supplied complete in a neat and handy form. Those of our readers who have access to our volume for 1891 will find the process described in detail by Mr. Warnerke. The address of the Company is 72, London-wall.

Bristol International Photographic Exhibition.—The entries for this Exhibition have now all been made, and we hear that the Bristol Committee are more than satisfied with them, both from their quality and number. The work of judging takes place this week, and the Exhibition opens on Monday with a *conversazione*, at which the Very Rev. Dean of Bristol will perform the inaugural functions. The exhibits are thoroughly international in their character, there being many frames from the United States, Canada, Russia, Sweden, and all parts of the Continent. The Committee have decided to issue cheap season tickets (*3s. 6d.* only) for the five weeks during which the Exhibition remains open. This will doubtless prove a great advantage to the local public, and will, we should think, add materially at the same time to the success of the Exhibition.

Forfarshire Photoographic Lantern-slide Competition.—*Honorary President:* Alexander Robertson, of Burnside, Sheriff-Substitute of Forfarshire.—*Honorary Vice-President:* Robert Whyte, Procurator-Fiscal of Forfarshire.—*Chairman of Committee:* Gilbert W. Don, Clocksbriggs House.—*Vice-Chairman and Local Secretary:* J. Watson Craik, Forfar.—*Treasurer:* R. Bruce, Banker, Forfar.—*General Secretary:* W. J. Anckorn, Arbroath, N.B. Rules and Regulations of Lantern-slide Exhibition and Competition: 1. The Committee will place the Forfarshire medals at the disposal of the Judges, whose decision will be final. 2. Entry fees 1*s.* for set of twelve slides. 3. The Competition is open to all photographers, no distinction being made between amateurs and professionals. Trade manufacturers barred. 4. The Slides to be forwarded to the General Secretary, together with the entrance fee, on or before December 30, carriage paid. 5. The winning Slides will become the property of the Forfarshire Exhibition Committee. 6. The Committee will not be responsible for any damage to slide exhibits. 1st Class—Landscape, Marine, and River Views. 2nd Class—Hand Camera. 3rd Class—*Genre.* Two awards in each class.

Presentation to Mr. Edgar G. Lee.—An Ordinary Meeting of the Newcastle and Northern Counties' Photographic Association was held on Tuesday, December 5, at the Art Gallery, Newcastle. Mr. J. P. Gibson, Hexham, presided over a very large gathering. Mr. John Watson read a paper on *Lantern Manipulation*, and afterwards gave an interesting demonstration of the various processes. The next business was a presentation to Mr. Edgar G. Lee, who is retiring from the Hon. Secretaryship, in which post he has been succeeded by Mr. James Brown. The Chairman, in making the presentation, referred to the past history of the Association, pointing out that, in its early career, it had associated with it many prominent scientists, such as the late Professor Marecco and Professor Herschell. It had had three Secretaries. The first, who put the Association on its legs, was Mr. J. B. Payne, of Messrs. Mawson & Swan. Then came Mr. Pike, who was succeeded six years ago by Mr. Lee. During Mr. Lee's term of office the Society had enormously extended, the membership rising from something like forty to 160. It had also taken a very prominent part in the photographic activity of the kingdom. The Association occupied a very good position as compared with other provincial societies, though he should like to see the general average of the work improved. They had in their ranks many eminent photographers, but the general average might still be raised. Alluding again to Mr. Lee, he said that gentleman had developed a reputation second to no man in the world as a lantern-slide maker. Mr. Lee had become a specialist, he had stuck to that one branch of photography, and by perseverance had raised himself to the high position he now occupied. Mr. Lee had always been most willing and anxious to assist beginners, and there was hardly a beginner who had not had the benefit of his advice. He then handed over the present, which consisted of a purse of gold, a silver inkstand, and an album. Mr. Lee, in returning thanks, said he should still continue his active connexion with the Association.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

DECEMBER 12,—Ordinary Meeting,—the President (Captain W. de W. Abney) in the chair.

The following were elected members of the Society :—Messrs. W. A. Cadby, L. Cohen, E. Farquhar, F. W. Grant, T. C. Hepworth, C. Job, Adolph Meyer, Spencer and Mrs. J. N. Hignett, and Mr. W. M. Warneuke.

The PRESIDENT announced that the Society had acquired a number of negatives by Rejlander, and that prints would be on view in a short time.

Messrs. W. S. Bird and Thomas Bedding were elected Auditors of the Society's accounts.

DISTRIBUTION OF THE IMAGE IN MULTIPLE FILMS.

Mr. S. HERBERT FRY read a paper on this subject, in which he dealt with the theoretical features of the Sandell multiple-coated films and their practical treatment. He said that the respective films not only differed in sensitiveness, but also as to character of image, and were, besides, physically dissimilar. The top film produced abundance of detail in the brilliantly lighted parts of the picture, and the bottom emulsion clear shadows. The multiple-coated film might thus be described as a composite film, having opposite photographic properties. In his estimation, it was not possible to make one emulsion having all the qualities required, and that an equal effect could not be obtained by mixing emulsions of different characters. After pointing out that light exercised a selective action on multiple films, the more energetic rays exercising their function on the lower and less-sensitive emulsion, he said that, in an ordinary film, those rays passed through and caused halation. The multiple film acted as a light filter. Better and truer renderings were obtainable with a multiple than with a single and homogeneous film. In the case of an abnormal exposure, a selective developer must be used. He would begin with one weak in alkali. Such a one would attack the lower film first, and, when sufficient density was obtained, a normal developer could be used to produce detail. He could not say whether the slow film influenced the top, and, as regards solarisation, he said he did not find any noticeable effect produced, if development were continued far enough. The more reversal there was, the more image there must be developed in the lower film.

In reply to Mr. Warnerke, Mr. FRY said the films could only be stripped in the first, wet stage.

The PRESIDENT, in moving a vote of thanks to Mr. Fry, said the use of multiple films was not new, as double films of collodion and gelatine had been employed. In a paper read before the Royal Society six years ago he (the President) had shown the advantage of using an emulsion sensitive to the ultra-red rays with another below not sensitive to them. One was able to separate the two, and get the whole of the spectrum together. It was a good opportunity of studying the image, as one acted as a feeder for intensity to the other. The top film by itself would give a feeble image, but it could be intensified. It was more preferable to intensify by the ordinary method of development. By having a substratum of sensitive salt, one was able to get any amount of density required.

THE LIPPMANN-LUMIÈRE-VALENTA COLOUR PHOTOGRAPHS.

Mr. F. E. IVES read a paper on this subject, which, in some respects, criticised the results in the same terms as in his paper read before the Philadelphia Society on November 8 [see page 798]. It was a question how much of Lumière's success was due to an attempt to carry out Lippmann's theory and how much to accident. He had not been able to believe in the possibility of producing the results. The images should be negative, but Lippmann's own photographs showed the greatest deposit in the high lights. He suggested that the rendering of the whites and blacks might be due to long exposure producing reversal. The action which rendered light and shadow was different to the action which produced colours. The two distinct actions proceeded together, and, therefore, as the process was not one indicated by Lippmann's theory, it must be regarded as partly an accident. He thought the results could be produced by interference. When in Vienna, Herr Valenta had shown him some results produced on plates sensitised with cyanine, the pictures being backed with Brunswick black and mounted under a prism. Chloro-bromide plates, sensitised with eosine, had also been used, with abnormal results, red being produced by the action of the blue, and violet by green. The colours were not produced in the film, but only by something practically equivalent to interference. Spectroscopic examination supported the view that none of the colours were pure. All the colours were mixtures. The second example, however, seemed corrected in the spectroscope. For reproducing correctly, the sensitive film should be scarcely thicker than a single wave-length of light. Having criticised the method of projection employed, the light being so powerfully concentrated that reflection from a black glass would appear as white on the screen, he concluded by saying that he thought the photographs were not obtained in accordance with theory. The results were more or less accidental, and successful working conditions could not be calculated, but must be worked out purely by experiment. [We shall take the opportunity of printing the paper in full on an early occasion.]

In the discussion which followed,

Mr. L. WARNERKE explained that M. Lumière's colour photographs were protected in order to secure them against damage in handling.

Mr. H. A. LAURANCE said he assisted in the preparations for showing the pictures at the Society of Arts, and imagined there was a prism over the images because there was a most beautiful spectrum thrown from the prism.

Mr. IVES said that it was quite right the pictures should be mounted, as the colours were exceedingly delicate. He did not know that M. Lumière had ever exactly stated how the pictures were mounted.

Mr. CHAPMAN JONES asked if there was any information that the colours were produced by the corresponding colours in the spectrum. In those Mr. Ives showed there seemed a small proportion of yellow.

Mr. IVES said that Herr Valenta stated that in the better examples the colours occupied their correct positions. In the pure spectrum there was very little yellow. The more impure it was, the greater the sensation of yellow.

Mr. T. SEBASTIAN DAVIS asked if the colours which had been projected by the prism were not mounted in front of the glasses?

Mr. IVES replied that the colours were more brilliant with the prism.

Mr. LAWRANCE asked whether the spectrum photographs Mr. Ives showed were taken in an arc light or daylight?

Mr. Ives said the light was taken from a large crater, so that there was very little of the carbon spectrum in it. He thought that the people who made the claims to which he had referred should photograph the Fraunhofer lines by the Lippmann method, by which no one had yet photographed the sun spectrum.

The PRESIDENT, in moving a vote of thanks to Mr. Ives, said he had photographed a sun spectrum by the Lippmann process, but by long exposure he got red where blue ought to be, and blue where red should be. He found that a great deal had to do with the exposure. It required a brilliant spectrum and a wide slit. He did not think the criticism as to the want of yellow in Valenta's results was a crucial one, as, by reducing the light of the spectrum, no yellow at all would be obtained. In all the photographs by the Lippmann method he had seen, there was one great fault, the want of being able to produce a pure red, it was always of an orange character. He did not suppose they would ever get pure colours by the method. As regards the use of the crater of the positive pole of the electric light, he found that to be a standard light in 1884, as a cubic square of one-eighth of an inch in the centre always gave the same light. He believed a patent had recently been taken out for it. Colour photography was yet in its infancy, and we must wait for more developments before we could say that everything was accomplished. His own belief was that photography in natural colours would be photography in pigments, but the latter faded. Becquerel's colours were purer than Lippman's.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 7, Mr. A. Haddon in the chair.

PHOTO-ZINCOGRAPHY IN HALF-TONE.

Mr. W. T. Wilkinson gave a paper on this subject [see page 800], exhibiting several screens of different degrees of ruling, nap and glazed rollers, zinc plates, and examples of images on zinc in various stages of preparation.

In the course of a discussion which followed, Mr. W. E. DEBENHAM recommended Schlippe's salt for intensifying the collodion negatives.

Mr. WILKINSON said there was a danger of getting veil with it.

Mr. DEBENHAM had used it after iodide, and found no veil. It gave a deep red-brown deposit. He thought it very generous of Mr. Wilkinson to publish his isinglass, white-of-egg, and bichromate process.

In reply to further questions from Mr. Debenham, Mr. WILKINSON said that

with his process there was no intermediate inkings, the plate being etched straight off. The etching fluid was nitric acid, the solution being of the consistency of vinegar; etching took about a quarter of an hour, the finer details in the high lights being watched for.

In reply to the Chairman, Mr. WILKINSON said that etching by a current of electricity was not commercial, although it was scientifically practicable.

In reply to Mr. Debenham, he said printing was done to about the same depth as collotype. He would not repolish a spoiled plate. The spoiled bitumen or isinglass film could be washed off with warm water and oxide of zinc used for the plate. As regards the distance of the ruled screen from the collodion plate, it was generally placed on the silvered-wire corners of the dark slide. The ruled lines of the screen were filled in with pigment. As to the use of mirrors, he had had one in use for five years, and had only had it resilvered once, at a cost of threepence. He had repolished it with baked rouge and fine cotton-wool in chamois leather, slightly warming the plate and polisher.

After Mr. Wilkinson had answered other questions, a vote of thanks was passed to him.

Central Photographic Club.—On Friday last Mr. Algernon Brooker, of Hastings, delivered his lecture, *Winchelsea and Rye*, illustrated by 140 slides. Starting from Hastings, he led his hearers on through Ecclesbourne and Fairlight to Winchelsea, pointing out the places of interest *en route*. He gave a short historical account of both Winchelsea and Rye, illustrated by ancient and modern maps, showing the great change which had taken place in the surface of that part of Sussex by the receding of the sea and changing of the course of the River Rother. Views of the church at Winchelsea, its monuments, and some details of carving were shown and described. Comparative exposures, made on "Sandell" and "backed ordinary" plates were called attention to. After various "photographic bits" in the way of gates and odd corners, Mr. Brooker proceeded to deal with Rye, and managed to get some amusement out of his description of the corporate seal. The lecturer's best hits in description were of the bakery at Rye and its doorstep tenant who at night always "felt the cold," and was at times troubled with "symminess in the head." The wise descriptions of the weather by the ferryman at Rye were also referred to. A description of the "pirates' chains," and the pillory in the Town Hall at Rye, and the difficulties surmounted in photographing them, followed by a series of paddling scenes on Hastings beach, brought a most instructive evening to a close.

Ealing Photographic Society.—December 7, the President (Mr. H. W. Peal) in the chair.—Two nominations for membership. An exhibition of members' lantern slides was given by Mr. T. Simpson, assisted by Dr. Gibbons. The slides first shown were the work of Mr. T. Crisp, and included views at Burnham Beeches, Virginia Water, Kew Gardens, Stanwell, Hillingdon, and the Brent; a characteristic scene at Brentford Market, and some effective studies of chrysanthemums from negatives on isochromatic plates. The Hon. Secretary (Mr. Murphy) contributed a series of views taken during a recent tour in the south-west corner of France, and comprising scenes at and near Bordeaux, Dax, Orttiez, Pau, Bayonne, Eaux-Chaudes, &c. He also showed some views on the Henley Regatta course, and in Ireland, and a pleasing *Sunset on the Mill Pond, Hanwell*. His final slide consisted of a reproduction of a placard dated 1813, giving a list of the prizes offered for competition at Ealing Fair in that year. Besides prizes for jumping in sacks, and grinning through a horse-collar, a pig was to be run for, a pound of tobacco to be smoked for, a shift to be run for by young women, and a pound of tea to be drunk for by old women. Mr. B. E. Peal furnished half a dozen choice views representing *Hanger Lane, Perivale Lane, Hayes Church, Swakelys*, &c. Mr. Roland Whiting showed some slides of microscopic objects, amongst which those depicting crystals of various substances as seen by polarised light were greatly admired. The exhibition concluded with an admirable series of slides by the President, reproducing the illustrations in David Roberts' *Egypt and Nubia*. These slides, which elicited frequent applause, were notable not only for their technical excellence as photographs, but for the artistic beauty of the original pictures. It was announced that the meeting on the 14th inst. would be a demonstration on *Enlarging*, the Society's enlarging apparatus and dark room being used. The following week there will be a demonstration of development with amidol, metol, and glycin.

Hackney Photographic Society.—December 5, Mr. W. Houghton presiding. —Question: "What effect in exposure would snow have in winter?" Reply: "Disregard the glare and whiteness and expose for the dark portions of the subject. Snow pictures are generally under-exposed. Fast plates give more density than formerly. Select a plate with a thick emulsion." Question: "What time is sufficient for washing a uranium-toned bromide print? The instructions say, 'Wash till all yellow traces disappear.' Prints had been left in a long time, and the picture nearly disappeared altogether." Reply: "One must watch them carefully and remove after inspection in daylight as soon as the last trace of yellow has gone, not forgetting the back of the paper." Question: "What advantages have isochromatic plates over ordinary ones for winter landscapes?" Reply: "There is always an advantage in yellow light. Mr. Birt Acres has said it gave roundness." Mr. HUDSON stated an interesting fact he had just read under date 1859, that a bullet in motion had been photographed. It was, however, explained to him that it was not done by a lens. The exposure is made by an electric spark; the electric contact is made by the bullet itself whilst passing the plate. A discussion then took place on excursion matters, with a result that a sub-committee was formed to arrange dates, places, &c., and leaders for the summer outings, and that a list be published in advance.

Putney Photographic Society.—December 4, Mr. H. Faulkner in the chair.—The CHAIRMAN said that in the absence, through illness, of Mr. Horsley Hinton, who was to have read a paper on *Work in the Field*, Mr. A. E. Leblanc, representing Messrs. A. Schwartz & Co., had very kindly undertaken to give a demonstration on *Dr. Andresen's Cartridges*. The Chairman further said that Mr. Horsley Hinton was now fortunately reported to be making satisfactory progress toward recovery, and that there was every reason to hope that he would still be able to give his paper before the close of the season. Mr. LEBLANC said that no doubt Dr. Andresen's preparations were well known in their usual form to most of the members present; he had come that evening to point out the advantages of the cartridge form. This form had been originally applied to developers only, and introduced for the convenience of tourists; but the immediate success of the new departure had been such that cartridges were at the present time issued for an acid fixing bath for general purposes and for a combined toning and fixing bath for albumen and gelatino-chloride papers in addition to developing cartridges of amidol, eikonogen, and metol. The advantages of the cartridges to travellers are numerous; amongst others may be mentioned that the salts are in a dry state and highly concentrated, and that they therefore occupy very little space; all risks of broken bottles and the wasted solutions being absorbed by and damaging and destroying other contents of the travelling bag were done away with; they were also very convenient in use; when required, it is only necessary to empty the contents of the cartridge into the proper quantity of water; the solution is then ready for immediate use. Each cartridge, being hermetically sealed, will keep indefinitely in any climate, and as each is only sufficient, for a limited quantity of solution, they will be found very useful in places where the ordinary chemicals will not keep satisfactorily in their dry or dissolved state, and for amateurs everywhere who only develop or tone small quantities at intervals. In summarising the qualities of the various developers, Mr. Leblanc said that eikonogen was first specially made as an all-round developer for negatives, papers, and lantern slides for India and China. Rodinal was a powerful developer, but, being a liquid, could, of course, not be used in the cartridge form. The amidol acid developer did not keep long in solution, and should therefore be mixed as required; it was a useful all-round developer. Metol was the latest of Dr. Andresen's developers, and combined the advantages of the others without any of their less satisfactory qualities; it would keep in solution for any reasonable time—he had personally used it nearly three months after mixing without noticing any loss of power. With this developer potassium bromide does not retard, but has only a clearing action; glacial acetic acid was the best retarder. Glycin is a special developer for lantern plates and reproductions; it keeps well in solution, and development may be prolonged without fear of fog or veil. The fixing cartridges make an acid fixing and clearing bath, and have the advantage that negatives or prints may be passed into it direct from the developer. The developing action ceases immediately, which is by no means the case where intermediate washing has to be resorted to. The combined toning and fixing cartridges made up a complete toning and fixing bath, equally suitable for albumen and gelatino-chloride prints, simply by being dissolved in the proper quantity of water, and was ready for use immediately. Mr. Leblanc then proceeded to develop a couple of negatives and some prints on Nikko paper (exposures unknown) in metol, and to tone some Solio and Paget print out prints; the results were very satisfactory, and the solutions made from the cartridges acted with the greatest regularity and smoothness. It should be observed that development should be carried much farther than appearances would at first lead one to judge; in fact, he always developed until the picture appeared in fair detail on the back of the negative. Prints should be printed fully for the for the combined toning and fixing bath, but in this particular there was no difference from the ordinary formulæ. Mr. Leblanc said that the use of Dr. Andresen's developers and fixing solutions did away with the necessity for very thorough washing between each operation, and that the great care generally necessary to keep all trace of other solutions away from any one was with them of much less importance; he had found no injurious effect from handling a negative in the developer with fingers which had just been in the fixing solution. He had never had any trouble with his fingers when working with metol, although he had used this developer even when there were cuts and scratches on them.

Richmond Camera Club.—Monday, the 11th inst., Mr. Cembrano in the chair.—Mr. Birt Acres delivered a lecture on *Clouds: their Form and Movement*. Mr. ACRES began by alluding to the part which clouds play in the economy of nature, and then explained the mode in which cumulus clouds are born of the sea, with the sun for their father; and how, owing to the more rapid radiation on land, the day-formed clouds are wafted landward at nightfall. He gave the theory of the trade winds, with their counteracting upper currents, and many other interesting facts and theories connected with his subject, concluding his introductory remarks with an explanation of the different forms of clouds, according to Howard's classification. Then followed a series of very beautiful lantern slides, mostly in carbon, illustrating cloudland in every conceivable form and aspect. Mr. Acres detailed his *modus operandi*; but, as it involved the polarising and analysing of the light, and as it transpired that the proper prism could not be bought for 100*l*., it may be doubted whether many members of the Club will follow it.

South London Photographic Society.—December 4, Mr. Maurice Howell (Vice-President) in the chair.—The evening was devoted to a demonstration (by request) of *Platinotype Printing*, by Mr. F. W. Edwards, the President of the Society. In working platinotype it is necessary to avoid dampness during printing, as it causes flatness and degradation of the prints. During cold weather, he considered it advisable to use the developer slightly warm. Cold solutions increased contrast, while a warmer developer brought out more detail. A properly exposed print could be left in the developer for any length of time without any fear of over-development. The presence of air bubbles at first did not matter; wet the spots, and they develop up like the rest of the picture. Large prints can be developed a portion at the time by drawing them through the solution again and again. It is necessary not to touch the prints before development with fingers which have become contaminated with acid from the fixing bath. Under-exposed prints may sometimes be saved by developing in a hot bath. The paper takes less time to print than albumenised paper. During printing, it must be shielded from damp by backing it up with rubber pads. Any one starting the process, Mr. Edwards recommended the use of one negative until good results were obtained. Between forty and fifty prints were developed, fixed, and washed during the meeting. Attendance, fifty-eight.

Tooting Camera Club.—December 7.—The second of this season's Ladies' Nights was devoted to the exhibition of slides by means of the optical lantern. Slides were shown by Messrs. Victor Robinson and A. H. Anderson, members. A picture by the latter gentleman, entitled *Tottie*, a photograph of a pretty little girl about three or four years old, whose facial expression was quite a study, was greatly admired. Some sixty slides kindly lent by Mr. A. R. Dresser were then exhibited. A set of comic slides by Messrs. Wilson & Co. of Aberdeen, lent by Mr. Nock, were also passed through the lantern. They were entitled *A Trip North*, and were photographic reproductions of engravings representing the adventures of three friends in Scotland.

Woodford Photographic Society.—December 7, the President in the chair.—Mr. H. T. Malby read a paper on *Copying*. Speaking of the new departure, frequently attended by failure, that amateurs find their first attempts to copy photographs, paintings, or engravings, he gave a record of his own work and procedure. The tripod being so very difficult to manipulate for copying to scale, lantern slides were shown of a simple hand-made contrivance for holding copy and camera, allowing longitudinal adjustment for focussing and lateral movement of either copy or camera for those cases in which an illustration had to be copied from one side or corner of a large drawing, the camera back being always parallel to the copy board. For line work the lecturer recommended the slowest plate possible, having been very successful with plates coated with the Ilford special lantern emulsion, and most with some specially thickly coated by the Britannia Works Company. For half-tone copying his best results had been obtained on Ilford ordinary plates; and, in working from coloured copies, Ilford isochromatic. Correct exposure was stated to be of the greatest importance, a Watkins exposure meter being recommended; and, for line work, backing the plate absolutely necessary. In addition to lantern slides illustrating the apparatus used, several were shown of the different classes of work, details of the methods of working accompanying their appearance on the screen. Next meeting (informal), December 21, Discussion on toning gelatino-chloride prints. Visitors invited.

Bath Photographic Society.—November 30, Mr. Austin J. King (President) in the chair.—Formal business having been dispatched, the chair was taken by the very Rev. Monsignor Williams, to enable the President to give a lecture, entitled *Through the Basque Provinces*. Mr. KING commenced by saying that a man must be very hard to please who cannot find much to interest him in the district which lies between Bordeaux in France and San Sebastian in Spain. The most wonderful vineyards in the world, every varying feature of climate and soil, almost every type of vegetation and every mode of cultivation, excite the attention of those whose interest it is to know what can be got out of mother earth and by what means. The geologist marvels at the strange features of the barren lands which lie around Arcachon, and the marvellously distorted strata of the Pyrenees. The lover of English military glory may rejoice at the survivals of English domination of these fair provinces, and gaze on the redoubts, ruined bridges, and blackened walls which tell of Wellington's invasion of France at the end of the Peninsular War. The student of ethnology will find in the Basques a people more ancient than any inhabiting Europe. Does any one exult in the glorious majesty of some huge mountain? Let him wander amidst the Eastern Pyrenees, and gaze on the hills hoary with perpetual snow, dressed around the base with most luxuriant vegetation. Does the fierce oncome of the mighty sea excite his fancy? Let him stand on the rocky coast of Biarritz or St. Jean de Luz, and see the rolling billows of the Atlantic roaming in from the Bay of Biscay with a resistless force which hurls about vast rocks and mighty breakwaters as a child may play with shingle on a river's bank. If he cares to see nature at her best, a thriving and a happy people, and a land abounding in comfort as well as beauty, if he asks but to be allowed to *rest*, here he may spend days, enjoying idleness as he only does who regards it alike as a rest from labour and a preparation for more. The route chosen was by steamship *Liguria*, from Liverpool to Bordeaux. The passage was not a pleasant one, rough sea, cold wind, and rain. Pauillac was reached in three days. On one side of the Garonne is the St. Emilion district, on the other that of Julien. Pauillac itself includes the vineyards of the Château Lafitte, which produces the costliest wine in the market. From Pauillac to Bordeaux is a run by train of about two hours. As the country is flat, and there are no tunnels or bridges, the railway carriages carry two stories. Bordeaux is a large city, 242,000 inhabitants, and occupies a magnificent position on the Garonne. The year has been wonderfully prolific for wine, and the difficulty has been to obtain enough casks. The appeals for coopers in the windows on the quay being almost piteous. The lecturer next described some of the customs of the casking fraternity and the more important features of the city. Passing on to Arcachon, a seaside resort, some amusing peculiarities of the place were given. Lourdes was next visited, and many pictures were shown illustrating the buildings, the castle in which Napoleon imprisoned Lord Elgin in 1804, the Upper and Lower Church, general views of the town, &c. The number of pilgrims, said the lecturer, is immense. They arrive by thousands, sometimes even by tens of thousands, and every evening there is a procession. To see these thousands of persons, men, women, aged old souls with one foot in the grave, and children scarcely able to walk, gentle and simple, bearing shaded candles in their hands, winding up and around the paths on the hills and mountains, singing psalms and canticles, will produce a wondrous impression even on the most callous. Leaving Lourdes, Pau was next visited, and thence to the little seaside town of St. Jean de Luz, about twelve miles south of Biarritz, and a few miles from the Spanish frontier. The district between Bayonne and San Sebastian is still peopled by the Basques. In south-western France and north-western Spain they hold their ground with a tenacity which is one of the marvels of history. These Basques seem never to have been troubled by national aspirations. The French Basques are as loyally French as the Spanish Basques are loyally Spanish. Their ambition has ever been to manage locally their own affairs. They speak a language of their own, which is neither French nor Spanish, nor a mixture of the two. It is a distinct language of quite another family. Their churches are all built of one type; the men occupy the tier gallery, the women the centre. Three peculiarities are very striking in these people. The Beret, or cap, something in shape like a Tam O'Shanter, the canvas shoes, with soles of jute, and bound round the calf with tapes, and the walking-stick made of medlar saplings. Hand-ball is the national game, played in many different ways. The lecture, which was well attended, was illustrated with upwards of sixty photographic lantern views, both the negatives and the lantern transparencies having been specially made, by Mr. King for the purposes of this lecture, and from a technical point of view they were most satisfactory as displayed on the screen. Articles peculiar to the Basques were on the table for examination after the lecture, also a large number of stereographs, to further illustrate the scenery and customs of the people. At the conclusion of the lecture, the CHAIRMAN (Monsignor Williams), in felicitous terms, very cordially returned thanks to the lecturer.

Birmingham Photographic Society.—December 5, Mr. J. T. Monsley in the chair.—Mr. Fry, representing the Paget Prize Plate Company, demonstrated the development of proofs on printing-out paper which have only received a part of the normal exposure. The process consists of immersion in bromide solution, then development with hydroquinone, and afterwards the ordinary toning. This gave satisfactory results from prints only about one-tenth exposed.

Leeds Photographic Society.—December 7.—The forty-second annual report was read. The Society was founded in 1853, and is therefore the oldest in the United Kingdom. The subjects brought before the Society at its meetings during the year have been of great interest and importance; indeed, in this matter it is believed that the Society compares favourably with any in the provinces. The following gentlemen were elected as Committee for the ensuing year:—Messrs. Herbert Denison, J. H. Walker, H. P. Atkinson, B. A. Burrell, F.I.C., T. Butterworth, Godfrey Bingley, L. A. Warburton, H. L. P. London, Robert Steel, and Dr. Jacob. The best thanks of the Society were given to Mr. W. A. M. Brown for his gift of this year's photographic periodicals; also to Messrs. Pearson and Denham for their books. Mr. Godfrey Bingley exhibited a large collection of his new lantern slides—Views in Yorkshire, Scotland, West Somersetshire, North Devon, and Cornwall. His negatives were chiefly made on isochromatic plates and films, and showed very fine results. He received the best thanks of the meeting. Mr. Denison showed some slides made by the carbon process.

Liverpool Amateur Photographic Association.—November 30, Mr. William Tomkinson presided.—A lantern lecture was given by Mr. W. P. Christian on *Quiet Corners in France and Italy*, in the course of which photographic views, taken by the lecturer, of famous old towns and villages situated near the Italian Riviera, Venice, and the Italian lakes, were thrown on the screen, with the most pleasing results. A sample Thornton-Pickard automatic camera stand was exhibited to the members at this meeting.

EXTRACTS from the annual report: — "With the increased accommodation afforded by the new club-rooms, it has been the endeavour of the Council to further the usefulness of the Association in every way possible, and they allude with great satisfaction to the increased number of practical demonstrations, lantern evenings, &c., held during the year. From February 23 to the end of April, every Thursday evening was set apart and some subject of interest provided, a special feature being the series of six practical demonstrations by Mr. W. T. Wilkinson, of Manchester. Owing to the large number of members who availed themselves of these meetings and the benefit derived, the Thursday evening series were resumed on November 2, and it is intended to continue them until the end of April.—A pleasant gathering took place on the afternoon of Thursday, April 13, when four lady members—viz., Mrs. Marriott, Miss Adams, Mrs. Morrison, and Mrs. Southell—entertained the members to afternoon tea.—On April 10 a very successful auction of photographic goods, the property of members, was held in the club-rooms, when over a hundred lots were offered, and good prices realised.—The coffee meetings, held at four o'clock every Wednesday, have been very well supported; much useful work has been exhibited and valuable hints given to beginners, and matters relating to photography have been discussed in an informal way.—It is with deep regret the Council have to record the death, on November 9, of Mr. T. S. Mayne, a most ardent worker, and to whose personal influence and energy much of the success attending the International Photographic Exhibitions held in Liverpool, 1888 and 1891, was due. They have also to record the death of three other members of the Association, Mrs. Nicklin, Mr. James Lahy, and Mr. J. R. Jacksonr.—The number of members at the beginning of the year was 278; new members elected during the year, 56; resignations, lapses, and deaths, 25; leaving 309 members on the roll at the end of the year.—The excursions, with the exception of those to Ince Blundell in the early part of the year, and to Shrewsbury and Wenlock Abbey, did not receive the support deserved."

Sheffield Photographic Society.—December 5, Mr. Ernest Beck in the chair.—Mr. Richard Keene, of Derby, gave his lecture, entitled *Six Days' Photographic Ramble over Derbyshire Hills and Dales*, which was illustrated by 150 slides. Most of the pictures were taken nearly thirty-eight years ago, and, although some of the landmarks had been destroyed and many of the old inhabitants passed away, most of the old halls were in almost as good preservation as ever, notably Haddon Hall, which is always a happy hunting ground for the photographer.

Midland Camera Club.—December 1, Dr. H. Edwards in the chair.—A new Thornton-Pickard tripod stand was exhibited. The report of the Exhibition Committee was received and adopted. The report stated that, photographically, the exhibition was a decided success. Objection was taken to the exclusion of professionals from the members' classes; and, judging from the opinions expressed, it is very unlikely that any such distinction will be made in future. The office of Treasurer being vacant, Mr. T. H. Cox was elected, and Mr. H. Cooper takes the office of Librarian. At the close of the business, a number of lantern slides were exhibited by Messrs. C. Parker, H. Parker, H. Cooper, C. S. Baynton, G. Warren, and R. J. Bailey.

Widnes Photographic Society.—December 6, Mr. V. C. Driffield in the chair.—A paper was read by Mr. ARTHUR WAREING on *The Chemistry of Photography*, dealing with all the more important reactions involved in the production of a photographic negative. After having dwelt on the desirability

of a correct understanding of the scientific principles upon which all photographic operations depend, which, although to the amateur not an absolute necessity, is, at any rate, most likely to enable him to attain to the highest perfection in the pursuit of his art, the essayist explained the various theories (which have from time to time been published) of the action of light upon the sensitive film, concluding that the result was a physical rather than a chemical one. He illustrated the distinction between the physical action of light tending to the production of amorphous forms, and the chemical action producing elementary dissociation or molecular disarrangement. He then described the method of preparation of a gelatino-bromide emulsion, the coating and drying of the plate, the method of development, and its final fixation. He concluded with an explanation of the processes of intensification and reduction, explaining the circumstances under which either might be necessary. Messrs. Driffield, Newburn, and Warner commented upon the paper, and complimented the essayist upon its very able and comprehensive character, and a hearty vote of thanks was accorded to him.

Edinburgh Photographic Society.—December 6, the President (Dr. Drinkwater) occupying the chair.—A paper, the second on the rota, entitled, *Brief Notes on Lantern Slides*, was unavoidably postponed, owing to the rather sudden indisposition of its author, Mr. William Hume. An illustrated (with lantern views, &c.) paper on *Matters Pertaining to the Art Side of Photography*, was read and dilated upon by Mr. JAMES PATRICK. His contention was, that there was no such thing as mechanical aids to the composition of a picture, by which he meant to convey that a picture could not be composed, or even selected, by rule, yet there were a few principles, arrived at by the study of the best works of the "masters in art" which, if carefully and judiciously applied to every picture, would greatly conduce to success. In showing about thirty transparencies from his own pictures, Mr. PATRICK pointed out the application of these principles as being helpful in the good composition of views from nature where there could only be choice or selection, not arbitrary making of subjects. The lecture and demonstration were wound up by an urgent wish that the members in their outdoor work should do more than pourtray the mere external beauties of nature, which were patent to all; they should rather strive, in dealing with subjects that had the elements of poetical and sentimeutal beauty, to convey, by their treatment of such, a little of the feeling excited by the subject itself, holding that works so rendered, however imperfectly, would do more to elevate, and stimulate, and to raise photography in the scale and as a fine art, than all the bare and bald renderings of the hard facts and prosaic details of nature, however excellent might be their mere photographic truth and skill. A short conversation followed, in which several members took part. The remarks were all void of the controversial spirit, being rather the expressions of individual taste than the laying down of any special lines or infallible rules for producing effects. After the routine of minute reading, &c., was over, five new members were admitted by ballot—Messrs. Allan, Cumming, Grey, M'Culloch, and Slater. The PRESIDENT then intimated the general course of business for the remainder of the session. There would be three Popular Meetings: the first, on December 21, by Mr. W. Lamond Howie, on *The Scottish Alps;* the second, by Mr. James Patrick, on January 26, *Through Fife with a Camera;* the third, on February 23, for the usual display of members' work; also that a series of lectures on photographic subjects would be given during the season, and, where necessary, the papers at the monthly meetings would be demonstrated once a week in the dark room of the Society.

Photographic Society of Ireland.—November 23, Professor J. A. Scott (President) in the chair, when the lecture, entitled *Photographic Sketches Here and Elsewhere* (illustrated), was delivered by Mr. V. E. Smyth. Mr. Smyth showed a varied assortment of slides representing tit-bits in Holland, Switzerland, Italy, and at home, and described a tour through these countries.

FORTHCOMING EXHIBITIONS.

1893.	
December.....	*Madras. The Hon. Secretary Amateur Photographic Society, Madras.
,, 18–Jan. 22, 1894	*Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—I notice a letter in your last issue from the Britannia Works Company *re* the above subject, and having looked through the ALMANAC, and finding that no doubt it was my article therein which had given them offence, may I point out to them that I wrote against gelatine papers as a whole, and not against any particular makers? If my article has given them, as it appears to have done, a free advertisement, I am sure they ought to be very much obliged to me.

First as to my contention that gelatine paper was more expensive than albumen home-prepared (not ready-sensitised). This I maintain is correct. True, I did not in my calculations reckon the cost of labour, plant, &c., but for argument's sake we will place to the credit of gelatino-chloride, 3*s.* 10½*d.*, leaving albumen still the cheaper by 4*s.* per quire, although I do not admit for one moment that labour and plant would cost this. Secondly, are we to infer that with gelatine paper there is no waste? My own experience is quite the reverse. I maintain that there is quite as much, if not more, than with albumen. True the paper is a trifle larger in the sheets, but, as they have to be trimmed as a rule before toning, this is not a very great advantage, the paper being very liable to become affected by damp, although protected by a pad of indiarubber. On a fine dry day printing a rich purple, on a wet day a foxy red, I ask you, sir, does this not affect the resulting tone of the print? For this reason I maintain that it is more difficult to get twelve prints alike in tone and depth of colour than it is with our old friend albumen.

I ask the gentleman, whoever he may be, which is the simplest to work, and which gives the best all-round results? As he appeals to practical men, if he is practical himself, which, of course, I have no reason to doubt, he must be able to answer this question, but naturally his interests will be on the other side.

Now, as to the consumption of more gold. Again I maintain I am not in error, or else why do the Company, or, for the matter of that, other makers, give in their formula two grains of gold to the sheet? Surely, if the paper could be toned with, say, one grain, is it not a great waste to use two grains? It is a well-known fact among practical printers that certain brands of albumen paper can be toned with less than one grain of gold per sheet, although one grain is given as the standard quantity, so will leave it to your readers where the false statement comes in.

As to yellow prints and double tones, no doubt careless working will account for this, but in my own case I obtained them although I followed the instructions to the letter; this was some months back, as I have ceased using it now. In conclusion, I may inform the Company that I have no interest either way, pecuniary or otherwise, in the rise or fall of gelatine or albumen paper, but, being asked by the Editor for a practical article for the ALMANAC as in former years, wrote what I considered would be an interesting subject to its many readers. I have no wish to enter into a controversy; but, as the Company have forced themselves to the front by their letter, it gives me no other option but to reply to them, and will leave your readers to judge who is in error.—I am, yours, &c.,

Rose Cottage, Bowbridge, Stroud, Glos. J. H. SMITH.

To the EDITOR.

SIR,—Notwithstanding the Britannia Works Company's denial of the experiences as stated by several contributors in your ALMANAC, I beg to say I am yet another user of above paper who has found many of these experiences perfectly correct. I am not a "scribbler" in your ALMANAC or any other, nor have I any interest in any photographic paper company whatever, either albumen or otherwise. I can truthfully say that gelatine paper does consume more gold than albumen, and, if good, even tones, approaching purple, be looked for, considerably more. I have never found yellow stains, but I have found yellow prints. In short, my experience (after exhaustive trials with both plain and distilled water) is this: You make up bath to 16 ounces, as directed, with 2½ grains of gold. Take, say, a tube or packet yielding 6 10 × 8s. Tone 3 pieces; these proceed beautifully, and tone in about 6 to 10 minutes. Pour toning bath back into bottle. Try and tone remaining 3 10 × 8s in 3 or 4 days. Now these absolutely refuse to tone, and, if kept in bath for 20 or 30 minutes, high lights get slaty, and, if put in hypo, come out so with the rest of the picture yellow. Adding more gold only seems to make print more washed out than ever. I suppose I shall be told "*gold deposited*"—if so, it is due to the paper. I thought so; bought new everything, even to bottles. All the same. The only way to tone remaining three is, remove from old, wash, and place in a freshly made bath, throwing the old one, with the greater amount of gold, down the sink. It is quite possible that this procedure may satisfy small workers, but I found it impossible to tone a large batch, getting all prints even, unless I am prepared to lose a quantity of gold. (How I proceeded for years with the old albumen, using acetate or lime, was, after toning, pour back into bottle, adding gold to sheets used. These baths have worked, more or less, for 3 months.) If the Britannia Works Company, with all the means at their disposal, will show me and numerous others how to avoid this behaviour of the toning bath, I will thank them.

I beg to apologise for using so much of your valuable space, but I like the process immensely, and should be deeply grateful to any one who could let me know how to successfully work it.—I am, yours, &c., for once a SCRIBBLER.

P.S.—I send you, Mr. Editor, a parcel of prints to show you that I think my knowledge of photography should enable me to manage printing-out paper.

[The prints referred to will be retained in our office for a few days to enable those interested to call and examine them.—ED.]

SPOTS AND PINHOLES.

To the EDITOR.

SIR,—In THE BRITISH JOURNAL OF PHOTOGRAPHY for September 29 is a letter from a gentleman named Fisher upon the above, and, as a careful reader of the JOURNAL for many years, I have not seen any reply given to it. He states the interesting fact that the plates of one maker gave spots and pinholes *ad libitum*, whilst those of two others were entirely free from this defect. He put the fault down to dust and a defect in the film from the plate being imperfectly cleaned previous to coating, and from blistering when drying after coating, also frilling at the edges. So much for the case.

This apparently inexplicable puzzle is easy of solution when you get the key to the riddle. Many years ago the writer experienced the same trouble, and returned to the makers some dozens of plates in consequence. The time occupied in touching out spots in a gross of valuable negatives was hard lines, both for himself and assistants; and, after many experiments had been made to discover the cause, it was proved to occur in every brace of plates which had tissue paper between them, to the non-removal of the antichlor (hypo) left behind in the paper, which, acting on the film by pressure, having been possibly packed while warm and before being desiccated, the spots on one plate were reversed. Other makers whose plates he used put blotting-paper between them, and there was never any defect. Even after five or six years' keeping the plates were in excellent order. Your correspondent can prove this for himself by taking one of the same brand of plates and placing a sheet of the defective tissue over the film side, and giving it a full exposure in a printing frame to a good light, then developing with our old friend pyro and soda, and a good black surface will be formed, on which the pinholes, &c., will be fully brought out if the paper be the same. That is how we discovered it.

Trusting that this explanation may meet the difficulty and be an assistance to others,—I am, yours, &c., HARDING WARNER.

Malvern Link, December 11, 1893.

ROLLABLE FILMS.

To the EDITOR.

SIR,—To the users of the rollable films now in the market the letter of Mr. Bourne and your Editorial will be welcome. After some years' experience with Kodak films, I have come to the conclusion that the tendency to curl and twist in those films varies in different spools and is more pronounced in the films sent out of recent years than in those made four or five years ago. So marked has that tendency become, that of all the spools exposed by me during the past season abroad I have found very few films that would remain flat on the dish during development, and therefore now find it advisable to place the film face upwards on glass, and secure each end to the glass by an elastic band. If kept in that position during development, fixing and the subsequent washing, I find that there will be very little difficulty with the films afterwards. Of course, the mark made by the elastic band at each end will slightly curtail the size of the negative.—I am, yours, &c., CELLULOID.

Prestwich, Manchester, November 28, 1893.

RAPID FILMS *VERSUS* PLATES.

To the EDITOR.

SIR,— Mr. Conybeare treats the differences in our views so reasonably and with so evident a desire to get at the truth, that I think we ought to work together to unravel this subject. But he will allow me, I hope, to say that his own experiments show that he does not take the precautions I consider necessary, as he says that one of his was inconclusive, "due to either the light having gone off between the two exposures, or showing it to be a less powerful developer," which indicates that he did not take the precautions I consider necessary to secure a perfectly equal light which, however, may be easier in this climate where we have sunshine on some days unbroken by a cloud from sunrise to sunset. I always take the midday of one of these days for comparative experiments.

But Mr. Conybeare may remember that I noted the fact that the great difference I found in extremely short exposures, as between films and plates, did not appear in time exposures. This renders the problem more puzzling. Then, the quality of the plates is another element of uncertainty, and I am almost disposed to think that there are brands of plates made on the Continent quicker than any I have been able to get from England. The fact, is that I have got fair negatives with an exposure of 1-1000 sec. by the Thornton-Pickard estimate, with a Schleussner plate, while with no film have I been able to get the same at the lowest power of the focal-plane shutter, at the speed of 1-200, *i.e.* But my experiences were not made, as Mr. Conybeare supposes, in "ordinary work" but mainly as experiments for the purpose of deciding this question which seems to me of great importance.

I said that the very rapid films fogged after two months, which does not involve, as Mr. Conybeare seems to think, a change in my statement, but simply that the films which had the reputation of being the most rapid in the market went bad after two months, while the rapid films of other makers are good after eighteen months, but not so rapid to begin with. I have no doubt that the celluloid has a certain chemical effect on the emulsion that is put on it, and to determine this the makers of the very rapid plates might help us by coating plates and films alike with some of the most rapid emulsion they can make.

As to amidol in comparison with other developers, I have given it the most severe and exact tests in my power, and I find that it does not give the results that pyrogallol does. This is the opinion also of the most careful and scientific experimenters I know. I consider it as on a level with eikonogen, and the two the least energetic developers on the list.

As to the reason of the deterioration of films, I believe that the letter of Messrs. Guiterman touches the truth; but, as I know nothing of the nature of their wares and the difference between them and other, I can go no further. The whole subject is mysterious, like many chemical combinations. There seems to be some relation between extreme rapidity and rapid deterioration, and this corresponds to the condition with plates, of which the slowest keep best.

I enclose you two prints, taken at the highest speed of the Thornton-Pickard focal-plane shutter, to show you what I got with plates; with films I did not get a printable image. I am, yours, &c.

W. J. STILLMAN.

MESSRS. HURTER & DRIFFIELD'S WRITINGS.

To the EDITOR.

SIR,—It is frequently assumed that Messrs. Hurter & Driffield have not written any papers on their method of speed determination of plates in a popular and easily understood form. This assumption, like many another one with respect to Hurter & Driffield's work, is quite erroneous. We are now reprinting some of these papers, and shall be pleased to supply them free to any of your readers; or, if your space permits, you may possibly like to reprint them in THE BRITISH JOURNAL OF PHOTOGRAPHY.—I am, yours, &c., MARION & Co.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Wanted, 8½×6½, or 12×10 rapid rectilinear lens, by a good maker, in exchange for quarter-plate hand camera, fitted with eighteen single metal slides, focussing screen, finder, and rapid-view lens.—Address, W. HOLMES, Photographer, 136, Derby-road, Heanor.

Wanted to exchange a seven-string banjo, nickel-plated hoop, twenty-four brackets, splendid tone, in American leather case, new last August, for half-plate camera, no lens, or an enlarging lantern.—Address, J. COX, 26, Edward-road, Clarendon-park, Leicester.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

CATALOGUE REGISTERED:

Thornton-Pickard Manufacturing Company, Altrincham.—*Catalogue of the Thornton-Pickard Photographic Specialities as appeared in* THE BRITISH JOURNAL ALMANAC *for* 1894.

PHOTOGRAPHS REGISTERED:

George Emberson, jun., Chertsey.—*Four photographs of Miss Nelly Wick, the Champion Shaver.*

Richard Tudor Williams, Monmouth.—*Two Photographs of His Eminence, Herbert Vaughan, Cardinal Archbishop of Westminster.*

W. C. GORDON.—Two photographs were registered.

A. M'CANN.—As chemicals work slower in cold than in hot weather, you might try the effect of a gentle heat. If this fails, write to the makers.

GEORGE BANKART.—1. Yes. 2. Yes, by Ross & Co. 3. They are now advertised; see advertisement in ALMANAC. 4. In all probability. Thanks for enclosure.

J. P. W.—If you refer to the formulæ in the ALMANAC, you will find several that are excellent. Try one or more of them, and adhere to that which suits your purpose best.

W. MURREN.—It is evident that the toning bath you employ is not adapted for that special paper. We have used a good deal of it, but have not obtained weak tones such as those of the specimens enclosed.

CHAS. JONAS.—If the gelatino-chloride paper has become the colour of "whity brown shop paper," the best way to utilise it is to burn it, and add the ashes to the residues. There is no way of using it photographically.

ANDREW SMALL.—Burton's book on *Photo-mechanical Printing* (published by Marion & Co.) may suit you. There is also a translation, by Mr. E. C. Middleton, of a book on collotype by Schnauss, which enters fully into the subject.

W. G. RAINSFORD, D.D. (President, Crewe Amateur Photographic Society).—We made repeated applications for particulars of your Society's officers, &c., for inclusion in the ALMANAC, without receiving any reply. Hence its exclusion.

FOCUS.—1. It will not pay to grind focussing screens by hand. 2. Most photographers back their own plates. If you have any preparation better than can now be obtained, you might give it publicity. 3. Write to the principal dealers.

H. P.—Your query is one that should be referred to a solicitor. We cannot in this column undertake to give advice on legal matters as regards the law of "Landlord and Tenant," although either the landlord or the tenant may be engaged in the photographic profession.

E. BLICK.—We cannot recommend any dry plates of better quality than those made in this country. We have never heard before that plates of better quality are made on the Continent than here. Be that as it may, English plates are probably more used on the Continent than those of native production.

W. RANOR.—It would be impossible to say which is the most permanent—gelatino-chloride or collodio-chloride prints—as the former have only been on their trial for a few years. The latter have had a longer trial. We have some by us that we made over a quarter of a century ago, and they show no sign of changing.

JOHN DORMER.—We cannot account for the flare spot in the micro enlargement unless on the assumption that, having removed the eyepiece, there is reflection from the inside of the tube. This you will be able to ascertain from personal observation. If it prove to be so, then a remedy will be found in lining the tube with black velvet.

J. COOK.—The colouring is nice and effective, and you should persevere in the development of the industry. How any one can obtain a patent for a similar system of colouring that can be valid rather puzzles us, as sets of liquid colours for this purpose have been in the market for many years. We shall know better when the specification is published.

CLUTHA writes: "In your issue of 1st inst. (supplement, p. 116), Mr. James Lewis refers to a vegetable parchment which is obtainable in rolls of sixty inches in width, which makes an admirable translucent screen. Could you kindly mention in your next number the address of some firm which supplies it?"—Messrs. Bemrose & Son, Old Bailey, supply it.

S. X.—Most of those who work professionally use a dynamo machine for the decomposition of the copper. But one we assume is not available in your case, therefore we should advise you to employ a Smee's battery of a tolerably large size. For the size plates you mention, the platinised silver plate should not be less than eighty to ninety square inches.

T. S.—We should advise you not to carry out your idea of making a collection of photographic copies of bank-notes of the different denominations, as an attraction to your showroom. Your friend the bank clerk, who promised to lend them to you, ought to have told you that to reproduce bank-notes in any form was illegal, and would subject you to prosecution if the authorities were aware of it.

CURATE.—If the music is copyright it would be piracy to copy it, even for lantern slides for your own entertainments in the parochial rooms, and in copying it you would, of course, render you liable to the penalties according to the law. There would be no harm in asking the publishers for their permission. They might possibly accord it, but that is somewhat doubtful if they hold an unexpired copyright.

THOS. A. MORYSON.—The imparting of a matt surface to paper prints by the application of matt varnish was suggested and tried many years ago, but no one seems to have cared much for the effect produced. Far otherwise was it with stereoscopic transparencies, as produced by Ferrier & Soulier some forty years since. The matt varnish employed by them was, we think, composed of a solution of white wax, and gave a grain so fine as to be imperceptible even by a high magnifying power.

SYNTAX.—Although the Copyright Act is in a very unsatisfactory state, it is quite clear on the point upon which you seek information. If any one has pirated a picture in which you hold the copyright, you have your remedy in a court of law. The infringer is liable for penalties or damages. We do not remember the details of your previous communication. The photographers referred to agreed to give the illustrated papers permission to reproduce the pictures, in which they hold the copyright, for 21*s.*; but this does not bind any one else to do the same. Every one has the right to make what terms he chooses.

CHESTERFIELD.—If the cylinder has been tested by your boiler-testing apparatus every time before it is sent away to be charged to double the pressure of the gas when it is filled, we should not care about having much to do with that vessel when fully charged. Have you read the expert's evidence given at the inquest on the late Bradford catastrophe?

SELCINNUR.—To obtain the full benefit of the nine-inch condenser when used with a small plate, let such plate be placed so far from the condenser as just to be covered by the cone of light emerging therefrom, and employ an objective no longer in focus than to cover the plate and take up all the rays transmitted through the condenser. An objection to using stereoscopic transparencies as lantern slides lies in the fact that they are, or ought to be, much denser than the latter. But, if thin, they will answer quite well.

HOWARD DALE.—We occasionally use the Kodak, and with uniform success. An aperture of *f*-11 amply suffices for snap-shot work. Some workers use a much smaller stop, *e.g.*, *f*-16, and get good instantaneous effects. Of course much depends upon the lighting of the subject, and, if the weather is dull, the speed of the shutter should be made slower than on a bright summer day. With thin films there will be practically no halation. They are quite easy to develop and dry, and the exposed portions may be detached from the remainder on the roll.

CYMRO.—A portrait lens must be specially constructed to allow of the reversion of the back crown. Among the peculiarities of construction are these:—The front combination should be of much shorter focus than the back, the curves of the back combination should be of longer radii than in the present form, and the distance between back and front rather less. There is always a difference between the back and the equivalent focus of a portrait combination. Your stop marked *f*-8 is not quite correctly marked; *f*-9 or, possibly, *f*-10 would more correctly represent its value.

COLLOTYPE asks: "What is the best form of hand machine for collotype process—the ordinary litho with scraper, or the one with vertical pressure? Also do you know of a thoroughly practical man that would teach the process?"—In England the ordinary typographic press, such as the "Albion Press," as supplied by all dealers in printers' materials, is the one most generally used. On the Continent presses with a scraping pressure are more generally employed. An advertisement in the columns of the business portion of the JOURNAL will possibly secure you a tutor.

VARNISH AND FROST writes: "Can you inform me how I can take the frost out of varnish on oil paintings? I had twenty varnished during an afternoon this week, and next morning they were all dull and 'starred' with frost. Have revarnished one as an experiment, but it comes through again just the same. They are all direct portrait paintings in oil."—From the description we do not understand the case, unless an unsuitable varnish was employed. We have never heard of an oil painting, not on a photographic basis—and that is what we surmise is meant—being "starred" by the varnish, or by any varnish that is usually employed for such pictures.

E. MILLHOUSE says: "I have recently taken up the carbon process, using ——'s paper and instructions. Everything went smoothly enough until the second transfer came along, and in every case I was unable to strip the final support from the temporary support. Increasing the amount of yellow wax in waxing solution has been tried without success. I have, of course, followed out the instructions in every respect. Besides soaking the final support in warm water, I have tried cold water before applying to temporary support. Can you kindly suggest one or two probable reasons for my failure?"—Our correspondent fails to say what was the temporary support, whether glass, zinc, or Sawyer's flexible support, and the kind of waxing solution employed. If either of these supports was employed, with the wax solutions recommended for them, there should be no difficulty.

PYRO writes: "Would you be good enough to reply to the following through THE BRITISH JOURNAL OF PHOTOGRAPHY? I have completed an invention which I wish to patent, but have not the necessary capital. Would it be possible to register it first and patent it afterwards? What would it cost to register? Supposing I registered my apparatus, how long should I be protected? If anybody copied or made apparatus like mine, I suppose there is a penalty for so doing? The question is, Can I register something that is made, or does registration only apply to photographs and trade marks? I should feel much obliged for your reply."—Registration does not apply to apparatus. Our correspondent can obtain provisional protection for his invention for twelve months, the cost for which is twenty shillings only, if he does not employ a patent agent. If, before the end of nine months, he lodges the complete specification, a patent will be secured for four pounds, which will last for four years.

RECEIVED.—*Handbook on the Use of Compressed Oxygen*, by K. S. Murray. In our next.

WINDSOR CASTLE

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1755. Vol. XL.—DECEMBER 22, 1893.

SOFT PRINTS FROM HARD NEGATIVES BY THE CARBON PROCESS.

In the article on carbon printing a fortnight ago, the subject of obtaining vigorous prints from feeble, or perhaps it would be more correct to say the delicate, gelatine negatives of the present day, was dealt with. We here propose to deal with another and opposite phase of carbon working, for it is not an uncommon thing, even now, to sometimes find negatives of quite an opposite character to those alluded to. We do not mean simply vigorous ones, in which the lights and shadows are in perfect harmony throughout, but that class in which the high lights are dense and hard, while the shadows are thin and bare—such, indeed, as used to be termed of the "soot-and-whitewash" type. Negatives of that nature were much more prevalent in the collodion days than they are now, and it was those which gave the greatest trouble to the inexperienced carbon worker in times past.

Reference was made in the previous article to the fact that very little had been done — or, at least, published — as to modifying the working of the carbon process so as to adapt it more completely to the delicate negatives now so general, as in the case of some other processes. It so happens, however, that this process is capable of variation, to suit different requirements, to perhaps a greater extent than any other printing method. What was published as the best condition for working when the average type of negatives was so different from what it is now has been handed down, and usually accepted by novices as the most suitable at the present time.

A little consideration will suffice to show that, to obtain the best results from negatives of an extremely opposite character, the object will be to exaggerate the contrasts in the one case, and subdue them in the other. It is the latter point that will now be considered. It is well known to all experienced carbon workers, that the more highly sensitised the tissue is, or, to be more correct perhaps, the more bichromate it contains, the softer, and with less contrasts, will be the resulting prints. Therefore the tissue to secure this end must be highly sensitised, and, if the sensitising is done at home, a bath of even seven per cent. may be used, and a tolerably long immersion allowed with advantage. There is, of course, a limit to the strength of bath that can be used, inasmuch as, if it be of too great a strength, some of the bichromate salt will crystallise out on the surface of the gelatine as it dries, which would, of course, be detrimental. Tissue that is so strongly sensitised as this must not be expected to retain its solubility for so long a time as that which contains a smaller proportion of the bichromate. But the quicker it is dried the longer it will keep, and it so happens that quickly dried tissue, as a rule, gives softer prints than that which has taken a long time to dry. Hence there will be a double anvantage gained by drying this particularly sensitised tissue more rapidly than usual. This highly sensitised tissue, although it will not keep so long as more weakly sensitised, may, if quickly dried, generally be found to retain its solubility for a week or ten days. In the former article it was mentioned that tissue that was sensitised in the making prints, as a rule, with less contrast than that which is rendered sensitive afterwards. For this reason it will be an advantage, as well as a greater convenience, to employ the former.

As to the printing, this should be done in a strong light—direct sunlight if that be available—so that the densest portions of the negative are quickly penetrated. As the "continuating action" has a tendency to increase the contrasts, it follows that the picture should be developed soon after the tissue is taken out of the printing frame. Here is a very useful dodge that is usually adopted by carbon workers when dealing with negatives of the "soot and whitewash" nature. After the tissue is removed from the frame it is exposed to light for a few seconds, but not sufficiently long to produce fogging or veiling of the high lights, when the print is developed. This slight exposure seems to fix or complete the feeble action the light has exerted through the densest parts of the negative, and prevents the more delicate tints of the lights from washing away before the development is completed. In working from hard negatives over-printing should be avoided, so that moderately cool water will suffice in developing. Then the deepest shadows can be locally reduced by pouring over them a fine stream of hot water from a jug, or by rubbing them with a soft camel's-hair brush, or the two artifices combined.

There is yet another means by which the carbon process can be modified to meet extreme requirements, namely, in the manufacture of the tissue itself. By varying the composition of the gelatinous matters employed, and the apportionment of the pigment to them, the manufacturers are enabled to adapt the tissue to almost every possible requirement. But, as our readers are scarcely likely to go into making their own tissue, it will be needless to enter into this phase of the subject. They may, however, rest content that with the tissue now supplied by our best makers they will obtain that which is best suited to average negatives, and which, with a little modified treatment, will yield results equal to every practical requirement.

THE WET-COLLODION PROCESS.

II.—How to Make Pyroxyline.

Although we have described the making of soluble cotton as a somewhat messy process, we can, nevertheless, recommend that, from an educational point of view, it should be tried. We shall commence by describing a method extensively practised many years ago on account of its simplicity and the good results obtained.

Have in readiness some clean carded cotton-wool, and separate it in tufts, and into a porcelain vessel of suitable capacity, such as a breakfast cup or a bowl, according to the extent of the operations, place a quantity of finely crushed dry nitrate of potash. We always employed the common saltpetre of the shops for this purpose. Now pour in slowly enough sulphuric acid to form a thick solution of the consistence of boiled oil or furniture varnish. A glass rod must be employed for mixing the nitre and acid. The cotton is now immersed in this, tuft by tuft, taking care that each, by the action of the glass rod, is thoroughly submerged and made wet throughout before another is added. Turn the cotton well over to ensure its all being acted upon by the solution. Do not add more cotton than can be easily brought into contact with the liquid. After remaining for from three to four minutes, the cotton, which is now pyroxyline, is lifted by means of two rods or slabs of glass, and transferred to a basin of water, in which it is thoroughly washed in several changes of water. The water is finally wrung out, and the cotton spread out on a towel to dry in a current of air, this being facilitated by pulling asunder the now tangled tufts. When quite dry, it will be found to have considerably increased in weight.

For those who prefer to work to scale, the proportions given by Count Montizon may be adopted, which are: one and a half ounce nitrate of potash, ten drachms of sulphuric acid, and forty grains of cotton. We have made pyroxyline by this formula, but always considered that the proportion of sulphuric was too small. We have also worked by the proportions given by Ash Haddow, which are: five parts of nitrate of potash, ten parts of sulphuric acid (by weight), and one part of water.

When the mixture is made, it is accompanied by the production of heat, and it is important that the cotton be added before it is allowed to cool, for, as it cools, the mixture becomes quite thick.

The final washing of the cotton should be given with tepid water, to ensure the removal of the bisulphate of potash, for if any traces of this salt be left in the cotton, although, so far as we have found, it does not lessen the sensitiveness of the resultant collodion, yet does it impart a certain degree of opalescence to the collodion film when spread upon glass. This does not interfere with its utility for negatives, but is apt to be detrimental to its employment for positives and lantern ransparencies.

When cotton has been prepared as directed, it is not really *gun* cotton, which is prepared in a slightly different manner. It is, however, explosive in a slight measure, and hence, if the drying is completed by spreading it before a fire, exceptional care should be taken that no sparks get near to it.

We believe that almost all the large makers of soluble cotton now do it by the admixture of nitric and sulphuric acids. When these are mixed in nearly equal proportions, and allowed to get cold, the cotton treated by immersion therein is highly explosive, but very sparingly, if a tall, soluble; but, by warming the mixture before immersing the cotton, the solubility is increased, and what photographers desire is, the extreme of solubility without explosive qualities. These properties are imparted by weakening the acids in a slight degree by the cautious addition of water, and raising the temperature to 130° Fahr. previous to the immersion of the cotton.

Haddow, the earliest and most exhaustive experimentalist in this direction, availed himself of these facts in order to produce collodion wool by the use of acids, without the trouble of calculating the proper mixture according to their strength. He mixed five parts by measure of sulphuric acid and four of nitric acid (not lower than 1·4 sp. gr.) in an earthenware vessel, and added *small* portions of water at a time, testing after each addition by the immersion of a tiny portion of cotton. This addition of water was continued until a fresh piece of cotton was found to contract and dissolve on immersing. When this took place, half the quantity of sulphuric acid originally used was added, after which as much cotton as could be soaked was immersed for ten minutes, care being taken that the temperature of 130° was maintained. Thorough washing in several changes of water follows, litmus paper being employed to indicate the total removal of the acids. This gives a cotton that dissolves perfectly and instantaneously in ether without leaving a film behind, and the film it produces is of great strength and transparence.

Instead of cotton-wool, filtering paper is preferred by many in the preparation of pyroxyline. It is certainly easy to manipulate, but beyond this it does not appear to possess any special advantage. Linen, too, has by some been strongly recommended. For this we have this good word to say—that, when dissolved in ether, it gave the strongest and toughest film we have seen.

It is impossible to say from an examination of the collodions of commerce whether they are prepared from wool, paper, or linen, as information of this nature is not usually given to the world by the respective manufacturers.

PHOTOMETERS FOR USE IN PRINTING.

Although the rapid spread of process work and the revival in popularity of carbon printing have given a prominence to the employment of the photometer that did not exist a few years ago, there are other applications of the instrument equally useful in their way, but almost, if not altogether, neglected at the present time. In the two branches of printing above alluded to, a photometer of some sort may be said to be an absolute necessity, and is consequently provided as a matter of course; but in more than one department of both professional and amateur work, although no thought is given to the matter, considerable advantage is to be derived from its systematic use.

To give but one or two examples, let us mention the production of opals or transparencies on print-out emulsion plates, a class of work which, in the absence of specially constructed frames, allowing of the accurate preservation of register while the progress of the printing is watched, is little better than guesswork. Such frames are necessarily expensive, and, unless required for regular use, as in a professional establishment, are seldom provided, the amateur or other small producer preferring to trust to luck or subterfuge in securing accuracy of exposure. Intimately connected with the same branch of printing is the newly introduced system of development of gelatine-chloride proofs on paper, which promises to be largely employed during the duller months of the year, if not, indeed, even during the

summer. Here we have little hesitation in saying that considerably more uniform success would be obtained if the exposures were gauged by means of the photometer rather than by mere inspection.

But another phase of the question may be looked at, and this refers chiefly to printing in platinotype, though, in a less degree, also to gelatino-chloride. It is needless to point out, much less enlarge upon, the necessity in the former process for guarding the paper against damp before and during exposure and previous to development. The importance is less generally recognised of treating gelatino-chloride paper with similar, if perhaps not such rigid, care; but the necessity does exist, nevertheless, and many of the complaints of failure and want of uniformity of tone would remain unheard of if a little more trouble were only exercised in the matter of protection of the paper from damp.

At this period of the year it avails little to keep the printing paper, whether platinum or gelatino-chloride, in calcium tubes or other damp-proof receptacles, or to back them up in the printing frame with indiarubber sheets, if, every time the frame is opened for the examination of the prints, the latter is freely exposed to an atmosphere heavily charged with moisture. The very fact of the paper having been previously kept in a state of practically perfect desiccation renders it all the more liable to absorb with avidity the moisture to which it is presented, and, almost before it is possible to suspect it, the seeds of future harm are sown; but, if the exposures are made by means of a single photometer, there is no need to open the frame at all; and, provided both negative and paper are thoroughly dry to commence with, and are put into the frame in an ordinary warmed room—as all printing rooms should be—the print, after exposure, may be returned to its case in absolutely the same condition after exposure as before. This is certainly not the condition of affairs when it has been opened for examination half a dozen or a dozen times in a cold, damp atmosphere, such as prevails as we write.

For these and similar purposes a simple form of photometer will be found a most valuable addition to the photographer's appliances, whether he be amateur or professional. But here we would ask those of our readers who are not technically acquainted with the instruments used by photographers under this name to grasp fully what is meant by the term, and to distinguish between that and the somewhat similar term "actinometer." The latter, as usually employed by photographers, is an instrument designed to measure the actinic or chemical value of the light, and is used as the basis upon which to work out a series of calculations, perhaps with the assistance of an "exposure table." "Photometer" is the designation applied, outside photography, to the instruments used for estimating or comparing the relative illumination, or candle power, of artificial lights; but, as used in photography, it signifies rather a means of registering the amount of work done by the light in a given time.

Very many different patterns of photometers have been introduced and used during the past thirty years, and some of these are articles of commerce. In its simplest form, as applied to photographic purposes, the photometer partakes of two principal types, which may be illustrated by the "Johnson" and "Woodbury" instruments, introduced by the late J. R. Johnson and the late W. B. Woodbury respectively. The first consists of a scale of "tints" of gradually increasing density, formed by the superposition of a successively increasing number of thicknesses of fine paper or other material, behind which a piece of sensitive paper is exposed. By experiment, the printing value of a negative is ascertained; that is to say, the number of the tint on the photometer that is impressed during the same period as that required to give the best result with that particular negative. This number having been once ascertained, all that is necessary is to expose the photometer side by side with it, and, when the ascertained tint is impressed, the exposure of the negative may be taken as correct.

In the type of instrument of which Woodbury's is the most familiar form, a series of coloured tints made to represent the successive colour assumed by a piece of sensitive paper are ranged in a circle round a central aperture of clear glass, behind which a strip of test paper is exposed. This instrument is used in the same manner as the former, the reading being complete when the centre aperture presents the same colour as the tint which has been found to best suit the negative under treatment.

Of the two forms, the latter would undoubtedly be the more convenient, if it were only possible, in the first place, to accurately represent artificially the colour produced by the action of light upon any kind of sensitive paper, and, again, to prepare a paper which will invariably give the same colours. No one who has used either albumenised or gelatino-chloride paper—and these are the only ones that are practically available—will have much faith in the possibility of securing with the same exposure, or, indeed, with any exposure, the same gradation, and, above all, the same colour. In the matter of gradation some specimens will print harder than others, or, in other words, take a comparatively shorter time to produce a certain depth of tint, while, in the matter of colour, that may be anything, from brick-red to rich purple.

This, in fact, constitutes the weak point of the Woodbury and similar types of photometer, for it requires but a brief trial to convince any one of the extreme difficulty of judging the relative depth of two tints that are dissimilar in colour; moreover, when a certain depth is reached, it is next to impossible for the eye to distinguish between slight variations, even though the colour be the same. Attempts have been made to overcome the first difficulty by examining the tints under yellow or other coloured glass, so as to practically produce a monochromatic scale, while, to get over the difficulty of distinguishing between tints of considerable depth, the alternative of printing out two or more tints of a lower grade has been adopted. Neither of these has, however, proved completely successful, and for moderately accurate work the coloured scale is little used.

With the graduated translucent scale, however, the question of colour is altogether unimportant, provided the sensitive test paper is impressed by the same coloured rays as the surface to be tested. For example, a test paper sensitive to the green and yellow rays would obviously be of little value in testing a film impressed only by the blue and violet rays, and *vice versâ*. It follows also that the translucent screen or scale should itself be as free as possible from chromatic peculiarities; that is to say, it should be as neutral in character as possible, or, if required for use with films possessing any colour peculiarities, should approach as nearly as possible to the same character. For general purposes, nothing has been found better than successive layers of tissue or other fine paper, as white and free from colour as possible. Then the various grades are produced by increasing degrees of opacity irrespective of colour. If, on the other hand, a screen were formed of, say, thin transparent

films of coloured ge at ne, we should naturally expect, if not an altogether different scale of gradations, at least a scale that would vary with every different source of light, and not improbably at every different hour of the day and season of the year. Want of attention to this most important point has rendered untrustworthy many examples of the graduated scale that have passed through our hands.

One other point that cannot too strongly be insisted on is the necessity in all cases of suiting the trial paper used in the photometer to the sensitive film to be tested as first referred to. Neglect of this important point, or, rather, the practical impossibility of attaining it, is the chief reason why a really accurate actinometer for use in measuring camera exposures is a practical want. Thus, to employ a chloride paper in the photometer in timing the exposure of bromide enlargements would be a palpable absurdity, since the chloride paper is wholly unimpressed by any rays lower down in the spectrum than the blue, while the bromide is more or less sensitive to all the visible rays, but markedly so to the yellow. The consequence would be that, if with one particular kind of illumination an absolutely correct reading were possible, it would be altogether inaccurate when the light was changed.

This difficulty need not operate, however, so far as our present purposes are concerned, as these refer principally to the "print-out" processes in which chloride of silver, bichromated gelatine, platinum, and bitumen are employed, none of which exhibit any appreciable sensitiveness except to blue and violet rays. Although the different processes may vary, and do very materially, in absolute sensitiveness—take, for example, platinotype and bitumen—there is no reason to anticipate any serious inaccuracies in the readings obtained with chloride of silver paper, whichever of the processes it may be applied to.

Wherever possible, it is, of course, advisable to employ the same or a similar test paper in the photometer to that being tested—gelatino-chloride for gelatino-chloride, and albumen for albumen; but it is obviously impossible, except at great trouble and inconvenience, to use carbon for carbon, or indeed to be strictly accurate. But the agreement between the different results is practically so close that there need be very little difficulty in working with a tolerably uniform sample of either albumen or gelatine paper.

Of course, for strict accuracy, the proper plan will be to prepare a special paper, as is always done for purely scientific purposes; but we are not now thinking of any such extreme niceties, and we think it will suffice for all the purposes of every-day work to place reliance upon the paper in actual commerce. Any variation, if such there be, will not be sufficient to cause any serious trouble with the carbon and similar processes, while in the case of albumen or gelatine papers the variations will be identical, both on the photometer and the printing frame.

The most important point that remains is to secure a satisfactory graduated scale, and that part of the question will be treated in a separate article.

Non-rusting Bunsen Burners.—Every one who has had much experience in the use of Bünsen and other gas burners in the dark room or laboratory is familiar with the rusty and generally uncomfortable appearance they attain after a little hard use, and sometimes without any service, simply after being placed aside on a shelf. There seems every reason to believe that such effects may be entirely prevented by the use of Fletcher's "Chematto Enamel." All burners of cast iron so coated are unchangeable by even a continued red heat, and appearance may also be considered, for enamel-coated burners, either dead or bright, can be had in any colour, or in gold or silver, and all alike unchangeable by heat. Our readers must not expect an "Aspinall enamel" effect, but for burner or gas fires the appearance is both neat and cleanly.

Art Progress.—The Duke of Westminster, speaking at the presentation of prizes to the successful students at the Chester Science and Art Schools the other evening, paid a high tribute to mechanical photography. Referring to the progress of art, he said the various processes now being carried out enabled almost the poorest of our fellow countrymen to have very beautiful works of art upon their walls. Notwithstanding the rapid spread of art teaching, it seems somewhat a pity that high-class photographic reproductions of the Old Masters in our national collections are not obtainable by students at a more moderate price than they are.

Easy Rule for Converting Thermometrical Degrees.—The frequent use of Fahrenheit or Centigrade degrees in one and the same periodical show that there is still by no means a universal preference for the latter, hence a ready mode of converting one into the other will be useful. We notice in a recent issue of the *Chemical News* the following communication from Mr. G. Watmough Webster, F.C.S., bearing on this subject:—

I think many of your readers will be interested in the appended rule for the mutual conversion of degrees Centigrade and Fahrenheit, which I devised many years ago for simplifying the usual method of calculation as given in various technical manuals, the latter being cumbrous and not quickly performed, except by an expert reckoner. Almost any one can readily make the conversion by the new rule without even needing paper and pencil. Such a method might be expected to have been published before, but I have not seen it, nor has any one to whom I have imparted it.

To reduce a given number of degrees Centigrade to Fahrenheit.

Rule.—Double the number and subtract one-tenth of the result.

Fahrenheit to Centigrade.

Rule.—Increase the number by its ninth part and halve the result.

The necessary subtraction or addition of 32 at the proper stage is performed in the usual manner.—I am, &c.,

Temperature of Ignition.—In the use of the mixed gases for lantern purposes, the question sometimes arises as to whether coal gas or pure hydrogen is most readily exploded in case of a rise of temperature. An important contribution to our knowledge of the matter has recently been made by Prof. Victor Meyer in conjunction with his assistant Herr A. Münch. It was found that with purer hydrogen and oxygen the initial temperature required to cause explosion varied between 612° and 686°, no difference being found whether the gases be dry or moist. The presence of platinum foil prevented explosion, quick combustion always took place even when a temperature of 715° was reached. When hydro-carbons were used with oxygen, it was found that the temperature needed to induce explosion was lower the greater the proportion of carbon present. Thus the mean temperatures of explosions with methane, ethane, and propane were 667°, 616°, and 547° respectively. It will thus be seen that, whatever the difference may amount to in practice, it is a fact that pure hydrogen and oxygen will be more difficult to explode than mixtures of coal gas and oxygen.

BRISTOL INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

I.

The Bristol International Photographic Exhibition was opened on Monday last, December 18. It is to remain open until Monday, January, 22, 1894. The Exhibition is being held in the galleries of the Academy of Arts at Clifton, a noble suite of rooms admirably adapted for the purpose, and such, indeed, as seldom falls to the lot of a photographic society for the purposes of an exhibition. About a thousand frames of photographs, &c., are placed on view, and they are disposed with such excellent taste and judgment that the visitor

may pass from room to room and be greeted with a variety of *ensemble* and effect such as is usually absent from most collections of pictorial photographs.

So many notable photographic exhibitions have been held since the occasion, ten years ago, when the Bristol Society held its last display, "so many things," as the late Lord Beaconsfield is alleged to have remarked, "have happened since then," that the Council may well have been excused if the Exhibition just opened was entered upon with a certain degree of trepidation.

For exhibitions of a high order are to-day, in a manner of speaking, as common as blackberries in September. Ten years ago it was different. Still, the result has justified the Bristol Society's enterprise, for it has emerged from it with *éclat*, if not triumph. Not merely does the Exhibition amply uphold its international character, three continents as it were being represented in it, but, from a general point of view, we accord it unstinted praise as fully representative alike of modern photographic work and workers. To scan down the list of exhibitors is to encounter the names of the principal exponents of latter-day photographic art. One feature deserves pointed notice, and that is, the almost total absence of prominent examples of the fuzzy school in the manner of the Dudley Gallery. Neither the Exhibition nor the visitors thereto will be the worse for this. The judging appears to have been well done, the "tail" of the display is a small one, and, on the whole, the Exhibition has undeniably earned the stamp of success. We trust that the West of England public will take every advantage of the opportunity given them by the Bristol Society to study photography in its latest and most agreeable phases, and that the financial results will be as gratifying as the artistic. To Mr. Hood Daniel (the President) and to Mr. Bligh Bond (the Hon. Secretary) every congratulation is due.

The Judges' Awards.

The Exhibition comprises twenty-one classes, which, to our thinking, is too many. The Judges were Messrs. S. P. Jackson, R.W.S., Valentine Blanchard, B. Alfieri, Payne Jennings, and H. A. Hood Daniel (President of the Society). In their report they say that "the Exhibition is exceptionally large, and the classes with few exceptions are so strong and of so high an average grade of quality that the difficulties presenting themselves could only be overcome and justice done by the award of extra medals." Their awards are:—

Class I. (Champion), gold medal, No. 176, *Kelp Gathering, Iona*, W. M. Warneuke; first extra silver medal, No. 130, *A Still Delight Steals o'er the Earth*, J. B. B. Wellington; second extra silver medal, No. 185, *Saturday Afternoon*, F. M. Sutcliffe; third extra silver medal, No. 308, *Miss M. Wilson*, H. S. Mendelssohn. Class II. (Large Landscapes), silver medal, No. 8, *On the Derwent*, Bernard Lintott; bronze medal, No. 50 (*a*) *Sun, Fog, and Frost*, (*b*) *A Winter's Day*, (*c*) *Stanford Lane*, Robert Frost; extra bronze medal, No. 55, six *Views along the Streams of Normandy*, Rev. Precentor Main. Class III. (Small Landscapes), No. 201, *Strand on the Green*, Henry Smith; bronze medal, Nos. 238–246, a hayfield series, Walter Norgrove. Class IV. (Large Marine), silver medal, No. 813, *On the Top of the Tide*, Bernard Lintott; bronze medal, No. 796, *Whitby Harbour*, F. M. Sutcliffe. Class V. (Small Marine), No. 292, eight views by H. Oswald Isaac, and Nos. 280, 286, 297, three frames by Mr. H. W. Bennett, bracketed equal, each receiving a silver medal. Class VI. (Large Instantaneous), bronze medal, No. 524, *Toby and Jack*, Edward Hawkins. No silver medal awarded. Class VII. (Small Instantaneous), silver medal, No. 528, hand-camera studies, Percy Lewis. No bronze awarded. Class VIII. (Interiors), silver medal, No. 627, *The Choir, St. Paul's Cathedral*, H. W. Bennett; bronze medal, Nos. 673 and 675, *Haddon Hall* and *Tewkesbury Abbey*, Harold Baker; first extra bronze medal, Nos. 637, 655, 656, *Library, Hampden House; Grand Hall, Mentmore; Interior, Waverley Abbey*, S. G. Payne; second extra bronze medal, No. 685, three interiors, G. Hepworth. Class IX. (Architecture), bronze medal, No. 581, *Gateway, Whitby Abbey; South Porch, Tatton; Porch, St. Stephen's, Bristol*, W. Crofton Hemmins. No silver medal awarded. Class X. (Small Portraits), silver medal, No. 459, *Portrait Studies*, Harold Baker; bronze medal, No. 467, Harold Baker. Class XI. (Large Portraits), silver medal, No. 417, *Portrait of a Child*, W. M. Warneuke; bronze medal, Nos. 472 and 473, *Rev. Stopford Brooke* and *Mr. H. E. Davis*, Fred Hollyer. Class XII. (*Genre*), silver medal, No. 355, *Where'er you go, &c.*, Miss E. J. Farnsworth; bronze medal, No. 358, *Life in a Court*, F. M. Sutcliffe. Class XIII. (Enlargements), silver medal, No. 850, *Polar Bears*, H. Sandland; bronze medal, No. 860, *Reflections*, W. A. Cadby. Class XIV. (Transparencies), silver medal, No. 874 and series, E. Brightman. Class XV. (Stereoscopic Transparencies), silver medal, No. 919, J. H. Spencer. Class XVI. (Lantern Slides), silver medal, No. 885, T. M. Brownrigg; bronze medal, No. 891, George Hankins. Class XVII. (Scientific), silver medal, No. 691, &c., enlarged photomicrographs, W. I. Chadwick. Class XVIII. (Botanical), bronze medal, No. 564, *Fruit*, J. T. Hopwood. Class XIX. (Zoological), silver medal, No. 730, *Animals at the Zoo*, H. Sandland. Class XX. (Local Survey), silver medal, Nos. 770–777, *Bristol Churches*, E. Brightman; bronze medal, No. 763, *Bristol Churches*, W. C. Hemmons. Class XXI. (General), silver medal, Frena camera; bronze medal, No. 1012, *Pompeian Lady*, F. Hollyer; first extra bronze medal, No. 334, flashlight portraits, F. Bromhead; second extra bronze medal, Allendale slide changer. Total, forty-one awards. There are 189 exhibitors, and, including a loan collection, Judges' exhibits, &c., 1023 exhibits.

The Classes.

The class for large landscapes is, undoubtedly, a good one, Mr. Bernard Lintott's medal picture, *On the Derwent*, a carbon study of cattle in the foreground of a river, trees and hills rising off to the distance, being full of quiet dreamy charm and softness. Mr. R. J. Fry has three Welsh views, ably executed; and there is an Alpine series by Mr. W. England. Mr. Wellington shows his familiar *Evening on the River Thames*. A word of praise is due to Mr. E. Hawkins for *Winter* and *Hoarfrost*, two carefully treated studies of not easy subjects. Mr. R. Frost, however, with three small views of a similar nature, is even more successful, the bronze medal going to him for a frame of delightfully printed studies on Matt P.O.P., their delicacy and gradation being remarkably good. Extremely interesting are the Rev. Precentor Main's capitally executed *Views along the Streams of Norway*, the treatment of the subjects, chiefly houses on the banks of rivers, converting them into very pleasing pictures. The reflections in the water and the technique are good. As an example of misapplied industry, Colonel Senior shows a view of the *Marble Rocks, Jubbulpore*, apparently printed on ferro-prussiate paper. The picture is a blot on the class. Precentor Main has two other frames, *Old Bits of Rothenburg* and *On the Pegnitz, Nuremberg*, characterised by great charm, the latter being nice examples of gelatino-chloride printing. Mr. Lord's *Fenland*, a river view, some delicately handled Alpine views by Mr. W. Moline, and some large pastoral studies by Mr. Worsley Benison will attract notice. Mr. G. T. Harris has a good view of *Rossett Mill*, and if the Rev. H. B. Hare could have managed to have left out the two small boys from the foreground, we should have better liked his *Oldoun Bridge*, which, however, is a capital view of an ancient bridge over a stream, with bare trees and antiquated houses composing an excellent bit of work. On the whole, this is a good class, unspoiled by impressionistic eccentricities, and dominated by the vast and ubiquitous *Wave* picture of Messrs. Elliott, which will certainly awe Bristolians by its mammoth proportions.

The awards in the Champion Class will be found above. The class is a large one. It included Lord's *You Stupid Boy* and *How's that?* Burrow's *Mining Series*, Sutcliffe's *Stern Reality*, Shapoor Bhedwar's *Feast of Roses* series, Warneuke's *Ethel*, and *Miss Laura Johnstone as Desdemona:* F. W. Edwards's *The Nave, Westminster*, Byrne's portrait of *Mr. W. K. Selle*, Wellington's *Eventide*, Cadby's *Study of a Child*, Treble's *Wretched Criminal*. Miss Clarisse Miles has several examples of home portraiture of ladies, evidently taken by flashlight. The poses are in all cases graceful, and the treatment good, but the lighting is, in some instances, imperfect. Mr. Byrne's *Richmond Horse Show* series is also included, as well as Mendelssohn's *The Misses Wilson*. Many other well-known pictures are hung, and the class, take it all in all, is a fine one, although it contains a few mediocre works, which could only aspire to Championship honours in company inferior to this. A grand piece of work, by Fred Boissonas, of Geneva, *The Troglodytes*, or cave men, as they may be supposed to have been in remote ages, is a monument of creative and

photographic skill. On the banks of a river, bounded by lofty rocks, some of these strange creatures are grouped about a primitive craft, others being in a cave in the rocks. If devoid of pictorial prettiness, this work is of profound interest. It certainly deserved judicial recognition.

Numerically large, Class III. (Small Landscapes) is perhaps only of average merit. Mr. Henry Smith's medal for a soft view of *Strand-on-the-Green* was luckily earned. The same gentleman shows a rustic bit, with a church in it, and labels it, *Hark! the Sabbath Bells are Pealing*. Query, why? Mr. H. O. Isaac's eight pretty little landscape studies are nicely printed in platinum, and Mr. Lintott also shows a frame of small but tender Derwentwater views, apparently printed in platinum, one of them being from the original negative from which his enlarged medal picture was made. To our thinking, Mr. Lintott's work is the best in the class; it is admirable in technique and thoughtful in execution. Mr. Walter Norgrove's *Scenes in the Hayfield* possess merit, albeit the subjects are rather commonplace and hackneyed.

As to Class V. (Small Marine), we have noticed Mr. H. W. Bennett's *Stiff Breeze* (silver medal with other subjects, including *A Race Home*) before, but it loses none of its charm on reinspection. Mr. W. P. Marsh has a series of seascapes (some with wrecks), in which he has secured some striking and faithful effects. Mr. W. J. Crudge also shows waves, capitally caught and well printed; and, among a large number of excellent marine and yacht studies, a series by Mr. H. O. Isaac are conspicuous by their crispness and clearness. Indeed, the seascapes form a capital class. Here, thank goodness, are no astigmatic abominations; all are clean and sparkling, and yet full of movement.

Gallery No. 2 is set apart for three Classes, X., XI., XII. (Small Portraits, Large Portraits, and *Genre*), and, though we are forced to say that it contains a not inconsiderable quantity of commercial work of a commercial quality, take it on the whole, the portraiture will be found as good, and should be as attractive, as any other section of the Exhibition. First to attract attention is Mr. Mendelssohn's Champion Class medal portrait of *Miss Wilson*, a small soft study, printed to a charming brown tone. Several of Count Gloeden's figure subjects are spoiled by the proximity of some portraits by the same gentleman, rather hard and chalky. Mr. T. Protheroe, of Bristol, has a frame of six large portraits, all evincing great care and taste, and well printed in platinum. Mr. Protheroe's other exhibits are, perhaps, less successful. A pleasing little portrait of a lady reclining, by Mr. D. J. Scott, is labelled, *Portrait of a Gentleman*. A series of six flashlight studies of dramatic themes—scenes from *Ours* and other similar subjects—well deserve their award, as they are capitally executed, the lighting having been arranged to secure harmonious and natural effects. Miss E. J. Farnsworth sends several of her delicately handled and unconventional classical studies, for one of which she has gained an award. This represents a female figure with a lyre. The facial expression is capitally caught, but there is less freedom in the pose of the figure than in Miss Farnworth's other efforts, notably the always-pleasing *Cupid Captive*. Hard by hangs Mr. Sutcliffe's medal picture, two old women gossiping, illustrating *Life in a Court*. This is a capital bit of figure arrangement. The faces of the models are lifelike, but the lighting of the picture strikes us as being incorrectly translated. Mr. Ernest Lambert's large studies of heads show that he pays due regard to the conservation of character in his subjects, which is not the case with many other exhibitors in this room. Lewis Cohen's *Bivouac* is included. In the *Genre* Class there is a group of four kittens, startled by something that has put them *On the Alert*; it is very cleverly done. The agreeable inscription, "sold," will show how quickly clever work of this kind is recognised. Mr. W. P. Marsh is the producer of the picture. Two frames of agricultural studies, depicting farm scenes and farm folk at work, by Mr. W. Crofton Hemmons, of Bristol, have simple and attractive themes, skilfully executed, except, to our thinking, in so far as relates to the focal treatment, which is of the ultra-diffused kind. There are effects lying between crispness and fuzziness which Mr. Hemmons and others may well be advised to cultivate in preference to "impressionistic" renderings, which are only recognised as artistic by a self-conscious and ephemeral handful of egotistical heretics. *The Village Corn Doctor*, by Mr. F. Stewart Seed, which shows the operation indicated by the title in progress, distasteful in its subject, and should not have been hung. In addition to his *Naver* and *Feast of Roses* series, Mr. Bhedwar sends some striking portrait studies; but one of them, *To Thee I Pray*, a girl with uplifted head, has a most strained and unnatural effect about the throat, which could have been averted in the posing of the head. Prince S. C. del Barma has also some portrait studies of Indian ladies, and Mr. Mendelssohn several other examples, notably two of *Miss Wilson* and *Mr. Gladstone*, which are very fine.

Mr. Alfred Freke's large portraits are capitally done, technically speaking, but one representing three young ladies has a great deal too much "linear repetition" in the arrangements of the arms and the disposition of the figures generally. The silver medal for small work goes to Mr. Harold Baker for a frame of *Portrait Studies*, printed in sepia carbon. The ladies (the Dene sisters, we believe) are all most artistically posed, the light soft and subdued, and the whole effect exceedingly tender and agreeable. Mr. Baker also takes the bronze medal for a frame of platinum portraits. Mr. W. W. Winter shows several large portraits in his usual style, and Mr. Byrne is, we think, best represented by his pretty and pleasing studies of children. Two of his large frames of portraits of ladies are perfect in technique, but the faces of the aristocratic sitters are quite expressionless. One frame shows a group of singularly beautiful ladies in a box *At the Opera* (platinum), but it is not easy to tell whether they are amused or not at the performance. The other is intended to tell a tale of *Sympathy*. A lady, with a letter, is kneeling with bowed head before another lady. If the former is mentally distressed, her face does not show it; if the latter feels any sympathy for her friend, she very successfully conceals it. But perhaps the large and aristocratic *clientèle* Mr. Byrne possesses is not given to allowing its emotions any facial expression? Mr. Hollyer's portraits of the Rev. Stopford Brooke and Mr. H. E. Davis deservedly take a medal, and the same gentleman shows his clever *Paderewski* and the late *Albert Moore*. In *genre* perhaps nothing is so successful as Dumont's *Love Letter*, two women in the field, laughing over the amatory missive in the most natural manner.

We shall conclude our notice of the Exhibition next week.

ON THINGS IN GENERAL.

The communication regarding copyright photographs printed in this Journal, p. 372, is worthy of the attention of all photographers possessing photographs likely to be utilised by the publishers of newspapers and magazines. I am afraid it is rather a *brutum fulmen*, although I am sorry it should be so, for I am entirely in sympathy with the meeting. The point is here: If a photographer possesses a picture which had the copyright properly secured, he has the law in his own hands; he can charge what he likes; if the photographs have not been registered with the necessary conditions complied with, he may ask a guinea, but he is not likely to get it. The utmost recognition I ever received when one of my photographs has been utilised, has been a copy of the paper containing the piracy, and this rule has been more "honoured in the breach than the observance." It may be well, while I am on this subject, to recall a few conditione overriding this copyrighting, though they are well known by some. In the first place, any photograph, whenever taken, can be "registered," as the provisions required for conferring copyright are termed. But the copyright cannot be sustained unless certain conditions prevail. When the first copy of the photograph is sold, a distinct bargain has to be made as to who is to possess the copyright. If such bargain be not then made, there cannot, at any future period, be any copyright. This point is continually lost sight of. When such bargain is made, a description or replica of the picture is to be sent to Stationers' Hall, and a special form filled in entailing a small fee. Here let it be noted that the "residence" of the photographer must give, not his place of business if he lives away, but the address of his dwelling-house. From this it will be seen that, if any photographer happen to discover that he has a negative of any person or place suddenly become popular or notorious, it is no use (if any copy had ever been sold) for him to rush off and "copyright it;" it would be money and time thrown away

The discussion upon celluloid which we have recently been having in these columns, will prove very useful in causing us to look at home, *i.e.*, to examine our film negatives and test the staying power of exposed films. It is not as though this substance were a definite chemical compound of known composition, structure, and properties, for it is far from possessing such certainty of structure. It and its allies are simply mixtures having pyroxyline as a main constituent in combination with other known and unknown ingredients. What their action may be in the film cannot be predicted with certainty, experiment alone can determine what, or if any action, the constituent ingredients may have upon the film exposed and unexposed.

Mr. Ives' paper upon the Lippmann-Lumière-Valenta photographs will set many photographers thinking. That the results so far obtained are very remarkable and very interesting goes without saying; but the whole burden of his paper may be said to be summed up in a suggestion, or, perhaps, one may say, query, as to the possibility of the results being brought about, not in accordance with the lamina theory, but by some other hitherto unexplained action. Not to put too fine a point upon it, is not the explanation simply an *ex-post-facto* one?

Readers of the LANTERN SUPPLEMENT should notice the remarks, on page 119, upon translucent screens. Where there is space to permit the image being thrown through, instead of upon, the screen, the effect is very beautiful. I am now referring, not to effects for large exhibition rooms, but more in the direction of private-house exhibitions or for a few dozen spectators. The most beautiful effects of the kind I ever saw were produced by throwing the picture on a piece of ground glass over four feet square; the effect was exquisite. This is, however, costly and cumbrous, and an almost equal substitute may be obtained by using, in lieu of glass, a piece of "tracing cloth," which may be obtained from any fine-arts dealer, the greatest width obtainable being forty-two inches. It might not be a pretentious piece of information to some readers to say that the ordinary linen screen does well; but it must first be wetted, and kept wet, or the light will not show through. I have seen exhibitors wet a linen screen when the picture was thrown upon the audience side. I need scarcely add that to do so is worse than useless; the reflecting surface, instead of being improved, is rendered inferior for the purpose.

There can be little, if any, need to reply to the strictures of a writer who after stating, respecting the Show in Pall Mall, "I approve of the decisions of the Judges," and expressing his contempt for those who differ from the Judges, calmly replies, when asked his opinion of one particular picture honoured with a medal by these Judges, that he is "not sufficiently acquainted with that picture." If he, A. R. E., had made the same admission with regard to art subjects generally, he would not be contradicted by me. I have, however, to thank him for his advice, well meant, doubtlessly, but very funny. May I venture to reciprocate? He is exercised in his mind to see how breadth can exist in presence of violent contrasts. Let him study a few of Rembrandt's pictures, and then make himself acquainted with some of the elementary canons governing lighting and composition. I wish A. R. E. and all my readers a Merry Christmas and a Happy New Year.

FREE LANCE.

THE DEVELOPMENT OF GELATINO-CHLORIDE PAPER.

A GOOD deal has appeared latterly on the subject of the development of the partially printed image upon the ordinary gelatino-chloride "printing-out" paper, and, like many others, no doubt, I have tried my hand at what promises to be a new power at this period of the year. My trials have been, not with the paper specially prepared for development, but with ordinary Solio, and, while the success has been variable, it is scarcely fair to blame either the paper or the system for the failures, but rather to argue from the successes that much better would have been done under more favourable conditions.

On first consideration, it did not seem to me likely that the ordinary papers prepared for printing out would offer any very great chance of satisfactorily passing the ordeal of development, as there appeared to be no guarantee of their having been sufficiently protected from the light before reaching the consumers' hands. But, on reading your leading article, and thinking the matter over, it struck me that, as a visible image seemed necessary in order to ensure a proper development, so long as the paper remained white to start with there was little danger of any injurious action arising from its chance exposure to light during preparation. Subsequent trial showed this to be the case, although I have since discovered that the absence of any visible discolouration does not necessarily prove the paper to be amenable to successful development.

As a matter of fact, I have found that some packets of the same (Solio) paper develop perfectly, whilst others, of different emulsion numbers, veil or fog badly under precisely the same treatment, and, indeed, in spite of any change of developer or other modification that I can suggest for surmounting the fog. The paper I use is white, not tinted, so there can be no suspicion that the variable action is due to the colouring matter; and, so far as I can judge, there is no visible discolouration from previous action of light. In some cases I have noticed a slight discolouration of the edges of the cut sheets from age or exposure to the atmosphere, but this cannot be set down as the cause of failure since, oddly enough, some of my successes have been on such paper.

My first attempt was made with some very slightly under-printed proofs that I picked out from a number that were awaiting toning, and the process of development was roughly conducted in full lamp light in the belief that the paper was absolutely unaffected by that class of illumination, but of that more anon. The result amply proved not only the capability of the paper to stand development, but also showed that with an almost fully printed picture it was possible to add as much or as little to it as might be desirable, and also that the tone and gradation were quite equal to any that could be obtained in the legitimate way of printing out.

On more recent occasions, when I have similarly picked out a few prints that appeared deficient in strength, and have submitted them to development, I have met with cases where one or more prints have fogged or stained, but this I had always attributed to some carelessness on my own part, or to imperfect washing or bromising, until an incident arose which showed me plainly that it is possible to have the paper in a perfect condition for printing out and yet quite useless for development.

I had recommended the development process to a friend who required a number of prints at short notice, and could not get them off owing to the dull quality of the light. Accordingly, he made the attempt of printing a number of proofs to various depths, from a faintly visible image to almost full strength, and brought them to me to be initiated in the mysteries of development. As it happened, my dark room was temporarily dismantled, and we were constrained to carry out the development in diffused daylight, using every precaution to expose the paper as briefly as possible to its influence. Suffice it to say that not one print, whether lightly or well exposed, would develop with even the most tolerable clearness; in fact, every one became more or less—chiefly the former—heavily veiled.

Everything appeared to go on satisfactorily until the image was nearly sufficiently developed, and apparently without any regard to whether it was a weak or a strong impression to start with; then suddenly, but rapidly, the whole clouded over, and in a few seconds the hitherto perfect image was buried in fog. As I have said, the result was the same whatever the exposure might have been, so that it could not be a question of exposure. I at first thought it arose from insufficient immersion in the bromising solution, but this proved not to be case, and there seemed no way out of the difficulty except to suppose that it was the development in daylight that had done it. My friend departed, leaving me the remainder of the prints to do the best I could with, and a sarcastic remark on the not too conspicuous success of operations so far.

In the evening the remainder of them were developed by lamplight, but with a precisely similar result, hopeless fog in every case, only varying in intensity and character with the development employed, and the duration of its application. Hydroquinone, amidol, metol, and para-amidophenol were in turn tried, the strength being varied from full negative strength to a degree of dilution that would scarcely operate at all; the quantity of bromide added was increased to as much as five grains to the ounce, and the bromising solution at last, as an experiment, made 100 grains to the ounce. But all to no purpose; before the image was fully developed, the inevitable veil supervened. As a last resource some bichromate of potash was added to the bromising solution, but still, so long as any developing action remained, the fog appeared, and the image at the best was but thin and meagre.

The idea then occurred to me that possibly even lamplight was too powerful, though that could scarcely be in view of my previous successes; however, to test it, a piece of the same paper, hitherto unexposed, was placed in a printing frame partly covered, and placed on the table a couple of feet from the lamp (a duplex), giving a good light. I was called away, and there it remained unexposed for about

an hour. Upon taking the paper out of the frame, to my surprise there was a very faint visible darkening of the exposed portion, showing that even for printing-out purposes, Solio is sensitive to lamplight, and I fully anticipated that that experiment was useless. Not so, however, for on development, the exposed portion developed up faintly but distinctly, while the covered portion remained perfectly clear until the inevitable veil spread over the whole, and, which is the most important point, exhibited a far greater density than the actual exposure.

It is palpable, therefore, that there is a condition of the paper in which it is subject to spontaneous reduction by the developer without exposure to light, but in which condition it is still capable of perfect action in printing out. This would be perfectly intelligible if it were invariably the case, and might be set down to something akin to "chemical fog" in a negative emulsion. But I have another sample of the same paper which behaves in precisely the same manner in direct printing, which is presumably prepared in exactly the same manner, and which yet develops with perfect clearness.

The last experiment is, I think, important. Had the slip of paper been but briefly exposed as was originally intended—that is to say, insufficiently to produce a visible image, the result could at best have been negative as it turned out. But the fact of the unexposed and absolutely uncoloured portion showing a denser darkening under development than the visible exposed part shows conclusively that the effect is not that of light. What then is it? Clearly it is not "free silver," for the employment of the bromide bath precludes the possibility of that; nor can it arise from the imperfect conversion of the chloride or other salt of silver in the film, for, as I have already fully stated, I took every precaution, both by prolonged immersion and strengthening of the bath, to secure the completeness of that action.

If the results were arrived at with papers of different manufacture, an intelligible explanation might be found in some possible variation in the formulæ—the presence, for instance, of some salt of silver not amenable to the converting action of the bromide bath. But it is scarcely a feasible supposition in this case that different batches of the same maker's paper are prepared by different formulæ. I can only suppose that, in the keeping of the paper, a point is reached at which some decomposition begins to set in, but which produces no visible change in the paper. And yet the fact remains that where there are *visible* signs of incipient decomposition clean development has been possible.

I leave the mystery in the hands of yourselves and your readers, in the hope that some solution may be found. Meanwhile, it is, I think, worth recording the facts, as thereby some fellow-readers may be induced to try again if the first attempt is not a success.

W. Lindsay.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION COMPETITION.

The Annual Exhibition of members' productions for the purpose of medal-awarding was held last Thursday, the Judges being J. McDougall, Esq., a well-known Liverpool artist; Mr. George Thompson, and Mr. G. Watmough Webster, photographers; while the latter gentleman and Mr. Edward Whalley adjudicated upon the lantern slides. We append the Judges' report, with the list of prize-winners.

To say that the works were those of the Liverpool Society is to say they were excellent, and it must be admitted some very beautiful pictures were brought together. It will be observed that all the prizes were for sets of six, with the exception of stereoscopic slides (sets of three) and enlargements, one only by each exhibitor being needed to be in competition.

Taking the Champion Class first, there can be no doubt about the beauty and superiority of the winning set, which included some studies of sheep of remarkable beauty. All were printed in a rich reddish bistre tint, which perhaps was a little strong in colour, though in nowise detracting from their effect. As showing how much depends upon the medium in which a photo is printed, it may be noted that, when some of these subjects were treated as lantern slides, much of their beauty was lost. In Class II. there was an *embarras de richesse*, and the Judges must have experienced some considerable difficulty in picking out the best; many sets containing pictures which were equal to any in the room, but the whole set failing to reach the same standard. Herein will be seen the great advantages of the "set" system. Without for a moment suggesting that what we are about to say here is to be held as referring to the pictures under review, it is common knowledge that the most indifferent photographic workman at times obtains, by what can only be termed chance, a picture of real beauty, though that remains for ever his masterpiece: To produce six pictures cannot be the effect of chance, and a set of that number, all good in technical excellence and pictorial beauty, proves the possession of skill far above the average.

Class III. was a small one, but the Judges had no need to withhold the second medal through absence of merit.

The lantern-slides competition was very close, twenty-seven sets in all being adjudicated upon, all being passed through the lantern, some of them many times over. The merits of two were so close, that the Judges awarded equal first to them, giving the bronze medal to another set very little inferior. Scarcely any of the pictures being named, it is only possible to speak in general terms; but, with regard to the winner in this class, we may say that the subjects were most varied, landscape, architecture, and flowers being included.

In Class V. the medal-winner exhibited an enlargement from an Italian courtyard with a figure at a fountain. The richness and juiciness of the shadows from a negative which, judging by the small print shown, seemed to be of indifferent merit, were very remarkable. In this class our own opinion leant to a very quiet, effective river scene with small yacht riding at anchor, though the artistic quality was sadly marred by the manner in which the picture was cut into two by the heavy line formed by the mast and its reflection in the slightly rippling water.

There were only four stereoscopic pictures, but the winning three were of great beauty, good transparencies, rich in tone, and of even quality, the subjects also being well chosen. The hand-camera work in Class VII. included some good work, some of the pictures, however, being in a sense out of court, owing to the subjects being such as could be done by a camera on a stand with several seconds' exposure.

The President offered a special prize for a ladies' class. This was not well filled, and, if we may say it, we have seen some better work by lady members of the Liverpool Society.

The new rooms of the Association, including office, committee room, dark room, enlarging room, and studio, are excellently adapted for the purpose, and the Society may be congratulated upon having one of the best homes in the country for meeting in and practising their art. They cost in fitting several hundred pounds, which the success of the triennial exhibitions have enabled them to meet without getting into debt. We are sorry to hear that next year it is not probable that they would hold an exhibition, though the triennial period would have arrived.

Extract from Report of Judges.

"We have much pleasure in handing in the accompanying awards, which, we are glad to say, are our unanimous judgment. We think it right to observe that, owing to the great excellence of individual pictures in some of the groups, we have had a little difficulty in arriving at a definite opinion. Especially was this the case in the Champion Class, and we cannot forbear drawing attention to the conspicuous beauty of two (unnamed) pictures in the group 'Art,' one a river-side view and the other a hill-side with cattle in the middle distance.

Signed { John McDougal. G. Watmough Webster. Geo. E. Thompson."

Class I. (Champion), Mr. T. F. Lloyd.

Class II. (Half-plate and under), first, Mr. Jos. Appleby; second, Mr. Geo. Allday.

Class III. (Over Half-plate), first, Mr. C. A. Simmins; second, Mr. H. Holt.

Class IV. (Lantern Slides), first, Mr. F. Anyon, Mr. Jos. Earp; second, Mr. T. B. Sutton. Extra medal allowed.

Class V. (Enlargement), Mr. Wm. Tomkinson.

Class VI. (Stereoscopic Slides), Mr. W. S. Elsworth.

Class VII. (Hand-camera Work), Mr. H. B. Forrer.

Contains a considerable number of extreme merit. G. W. W. E. W.

MR. JOHN HOWSON ON "MATT P.O.P."

On Friday evening, December 15, at the Central Photographic Club, Mr. Howson gave a demonstration on toning and fixing Matt P.O.P., which he prefixed with a paper dealing with the subject. There was a large attendance, including many professional photographers. Mr. F. W. Edwards occupied the chair.

Mr. Howson said: "Whilst I recognise freely that for many purposes and many tastes the glossy surface given by the ordinary Ilford P.O.P. gives results that cannot be surpassed, we have felt that there were still further fields to be conquered in the realm of photographic printing. We set ourselves to master the great problem of how to combine the artistic with the practical, the beauty of a matt surface with the truth and gradation only found hitherto in the enamelled surfaces. Such has been the aim of many workers before us, and many are the attempts that have been made, but I make bold to say that nothing but failures, failures of the most pronounced kind, have been the result. We have had plain salted papers, but their only claim to notice has been the absence of gloss. Such papers are useless in these days when sensitised papers must have keeping qualities. They could not be used unless prepared freshly week by week. Worse, however, is the defect arising from the burying of the image in the fibres of the paper. Prints lacked utterly all truth of gradation, and shadows were masses of darkness unrelieved by any detail. Then we have had *so-called* matt emulsion papers which had the same

fatal failing of clogged shadows, and had not, in fact, a real matt surface at all; being made by simply making the emulsion thinner than usual, they were neither glossy nor matt, and combined the disadvantages of both without a single redeeming feature. So much for past history, and now with pride I point to the Ilford matt P.O.P. as a perfect and complete solution of the hitherto unsolved problem. Nothing of its kind has ever been made before, and the future offers nothing that can equal it. Its qualities are beyond rivalry, and leave nothing to be hoped for or desired. Whatever we at Ilford have done in the past to advance photography (and we may fairly claim to have been a factor in such progress) is dwarfed into nothing, compared with the possibilities arising out of Ilford matt P.O.P. We do not speak in vain vapourings, or without good grounds, for our self-gratification."

After quoting several favourable opinions on the paper, Mr. Howson proceeded :—

"We have dozens of other letters all in the same strain, and I have limited our quotations to the first half-dozen opinions received, so as not to weary you with repetition, and I will add only one more opinion, viz., that of the editor of one of the photographic journals, who thus concludes his notice of the paper: 'This paper marks a departure in photographic printing, and we hardly know which to congratulate most, the big family of photographic workers for the increased power put into their hands, or the Company to whom the world is indebted for this vehicle of expression.'

"I will not lay too much emphasis on individual opinions, even though they are from some of the best workers of the day, but leave you to judge for yourselves from examples how far our views are justified by results.

"Not alone in point of surface, but equally in tone, is there a great advance artistically. The deadness of the surface refines the colours, and makes them more in accordance with the canons of art and the tastes of those who hope great things for the future of photographic art. From warm browns and sepias to blacks of a soft, velvety richness, not too cold or glaring, but restful to the eye, is the gamut of colour within our reach, and, withal, a perfection of gradation never before touched, an absolute freedom from double tones, and a delightful ease of manipulation, which one attempt with the paper will prove beyond doubt.

"This brings me to the practical advantages of the paper, apart from its artistic merits. I have spoken of truth of gradation and possibilities of colour, which may be said to be both artistic and practical merits; and when I add that these results may be obtained without any special precautions, or any alteration of manipulation, either in printing, toning, or mounting, I surely have said enough to justify the highest praise that could be accorded to the paper.

"Prints on Ilford matt P.O.P. are printed in the usual way, toned (side by side with the ordinary P.O.P. if you like) in the Ilford sulphocyanide bath, and mounted with starch paste just in the regular way. From printing to finishing you may work the papers side by side, ignoring absolutely the fact that they differ in any way, and when mounted you have the two kinds of prints, which is as different as possibly could be, with out one iota of extra care or trouble. Indeed, until they are mounted and dried, you are hardly aware that the two papers differ in the slightest degree.

"Now, I ask you, was anything equal to this ever attempted, or ever dreamt of, up to the present, let alone accomplished?

"There are two well-defined and great advantages accruing to the professional photographer in connexion with this paper. First, if he wants, as is most probable, prints on both matt and glossy paper from the same negatives for a sitter, he can produce them without a single moment's extra trouble, no necessity for another class of paper or another set of manipulations, and from the same negative similar results will be obtained. It is quite unnecessary to take into consideration that, for a glossy print, you must have a negative of such and-such-quality, and for matt prints one of quite a different class. Ilford matt P.O.P. yields good results from a wider range of negatives than any paper I have ever tried; be the negative hard or soft, prints from it will compare more than favourably with any other paper.

"Secondly.—There is, and has been, a cry from the professional photographer: Let us have something new to offer to our sitters—something to attract attention and compel new business. Such a want is fully answered by matt P.O.P. Prints on it can be produced, as I have shown, so easily, and, what is of more importance, of such quality that few sitters would object to pay a considerably enhanced price for such work—a price which, in view of the absence of extra labour, and but a small increase in cost of paper, must yield a more than proportionate return to the photographer. I speak here to the profession, and urge you not to throw away an opportunity so plainly put before you. Don't fail to show your sitters such prints, and don't above all, I beg, rush in and cut prices in the race for business. If an improved style of portrait is worth more to the public, as this is, it is also worth more to you, and deserves and will yield better business if you will let it.

"Of the actual manipulations and points to be noted therein, there is little to be said. Matt P.O.P. prints, much like its predecessor, lose but little in toning, &c. The progress of toning is judged in exactly the same way, and it need only be borne in mind that prints dry a little colder in colour than they appear when looked through whilst wet; and also a little darker in image than when looked at on the surface.

"Warm tones are best obtained by a bath diluted with its own bulk of water, and rich blacks by a bath with double gold, whilst sepias are to be had by toning for a short time in a bath rich in gold. I would mention once again, though it ought to be unnecessary, that good blacks are unattainable, except with a negative full of vigour and well graduated. A poor negative will never yield such a print by any process or any scheming. Mounting matt P.O.P. prints is one of the easiest possible processes. Well-boiled and strained starch paste is the best mountant, and is best applied to the print whilst it is wet; the print is placed on the mount, and rubbed down with a damp sponge or a piece of oil paper, such as is used with a letter-copying press. If any mountant gets on the face of the print, a damp sponge, carefully applied, will remove it. With only ordinary care nothing further need be done to the print, for matt P.O.P. mounts with more ease than does the glossy, but, if required, matt prints, when mounted, may be lightly cold-rolled, but must not have either heavy pressure or heat. Spotting is done with the usual colours mixed with water only, and from the very nature of the surface is much less likely to show than with other styles of printing.

"For the rest, all the many hints given from time to time *re* P.O.P. apply with equal force to both papers, and therefore they need not be referred to, except so far as I shall touch on them in the practical demonstrations to follow.

"Finally, let me say a word or two of a personal bearing. It has been said that the man who makes two blades of grass grow where only one flourished before deserves well of his country. Adapting this saying to ourselves, we may claim to have added something to the well-being of the British nation; for we have not only planted the original blade (P.O.P.), but have now added the second (matt P.O.P.), and have, in so doing, brought to England a volume of trade, which hitherto has been, for the most part, in the hands of our Continental friends. To have done this in the present day, when the cry is, 'English supremacy in trade is decaying,' is no mean accomplishment, and we feel some pride in being the means whereby such a result has been achieved."

At the conclusion of the paper Mr. Howson proceeded with the demonstration, observing that the prints lost very little in toning and fixing. He laid great stress on the necessity for a thorough washing, and said the surface was not so easily damaged as that of the ordinary gelatine paper. Both kinds of prints could be toned side by side. After the first washing an alum bath was recommended, followed by a thorough washing. The prints should be kept moving. The paper did not blister. The alum bath should not be used a second time. For toning bath, sixty grains of sulphocyanide of ammonium were dissolved in thirty-two ounces of water, and two grains of gold added. The darkest prints were taken first, two at a time, and when in the bath it was shown that the glossy prints could not be distinguished from the matt prints. Mr. Howson mentioned that the colour of the prints came back in the fixing bath, and that they dried colder, and that the colour seen on the surface of the prints was the colour that would be obtained when they were finished. A considerable range of colour from sepia to black was obtainable, but not engraving black. Fresh hypo was recommended for each batch of prints.

Several prints were toned and fixed, and a number of finished specimen prints were on view.

Mr. B. J. Edwards, in the course of a few remarks, referred to his previous experiences with matt paper, and said that matt-surface paper was one of the most permanent in its results. He endorsed Mr. Howson's remarks as to the relief it gave from monotonous grey tones, and said that no doubt the gloss in printing papers would be got rid of altogether in time.

The Chairman said that he discarded silver printing some years ago, but he had taken to it again. He had only had two days' experience with the paper, which he found dried harder and darker. He asked whether images with black tones were more permanent than those of brown tones?

Mr. E. J. Wall had tried most baths with matt P.O.P., and found that the paper worked well with all. It was also an easy paper to mount.

Mr. Howson, in replying, said that, as to whether black toned prints were more permanent than the brown, the more gold there was on the print the more permanent were the results. In regard to platinum toning, he himself could not tone with it without degrading the whites. He did not get any advantage over gold, and the same applied to uranium. He had also tried them mixed, but had never got so far as with the sulphocyanide bath. There was no necessity to go outside the sulphocyanide bath for sepias. A vote of thanks to Mr. Howson concluded the proceedings.

In a recent case in the United States Courts a deed to a certain piece of land was offered in evidence which bore the signatures of only four of the five interested heirs. A vacant space occurring where the fifth signature should have appeared led the attorneys to suspect that it had originally been placed there. Accordingly, the services of an expert photographer were engaged, and he photographed the document in the presence of the Clerk of the Court, who could not allow the original to leave his hands. The plate upon development showed traces of the missing signature, and a ten times enlargement plainly revealed it. The case in question was one which had been before the Court for a number of years, and the photographic evidence introduced reversed all previous decisions, securing the ownership of the land to the rightful heirs.—*Anthony's Bulletin.*

"HYDROXYL-MONOHYDRIDE."—A HOAX.

Journalistic Sympathy.—We deeply sympathise with our esteemed contemporary, *Photography*, in the severe misfortune which befell it last week. Taking advantage of the excusable ignorance of the staff upon chemical matters, as well as pandering to our contemporary's weakness in seeking to be in advance of its journalistic competitors with the latest scientific news, some malicious person has made it the victim of a deplorable piece of deception. Our contemporary prints the report of a meeting of an alleged new society at Brondesbury. The names of members, officers, and the meeting place are given in a matter-of-fact style, and the technical proceedings of the first meeting are reported in the customary phraseology of such literature. The President of the Society, Dr. Burton Coxe, details some experiences in development, which are of such an interesting nature that we feel compelled to quote them, and to afford them the well-deserved honour of a paragraph all to themselves.

"Hydroxyl - monohydride."—"Dr. Burton Coxe, who,' says the report, "was received with applause, said he had lately been experimenting on the lines of Colonel Waterhouse, with the addition to the developer of various little-known substances, and, if he had nothing revolutionary to tell them as to his results, he had certainly had some interesting experiences to relate. Perhaps the most promising effects had been produced by the addition of *hydroxyl-monohydride* in varying proportions. He found that a large addition had a decided slowing action, but in moderate quantities its action was very beneficial, especially in enabling the developers to flow freely, and he should now be very sorry to develop a plate without it. Perhaps the best way to employ it was to use it to make up the stock solution of pyrogallic acid with the addition of sulphite. It might be produced by treating anhydrous hydroxyl with nascent hydrogen, the reaction at a high temperature being very energetic, and the result being the pure compound. The commercial article was frequently contaminated with chlorine or carbonic acid in combination with some of the calcium salts; so he advised those who wished to use it to make it themselves. The yellow tint sometimes seen in the home-made article was due to organic matter in solution, but it had no deleterious effect. It should be used freshly prepared, as, if kept, it underwent decomposition with the liberation of ammonia. He passed round a number of negatives developed by it, and which were much admired." In another part of his issue the editor of *Photography* draws attention to the foregoing communication in these words: "Dr. Burton Coxe has been experimenting with hydroxyl-monohydride in development, and thinks very highly of it. A reference to this is found in the report of the meeting of the Brondesbury Camera Club."

A Discreditable Hoax. — We cannot say whether the Brondesbury Camera Club, its officers, members, meeting-place, Dr. Burton Coxe, &c., have any existence in fact, but we should not be surprised to find them as mythical as Mrs. Harris. It is, perhaps, hardly necessary for us to inform our readers that the substance with which "Dr. Burton Coxe" has been making such successful experiments in development, hydroxyl-monohydride, is simply that harmless, necessary ingredient of all developing solutions—common water. Our contemporary has been hoaxed. We are sorry that anybody can be found with such an uncharitable mind as to trade upon a journalist's lack of knowledge, and to hold him up to ridicule in this manner. We commiserate *Photography*, which journal has surely done nothing whatever to incur such treatment. Our aspiration is, that the author of the hoax may be discovered, and held up to the opprobrium he deserves.

Our Editorial Table.

Hand-book on the Use of Compressed Oxygen.

By Kenneth S. Murray.

As Mr. Murray says in his preface, "the subject is undoubtedly one of growing importance," and we can endorse the fact that it is one on which the author can write with some degree of authority. Various methods by which oxygen can be made are described, including of course the Brin process, in which the author is interested; the compression of the gas in cylinders; the construction and testing of cylinders, valves, unions, pressure gauges, and everything necessary to be known in this connexion, are all fully and ably treated. This work ought to be in the possession of every one interested in the use of compressed gases. It is published by Ede, Dearberg & Co., 40, Queen-street, E.C.

A selection from the timely Christmas and New Year's cards by Messrs. John Patrick & Sons, of Edinburgh, have been forwarded and are now before us. Comprising as they do photographic subjects of all kinds, from the "roaring joys of the ice-bound loch," the much-boomed "golf" course, the haunts, homes, and picturesque scenes which Scotland supplies in such abundance, they should be a welcome addition to the numerous souvenirs of the season.

They are well got up in cabinet size, on light, tasteful, appropriate mounts for postal dispatch, and what is more to the purpose, are of fine artistic feeling and quality as well as moderate in price.

Photographic Mosaics for 1894.

E. L. Wilson, New York.

The illustrations in Mosaics this year are with a few exceptions from the hand camera of Mr. A. R. Dresser, who illustrates his "Tour in Brittany" with them. Following an excellent epitome of progress by the editor, we have a section composed of papers selected from English and other journals of the long ago, illustrative of the opinions which then prevailed, there being twelve of those. A series of eighteen papers, written expressly for the Mosaics, completes a well-printed and useful book.

News and Notes.

Photographic Club.—December 27, Monthly Lantern Meeting.

London and Provincial Photographic Association.—December 28, Mr. Howson will give a demonstration of the P.O.P. matt paper, and Mr. Liddle will discourse on *Celluloid and its Imitators*. January 4, Mr. Howard Farmer will read a paper, *Hurter & Driffield; or, the Man with the Money Bags*.

Exeter Amateur Photographic Society.—An Exhibition of Photographic Work will be held at the Art Gallery of the Albert Museum in Easter week, 1894, when twenty silver and bronze medals will be offered for competition. Further particulars will be published at an early date. The Hon. Secretary is Mr. John Sparshatt, Fairfield House, Alphington-road, Exeter.

Messrs. Elliott & Son, of Barnet, write: "If you will kindly turn to the Index of Advertisers in The British Journal Photographic Almanac, 1894, you will see that, after our name, you have, by error, printed the words 'collotype printing' instead of 'carbon;' the consequence is that, during the last few days, we have had three inquiries for our prices for this process, which we do not work; at the same time, we lose a small advertisement for carbon. We should be much obliged if you will rectify this."

The 1894 Convention.—The Council of the Photographic Society of Ireland are reminding photographers that the Annual Meeting of the Photographic Convention of the United Kingdom for 1894 will be held next July, in Dublin, under the auspices of the Photographic Society of Ireland. The members of the Photographic and Scientific Societies, Universities, &c., have taken the matter up so warmly that there is every probability of the coming meeting being one of the largest and most successful ever held.

Photographic Society of Ireland.—The Council have decided to offer the following special medals for open competition amongst amateurs at the forthcoming Exhibition of the Society, viz.:—Class A, the Society's gold medal, for the best set of four Landscapes (any size). Class B, the Society's silver medal, for the best set of two Enlargements. Class C, the Society's silver medal, for the best set of six Lantern Slides. The Exhibition will be opened, on January 15, by a full-dress *conversazione*, and will remain open until January 29. The Hon. Secretary is Mr. John A. C. Ruthven, 35, Dawson-street, Dublin.

On Saturday, December 16, at the Queen's Hotel, Clifton, the members of the Bristol Photographic Association held their first annual dinner, the President (Mr. H. A. Hood Daniel, F.S.I.) in the chair. The toast of "Success and Prosperity to the Association" was given by Mr. Thomas Bedding (The British Journal of Photography). Mr. Valentine Blanchard replied for "The Judges." "Success to the Exhibition" was also given, and the speakers generally congratulated the Association on the quality of the Exhibition. Mr. E. Brightman (Vice-President), Mr. Bligh Bond (Hon. Secretary), and other gentlemen also spoke during the proceedings.

The Fountain Air Brush.—Before the members of the Photographic Club, on Wednesday, December 13, Mr. Charles L. Burdick, Chicago, demonstrated the use of a new air brush, the "Fountain." In appearance it is not unlike a fountain pen, being very neat and small. It is held in the hand like an ordinary pen or pencil. Air pressure, worked by the foot in the usual way, actuates the liquid spray, the pressure and volume of which is controlled by the forefinger pressing a small disc at the end of the brush. Besides the ordinary black pigment, the usual water colours may be used. An extremely fine grain is given, and this, again, may be regulated by the operator approaching or receding from the surface upon which he is working. This is placed on an easel. Mr. Burdick produced some very fine freehand work, and also showed several beautiful examples of coloured portraits on a basis of black crayon. He states that the brush may be used for working up bromide enlargements, or the outlines only may be first produced, and the remainder of the picture filled in. In the hands of a skilful manipulator the Fountain Air Brush should prove useful for a variety of photographic purposes. No doubt artists would also find it very handy.

CROYDON CAMERA CLUB'S LANTERN SHOW.—The second monthly display of this season, consisting of photographic views on the screen, was held on Wednesday, the 13th, at the Braithwaite Hall, when a large audience assembled. The first part consisted of about a hundred views, depicting "that flourishing corner of the black man's garden," as the lecturer described it, namely, South Africa and the Cape. After twenty minutes' interlude of songs and banjo duets came the second part, which included a series entitled *Good-bye to Old Croydon*, by Messrs. Carden, J. Smith, and G. R. White (members of the Club), and various slides by other members, viz., J. Packham (twelve brilliant photo-micrographs), H. E. Holland (South Devon and Surrey scenery), G. Paice (horses and waves), and J. Smith (thirty-six, many very fine), especially satisfactory being several from negatives taken at Club excursions to Byfleet and Forest Row.

AN International Photographic Exhibition will be held in the Art Gallery, Grainger-street, Newcastle-on-Tyne (by arrangement with Messrs. Barkas & Son), from April 13 to April 28, 1894. A special section will be devoted to photographic apparatus and appliances, photo-mechanical printing processes, and other trade exhibits, for which a special gallery will be set apart. The Judges will be Messrs. Wm. Crooke (Edinburgh), F. M. Sutcliffe (Whitby), and G. E. Thompson (Liverpool). The following is the schedule of classes and awards:—Open to professionals and amateurs. Class A (Landscapes), silver and bronze medals. Class B (Portraits), silver and bronze medals. Class C (*Genre* and Figure Studies), silver and bronze medals. Class D (Architecture), silver and bronze medals. Class E (Instantaneous), silver and bronze medals. N.B.—In accordance with the regulations of the Judges' Conference, awards go to one picture, except in case of a connective series, but it is desirable that exhibitors should send at least three pictures in any of the above classes. Class F (Enlargements), silver and bronze medals. Class G (Hand Camera Prints, series of six), silver and bronze medals. Class H (Lantern Slides, series of six), silver and bronze medals Class J (Stereoscopic Slides on Glass, series of six), silver and bronze medals. N.B.—In Classes G, H, and J, exhibitors may send more than one series, but each set must be kept separate. Champion Division, open only to pictures which have been medalled at an open exhibition. Class K (Landscapes), silver medal. Class L (Portraits), silver medal. Class M (*Genre* and Figure Studies), silver medal. Class N (Lantern Slides, series of six), silver medal. N.B.—In Class N exhibitors may send more than one series, but each set must be kept separate. Members' Classes, open only to amateur members of the Association. (In these Classes the work must be entirely the production of the exhibitor.) Class O (Series of Three Pictures, any Subject, half-plate and above), silver and bronze medals. Class P (Series of Three Pictures, any Subject, 5×4 and under), silver and bronze medals. Class Q (Series of Six Lantern Slides), silver and bronze medals. Class R (Series of Six Stereoscopic Slides, on Glass or Paper), silver and bronze medals. All correspondence and inquiries must be addressed to the Hon. Secretaries, Photographic Exhibition, Art Gallery, Grainger-street, Newcastle-on-Tyne.

PATENTS COMPLETED.

IMPROVEMENTS IN GROOVED METALLIC STRIPS FOR BOXES FOR CARRYING AND STORING OR PACKING PHOTOGRAPHIC PLATES AND OTHER PLATES, AND FOR OTHER LIKE PURPOSES, AND IN THE METHOD OF AND TOOLS FOR MAKING THE SAID GROOVED METALLIC STRIPS.

No. 1195. WILLIAM HENRY DUGARD and GEORGE HEATON DUGARD, both of Vulcan Mills, Bridge-street West, Birmingham, Warwickshire.—*November* 18, 1893.

OUR invention consists, first, in shaping in the manner hereinafter described the bottoms or closed ends of the said grooved metallic strips for the purpose of reducing to a minimum those parts of the surfaces of the said grooved strips with which the photographic plates carried or packed in the box can come into contact, and hence diminishing the liability to injuring the said plates.

The grooved metallic strips to which our invention applies consist of a strip of thin sheet metal so shaped or corrugated as to form, side by side, a series of parallel grooves with closed bottoms, the walls of the said parallel grooves consisting of double folds or thicknesses of metal. According to this part of our invention, we make the bottom part of each groove of an angular figure or of a semicircular figure, and the parallel sides of the grooves of such depth that the surface of the grooves with which the photographic plates can come into contact, when the plates are packed or stored in the said grooves, is reduced to a minimum. That is to say, instead of the edges of the photographic plate bearing on the whole surface of the sides of the grooves, as in grooved strips of the ordinary kind, the said plates, when the improved grooved strips are used, bear principally against the angular or curved bottoms of the grooves of the strips.

We prefer to form each strip with seven grooves, the outer grooves being narrower than the five inner grooves, each of the said inner grooves being of sufficient width to permit of the sliding in it of two plates, and the outer narrower grooves being only of the width proper to receive a single plate.

Our invention consists, secondly, of the following method of, and tools for, making the metallic, grooved strips hereinbefore described, and other grooved strips.

We make the said grooved strips in long lengths from strips of thin sheet ductile metal or alloy, such, for example, as brass by drawing the said strip through one or more pair of dies so shaped as to gradually corrugate the strip lengthwise and afterwards shape it to the proper form.

We will describe our method of manufacturing the improved grooved strips hereinbefore described in conjunction with the two pairs of tools which we prefer to employ.

The first pair of tools consists of two dies having corrugations upon their opposed faces, the said dies being preferably carried in a frame, the lower die being fixed on the bed of the frame, and the upper die being made capable of sliding to and from the said lower die by means of an adjusting screw. The said corrugations in the opposed faces of the dies taper from the entrance to the emerging end; that is, the corrugations are widest at the entering end, and gradually taper or become narrower as they approach the emerging end. The tapering corrugations are also shallowest at the entrance end, and gradually deepen as they approach the emerging end of the dies where the tapering corrugations are narrowest.

The upper die having been adjusted upon the lower die so that the space between them at the entrance end is just sufficient to receive the long sheet metal strip of which the grooved strip is to be made, the said strip is taken hold of by a pair of tongs, and drawn through the pair of dies by means of a draw bench. As the strip is drawn through the closed pair of dies it is gradually corrugated lengthwise, and passes from the emerging end of the dies in the form of an open corrugated strip. This open corrugated strip is finished by subjecting it to a drawing operation through a second pair of dies having larger parallel corrugations so shaped as to give the required figure to the bottoms of the finished grooved strip, as well as to enlarge alternate corrugations by compressing together the sides of intermediate corrugations, and thereby forming parallel grooves, the walls of which have a double fold or thickness of metal as hereinbefore described.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 14, Mr. Alexander Cowan in the chair.

Mr. HODD asked if an acid state of the bichromate bath for carbon printing had any bad effect.

Mr. W. E. DEBENHAM said that it should not be more acid than the bichromate itself was. ANY acidity could be reduced by ammonia.

Mr. P. EVERITT had been able to get clearer margins by the use of ammonia.

Mr. MACKIE said that the Midland Railway Company had recently introduced a rule forbidding the carriage of gas cylinders in passenger trains.

It being a Lantern Evening, slides were shown by Messrs. J. Austin, Bayston, and other members, followed by slides (shown by Messrs. Newton & Co., and shortly to be published by them) from Mr. Burrow's negatives illustrating work underground in the tin and copper mines of Cornwall.

Mr. T. E. Freshwater brought a sample of a new kind of lime called the "Newtonian," one of which was used in the lantern. They are turned from hard stone-lime, and are very enduring.

MANCHESTER PHOTOGRAPHIC SOCIETY.

DECEMBER 14.—This meeting took the form of what proved to be a very enjoyable social evening, at which many of the members exhibited, in an informal way, quite a good show of photographic prints, stereoscopic transparencies, &c., rendered doubly interesting to the visitors by the particulars and information which, from the nature of the meeting, the members were able to give. Messrs. Thornton-Pickard contributed a number of their specialities, including their new automatic camera stand.

During the evening, a good commercial set of photographs of the Chicago World's Fair were shown in the lantern, and the meeting concluded by a lantern show of members' slides.

Brixton and Clapham Camera Club.—December 5, Open Lantern Meeting Dr. J. Reynolds, F.R.G.S., in the chair.—Several slides by members were passed through the Club lantern, after which a set of slides contributed by the Southsea Amateur Photographic Society for circulation by the Photographic Society of Great Britain were exhibited.

East London Photographic Society.—December 12, Ordinary Meeting, Mr. E. Stone in the chair.—Mr. John H. Gear was elected a member, and was unanimously voted President of the Society in the place of Mr. G. S. Pasco, A.P.S., resigned. A question from the question box was read: "What is the best method and plate to use to photograph a piece of red granite having gilt letters upon the surface?" An isochromatic plate, stop *f*-22, a dull light, and short exposure, was recommended, and the developer to be compounded with three times the normal quantity of pyro. The remainder of the evening was then devoted to a discussion on the negatives from which the prints were taken which had gained awards at the recent Exhibition of the Society.

Greenwich Photographic Society.—December 6, Professor Haddon in the chair.—Mr. FRY demonstrated the Paget Prize Company's printing-out papers. Upon their process of development, he said that the keynote of success was a thorough bromising of the print in the first place, and complete elimination of the developer before toning in the second. As regards the bromising, dirty backs to the prints or muddy whites were a clear indication of insufficient time in the bromide bath. Briefly, this part of the process could easily be insufficiently done, and could not be overdone. To leave the partly printed pictures in the ten per cent. bromide for at least ten minutes was a safe plan. In addition, it might be noted that, the less the visible impression or image, the greater the need for a more prolonged stay in the bromide bath. He was often asked whether other developers would do. No doubt they would; but, as the Company's hydroquinone formula had been most thoroughly tested, and found perfectly reliable, what purpose could be served by changing? He saw no reason. After thorough bromising, the important point is to clear the print from developer before toning and fixing. Unless this be done, the depth of the print continues to increase during toning, and it is impossible to say exactly how far the printing will advance, as everything depends upon the amount of reducer (hydroquinone) left in the paper. If the developer were cleared from the print, however (five minutes in running water is sufficient), no further increase in density takes place, and no occasion for exercising speculative judgment as to how far the print will alter in density arises. After Mr. Fry had demonstrated the process, Professor HADDON said that the thanks of all were due to the Paget Company for a useful method of producing prints after a slight exposure to daylight. Any business man who would get up an hour before breakfast could make in that time as many initial exposures (which could be completed in the evening) as would occupy him all day to make if he were obliged to print an image right out. Any person could see the advantage of this addition to our knowledge. He was glad that Mr. Fry had called attention to the necessity of longer bromising of the print. The action of the bromide was to convert the chloride and organic salts of silver in the paper to bromide of silver, which was not so easily reduced by light action under a developer, and was therefore more under control. As far as the washing out of the developer before toning is concerned, he referred to some experiments made by Mr. Grundy and himself, and pointed out that the *method* of washing was most important, and deprecated long soaking as being not only useless, but prejudicial. Upon the question of separate *versus* combined toning baths, Mr. HADDON said the evidence was not conclusive. He had seen prints made thirty-five years ago, toned and fixed in a combined bath, which were practically unaltered, whilst others made comparatively recently were faded. The same remarks applied to separate baths.

Hackney Photographic Society.—December 12, Mr. Robert Beckett in the chair.—Mr. GRANT asked for information regarding the Hill-Norris plates. He found that, unless you gave exact exposure, it was impossible to obtain density. The CHAIRMAN also agreed with this remark, and suggested redevelopment as an improvement, as a better result could always be obtained than by developing all at once. The soluble salts could be easily removed from the plates in a very little while. The plates were very easily dried. Mr. SMITH asked if isochromatic plates were beneficial for exposnre upon winter scenery. Wherever there is a tendency to yellow light these plates were very good. The plates also recommended were those of medium quickness, with a thickly coated emulsion. Mr. Leblanc, of Messrs. A. Schwarz & Co., then proceeded with a demonstration upon Dr. Andersen's developing, fixing, and toning cartridges, and some good results were obtained. They were strongly advocated for tourists, &c., who wished to test their exposures whilst on a journey, as they were so easy to manipulate, and saved taking a quantity of chemicals, &c., on tour. An advantage claimed for the fixing cartridges was that it could be used over and over again, and therefore a decided advantage over ordinary hypo. Glycin, as a developer, was strongly urged for use by beginners. A vote of thanks to the demonstrator closed the evening.

North Middlesex Photographic Society.—December 11.—Some time was consumed by discussions as to the Exhibition just recently held and also the nomination of the executive for the coming year. The members who had received sample packets of the Barnet lantern plate brought their results for inspection and criticism, and a good opinion of the capabilities of the plate seemed, in most cases, to be formed. The Thornton-Pickard tripod was also examined. Information was asked, and a discussion took place, on the question of the possibility of producing pictures that should show unmistakably the effect of a bright sunny day. Most members thought it a desirable attainment, and that it could be done, but seemed somewhat hazy as to how to work for the desired end. Mr. AVERY said he thought that, by giving an exposure just slightly under the normal, developing with a developer, very strong in pyro and weak in bromide and ammonia, until the high lights were fully developed, then washing that off and flooding with another developer, weak in pyro and strong in bromide and ammonia until the detail was all out in the shadows, a negative could be got which, if printed in carbon, would certainly show sunshine. Mr. MCINTOSH was in favour of rehalogenisation.

Richmond Camera Club.—December 18.—In lieu of the promised demonstration by Mr. Borghoff, an interesting novelty was introduced into the Club's proceedings in the shape of a lecture by Mr. BREARLEY on *Japan and the Japanese*, with lantern illustrations, the work of native artists. Mr. Brearley's long residence in the country well qualifies him for the post of lecturer, and his short introductory paper gave a graphic and comprehensive review of the salient characteristics of the land and its people. A large number of slides were then shown, comprising figure studies, street scenes, landscapes, Shinto and Buddhist temples, religious and social ceremonies, and a variety of other subjects. All the slides were colonred, and, little as coloured slides commend themselves in the general way to photographic connoisseurs, it must be confessed that that these, for the most part, showed such delicate and artistic treatment as to compel the admiration of all present, and to suggest a comparison with the English coloured slide by no means favourable to the latter. In fact, the difference would seem to be that in Japan slides are coloured by artists, in England by mechanics.

Woolwich Photographic Society.—December 14, Major C. D. Davies presiding.—At the conclusion of the usual routine business, Mr. W. H. BARNES read a paper on *Isochromatic Photography*, taking up, in turn, the advantages of isochromatic plates for copying oil and water-colour paintings, for photographing flowers, landscape and portrait work. The paper was pictorially illustrated with a number of photographs taken on ordinary and isochromatic plates, with and without the yellow screen, for the purposes of comparison, and further enabled Mr. Barnes to point out clearly when the screen can be successfully employed and when it is better to rely wholly upon the qualities of the plates. He concluded by passing a number of slides through the lantern for additional illustration.

Ashton-under-Lyne Photographic Society.—December 14, Mr. Greenwood in the chair.—An address was given on the subject of *Photographic Chemistry* by Mr. STEPHEN SHARP, chemist. Mr. Sharp illustrated his subject by giving numerous tests of the various chemicals used in photography, and showed the members some simple methods of judging the purity of them.

Derby Photographic Society.—December 13, Mr. R. Keene presiding.—It having been suggested to hold an Exhibition of Photographs in 1894, similar to that held at the commencement of 1893, this question was first brought under consideration to ascertain whether sufficient new work could be obtained from the members to make the Exhibition a successful one. It was arranged that it be made a biannual one, so that the next will take place early in 1895. It was also agreed to hold an Exhibition of Lantern Slides (made by the members) early in 1894, to which all interested in photography could be invited. The Rules of the Society were also revised, and the night of meeting altered from the second to the third Tuesday in each month, October to April inclusive, out-door meetings to be held from May to September. It was decided to hold the annual dinner early in January next.

Hexham Photographic Society.—December 12, Mr. Jasper Gibson (Vice-President) in the chair.—The prints and slides sent in to the recent Members, Competition were on view, and a number of members' slides were put through the lantern. Mr. W. PARKER MORRIS, the Assistant Hon. Secretary of the Newcastle and Northern Counties Photographic Association, gave a lecture on *Lanterns and their Manipulation*, and explained the construction and method of working his powerful limelight lantern. The lecturer was accompanied by Mr. Edgar G. Lee, who is well known as being one of the best lantern-slide workers of the day. A number of his slides, which are now being published by Mr. J. P. Gibson, Hexham, illustrating *Child Life in the Slums*, *Street Life*, *The Herring Fishery Industry*, and *Marine Studies*, were shown upon the screen, and were much admired for their artistic treatment as well as for their local interest.

Ipswich and Suffolk Photographic Society.—A *conversazione* was held at the Carr-street Rooms on Friday, the 15th inst. A large exhibition of pictures was furnished by the members. The President (Mr. J. Dixon Piper) showed about thirty views, mainly 24 × 20, taken direct, and Mr. Pringle (late Secretary) also contributed some charming landscapes. Altogether nearly 300 frames were hung. A quantity of apparatus was shown. A half-plate camera, with aluminium fittings by Park, attracted considerable attention, and Messrs. Marion's cameras were also much admired. The European Blair Camera Company made a good exhibit of hand cameras. Beck's also made a good show of Frenas and work done by them. A new hand camera, to carry eighty cut films, quarter-plate, the Malda, was on view. Messrs. Houghton, Eastman Company, Blackfriars Company, Thornton-Pickard Company, Elliott, Taylor, Tylar, Cresco-fylma Company, and many others were also represented. Messrs. West & Wilson sent a number of lantern slides, which were shrown on the screen by Mr. J. C. Wiggin. Music was provided at intervals by Mr. Charles Cooke and leading local amateurs. The Committee furnished refreshments in the interval, and a very pleasant evening was spent. About 200 of the local enthusiasts and their friends were present, including the Mayor and many members of the Corporation.

Liverpool Amateur Photographic Association.—On Thursday, the 14th inst., under the presidency of Mr. Arnold Cleaver, the Annual Meeting of this Association was held in the Club-rooms, Eberle-street. An entirely new feature was introduced to the meeting by Mr. H. Simpson (an old member of the Association), consisting of a lecturer's automatic optical lantern, which the lecturer has entirely under his own control, no operator being required. Previous to the exhibition, the lecturer places in order all the slides he requires to illustrate his lecture. The lecturer may face his audience, the lantern being placed in the usual position at the back of the hall, and, by means of a pneumatic tube connexion, he dissolves the pictures, changes the slides, and works the limelight. The entire arrangement is altogether unique. After the usual business routine, including the election of twelve new members, the competing pictures, which were arranged round the room, were awarded prizes as follows:—Champion Class for Past Prizemen: The gold medal of the Society, Mr. T. F. Lloyd; for half-plate and under, silver medal to J. Appleby, bronze medal to G. Allday; over half-plate, silver medal, C. A. Timmins; bronze, H. Holt; for enlargements, silver medal, William Tomkinson; for hand-camera pictures, silver medal to H. B. Forrer; and stereoscopic slides, silver medal,

W. S. Elsworth. In the lantern-slide competition the Judges had great difficulty in making a selection. Finally it was decided to award two silver medals for equal merit, viz., Joseph Earp and F. Anyon; bronze medal, T. B. Sutton; and the President's prize, open to lady members only, has again fallen to the lot of Miss Rose Collier.

Midland Camera Club.—December 15, Dr. Edwards presiding.—Mrs. W. D. WELFORD gave a demonstration on *Cresco-fylma*. She stated that success had rewarded her first attempt, and claimed as advantages the smaller apparatus necessary, and the absence of an enlarging camera or dark room when cresco-fylma is used. The proportion of cresco-fylma used in operating was 1½ ounces to ½ ounce water. Four transparencies were placed in dishes containing the above liquid, and in about two minutes the films floated off, and were placed in larger dishes containing water, and opal being placed therein. In twenty minutes the transparencies had enlarged from half to whole-plate (no loss of density being noticeable), and were then floated on to the opals, removed and dried. Questions as to the nature and uses of cresco-fylma were asked and answered. At the close of the demonstration some lantern slides by Mr. and Mrs. Welford were shown, those of clouds being very much admired. Mrs. Welford concluded a useful evening by eulogising the hand camera for clouds, street scenes, and seascapes.

Dundee and East of Scotland Photographic Association.—December 7' Mr. J. D. Cox in the chair.—A Lantern-slide competition took place, for which ten members entered, each sending in six landscape views. The prizes were adjudged by the meeting as follows:—1, Mr. D. Ireland, Broughty Ferry; 2, Mr. V. C. Baird, Broughty Ferry; 3, the Rev. E. J. Gough, Dundee. Mr. Murray Feathers gave a lecture on *The Capabilities of the Camera*. Some excellent pictures, illustrative of the different branches of the photographer's art, representing statuary figures, animals, landscapes, stellar photography, &c., were shown on the screen. Among the most noteworthy of the photographs are representations of the statuary in Dundee Museum, taken by the electric light, and an interesting collection of views of the Chicago Exhibition. Mr. Feathers gave racy descriptions of the different slides.

Glasgow and West of Scotland Amateur Photographic Association.—December 18.—Fourteen new members were elected. Mr. J. C. OLIVER gave a demonstration of negative retouching, using an enlarged paper negative, on which he pointed out the modifications required, and showed how they might be effected. Negatives in various stages of retouching were handed round, and transparencies from retouched and untouched negatives were shown by means of the lantern. A large number of slides by members were shown on the screen. An Exhibition of members' work will be opened on December 25, and will be open to the public for a fortnight.

Glasgow Photographic Association.—December 7, Mr. John Stuart (President) in the chair.—Two new members were elected. One question was in the question-box, viz., "What is the experience of members who have used the Sandell plates?" Several members had tried them—some with success, others got rather indifferent results with them. Amongst the difficulties experienced were, fixing of the plate and prevention of green fog. After the President had given his opening address, the Treasurer's and Secretary's reports were read and adopted. Mr. STUART then gave a demonstration of the developing of printing-out papers, using all the best known makes. The members watched the various manipulations with great interest. Mr. Stuart drew attention to the fact that prints from soft negatives could have more vigour given them by using a stronger developer, and those from hard negatives could have the contrasts decreased by employing a weaker developer than the normal one, and giving more time to the development, and recommended that the prints should remain in the bromide bath for fifteen minutes. He said that, if the prints were exposed to much strong daylight during printing, there was a tendency to have the whites greyed, and which often showed on the back of the print. He also showed, by the use of a brush, how hard parts of the print could be much softened. During the demonstration, Mr. Stuart showed a large number of prints made on the new P.O.P. matt-surface paper; they were passed round, and much admired by the members. Some of the prints had very pure whites, with rich blacks. It was generally conceded that, for artistic work, such a paper was much wanted. Mr. Stuart also showed a sample of matt bromide paper, to be shortly sent out by the Ilford Company, and which will admit of being worked upon with the greatest facility with the brush or pencil. A large collection of lenses, in their various stages of manufacture, for the making of photographic objectives, kindly lent for the use of the Society by Mr. J. H. Dallmeyer, London, were shown to members. Mr. Brown showed a photograph taken at Lamlash by moonlight, with one and a half hour's exposure; it was somewhat similar to an under-exposed one taken in the usual way. Mr. Platt showed a group, taken in Airdrie, after an amateur dramatic performance; it was from a 15×12 negative, which was taken by means of Mr. Stuart's flashlight apparatus. The print was much admired; the only fault found with it was, that the lens did not quite cover the plate at the edges. Transparencies by Messrs. Watson, Hanbidge, and Lindlay Miller were passed through the lantern. A meeting of the Society and friends of members will be held early in the year, and will take the form of a smoking concert.

Kilmarnock Amateur Photographic Society.—December 15, the President (Mr. T. Ferguson) in the chair.—Mr. MILLAR gave a demonstration with gelatine papers, viz., Ilford P.O.P., Solio, Nikko, Paget printing out by development. Each of these papers was illustrated by views that had been taken in Arran. For developing Nikko paper, Mr. Millar uses half a drachm of rodinal to two ounces of water. The following was given as a good recipe for mounting gelatine prints:—Best Bermuda arrowroot, 3½ ounces; gelatine (Nelson's No. 1), 160 grammes; methylated spirits, 2 ounces; carbolic acid (pure), 12 minims; water (cold), 30 ounces. Mix the arrowroot into a stiff cream with a portion of the water, while the gelatine is placed to soak in the remainder. When the gelatine is softened and the arrowroot well mixed, pour all together into an iron saucepan and bring to the boiling point. Keep at this heat for about five minutes, being particularly careful to stir continually from the moment the mixture is placed on the fire. When sufficiently cooked, pour into a basin to cool. When cool, add the carbolic acid and spirit (previously mixed) in a thin stream with constant stirring. Then bottle, and keep well corked.

Munster Camera Club.—December 5, a demonstration on the *Ethoxo Light* was given by Mr. W. Ringrose Atkins, F.C.A. Mr. John Day, President, occupied the chair.—Mr. ATKINS, in the course of his remarks, explained the manner of producing limelight by the combination of oxygen and hydrogen gases, and described the different kinds of "jets" used. He then referred to the light generated by passing oxygen through the vapour arising from methylated ether, or benzoline, illustrating his remarks by an exposition of Lawson's New Patent Ether Saturator, the construction and working of which he explained by means of photographs taken by himself and projected on the screen by means of the identical instrument itself. This appliance gives a beautifully brilliant white light, undoubtedly surpassing in brightness the usual oxy-hydrogen safety jet, and its manipulation is extremely simple. Mr. Atkins stated, in continuation of his remarks, that the convenience of the saturator in places where no hydrogen can be had would be very great, and, further, that he considered that the amount of danger which undoubtedly existed in some of the older forms of saturator was minimised in the case of the new instrument, which he used in conjunction with one of Messrs. Riley Brothers' (of Bradford) "Prestantia" lanterns, with a lens of six-inches focus. Mr. Atkins then exhibited a number of photographic slides made by himself and Messrs. Scott, Bennett, Egan, &c., which were highly satisfactory. A discussion ensued, in which the President and Messrs. H. Lund (of the Chemical Department of the Royal University), A. Newsom, R. S. Baker, R. M'Kechnie, J. Bennett, &c. took part. Mr. Lund's remarks were most interesting, and his description of the earlier pattern saturators showed his complete knowledge of the subject.

Photographic Society of Ireland.—December 8, Mr. Hedley (Vice-President) in the chair.—Subject, *Colouring Lantern Slides*, by Professor J. A. Scott. The lecture, one of the most interesting given before the Society, was largely attended by members and visitors. Many ladies also were present. Dr. Scott opened the lecture by showing some diagrams which he had partially coloured for demonstration purposes, so as to make certain portions of the subjects more striking, and said that while doing this he was led to try various styles of colouring, such as flowers, views, &c.; and to show the effect some coloured slides of apple blossoms, narcissi, &c., also Alpine scenery and other views, were thrown on the screen. At the same time the Professor expressed the opinion that most good photographs were better uncoloured, but that a bad one could be considerably improved. The varnish colours proved unsatisfactory, as they took so long to dry, even when heat was applied, unless special media were used. Experiments with oil colours showed they were insufficiently transparent, the best of these being only good when applied in thick coats, and utterly failed when merely thin washes were given. What proved satisfactory in Dr. Scott's hands were the aniline dyes, and these in all cases would not suit—only those known as the acid dyes, such as picric acid, Essin soluble blue, and some others. Those dyes are applied with a brush in washes if the gelatine be previously soaked in water, or best if the colouring be carried out immediately the final washing is concluded, and the surface gently dried with a handkerchief to remove superfluous drops of water. The dyes have the effect of staining the gelatine, and show very little or no tendency to run beyond where the brush has touched. A little dextrine is mixed with the dyes when painting on plain glass or gelatine. Another point about the staining is that the colour be kept very dilute; otherwise they appear too bright. The slides showing the effect of the colouring were in all cases received with applause, and, after a vote of thanks was passed to Dr. Scott for his instructive lecture, a most successful meeting was brought to a close. The Hon. Secretary (Mr. Ruthven) announced that the Society's Exhibition would be held next January, when a gold medal would be offered for the best picture sent in by amateurs (open competition). Particulars can be had from Hon. Secretary.

FORTHCOMING EXHIBITIONS.

1893.

December ..... *Madras. The Hon. Secretary Amateur Photographic Society, Madras.

,, 22–Jan. 22, 1894 *Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

PHOTOGRAPHIC COPYRIGHT.

To the EDITOR.

SIR,—Referring once more to the vexed question of copyright in photographs, would it not be possible to get a short measure added to the Copyright Act, by which any professional photographer, on paying a fixed sum—say, 5*l.* or 10*l.* per annum—would be enabled to protect *all* photographs sent out of his establishment?

I have no hesitation in saying there are many professionals, doing a large business, who do not pay so many shillings during the year. This would mean an increase of revenue, and need not prevent registration, for those who prefer it. This measure would, I think, if carried out, effectually scotch the pirate and cheap enlarger.—I am, yours, &c.,

SUGGESTION.

To the EDITOR.

SIR,—I have heard it stated that there was no copyright law applicable to Scotland under which the work of a photographer could be protected, and it would appear that the opinion that such is really the case must be freely entertained, at least by some speculative firms or individuals.

Those gentlemen, about this season of the year, generally flood many of the paltry shops in our small country towns with local views in the shape of trashy Christmas cards with New Year greetings printed upon them.

These productions are mostly pirated from the work of resident photographers, whose struggle for existence in these poor and scarcely peopled districts need not be made more desperate by the systematic thieving of his work, while the inferiority of said productions is very likely to affect his reputation, as they are probably palmed off upon the general public as being his own original work.

As a photographic artist I have been pretty severely dealt with in this way. It is very annoying to observe in shop windows these trashy abortions of my work, the original negatives of which cost me much anxious watching and waiting in order to secure the best possible results, reproduced in this unscrupulous manner by the speculative gentry I have referred to, aided and abetted, no doubt, by some of the paltry shop-keepers to which I have also referred.

If it were possible, I would endeavour to prevent a repetition of this unprincipled traffic in the reproduction of my work. To do this I suppose it would be imperative that duplicates of the subject should be forwarded, and registration secured before any copies are issued to the public.

I have no doubt there are many photographers similarly situated to me with respect to the pirating of their work, and it would confer a favour on me, as well it may be on others, were you to explain in your columns whether the further copying of any photograph could be protected by the ultimate registration of the original work.—I am, yours, &c.,

High-street (West), Leslie, N.B., December 18, 1893. D. ROSS.

THE SPEED OF PLATES: A CRITICISM AND A REPLY.

To the EDITOR.

SIR,—Under the above title Mr. Elder defends, against the criticisms which we passed upon it, a paper entitled "Rapidity of Plates," read by Captain Abney before the Camera Club. Although we are not members of this Club, we have, in obedience to its rules, confined our criticism to its *Journal*, "for private circulation only;" and we are much surprised that the Camera Club and its President, whilst enforcing silence upon us, have permitted Mr. Elder to give wider publicity to his remarks.

We do not suppose for one moment that Captain Abney engaged Mr. Elder as a special pleader; he is quite able to defend himself, and, as a matter of fact, published a written reply to our criticism a month afterwards. Nor do we suppose that Captain Abney approved of the style and the contents of this attack upon our work, the arduous nature of which no one can more fully appreciate than he.

But why this second reply on Captain Abney's behalf? We have pondered over this puzzling question, and find it more difficult to solve than the problem of speed determination. At first we came to the conclusion that we must have seriously offended Mr. Elder with some remarks we made with respect to his own paper, *Some Remarks on the effect of light on photographic plates*, but, on again perusing the record of these remarks, we have to dismiss the idea that we could have given such offence as would justify the attitude he has thought fit to take up. The inaccuracies in which his paper abounds, and its bitter and ungenerous tone inclined us to conclude that, in criticising Captain Abney's paper, we must, unknowingly, have criticised some of Mr. Elder's own work; and, were it not for our conviction that Captain Abney is the last person to need Mr. Elder's assistance, and that he would scorn to publish as his own work anything communicated to him by another, we should think that we had found the real key to the situation. As it is, we are at a complete loss to understand the motives which dictated Mr. Elder's angry and undignified reply.

Of some of Mr. Elder's statements we refuse to take any notice whatever. When he has studied and understands fully the work we have done, he will be entitled to be heard with respect, at present he has not mastered even the elementary part of our papers. To other of his remarks we are, unfortunately, obliged to reply lest our silence should be misconstrued, but our remarks shall be short.

Mr. Elder's definition of, and his remarks concerning the speed of plates, and the range of gradation necessary in negatives for artistic effects, are neither new nor correct, and any one can easily convince himself from our papers that we have fully considered these several points. If Mr. Elder is unable to produce two exactly similar negatives on plates of widely different speeds, we shall be pleased to give him a demonstration in Widnes, as we did before an audience in Liverpool. It is not true that we ever asserted that the ratio of gradation of a technically perfect negative must be the same as in the object portrayed; nor did we ever assert that the print from such a negative was perfect. It is equally untrue that the finest negatives have their gradations in that part of the scale which we have termed the "period of under-exposure." We have measured many wet-plate negatives, as well as dry, and we have invariably found that in sparkling negatives the opacities range from about 1¼ to 320. If Mr. Elder will produce a sparkling negative, the gradations of which lie between transparencies 94 per cent., and 16½ per cent., we shall be glad to have the opportunity of inspecting and measuring it. For the present we say that neither he nor any one else has ever seen a sparkling negative with such a range of gradation as he mentions.

That Captain Abney's method of speed determination gives numbers wholly at variance with the speeds found by our method was precisely the reason why we pointed out the weakness of a method depending upon a single density. We foresaw the fate which must, sooner or later, overtake Abney's method announced to the world in April; it is completely abandoned, even by its author, in November of the same year. We, and our friends, knew well that a method which depends upon "the period of under-exposure" must be liable to great variations and errors, the deciding densities being too small to permit of accurate measurement and reproduction, and that such a method must be utterly useless. The contradictions between the speed found by Abney's method and our own, we ourselves laid bare before the Camera Club. It is, therefore, no surprise to us, and it cannot be to any of the public, to find our statements verified by Mr. Elder.

Had Mr. Elder taken the trouble to ascertain, by means of the camera, which speed is the more nearly correct—Captain Abney's or our own,—such an experiment, carried out fairly and carefully, would have told a story which would have silenced the silly assertions dictated only by Mr. Elder's fertile imagination. For the present, we again affirm that the speed, as ascertained by our method, is a number to which the exposure in the camera must be proportional if a good negative be the desired result. We ourselves pointed out before the Camera Club that Abney's and our own methods could not possibly give the same, or proportional, speeds of a plate in absolute units; and we took the trouble to show the error Captain Abney had fallen into with his logarithms, which error led him to the conclusion that his method gave the same zero point, *i.e.*, the same speed, as ours. It appears to us that logarithms are also a source of trouble to Mr. Elder. He says that Abney's transparencies are proportional to the negative logarithm of the exposure. This is either not true, or, if it be, it is not in accordance with the "law of error" formula which Mr. Elder attempts to set on its legs again. Mr. Elder simply mistook the square of a logarithm for the logarithm of a square.

The question of Captain Abney's recent researches we intend to deal with separately before long.

There is only one other point to which we must allude. Mr. Elder wrongly accuses us of having unfairly criticised Captain Abney when we said that he attempted to prove that a parabola did not differ much from a straight line; and Mr. Elder endeavours to show that the Captain did not fall into this error. Let the Captain's errors sleep in the annals of the Camera Club; why drag them before the public, and compel us to again assert that he did commit this error, and that in the whole of the passage to which we refer (*Camera Club Journal*, vol. vii. page 129) the point of inflexion is not mentioned, and was not meant? Our criticism was not only just, but absolutely necessary.

To conclude, we adopt his own words when we say, "It would be too wearisome to hunt down the whole of the errors in Mr. Elder's criticisms to their bitter end." We have purposely steered clear of mathematics, as our object has simply been, as shortly as possible, to reassure our friends, and to show the general public that Mr. Elder's criticisms are unworthy of serious attention. While "he does not in the least seem to realise what is meant by the determination of speed," and does not offer one scrap of new experimental evidence, we have shown, and frequently demonstrated by experiments before the public, that a more than sufficiently accurate speed number can be assigned to any plate, without reference to any other plate; and that this number is expressed in units as absolute as the gramme or centimetre, though not as easily reproduced. We have also repeatedly shown the practical applications of which our system is capable, and we can only say to Mr. Elder, unless he wishes to still regard our work with a "jaundiced eye," do as others have done, who, with open minds, have only desired to learn the truth. Come to Widnes and see for yourself. F. HURTER & V. C. DRIFFIELD.

GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—We note the two letters in your issue of the 15th inst, and, as Mr. Smith has acknowledged that his estimate of comparative cost contained a very serious omission, we are perfectly content to leave this part of the subject where it is.

As regards "Scribbler," if he will pay us a visit at Ilford, we shall be

happy to teach him to work the paper, as he does not appear able to succeed without further help.

The remaining portions of the letters show to how great an extent the personal equation comes into play in the question. Yellow prints, impure whites in vignettes, are not met with *except where the photographer has failed to follow instructions*, and therefore such accusations are not indications of faults in the paper, but signs of want of thorough knowledge or care on the part of the worker.

Individual opinion counts for nothing against the opinion of the many, and, from our position as manufacturers and suppliers, we can state with certainty that 999 users out of 1000 find the paper all we claim it to be. Were this not so, we should not have found our first year's sales more than satisfactory, and our second (just closed) 300 per cent. better.

When the gentleman wrote in the ALMANAC (in all good faith, we are sure), "I think it will take something better than the present make of gelatine paper to supplant good old albumen," he has evidently very little knowledge of the subject beyond his personal failures, and his saying reminds us strongly of the saying of a good but equally misguided man who, in 1877, wrote on the subject of gelatine plates. This gentleman said that no photographer who was worthy of the name would buy a ready-made plate, and therefore he did not see much future for gelatine plates.

Comment or comparison is needless. We appreciate highly Mr. Smith's evident fairness, and his desire to avoid controversy, and, having pointed out what seemed to us to be his error, we do not seek a further free advertisement, as he puts it.—We are, yours, &c.,

THE BRITANNIA WORKS COMPANY, LIMITED.

FILMS *VERSUS* PLATES.

To the EDITOR.

SIR,—I have recently received a roll of thin film from the United States, with a number of various brands of plates for speed testing. The point of interest is that this package—dated October, 1893—bears the following printed warning:—"30—Sensitometer. This film must be used *within six months* from date hereon." Probably this is the first instance of a maker making reference to the non-keeping quality of a gelatine emulsion.

In justice to films, however, I may state my decided opinion that all the different brands of "the quickest plate made" sold in England ought to be labelled in a similar manner. I find most of them are deteriorated after six months' keeping.—I am, yours, &c.,

Hereford, December 16, 1893. ALFRED WATKINS.

SPOTS AND PINHOLES IN NEGATIVES.

To the EDITOR.

SIR,—Mr. Harding Warner has kindly replied in your columns to a note which I sent you some few weeks ago on the subject of pinholes in negatives. I ought at that time to have given fuller information upon my experience with these nuisances, but cannot regret the omission, because it has been the cause of eliciting a most interesting communication from your correspondent. Of the three brands of plates which I formerly referred to, Thomas's "Pall Mall" were in A. & M.'s grooved boxes; Obernetter's were, if my memory is right, packed with soft paper between the films; the third maker's were in grooved boxes. The two former gave perfect negatives when properly used, the latter were invariably covered with pinholes, there being no difference in the conditions of treatment of the three brands. The holes were in the films, leaving minute spots of clear glass; they were not merely specks of clear gelatine, and they were not visible until the film was dry, after the negative was completed. To the eye there was nothing wrong with the plates when examined as taken fresh from the boxes in which they were packed. For these reasons I concluded that the defect was due to mechanical, and not to chemical, causes.

I was especially interested in Mr. Warner's letter, because it gives another bit of evidence illustrating the danger of packing plates with silver paper between the films. This method of packing is my particular abomination. Why will not makers adopt the simple plan of laying the plates film to film, binding them firmly together, and then wedging them tightly in the outer coverings, so that the whole package is one solid mass which cannot be disturbed by shaking? I believe that many of the best photographers pack their exposed plates after this fashion when on tour. The Cadett plates in small sizes are packed in a manner which, in my opinion, is quite perfect; and, although the larger sizes of this make are not packed film to film, yet, shake the box as you will, there is no movement of its contents. I write feelingly on this point, for of late I have been preparing negatives for collotype printing, and found the greatest difficulty in obtaining plates free from mechanical defect of the film which has been caused by bad packing.—I am, yours, &c.,

Wimpole-street, W., December 16, 1893. F. R. FISHER.

THIOCARBAMID.

To the EDITOR.

SIR,—With further reference to ours of November 27, in which we drew your attention to Mr. Hauff's new preparation, thiocarbamid, used for removing stains and discolourations, for fixing and clearing, we have now pleasure in enclosing you herewith a certificate of the well-known Dr. J. M. Eder, of Vienna, and should be much obliged if you would publish it in the next issue of your paper. Thanking you, we are, yours, &c.,

FOREST BROTHERS.

17, *Philpot-lane, London, E.C., December* 16, 1893.

[We append Dr. Eder's certificate.—ED.]

CERTIFICATE OF THIOCARBAMID-HAUFF.

On October 10, 1892, Mr. J. Hauff, of Feuerbach, Stuttgart, submitted to me a sample of thiocarbamid, with the request to test same and report thereon in regard to the application of same in photography.

According to this statement of Mr. Hauff, thiocarbamid should possess the property (when added to the fixing bath) to prevent bromide silver gelatine plates, as well as chloride silver gelatine plates and bromide silver gelatine papers, from colouring the gelatine layer yellow, and should prevent the formation of so-called green fog.

The preparation sent consisted of some white crystals, and gave in water a colourless liquid. I found that it acts indeed (in acid solution) as a preventive against yellowish negatives.

I made a solution of—

Thiocarbamid	10 parts.
Citric acid or sulphuric acid	10 ,,
Water	1000 ,,

I immersed in this solution a pyro-negative strongly covered with green fog and after a short time the yellowish-green colour had disappeared. With amidol I was not able to obtain negatives showing green fog, and therefore could not make a trial.

If the salt is added to the fixing bath, it prevents the formation of green fog with plates and bromide silver papers; but it must be observed that the bath should be *acid*.

For fixing I found the following formula very useful:—

Water	1000 cc.
Fixing soda	200 grammes.
Thiocarbamid	10–15 ,,

To this solution is added 50 grammes of bisulphate of soda.

I would observe that plates as well as papers, before fixing, must be washed sufficiently so as to remove all traces of the developer.

As the action of thiocarbamid in the fixing bath is only of proportionately short duration, it is recommended to use an ordinary acid fixing bath, which, as is known, will by itself prevent to a certain extent the formation of green fog; and after the use of this, if necessary, the above discolouring bath can be applied, and which will become necessary specially for certain kinds of bromide silver gelatine paper. I can certify, therefore, that for this purpose the said salt, thiocarbamid, proves a good useful means of removing discolouration.

(Signed) DR. J. M. EDER,
Director of the K. K. Lehr- u. Versuchsanstalt für Photographie und Reproductionsverfahren in Wien.

Vienna, December 3, 1892.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance. The full name of the advertiser must in all cases be given for publication, otherwise the Exchanges will not be inserted.*

Will exchange capital brass banjo, twenty-one inches in diameter, for 12×10 or 10×8 camera.—Address, STEEL, 74, Goldstone-road, West Brighton.

Wanted to exchange a five-inch condenser for a "Lawson's patent Saturator and combined."—Address, E. J. CHESTERMAN, The Rise, Endcliffe-vale, Sheffield.

Will exchange three whole-plate metal double slides for good background, or for a rapid-rectilinear lens.—Address, H. STEEL, 74, Goldstone-road, West Brighton.

Wanted a 7×5 wide-angle lens in exchange for a seven-inch rolling press in good condition.—Address, GEORGE WILKINS, jun., The Nest, Christchurch-road, Bournemouth.

Wanted, second-hand collotype machine, in good order, for plates, not less than 15×12; particulars and lowest price; also reversing mirror.—Address, COLLOTYPE, P. O., Aberdeen, Scotland.

Will exchange first-class, five-string banjo, nickel-plated, for half-plate camera, lens with two or three slides, Lancaster preferred.—Address, JOHN K. HECK, 6, Clinton Place, Broomhall, Sheffield.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries and Exchanges, must be addressed to* "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

*** *It would be convenient if friends desiring advice respecting apparatus, failures in practice, or other information, would call at the Editorial Office either on Wednesdays from* 4 *to* 6, *or Thursdays from* 9 *to* 12 *noon, when some one of the Editorial staff will be present.*

PHOTOGRAPHS REGISTERED:

David Forbes, Glasgow.—*Two photographs of designs for Clydebank Union Church.*

John Moffatt, Edinburgh.—*Two photographs of a group of Rev. Dr. MacGregor and Rev. Wallace Williamson, of St. Cuthbert's Church, Edinburgh.*

M. J. S.—Thanks. It is very amusing.

W. MORTON JACKSON.—Received, thanks; next week.

G. V. NORTON.—You may rely on the permanence of York's lantern slides.

E. LIESEGUNG.—By the term "working stop," the stop with which the exposure was made is meant.

J. GRABOWSKI.—We know of no one who does that kind of work. Probably an advertisement would obtain for you the address of some one who does.

R. S. P.—Our opinion is that, when such statements respecting the lens, the plate, and the developer are emblazoned on the photograph, it is a tacit confession of weakness in the artistic ability of the photographer himself.

C. RAGGETT.—This query has been answered more than once within the past few weeks. If the music is copyright, it is illegal to make lantern slides of it for the use of school entertainments and suchlike Christmas festivals.

HOROLOGER.—There is a difference of nearly four minutes per day between solar and sidereal time. Twenty-four hours of mean solar time are equal to twenty-four hours three minutes and fifty-six and a half seconds of sidereal time.

S. T. A.—The retouching is very good if the bust is intended to represent a hairdresser's figure, but, if a living being, it is just the reverse. All modelling has been destroyed, and the portrait simply represents a lifeless wax figure.

T. A. W.—If the school committee will not permit the use of cylinders of compressed gas, the only thing we can suggest is to use bags, and make the oxygen yourself, or empty it from the cylinders into bags. Failing that, an oil lamp must be used.

J. CALOE.—Try the addition of a little gum or similar mucilage to the ink. The mere statement that the method you use is very simple does not enable us to give any opinions as to whether it is suitable for "typo-printing." The better way will be to try it for the purpose.

E. B. WARD.—The numbers on the stops are according to the old system of marking, which was to the idea of the maker of the lens. According to the system adopted by some, each smaller stop requires an exposure half as long again, while, according to others, it required to be doubled.

A. M. Z.—As to which of the hand cameras named is "the best" depends, of course, upon the requirements (and means) of the individual. They are all good in workmanship and effective in use; but, beyond that, we regret we cannot go. We do not recommend particular makes of apparatus.

T. W. ABBOTT.—The only way by which the reversal of the image, as regards left and right, can be accounted for is that the plate was placed the wrong way in the slide, so that the exposure was through the glass. This is a very common way of producing reversed negatives by the wet-collodion process for mechanical processes.

NO MONOPOLY.—If the Vicar has given the local photographer special privileges for taking the interior of the church and the ancient records and registers, on condition that he allows a small royalty on the sale to go towards the annual Sunday-school treat, it will not prevent your taking the exterior of the edifice and offering the copies for sale.

PROVINCIAL.—It is doubtful if compensation can be recovered. It is the railway company that you should have have looked to for compensation. If you could hear the broken glass in the box when it was delivered, acceptance should have been refused. Then the matter would have rested with the railway company and those who forwarded the opals.

ALBUMEN.—I. The discolouration of the acetate of soda toning bath may be due to the use of unclean dishes, or contamination with foreign matter. Some papers also have the property of disorganizing the solution. 2. Simply add a little more gold the day before the bath is next used, and occasionally a little more acetate of soda. The formula cannot be improved upon.

HANTS sends us some mounts that show decided marks of mildew. He says that they have been in stock for a year or more, and asks the cause. It is possible that the mounts were not thoroughly dry when received, or they may have been stored since in a damp place. They should not be used for silver prints, even if the mould is wiped off. Damp is the origin of the mildew.

A. C. BLAND.—There is no question that some of the mounts now supplied to photographers have much to answer for in the matter of fading prints. But they are by no means the sole cause, several other factors are at work, some of which are weak negatives, weakly sensitised paper, imperfect fixing, &c. Do not for a moment surmise that, because prints, whether gelatine or albumen, turn yellow quickly, the mounts must be the cause.

T. BRAMWELL.—You are evidently causing yourself an unnecessary inconvenience. For experimenting with the wet-collodion process, the subdued light required in the dark room when using gelatine plates is not at all necessary. If the window has a north aspect, a couple of thicknesses of orange cambric or one square of orange glass will suffice. Those who are only familiar with photography with dry plates have no idea the amount of light that may be used in manipulating wet plates.

F. S. T.—In asking if you can patent your new developing solution, you will certainly have an affirmative reply. You may patent anything you choose, within reason, and the patent will be sealed, unless any one should happen to oppose it, which is scarcely probable in your case. But it must not be assumed that, because a patent is granted, it would be valid if it were contested. If this were done with a very large proportion of the patents taken with reference to photographic matters during the past few years, they would fare badly.

B. F. MASON.—The distinction between "actinic" and "achromatic" is this: The former has to do specially with the bringing together at the focus of the lens the visual rays and those by which chemical action on the plate is produced; in other words, uniting the chemical and the visual focus; whereas, by an achromatic lens, this is not necessarily the case. Some lenses are quite achromatic as regards being quite free from colour, but they may not work quite to focus. Good telescope and microscope objectives belong to this latter class.

PRINTING-PAPERS WITHOUT GLOSS.

As our remarks will have a bearing on all kinds of paper free from added glaze, it is better not to employ the term "matt paper," seeing that, by an unwritten convention, the meaning of that term has gradually become so restricted that paper with a gelatinous surface, rendered dead or matt by artificial means, is now understood when the expression is used. That there should be a tendency to use paper free from gloss is a very satisfactory proof of the spread of artistic feeling. In the early days of photography, when plain salted paper was the chief medium of photographic expression, it must be admitted that there was far less opposition shown by artists of the brush than is unfortunately so often exhibited at the present time. The advent of albumenised paper—made slightly glossy at first, and very glossy after a time—vulgarised the products of the camera, and this, followed by the immense rush for the *carte-de-visite*, which flooded the country with ten thousand inartistic photographs for every good one, brought the art into a disrepute among cultivated outsiders that it is now only gradually recovering from. The growing taste for papers with dead surfaces will undoubtedly have some slight tendency in assisting to bring about a better feeling for the art qualities of photographic pictures.

The present year may be considered as an era in photography. From every quarter new matt paper is springing, and the cry is, "Still they come." There is such a plethora of processes and materials that the photographer may well be excused for shrinking from fixing upon a single style for his staple work, lest he should choose the wrong one. Let us run over the list. We have the old-fashioned plain salted paper, which may now, except for some special purpose, be considered as quite superseded, for under no circumstances when it is used can the same value be obtained from a negative as with modern matt paper; but when we come to drawing-papers, of various degrees of coarseness of surface, we cannot say the same. The walls of our exhibition rooms have shown us that a suitable negative printed on Whatman or other rough paper, presents a difficultly describable effect that is both artistic and attractive. Indeed, granted a few skilful touches upon the negative, it is sometimes difficult to determine whether a picture so executed be a photograph, a sepia, or an Indian ink drawing. When a view has been well selected and a good lighting effect secured, we question whether in the whole range of photographic processes we could obtain such beautiful results. Transparency is given to the shadows and a crispness to the lights that is unattainable by plain, smooth paper or that with matt surface. But in this direction we should greatly deprecate any tendency (and it has undoubtedly shown itself) to disregard considerations of permanency in the finished print.

As, however, this kind of printing would not commend itself for what we may call every-day work for the professional worker in the studio or the landscapist, we naturally now turn to matt paper. First on the list for priority of use must undoubtedly be placed autotype carbon prints. Prints in carbon, squeegeed upon a matt plate, and removed when dry, were produced, perhaps, a score of years ago, before the present name of autotype was adopted, and the delicate matt effect so obtained was most beautiful, and has never been excelled. It certainly was troublesome to execute, for in those days the surface employed to produce the effect was preferably a zinc plate roughened or "grained" by means of a special sand, till the grain was invisible. The metal being soft, these plates needed careful handling, as the slightest scratch or abrasion left a mark which was faithfully reproduced in every print attached to it. For many years the production of such prints bore a diminished proportion to those obtained by the single transfer process. This latter gave a slightly glossy surface half way between plain and albumenised paper, and, latterly, the Company have brought out a support which, by simple development, gives a matt surface with a slight gloss in the shadows, which is by no means inartistic, but naturally deficient in the delicate "egg-shell glaze" of the older kind.

We are thus led on to consider the media available to us since the introduction of gelatino-chloride paper, and which have crowded upon us so thickly of late. It is impossible for us to make invidious distinctions by pointing out any particular make as being superior to the rest; we should not attempt to do so if even there were one so superior. We have only to look at them from the point of view of permanency or otherwise. We think there can be no reason to doubt that they are at least as permanent as albumenised-paper prints, and very probably they will prove to be less liable to fade, if suitable toning and fixing baths be chosen for use. We note, with some trepidation for the future reputation of our art, that very many formulæ are published which in all probability will result in fading prints. It would be a thousand pities if the reputation gained by the supercession of the old combined toning and fixing bath in favour of alkaline toning should be again jeopardised by the use of solutions possessing similar defects. Whatever may become of matt paper in the future, every one should rigidly abstain from using a bath which would tend to unpermanent results.

Finally, let us add a word of warning. In many respects dull-surfaced prints—matt or otherwise—often greatly resemble platinotypes. Now, we can assert, as a matter of fact, that there have been such prints issued to the public under the false representation of their being platinotypes, and, so closely can they at times be made to resemble the latter that it would puzzle

an expert to detect the difference without the use of chemicals What we have to say is that every honest man should do his best to bring to justice such impostors, who, besides disgracing the name of photography, inflict an injury on the rest, and subject them to injurious suspicion. And our last caution must be to the honest workers. For experimenting with various silver paper, take every precaution with stock "over" prints to see that no possible future accidental error may occur. We know this is necessary from some remarks made to us by a professional friend, who said that it was only by accident that he prevented one of his assistants from innocently sending out as a platinotype a picture which he remembered was a silver print.

THE WET-COLLODION PROCESS.

III.—Dissolving the Pyroxyline and Iodising the Collodion.

In connexion with the making of pyroxyline we have been asked to give a formula for mixing the acids for the preparation of soluble cotton which will not necessitate the tentative method of Mr. Hadow, described in the previous article on this subject. Take equal parts of sulphuric acid of sp. gr. = 1·836, and nitric acid sp. gr. = 1·40, and, having mixed them, immerse the cotton as directed in the other cases. It is of consequence that the acids be of the strength indicated.

Collodion is commonly supposed to be a solution of "gun cotton" in sulphuric ether. This, however, applies to the collodion of pre-photographic times. We now know that "gun cotton" is not necessarily suitable for photographic purposes, nor is ether alone the most suitable solvent for the cotton.

What is the best solvent for pyroxyline? It will dissolve, if well prepared, in alcohol alone, and in rectified pyroxylic spirit (wood naphtha); but by far the best solvent and the one giving a smooth flowing and homogeneous film is an admixture of sulphuric ether and alcohol in nearly equal proportions, with a preponderance in favour of the ether.

Let us here pause for a moment to say that the alcohol of ordinary commerce, whether rectified or methylated, is too weak for getting the highest-class collodion from its use. It should be strengthened by the subtraction of some of the water present. As it is considered illegal to treat methylated spirit of wine with a view to the making of it "absolute," we conform to the laws, more especially as absolute alcohol is not necessary to the making of collodion, at any rate we have never found it to be so. But we can fall a little short of this and still be within the permission of the law, while at the same time we shall obtain it of a strength quite sufficient for our purpose.

Get a quantity of carbonate of potash, crush it to a fine powder and dry it in any convenient way, such as by placing it in a clean shovel and holding it over a clear fire for a short time. To the alcohol about to be strengthened, and which is now supposed to be in a clear bottle, add a handful of this and shake up well for a few minutes. Here is what takes place. The carbonate of potash is soluble in water, but is not so in alcohol. In course of a few minutes all the undissolved potash salt sinks to the bottom of the bottle and is covered by a supernatant solution of carbonate of potash solution in water, the water having been abstracted from the alcohol. The alcohol remaining as a supernatant fluid is stronger than it was by the abstraction of the water, which, as a solvent of the potash, now being much heavier, floats below. It only remains to carefully decant the spirit, which, if tested, is now very strong, its water having been abstracted.

This is quite strong enough for every purpose required in the making of collodion. If methylated spirit is wanted to be any stronger, it may be made so by distilling it from lime; but this, we understand, is illegal. Hence we do not advise it, especially as it is not necessary.

The way that we have found to be the most convenient for effecting the separation of the spirit from the potash solution is to have a clear bottle, like a brandy bottle, and with a graver or any hard steel point to drill a small hole as near to the bottom as possible. This will easily be done by using turpentine as a lubricant. Plug up the hole with a splinter of wood, and then nearly fill the bottle with the spirit that is to be operated upon. When the water has united with the potash it can be removed from the alcohol by withdrawing the wooden plug and allowing it to run off.

Some samples of pyroxyline that will not dissolve perfectly in ether do so very readily in a mixture of about four parts of alcohol and six parts of ether. Place eighty grains of the cotton in a sixteen-ounce bottle, and pour over it four ounces of alcohol, afterwards adding six ounces of ether. Cork the bottle and give it a good shake, by which every particle of the cotton should be dissolved. Some have imagined that the collodion is improved by the addition of three or four drops of chloroform to each ounce. We have made some with and some without this addition, and have found no difference between them. Label the bottle "Plain Collodion," and store it away for use as required. It will improve with age, and become as limpid-looking as distilled water.

The iodising of the collodion next claims attention. It is probable that no two makers adopt precisely the same compounds for doing this. Some use iodide of potassium, others that of ammonium, others prefer cadmium, or zinc, while the majority find that a judicious mixture of two or more confer advantages not belonging to either of them singly. So little as two grains of iodide of ammonium, previously dissolved in alcohol, and used for the ounce of collodion, have been known to give excellent results for positives; but for this the plain collodion, which contains eight grains of pyroxyline, would prove too rich, and would have to be diluted fifty per cent. before being iodised. But, along with the iodide, it is found to be much better, for both positives and negatives, that a certain proportion of the bromides be also present. The bromide of potassium is so very insoluble in ether and alcohol that it is better to avoid it altogether in favour of others which are soluble in that menstruum. The cadmium haloids possess the advantage of conferring great stability upon collodion, and we have known a cadmium bromo-iodised collodion remaining quite colourless for many months after being mixed.

For many years we have given preference to an ammonium and cadmium collodion prepared as below, and have found it to answer *every* purpose, being highly sensitive, possessing good fluent properties, and remaining stable for a long period.

Dissolve:—

Iodide of cadmium	65 grains.
Iodide of ammonium	25 „
Bromide of cadmium	19 „
Bromide of ammonium	11 „
Alcohol	5 ounces.

This dissolves easily, and is added to fifteen ounces of plain collodion.

PHOTOMETERS FOR USE IN PRINTING.

II.

Of the different processes available for the production of a graduated scale, we should be guided by the circumstances under which the photometer is chiefly to be used, and especially the class of negatives. In more than one professional establishment we know, the only photometer employed is a sort of "guide" negative, which is placed in a printing frame, and gives the time to all the rest; in other words, the remainder of the printing frames go untouched until the "guide" is found to be done, when they are all examined, and it is comparatively rarely that one of them has to be put out again. In such cases it is necessary to say the negatives are turned out of an almost faultlessly uniform character, the guide being only a fair sample of the bulk.

This plan would, of course, not work where negatives of every degree of density and gradation are produced, nor, indeed, do we imagine it would prove very reliable even if a number of separate plates were taken to represent different types, for where there are variations of density there are sure to be variations in gradation. Given two negatives of equal density in the lights, but possessing different gradations, it would be found next door to impossible to use either one as an accurate guide to the exposure of the other, especially in varying lights. Then, again, in process work such a course would be an utter impossibility, where nothing short of the absolute measurement of the work done would suffice. In the case of two half-tone negatives, similar exposures may possibly give two passable, or, we will say, equally good prints; but if they are printed independently, to get the best result possible with each, then very likely the exposures would be found to be widely different. In the case of process work this is more particularly the case, and what we require in this case, as in all others, is that the photometer shall register the amount of work done that has been found to produce the best result.

Given any particular negative, if we observe closely, we shall find that there is one degree of depth of printing that gives a better result than any other, but, owing to the nature of the subject, the variety of delicate gradations in the high lights, it is extremely difficult to judge accurately just when that point is reached. But there is no chance of mistaking a certain tint on a graded scale, so that, if we ascertain at which tint the best result is obtained, we can substitute the scale for the negative, and, taking the ascertained tint as the "highest light" we have to produce, we may ignore all lower gradations. We are, in fact, substituting, so to say, mechanical measurement for judgment which is apt to be fallible.

Probably no form of scale is at once so easy of construction and so generally efficient as the paper scale, such as is sent out by the Autotype Company at a very moderate price. It is, however, rather difficult to obtain a perfectly suitable paper, at once translucent enough and sufficiently even in texture, and the instrument requires great care in use afterwards in order to protect it from damage, as well as from dirt, which, naturally, will not improve its behaviour. The *papier minéral*, employed for the purpose of working up negatives, answers very well, but the best scale we have succeeded in making from paper was obtained with a more than usually fine sample of the thin waxed paper sold for wrapping purposes.

As regards the form of the instrument, for practical purposes this is immaterial, though, from motives of economy, it is not advisable to have it too large, either in actual area or in number of tints. For all ordinary purposes, a dozen tints will be found ample, and these may each be a quarter of an inch square, and occupy a strip in the centre of a slip of glass four inches wide by an inch broad. The glass is useful in protecting the paper scale from damage, though it is by no means necessary. A convenient plan consists in binding the separate layers of paper to the glass by means of the outer thickness the edges of which are turned over as in mounting a lantern slide. This outer layer, of course, forms part of the scale, and it can be so arranged as to be easily renewable when it becomes dirty by use, and thus considerably extend the "life" of the scale.

Although, perhaps, a little more trouble and, of course, necessitating an acquaintance with carbon printing, an exceedingly convenient method of forming the graduated scale is by means of bichromated gelatine, the sensitive tissue being subjected to gradually increasing exposures to form the steps of the scale. The exposure may be made in the following manner: take a strip of carbon tissue measuring four inches by one inch, and place it behind a piece of cardboard or thin metal having an opening measuring three inches by a quarter of an inch. The duration of the successive exposures will necessarily depend upon the strength of the light and the character of the gradation required, and may vary from a few seconds to several minutes.

Let us suppose that thirty seconds is the difference that is to be between each succeeding pair of exposures; the tissue with its cardboard shield is covered up with the exception of a quarter of an inch of the central aperture, which is then exposed to light for the requisite thirty seconds. The covering is then withdrawn for another quarter of an inch, and a second exposure made, and so on until the whole three inches have been exposed, forming a succession of twelve different depths of tint. The tissue is then developed upon collodionised glass in the ordinary manner, the portion covered by the cardboard shield forming a perfect "safe-edge," and the result, if properly executed, will form one of the neatest scales possible.

In using the commercial tissues, select one of a neutral black colour, if possible, in order to conform to the rule we have laid down with regard to absence of colour. But the most satisfactory scale of any for use with most negatives of modern type is one in which the pigment or colouring matter consists of reduced silver of precisely the same character as that forming the negative image. For this reason, many persons prefer to make their graduated scales by development upon the same kind of plate and with the same developer as those employed in making their negatives; but, before we pass on to that method, we may describe a modification of the so-called carbon process, by which a similar and, in some respects, better result may be obtained. This consists in colouring the gelatine with reduced silver, instead of with Indian ink and suchlike pigments. In our earliest attempts in this direction, made upwards of twenty years ago, pyrogallic acid and other reducing agents were added directly to solutions of gelatine containing various silver salts, either in solution or suspension. The results, however, were anything but satisfactory, as, besides the horrible colour of the mixture, the chemical action of the various ingredients was found to partially insolubilise the gelatine. The following method will, however, prove perfect in every respect.

Select a sample of soluble gelatine such as Nelson's "No. 1 Photographic" or their "Flake," and dissolve it to the strength

of about sixty grains to the ounce, and to each ounce add twenty grains of nitrate of silver, fourteen grains of bromide of potassium, and twenty grains of bichromate of potassium in the order named. The result will be a reddish-brown mixture or emulsion, which forms the sensitive medium. It may be prepared in ordinary gaslight, but both the emulsion and the tissue must be carefully protected from daylight. To prepare the tissue a sheet of paper is damped until perfectly limp, and squeegeed on to a levelled slab of glass, and a moderately thick layer of the emulsion poured on, allowed to set, and then hung up to dry with four strips of wood pinned to the edges. When quite dry it will probably be rather brittle, for which reason great care must be taken in handling it, though, if properly dried on strips of wood, there will not be sufficient "curl" in the tissue to cause much trouble. A little glycerine may be added to the emulsion to counteract the brittleness if it be troublesome.

This tissue is exposed in precisely the same way as the ordinary, only it will probably prove much more rapid. Before development, however, it is well to soak it in a solution of salt instead of plain water, which will discharge the red colour by converting the chromate of silver into chloride, the remainder of the process being the same as with the commercial tissue; but the result will be a scale composed of different thicknesses of bromide of silver. To bring this into condition for use it only now remains to reduce the silver bromide by means of development, using preferably the same developer that is commonly employed in the production of the negatives. In this manner a colourless or rather a neutral-tinted scale is obtained for use with negatives produced by the newer developers, or, in the case of pyro, the slightly yellow or brown tone that generally distinguishes such negatives.

Another very efficient plan when a definite gradation is required, if such be necessary for this purpose, is to employ a modification of the Woodbury process, which, however, does not necessitate any elaborate machinery. Build up the scale by pasting successive layers of paper or tinfoil upon a sheet of plate glass, and when this is dry press it in contact with a sheet of thin gutta percha softened by heat and backed up with another sheet of plate glass. A screw copying-press may be used, or, if not available, sufficient force is obtained by allowing the weight of the body to rest on the two plates placed on a firm table. When cold, the gutta percha will be found to bear a reverse impression of the scale which is used as the printing matrix.

The printing is performed by means of a gelatinous ink, consisting of a strong solution of gelatine—eighty grains to the ounce, suitably coloured, the adjustment of the proportion of colour being the important element in its preparation. The gutta-percha matrix is laid upon a sheet of plate glass, a pool of the ink is poured into the centre, a sheet of transparent celluloid, or thin, even glass, quickly placed upon it, and, over the whole, a second piece of plate glass. Even pressure is then applied by means of the hands until it is seen that the excess of ink has been evenly squeezed away. Keep the pressure on for a minute or two, until the gelatine has set, and in five or ten minutes the celluloid or glass may be separated from the gutta-percha matrix, bearing with it a beautifully graduated scale. The same matrix may be employed with ink of different strength to produce scales of greatly varying printing value. We omitted to state that the gutta-percha matrix should be slightly greased before each printing in order to ensure the gelatine parting from it.

The last method we shall describe is that in which the scale is made directly upon a collodion or gelatine plate; but, as the working of these is sufficiently well known to those who use them, we need not go further than to describe the method of securing the gradation. For this purpose nothing better can be found than the revolving disc, carrying apertures of various sizes, as this enables us to obtain any sort of gradation, either abrupt or gradual. A disc of light wood or stout cardboard is first inscribed with a series of concentric circles, and from each of the zones or bands so formed a varying portion is cut away, each successive aperture bearing a definite relation to the rest. This is caused to revolve in front of a well-illuminated surface, and is then photographed down to the size the scale is required, the result being a series of concentric graduated tints, from which a strip may be cut if desired.

We have spoken of the scales being formed in the shape of narrow strips, but obviously, where a number are required, as will often be the case, it is just as easy to prepare them in a larger size, to be afterwards cut down. Uniformity will be thus secured.

Patent Infringements.—A case of some little interest, now that so many patents are taken out in connexion with photography and other things, was decided last week. An action was brought by the Edison Bell Phonograph Corporation to restrain the Edison Phonograph Company from infringing two patents. "The infringement was the sale and use in England of a phonograph imported from America, which was made in accordance with Mr. Edison's patents." The injunction was granted (in fact the defendants did not defend the case) restraining the infringement with costs. The Judge also directed an inquiry as to the damages sustained by the plaintiffs. Clearly, as the Judge remarked, this is a valid patent; but this, we know, would not prove to be the case with a very large proportion of the patents granted in connexion with photography, if they were similarly contested.

The Chicago Awards.—The balance of the awards at the late World's Fair, about which so much dissatisfaction as to the system proposed to be adopted was expressed by other nations, has been struck. It appears that sixty-three per cent. of them go to other countries, and thirty-seven per cent. only to America. Mr. Thacher, the President of the Awards Bureau, accounts for this seeming reflection on home work by saying that the Special Commissioners selected the exhibits of foreign countries, while Americans exhibited their usual average commodities. (Humph!) It is more than probable that, if the foreign Commissioners had not made the firm stand they did with regard to the system of awarding first proposed, the balance might have been different. Be that as it may, we should have liked to have seen more of the awards for photo-mechanical work come to this country, instead of going to the Continent.

Amateur Photographers on the Frontier.—It is now proved that the two Frenchmen, whose case we have before alluded to, who were arrested some time ago at Kiel with photographic apparatus, negatives, drawings, &c., were not the innocent individuals they represented themselves as being, namely, tourists on a yachting trip, making photographs and drawings for amusement. At their recent trial at Leipsic, where they received severe sentences, they confessed that they intended to hand over to the French Government the results of their work, and that they employed an English yacht to ensure greater protection against molestation. This case of *bonâ fide* "spies" will only tend to make the German officials more vigilant, and particularly after this event with regard to those assuming English

nationality. By the tone of some of the French journals on the sentences passed, one may expect retaliatory vigilance on their side. Anyhow, English amateurs who may be wintering abroad must now be extra-cautious as to where they erect their cameras on the borders of either German or French territory. To be arrested, by either side, as a suspected spy, entails very unpleasant consequences, as some amateurs know to their cost.

Lantern Slides and Colouring.—At two Societies, within the last week or two, the subject of colouring lantern slides has formed a topic for consideration. At the Richmond Camera Club some were shown, the work of Japanese artists, which were considered by those who saw them superior to those produced here; and at the Photographic Society of Ireland Professor Scott gave a lecture on *Colouring Lantern Slides*. In former times they were painted by artists, and not on a photographic basis. When the photograph has to show through the colour, or the colour through the photograph, it is quite a different thing from the artists' working on bare glass, When this was the case the painter had to be an artist, and could command his price. As much was then paid for a single slide as would now purchase a dozen or two. Professor Scott in his lecture advocated the use of aniline colours for the work—by which we presume he meant colours of the coal-tar series generally. These are certainly well suited to the purpose, on account of their extreme brilliancy and transparency—the two most essential qualities for the work. It may be urged that these colours are fugitive; but this may be disregarded, except, perhaps, with two or three of them, when it is considered the short time they are subjected to the light. However perfect a series of photographic slides may be, the introduction of one or two really well-coloured ones always meets with a round of applause at any public exhibition. This is conclusive that good coloured slides are appreciated.

Oxygen in Illuminating Gas.—Referring to our previous paragraph on this subject, there are now more data available with regard to this singular apparent inversion of old ideas. The plan is now in actual operation in Huddersfield, and, at the last meeting of the Southern District Association of Gas Engineers and Managers, Dr. J. T. Thorne gave full particulars of the method—enriching ordinary coal gas by means of oxy-oil gas. His conclusions, in brief, are: First, The addition of oxygen to oil gas, preferably while the latter is still hot, not only increases the illuminating value of the oil gas when employed directly as an illuminant, but also when it is used to enrich other gas. Second, oxy-oil gas is a highly permanent gas, and, when used as an enricher of coal gas, actually increases the stability of that gas. Third, enrichment of coal gas by oxy-oil gas would cost about one-third of a penny per candle per thousand cubic feet. Dr. Thorne's further conclusion is, that this new gas, "oxy-oil," is superior to any process for enriching coal gas. As to what experience tells, that may be seen in *London*, the organ of the London County Council, for November 30. The Huddersfield Corporation have utilised the plan for over two months, with the result of obtaining a steady white flame, affording a better light, with a saving at the rate of 10,700*l.* per annum. Part of this is owing to the increased commercial value and superior readiness of sale of the coke produced under the new conditions. We have not hesitated to refer at length to this matter, and, indeed, any question connected with the utilisation of coal gas for photographic purposes. Our readers may be assured that the last word is by no means yet said in connexion with the use of gas as a photographic illuminant. Some experiments we have on hand in this connexion shall be described when the series are completed.

BRISTOL INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

II.

We resume our notice of the Bristol Photographic Exhibition.

Placed out of their class are a few landscapes which may possibly be overlooked by visitors, as they are in a kind of alcove separating two of the galleries. Of these, *In a Fog—Winter*, by Mr. S. G. Payne, is a really good attempt to obtain fog—we mean in a landscape, not in a plate. Rev. H. B. Hare shows a capital bit, *Landing the Trout*, and Mr. C. Moss is not unsuccessful with *Lowlands*, a view of a sombre heath. The Class (VI.) for Large Instantaneous was only patronised by seven frames of views, of no particularly high order of merit. Mr. A. W. Gottlieb shows an animated scene, *Life on the Sands*; Mr. E. Hawkins a study of two dogs, *Toby and Jack*, good in its way. The same gentleman's *Evening on the Thames* struck us as being faulty in the management of the reflections, a bright light in the sky not showing in the water. The Small Instantaneous (VII.) has twenty-three exhibits. Mr. J. M. C. Grove is represented by twelve studies of *Father Thames*, marked by "breadth of treatment;" Mr. Percy Lewis by some hand-camera studies of farm scenes. Mr. Charles Knight's series of circus studies are excellent examples of quick work, and Mr. J. Kidson Taylor's hand-camera landscape studies are bright, crisp productions, a remark that applies to some charming little cattle pictures which he also shows. Mr. Charles Job, in a series of ploughing, haymaking, &c., studies, is extremely successful, and, though Mr. Gerald Grey's shots at *Goodwood Races* are mostly uninteresting, one, showing a race in progress, the horses standing out against the horizon, is a good example of quick work.

In the Botanical Class (XVIII.) there are some lovely photographs of flowers and fruit, notably by Mr. Robert Frost. The award, however, goes to Mr. J. T. Hopwood for three representations of cherries and strawberries. Here, perhaps, it would be convenient if we refer to the Micrographical and Zoological Classes. In the first-named there are only four exhibits, but they are of great merit, Messrs. R. Kidston, Stanley Kent, and W. I. Chadwick sending splendid examples of popular subjects. We should have liked to have seen this class better patronised, as the field it covers is practically unlimited, while there is no end to objects of purely popular interest, which are suitable for treatment by photo-microscopic means. The medal goes to that enthusiastic photo-micrographer, Mr. W. I. Chadwick, for a series of thirty-five bromide enlargements of micrographic negatives, all excellent in execution, and, moreover, comprehending subjects of a popular kind. The Class for Zoological Subjects (XIX.) is good, but not satisfactory. The domain of animal portraiture offers unlimited opportunities for successful work, which, to be properly accomplished, requires a great deal of study, care, and patience. Nevertheless, the pleasurable charm of good animal photography so well repays the trouble and application it involves, that we should like to add every emphasis to our recommendation to amateurs to cultivate it. The silver medal is secured by Mr. Sandland for some humorous Zoo studies. Cats and dogs form the leading themes handled by the other exhibitors. Mr. L. B. Beard portrays the escapade of a dog who incautiously invades a table whereon sundry solid and liquid comestibles are placed, the result being that doggy's inebriety leads him into a sad state; and Mr. T. B. Sutton follows the adventures of a cat, who burglariously appropriates some fish. A little more care would have made both series intensely funny, instead of which they only convince us that photography has yet much to accomplish before it depicts animal humour as successfully as does Mr. Burton Barber, for instance. *Wild Chamois*, by Mr. Staeuble of Paris, is an interesting picture of its kind.

The Architectural Class (IX.) contains several examples of good exterior work, which, however, are not sufficiently striking to call for comment. Mr. Hemmons' medal series, *South Porch, Yatton Church: Gateway, Whitby Abbey; Porch of St. Stephen, Bristol*, are conscientious specimens of this kind of photography, in which Mr. Harold Baker also excels with with some sympathetic views of *A few Old Buildings*. Mr. Howell shows a capital view of *The Tower Bridge*, and Mr. J. T. Hopwood's large picture of *Fountains Abbey* is a creditable production. The others generally, however, are so good as to render detailed criticism unnecessary.

The Class for Interiors (VIII.) is a good and large one, something like eighty frames being sent in. Mr. H. W. Bennett's silver medal for a view of the *Choir, St. Paul's*, is well earned. Mr. S. G. Payne has a series of twenty-four interiors of country houses, in many of which he has minimised the defect of halation with great skill. He receives a bronze medal, as does Mr. Harold Baker and Mr. G. Hepworth. Excellent work in the class is shown by Messrs. Howell,

Farmer, F. W. Edwards, C. Court Cole, G. T. Harris, H. N. King, W. C. Hemmons, and others. Allied to this Class is that for the Photographic Survey of the Bristol district (Class XX.), undertaken by members of the Bristol Association. There are only four competitors in the class, which, having regard to the abounding wealth of interesting architectural and archæological subjects that Bristol and the surrounding district enjoys, strikes us as matter for surprise and regret. We hope the Bristol Association will in the near future take up this valuable branch of photographic work with greater zest. Still, the four gentlemen who are competing are represented by about thirty frames of exceedingly good and careful work. The silver medal goes to that veteran photographer, Mr. E. Brightman, for a faultless series of cathedral and church subjects taken at Gloucester and Bristol. Mr. W. C. Hemmons runs him pretty closely with a similar series, for which he obtains the bronze medal. The other competitors are Dr. Ormerod and Colonel Senior.

In the Class for Large Marine Subjects (IV.) some diversified efforts, embracing the deeply poetical and the severely practical, will be found. Among the former we noticed some large work by Mr. Worsley Benison, *The Requiem of the Sea*, the remains of a wreck washed up by the remorseless sea; and three other studies of waves, rocks and shore, of an ambitious nature, and showing much artistic feeling. Mr. W. P. Marsh shows one of his favourite subjects, *A Wild Wave*, Mr. A. Debenham and Messrs. West & Sons fine yacht studies, Mr. H. D. Arnott some good Yarmouth views. The silver medal goes to Mr. Lintott for *On the Top of the Tide*, a river scene with a barge in the foreground and the Tower Bridge breaking up the distance, the effect being capital. What a godsend that same Tower Bridge has been to photographers! Mr. F. M. Sutcliffe wins the bronze medal with his fine view of *Whitby Harbour*. Mr. T. M. Brownrigg and Rev. Precentor Main are also worthily represented in the class. Class XIII. (Enlargements) contains many technically good exhibits, but most of them are of comparatively poor account in artistic selection. We note with surprise how well some of Mr. Grove's small fuzzy Thames studies stand amplification without fatally outheroding Herod in the matter of lack of definition.

Mr. Sandland undoubtedly merits the silver medal for his enlargement of polar bears, and Mr. Cadby the bronze for the enlarged figure study, *Reflections*, a graceful child well posed, with the drapery well managed. Prints from the original negatives are shown side by side with the enlarged results. Colonel Senior has some interesting Indian views. We pass from the competitive photographs to notice the Judges' (non-competitive) exhibits, Mr. Payne Jennings being represented by half a dozen Devonshire views, one of them, *Fishing Boats off Brixham*, being as good a thing of its kind as is to be found in the Exhibition, the President of the Society (Mr. Hood Daniel) by a good collection of landscape studies, and Mr. S. P. Jackson by two frames of snap-shot work.

In the Transparency Classes some charming examples of glass positive work are shown. Of the larger varieties, Mr. H. N. King's transparency views in the Royal Palaces, and Mr. Brightman's series of cathedral and other subjects are a feast to the eye. It is a pity that large transparency making is not more decidedly encouraged than it is. Thirty-two sets of lantern slides were sent in for competition, which lack of time obliged us to pass over. We were gratified, however, to notice that nine sets of stereoscopic transparencies were submitted competitively among them, we ascertained by inspection, being some very pleasing examples of this delightful branch of photography. There is also a small loan stereoscopic collection by Messrs. A. W. Westrop and T. Davey.

There is a very instructive general loan collection, among which we noticed a portrait taken by Ponton's pinhole camera, a capital piece of work of its kind, having a quite Cameronian character. Messrs. Elliott & Son, Barnet, are represented by some well-executed examples of carbon printing, and there are several frames illustrative of chromo-collotype in three-colour printing, the negatives for which we were informed were made by the Bristol Hon. Sec., Mr. Bligh Bond, who is devoting much attention to this branch of work. Other contributors to the loan collections are Messrs. Beck (Frena enlargements), F. Hollyer, with some always-welcome and refined platino copies of well-known pictures; R. W. Thomas & Co. (Prints from negatives on Sandell plates); Henry Park (apparatus); Taylor, Taylor & Hobson (standard lens adapters); T. H. Powell, National Camera Co.; W. P. Marsh, and many others. Some special examples of early photographic work are also lent.

There are only two exhibits in the Apparatus Section, but they contain interesting collections of useful and timely apparatus, and, besides, emanate from local sources.

Messrs. Husbands & Sons of St. Augustine's-parade, Bristol, show some well-made landscape cameras (the "Exhibition"); an improved portable stereoscope, having vertical and horizontal adjustment to the eye lenses, constructed for large stereoscopic views made from $7\frac{1}{2} \times 5$ and $8\frac{1}{2} \times 6\frac{1}{2}$ negatives; lenses; dark-room lamps; instantaneous shutters; biunial lantern; mahogany body lantern; &c., &c.

Mr. M. W. Dunscombe shows the Dunscombe camera, stand and lenses; Ross's lenses; Beck's "Frena" cameras; Watson's cameras; "Shuttle" hand camera; "Lysaght" hand camera; "Nalda" hand camera; Blair hand camera and roll films; tele-photo lenses; photo-micro objectives; "Allendale" optical lantern; and other novelties.

ON A SYSTEM OF MEASURING AND NUMBERING THE STOPS OF PHOTOGRAPHIC LENSES.

[Photographic Congress.]

The brightness of the image of an object of given brightness placed at a given distance formed by a lens of a given focal length may be determined by the angular aperture of the pencil of rays diverging from a point of the object and entering the objective. When the object is situated at infinite distance, the intensity of the illumination cannot be determined by the *angular* aperture of a *cone* of rays, but may be found from the *diameter*, D, of the *parallel pencil of rays* proceeding from the object and forming the image, *i.e.*, from the diameter of the *effective pencil* of rays proceeding from the object. The latter case enters chiefly into consideration in photography, and in the following discussion it will be assumed that parallel light enters the objective. We shall also suppose that the effective pencil of rays is concentric with the axis of the objective.

The quantity of light entering the objective has been found to be directly proportional to the square of the diameter of the effective pencil of rays. The diameter of the effective pencil of rays, and therefore also the quantity of light admitted by the objective and forming the image, depends upon the effective diameter of the lenses or the diameter of the central diaphragm.

Every lens forms in itself a stop, and where no special stop is interposed between it and the object, the edge of the lens determines the diameter of the effective pencil of rays. In objectives having no stops, the diameter of the effective pencil of rays would always be the same. In order to obtain certain pictorial effects, it is necessary to provide means for modifying the diameter of the pencil of rays. With this object photographic lenses are fitted with interchangeable or variable stops (Waterhouse, rotating or iris diaphragms), by means of which the aperture may be varied. The position of the stop is governed by the type of the lens; it is not a matter of choice, if the capabilities of the lens are to remain unimpaired.

If we compare objectives of *different focal lengths*, admitting pencils of rays of the same effective diameter, D, we find that the brightness of the image varies in conformity with the following law: The brightness of the image is inversely proportional to the square of the focal lengths of the objectives.

Thus, if the diameter of the effective pencil of rays is denoted by D, and the focal length of the objective by f, then the brightness of the image is proportional to $\frac{D^2}{f^2}$. The ratio $\frac{D}{f}$ is termed the relative rapidity of the objective or of a certain stop belonging to it. The largest stop which yields a well-defined image represents the *maximum relative effective aperture*. With respect to the capacity and quality of the objective, it is *quite immaterial* whether the maximum aperture is determined by the diameter of the lens itself or by the stops appended to the objective. In order that the illumination may be uniform throughout the image from centre to margin, even with the maximum relative aperture, it is desirable to make the diameter of the lenses larger than is actually necessitated by the largest required aperture.

Various objectives, when stopped down in such a manner as to make the relative apertures the same in every case, produce the same illumination in the image and the same depth of definition, the ratio of reduction or magnification being the same. Objectives stopped down to the same degree of relative aperture, and used under precisely similar conditions as to illumination, require therefore the same exposure.

From this the fundamental importance of the relative aperture becomes at once apparent, and hence it may be inferred that it is a more correct plan to graduate the stops in terms of this relative value, *i.e.*, in terms of the relative aperture, than according to any absolute standard.

The question as to whether in the ratio $\frac{D}{f}$ the diameter of the stop may be substituted for that of the efficient pencil has repeatedly been discussed. In many countries this question has been answered in the negative, and correctly so; in England, however, the diameter of the stop still forms the basis of measurement. If there were but one type of photographic objective, more particularly only single lenses whose stops are situated on the side facing the object, there would exist no ambiguity. But, as there is a great variety of different types in use, the desirability of the uniform measurement of the stops compels us to adopt the *diameter* of the *efficient incident pencil* admitted by a given stop as the unit in determining the value of the relative aperture.

With all the doublets and triplets which are known to me, the diameter of the effective pencil is always greater than the diameter of the corresponding stop. The amount of the difference does not depend only upon the type of the objective, but also upon the maximum relative aperture in respect of which the objective is corrected spherically. I have examined a series of the most popular types and found the following data. If the value of the relative apertures $\frac{D}{f}$ is equal to $\frac{1}{20}$, then the ratios between the diameter, d, of the stop and the focal length of the objective in each case are as follows :—

	$\frac{d}{f}$
Aplanat, 1-4·5	1-24·5
Aplanat, 1-8	1-22·6
Antiplanat, 1-4·5	1-25·4
Antiplanat, 1-6	1-21·4
Anastigmat, 1-4·5	1-24
Anastigmat, 1-6·3	1-23·4
Anastigmat, 1-7·2	1-23
Anastigmat, 1-9	1-22·6
Anastigmat, 1-12·5	1-22

English opticians generally ascribe, therefore, too small a relative rapidity to their objectives. In the case of the portrait antiplanat, *e.g.*, the stop of 1-20 relative aperture would be described as 1-25·4; the erroneously ascribed relative rapidity $(\frac{1}{25}:\frac{1}{4})^2$ is, therefore, to the actual rapidity $(\frac{1}{20})^2$ in the ratio of 2 : 3. With other objectives this error is greater or less, and it is only in the case of single lenses with stops placed in front of them that the English system of measuring rapidities is correct.

The inconsistency of this system is obvious, and it can only be avoided by consistently taking the *effective relative aperture* as a measure of the stop with all types, in the manner recommended above.

In certain cases it becomes, however, a practical necessity to indicate the apertures of the stops in terms of some absolute unit, *i.e.*, in parts of the inch, millimetres, &c. This case may arise when one and the same arrangement of stops is intended for use with objectives of different types and various focal lengths, *e.g.*, with central iris shutters, stops for sets of lenses, &c. In such cases it is necessary to calculate for each lens the relative aperture or the number of the stop, or to find these values from tables supplied by the makers.

Now, instead of retaining the actual numerical values of the ratio $\frac{D}{f}$ in expressing the value of the relative aperture, it is more convenient to express D in terms of fractions of the focal length, f, taken as unity. Accordingly, in the ratio $\frac{f}{x}$, x would be the number which indicates how many times the diameter of the effective pencil is contained in the focal length of the objective. This value of $\frac{f}{x}$ is, by the majority of makers, stated on their lenses; unfortunately, there is a great diversity in the gradation of these values, and in the initial value taken as the basis. Generally, the f gradation is such as to make each stop correspond to half the relative rapidity of that represented by the preceding larger, and this manner of disposing the stops appears to be the only plan possessing points of practical utility.

Great difference of opinion prevails, however, in the matter of choosing the initial value. Dr. Stolze and Mr. Dallmeyer proposed $f\text{-}\sqrt{10}$, the Congrès International de Photographie of 1890, proposed f-10, and the majority of English makers have adopted f-4, the value proposed by the Photographic Society of Great Britain (U.S. No), as their basis for the graduation of stops.

These various propositions lead to the following scales of values:

1. Initial value: $f\sqrt{10} = f$-3·16.

f-3·16, f-4·5, f-6·3, f-9, f-12·5, f-18, f-25, f-36, f-50, f-71, f-100.

2. Initial value: f-4 (U.S. No).

f-2·9, f-4, f-5·7, f-8, f-11·3, f-16, f-22·6, f-32, f-45·3, f-64, f-90·5.

3. Initial value: f-10.

f-3·5 f-5, f-7·1, f-10, f-14·1, f-20, f-28·3, f-40, f-56·5, f-80, f-113·1.

None of these scales rest upon a theoretical basis; it is only a question of convenience and utility. The value $f\text{-}\sqrt{10}$ involves a few points of practical significance. Thus f-3·2 may be considered to be the greatest desirable effective aperture for *extra-rapid* portrait lenses; f-6·3 is the limit of extra-rapid instantaneous lenses; f-18 may be taken to represent the minimum aperture for short exposures, and f-100 is generally assumed to be the limit of the possibility of stopping down a lens without impairing definition by the appearance of diffraction phenomena. In fine, the numbers are comparatively convenient, and mostly integers and multiples of 2. The other two series do not possess these advantages, and I am therefore inclined to give preference to the first series.

The indication of the relative aperture of the stop is, however, not sufficient to ensure convenient use of the system of stops; it is, on the contrary, advisable to attach numbers to the stops, indicating in a direct manner the rapidity corresponding to the various stops. In this respect we have two conflicting opinions. Some maintain that the numbers should advance in the ratio of the times of exposure; others prefer numbers which vary directly as the *relative luminosities*. *Per se*, one view has as much claim to acceptance as the other. If, however, we consider general practical wishes, there can be little doubt as to which is the better plan. In the first place, it must be admitted that, in a numerical series, large numbers should be avoided, and, therefore, that those stops which are most generally used, and whose corresponding exposures are suitably indicated by such numbers, should be distinguished by the *smaller numbers*. Finally, it is desirable that these numbers should consist of whole numbers only.

Portrait photographers work chiefly with stops f-6 to f-9, landscape photographers and copyists at f-25 to f-50, and amateurs at f-9 to f-18, and, if we remember that the stops generally used are within the limits f-4·5 and f-71, all requirements would be uniformly considered if we were to take f-18 as our unit. Practically it would be immaterial whether the number varies as the exposures or the luminosities, and we should have the following series :—

1. Numbers varying as the relative luminosities—

Relative aperture	f-4·5	f-6·3	f-9	f-12·5	f-18	f-25	f-36	f-50	f-71
Number of stops	16	8	4	2	1	$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{1}{16}$

2. Numbers varying as the exposures—

Number of stops	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$	1	2	4	8	16

Irrespective of the ambiguity of the fractions, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, which might, in error, easily be mistaken to refer to the relative aperture, a system of numbering in which integers and fractions are made to enter into comparison is hardly calculated to meet with the approbation of photographers. Fractions should, as far as possible, be entirely avoided. Now the question is: Shall we take a greater or less aperture than f-18 as our unit? In my opinion, there is no difficulty in answering this question. The small stops are those mostly used (landscape, architecture, copies, &c.), and it is particular in the case of the SMALL *stops that it becomes important to have a convenient means of measuring the relative apertures*. With the larger apertures this exigency does not exist in the same degree, inasmuch as these are generally resorted to in instantaneous work, where it is impossible to regulate the exposures within exact limits. In these latter cases it is a simpler plan to compensate errors in over or under exposures by suitably modifying the developer.

From these remarks we conclude that it would be rational to take f-36 or f-50 as our unit, and, in order to minimise the occurrence of fractions, to let the number vary as the relative rapidities, *i.e., inversely as the corresponding exposures*. The remaining two or three fractions may, to avoid ambiguity, be expressed in decimals. Taking f-36 = 1, we obtain the following convenient system :—

Relative aperture	f-4·5	f-6·3	f-9	f-12·5	f-18	f-25	f-36	f-50	f-71
Number of stops (Relative rapidity)	64	32	16	8	4	2	1	0·5	0·25

In primarily considering the wishes of portrait photographers, *f*-9 would have to be taken as the unit, and the numbers would have to advance in the same ratio as the exposures.

The existing systems of numeration are all open to the objection that they involve high numbers, which, moreover, are allotted to the smaller stops mostly used. The system proposed by the Congrès International de Photographie of 1890, according to which *f*-10 is the unit, forms the nearest approach to the system which would realise the wishes which I have expressed. I should be glad to find my remarks act as a further incentive, in the interest of makers and users of photographic lenses, towards the establishment of a universal system of the designation and numeration of stops.

DR. PAUL RUDOLPH.

A PROFESSIONAL TO PROFESSIONALS.

[Abstract of President's Address to Glasgow and West of Scotland Photographic Association.]

I SHOULD like to say a few words to my professional brethren.

We are all feeling the hard times, and one often hears that photography is done. That I do not believe; but it will be done if you think nothing better can be done than fold your hands and call out, "Hard times." No; you must stand to work, see where you are behind, if there are others taking the butter from your bread. If you cannot lead, you surely can, at least, follow. There is never a photograph comes into our hands that something cannot be learned from it, if it should only be what to avoid. When looking round the show-cases of Glasgow, I often feel proud that I belong to such a city, and one of the members of the black art; for in no town do we see a higher standard of good photographic work. Still, there is much to deplore. Photographs in soot and whitewash, with many good characteristics of art feeling; others of the Henry Irving type, without the Henry Irving; others with faces such as one sees in barbers' blocks in their windows.

I remember once a famous photographer showing me the photograph of a lady, and asking me to guess her age. In my innocence I replied, About forty. "Ah, well, you are wrong, Stuart, my boy, that lady is close on seventy!" "Well, the more shame to you," was all I could say I do trust that the time will soon come when the man at the camera will be the photographer and not the retoucher. Many now express themselves as dissatisfied that all the beautiful natural and characteristic markings of the face should be obliterated. Gentlemen, let us have the truth, not the vulgar truth, but some semblance of it. The retoucher's work should never go farther than the toning down of the hardest lines, but not the entire obliteration of them.

There is just one other matter I should like to draw attention to, and I am done. It is that of the young men now starting to learn our art. If you think you will ever be an artist in the best sense of the word, it is not to be brought about without much labour and training. There are so many departments that there is considerable difficulty in advising the exact line to follow. Go to the School of Art at least two nights every week, attend the lectures of, say, Professor Mills, who will give you an insight into the various processes from a chemical and scientific point of view, as also some of the processes of mechanical photography. I hope the time is not far distant when every boy leaving school will have learned chemistry, how to handle tools, as also freehand drawing. The following illustration may serve to emphasise my remarks, and to show you how far back some of the lads of to-day are who make up their minds to study photography as a means of livelihood.

Some time ago a young lad applied to me for a situation as under-assistant. He had been about two years in a photographic studio, and, will you believe it? he had never developed a plate, neither had he toned or fixed a print, nor had he ever made up a developer or toning bath. He could put a piece of paper into a printing frame, watch it and take it out when ready, but beyond this his knowledge of photography was a blank obscurity; and as to scruples and grains they were out of his knowledge, and yet this lad had passed the Sixth Standard. If our future photographers are made of this stuff, what can we expect? I say, young men, you have hard work before you, and it will only be by diligent attention to all that is passing that you will ever come to anything. Study the JOURNAL, and never be without one at least of the many annuals and year-books. It is the custom to hang up Scripture texts in bedrooms. I think it would not be inappropriate for young men in any branch of business, but in photography especially, to write in large letters and hang up in their rooms the motto, "The cream always comes to the top."

JOHN STUART.

ANOTHER PHOTOGRAPHIC PLAYGROUND: THE TRANSYLVANIAN ALPS.*

THERE is no better companion for a traveller than a photographic camera; there are no finer recollections of an accomplished journey, than pictures taken by the traveller himself. They may be styled—as it is the fashion nowadays—topographic records, still they may be beautiful, and, after all, may give more artistic impressions than those more ambitious productions which are handicapped by the shortcomings of our art-science. But I am in danger to fall also, in the craze of the last fashion, into art definition, and I intended to send you, Mr. Editor, a few much more practical lines. Now, take a traveller with his camera; it is the question for him, where to go—Switzerland and Tyrol, the Rhine and Scotland, the seaside and Italy—for the long vacations, tours in Spain, Algiers, Egypt, and so on, offer, no doubt, fine travelling programmes, but they pass over much trodden ground. There are always men in search of novelty, and the latter is more valuable for the traveller who goes with his camera, as the pictures he brings home, will certainly gain through novelty, and may, in many instances, help science and be geographically interesting. To such photographic travellers or travelling photographers I last year pointed out in the ALMANAC Bosnia and Herzegovina as a splendid tour, and this year I wish to direct them again to a mountain chain already a little to the east of Europa, but as easily reached as either the Alpa of Tyrol or Italy, I mean the Carpathian Mountains in the Transylvanian part of Hungary. When once Vienna, this fine capital, is reached, you have a few hours' rail down to Budapest, or by Danube steamer, which is a very fine river journey. Budapest, the beautiful Hungarian capital, with over 500,000 inhabitants, is picturesquely situated on the Danube, and gives, seen from the neighbouring hills, pretty panoramic views. You will find there English photographic goods at Calderoni & Co.'s, opticians, where English is spoken. From Budapest you have express trains to Transylania, with sleeping cars, wagons, restaurants and all, from Vienna, for the cheap rates of the "Zonentarif" at the Hungarian State Railways. It is about 10 florins (18*s.*) first-class fare for the longest distance from Budapest to every direction, therefore the same for Nagy Szeben (in German, Hermanstadt) and Brassó (in German, Kronstadt), both pretty towns at the foot of the mountains.

At Brassó is Mr. Adler, a professional photographer, very kind to amateurs, and you can develop a plate or two to compare your exposures in this country. No doubt, gentlemen amateurs will not abuse his kindness.

The finest excursions from Brassó are those to the Buchech, and to the Königstein. If you are a little—a very little—of a mountaineer, you will go up the summits of both of these mountains, and will enjoy yourself in the finest mountain scenery, in the wildernesses of superb woods, fine rock crags, and the most beautiful panoramic views. There is no difficulty at all, you will only be able to walk on mountains without path for a few hours. Coming from Brassó, you will spend the night on both mountains in club huts built by the Transylvanian Carpathian Club.

From Nagy Szeben, the finest excursion is into the Negoi group, the summit of the Negoi being 8300 feet—the highest peak of the Transylvanian mountains. This part of the chain is of a different geological structure, and therefore the mountains look quite different from those at Brassó. On the Negoi you will find also a well-provided club-hut, wherein to pass the night before the ascent. A series of small mountain lakes and tarns reflect in this group the rocks, the snow fields, or the trees of the splendid forests.

A good guide-book, in German, for these mountains is, *Bielz, Siebenbürgen* (Vienna: Graeser). As mentioned, there is a club like the alpine clubs in the Alps, who built huts for the mountaineer, selected guides with fixed tariffs, publishing his year-books, and always ready to assist travellers. There are sections of the club in nearly all the towns, the direction is at Nagy Szeben, and in E. Sigerus, Esq., the Secretary of the Club, you will find a gentleman always ready to assist you.

Only one thing you will not find, no English travellers. There were a few in former years, Mr. Boner having even written his charming book, *Transylvania* (London: Murray), but in reality the Englishmen who in the last years come to Transylvania are mostly Nimrods, and, as I may now mention, when it happens that you are one of those who like to kill something, there is no better place for you.

But, again, I do not write for these, but for view hunters; and, as we are already in Transylvania, and going on into the mountains, I shall a few words address to the photographer. You are in the midst of mountains, whose summits gain a height of about 8000 feet from the plain, while at

* Received too late for the ALMANAC.

Bragw or Nagy Szeben have only 1500 feet. The mountains are either limestone, with the fantastic formations and the fine colours which are the property of these rocks, or granite, with his fine horns and needle summits. The greatest splendours lay in the forest of gigantic trees, unbroken and untrodden woods, extending over large tracts of the valleys and high up on the mountain sides. Even in the height of the summers, now is lying in the protected parts of the rocky faces of these mountains, and enhance their beauty. The walking days are comparatively short, and you have ample time to photograph. The picturesquely dressed people (Saxon-Germans and Wallachs) will serve you as admirable staffage. In the towns are pretty good hotels, and good shops to provide yourself for the mountains. There you find the club huts, carriages, horses, guides, and porters (the latter important for photographers who have not yet descended to the plate size $1\frac{1}{4} \times 1\frac{1}{4}$) at very cheap rates. A porter a day in the mountains costs about 150 kreuzer = three shillings; horses the same).

And, with all this, few travellers, and no English at all. So it is possible that the Secretary of the Carpathian Club, in his last year's report, still mentioned my photographs, taken twelve years ago, as still the best, and nearly the only to be had from the mountains. You will see by this that still nearly all is left for you. Go, enjoy yourself, and bring home a good number of topographical, artistic (by permission) records of the Transylvanian Alps.

MAURICE DE DÉCHY, Hon. Corr. R.G.S., Odessa.

WINTER WOES AND THEIR REMEDIES.

ONCE again the winter is fairly upon us, with its parties, balls entertainments, to say nothing of the chances of indulging in that most exhilarating of pastimes, skating; once again the festive season is here, and "still we are not happy." Photographers as a body hate the winter, to them Christmas and the New Year convey thoughts of frozen water mains, very few sitters, a bad light to take those who do come, difficulty in getting the prints off, dealers' bills coming in and very little cash to meet them with. It may be true that "all things come to those who wait;" but this adage should not be followed too closely by the photographic profession at this above all seasons. True, winter brings many troubles and trials with it, but the best way is to tackle them as they arise and turn them into money. Over and over again we hear the remark, "Oh, that's a winter negative, you know," uttered in an apologetic tone, as though a winter negative must of very necessity be a bad one; in point of fact, they mostly are poor, but it is not altogether the fault of the weather that such is the case. True, a picture taken with a dense fog between the subject and the lens cannot be expected to turn out a success, but an ordinary winter day's pictures ought, on the whole, to prove undistinguishable from an ordinary summer day's; that is, if the necessary care and precautions are taken. If the studio be left unheated and the sitter be compelled to pose before the lens while half frozen, no satisfactory results will be obtained. If the studio be thoroughly warmed, and the dark room otherwise, failure will still be the result, as the developer will act neither so quickly, nor so vigorously when icy cold. A cold developer means a slow developer and at the same time a thin misty image. To expedite the development most operators are inclined to increase the proportion of ammonia; this certainly quickens the process, but does not add any other good effect. Let those who doubt it try an experiment by taking two negatives under precisely the same conditions, then develop one with the cold developer, with or without additional ammonia, and use for the second a developer which has been kept for some hours in a room where there has been a fire. The difference will be very marked; one will be very plainly "a winter negative," the other, well, try and see for yourself.

Then, again, why will photographers insist upon using the same rapidity of plates in winter as in summer? The difference in cost between ordinary and extreme rapidity is not much, and is more than counterbalanced on a dull day by the number of failures entailed when using a slow plate. It is not in the province of this article to mention any special brand of plate (I think I hear the Editor observe, "No gratuitous advertisements!"); but I have in my mind at the present moment no less than three different makes which are especially suitable for winter work.

Frozen pipes are a nuisance to any householder, but to the photographer they are ten times worse; water for household purposes can be obtained even during the hardest frost, but for photographic purposes once "frozen out" means no development and no toning until the frost gives. Surely, then, it behoves all students of the art-science to have all the pipes in the house carefully covered with hay-bands or list, and the taps in the dark room and toning rooms always turned partially on even when there seems no chance of frost.

In winter the process of printing is necessarily slow, and home-made paper often discolours considerably in the printing frame before the picture is sufficiently dark; this may be easily remedied by putting an old spoiled (untoned) print at the back of the paper, which will then keep white for days, while one not so treated will become perfectly spoiled.

The sudden changes of temperature, which are constantly occurring, often cause breakage of negatives; and, as it is usually the most valuable that go, it is worth while to take every precaution against such accidents. A thick felt backing is by far the best to use, and the pressure on the spring of the frames should never be so strong in winter as in summer.

By far the greatest trouble is the lack of sitters. This can only be surmounted in one way; if you have five pounds to spare, spend it in advertising; if that brings in ten, spend that in the same way. Advertise in any way you like, but advertise. When you are not taking sitters, make special enlargements from the best negatives taken during the last summer. Get a dozen suitable frames and send the completed enlargements home on approval, fix your price moderate and you will find a ready sale; if one or two come back, you need only take out the picture, put another in the same frame and mount, and send that in the same way. Suppose you make fifty enlargements and sell thirty framed complete, the spec would be a good one; as a matter of fact, the proportion unsold will never nearly approach this if care is exercised in selecting the negatives to enlarge. Children and old people sell the best, and I have known cases in which one enlargement made and sent home on spec has led to an order for match pictures of the whole family. Of course, all your enlargements need not be made in the same size or style; due regard must be had to the means and status of the sitter; some would probably take a 12×10 bromide in black and white, while others would be more likely to be pleased with an opal in water colours or a 24×18 bromide or carbon.

Any enlargements you don't sell at once will make good specimens for next season, and will probably be purchased before that season is over.

Introduce and exhibit all the novelties you possibly can during the winter months; next to advertising, novelty is the soul of business, in fact it is a form of advertising.

Finally, however severe the winter, don't be cast down, keep on working all the time and don't talk about "winter pictures."

C. BRANGWIN BARNES.

ON THE PHOTOGRAPHY OF THE LUMINOUS RAYS OF THE SHORTEST WAVE-LENGTHS.*

MY endeavours were henceforth directed to bring into photographic activity the region between the lines Nos. 30 and 32, which hitherto, with the exception of line No. 31, had evinced no reaction to light, whether in my hands or in those of other experimenters. I sought to effect this, in the first place, without reference to graphic completeness, proceeding on the assumption that the previous want of success was due, not to the absence of all radiation, but to the imperfection of the method of observation.

I first strengthened the illumination with energetic short sparks, springing over close in front of the widely open slit, and, with the lenses fully open, I obtained on a Zettnow plate, after exposure for half an hour between the components of the line No. 32, first two marked lines, then —on prolonged exposure on both sides of the same line—a band of action composed of dense groups, which continually extended further with the increase of the illumination.

On an exposure of an hour and a half, the entire aluminium spectrum consisted of an almost continuous band, which ended only beyond the previous boundary of the ultra-violet, about at the wave-length 183 $\mu\mu$. That we have here to do with the spectrum itself, and not with an action of diffused light, was shown by the fluctuating intensities and the marked lines by which the newly acquired region is distinguished. In how far this is to be ascribed to the aluminium or to its impurities, or to the atmosphere, I must leave an open question. But for me, a more important consideration was the fact now ascertained, that the region between the main lines of aluminium, and a slight distance beyond, though hitherto regarded as void of light, displayed a quite unexpected wealth of rays.

Such being the case, it was to be expected that not aluminium alone, but other substances, would admit rays of such strong refrangibility

* Continued from page 770.

This conjecture was actually confirmed when I submitted a series of elements to examination.

I adduce below these spectra in chronological order. In place of a photographic reproduction, which I reserve for a future occasion, I give the main data of the experimental arrangement and the photographic result, in order to furnish some basis as to the energy and the number of the new lines, in as far as they lie beyond the wave-length 188·8 $\mu\mu$.

Among the lines enumerated various impurities may be represented, as I have indicated, at the passages in question. But this affects the here exclusively interesting fact relative to the profusion of rays in the region concerned in a vanishing degree only.

The appended numbers refer to the labels of the plates.

All the proofs were executed without a condenser, with a slit width of 0·040 mm. and of very sensitive plates (Zettnow's). The time of expoenre varied, and is given specially for each spectrum.

Cadmium, No. 2039.—Exposure, six minutes. Twenty-two new lines, two of them beyond 185·2; the most effective (4) in the immediate neighbourhood of the same length, mostly pale and moderately sharp.

Antimony, No. 2040.—Exposure, five minutes. Twenty-eight new lines, three of them beyond 185·2; the most effective (3) near wave-length 182·9. Except the three most refrangible all are distinctly shown, several very intense.

Bismuth, No. 2043.—Exposure, six minutes. Twenty new lines, three beyond 185·2; the most effective at ½ (Nos. 31 to 32). Most of them, especially the three most refrangible, pale and moderately distinct.

Cobalt, No. 2044.—Exposure, six minntes. Eighty-three new lines twelve beyond 185·2; the most effective (9) near No 31 towards No 30.' A large part of the lines intense and sharp; the remainder, including all beyond 185·2, very pale.

Platinum, No. 2045.—Exposure, six minutes. Eighty-one new lines, fourteen beyond 185·2; the most effective (15) nearly uniformly distributed over the spectrum, and surpassing in sharpness all the above-named spectra.

Copper, No. 2046.—Exposure, six minutes. Six new lines, one beyond 185·2; the most effective (2) near No. 30. All, even the palest, sharply drawn.

Lead, No. 2047.—Exposure, seven minutes. Six new lines, one beyond 185·2; the most effective close to the second component of No. 31; all the others very pale and indistinct.

Iron, No. 2048.—Exposure, ten minutes. Seventy-two new lines, four of them beyond 185·2; the most effective (4) between Nos. 31 and 32, but nearer to the former. The four most refrangible scarcely perceptible, the remainder more intense, but the less intense among them also imperfectly defined.

Calcium, No. 2049.—Exposure, seven minutes. Seven new lines, four of them beyond 185·1. Of the three most effective, one coincides with the more strongly deflected component of No. 31, whilst the two others form the extremity of the entire spectrum. The less refracted of these two exceeds in efficiency all the lines situate beyond 185·2 of all the spectra here in question.

Arsenic, No. 2065.—Arrangement of experiment as in the foregoing proofs. Exposure, probably eight minutes. Twenty new lines, six beyond 185. Except these six all strong, but not clearly defined.

Sodium, No. 2103.—Exposure, twenty minutes. A single new line, scarcely deviating perceptibly from the second component of No. 31, moderately clear but slightly intense.

Silver, No. 2107.—Exposure, three minutes. Twenty-eight new lines, six beyond 185·2. All the lines, except a single one situate near No. 31, and on its more refrangible side, very pale and chiefly indistinct.

Gold, on the same plate (No. 2107).—Exposure, seven minutes. Twelve new lines, three beyond 185·2. Of the five most efficient, three lie near No. 30, and a strong double line lies near No. 31, in both cases on the more refrangible side; all the others are very indistinct, even more so than with silver.

Nickel, No. 2108.—Exposure seven and a half minutes. Twenty-six new lines, seven beyond 185·2; of the three most efficient, two are near No. 30 and one a little less refrangible than No. 32. The entire region very pale, but well-defined.

Tin, No. 2111.—Exposure, ten minutes. Eighteen new lines, three beyond 185·2. Except a single line, which lies in the middle between Nos. 31 and 32 and develops an enormous energy, all the lines seem melting away and are pale and very indistinct.

Potassium, No. 2112.—Exposure, five minutes. A single line, of faultless design and great intensity, coinciding exactly with the more refrangible component of No. 31.

Tungsten, No. 2113.—Exposure, ten minutes. Seventy-five new lines, twenty-one beyond 185·2; all nearly uniformly distributed, but forming distinct groups with single well-marked lines. The intensity of this band, so rich in lines, decreases uniformly towards its more refrangible end. The design of the lines is uniformly clear.

Silicon, No. 2114.—Exposure, ten minutes. Eleven new lines, five beyond 185·2; one only intense and sharp, coinciding exactly with the more refrangible component of No. 31.

Chromium, No. 2132.—Exposure, seven minutes. Eleven new lines, only traces beyond 185·2; one only well-marked and coinciding with the more refrangible component of No. 31. All the rest very pale, and most of them perceptible only with difficulty.

Thallium, No. 2133.—Exposure, eight minutes. Eight new lines, three beyond 185·2; the four most efficient form a striking group between Nos. 31 and 32, the components of which decrease in intensity and mutual distance with the wave-length. Here again a line coincides with the repeatedly mentioned component of No. 31; but it is very pale, scarcely more than a trace. The design of the entire proof is very clear even in the more refrangible lines.

Molybdenum, No. 2136.—Exposure, eight minutes. Forty new lines, four beyond 185·2; the six most efficient are between Nos. 30 and 31, all very pale, the most refrangible mere traces, design of all being clear.

Mercury, No. 2139.—Exposure, seven minutes. Twenty-six new lines, nine beyond 185·2; the most efficient of all is close before No. 31; two other lines, likewise very energetic, are close to Nos. 30 and 32. The lines beyond 185·2 are associated as a group of lines, rapidly increasing in intensity, and gradually decreases with the growth of their natural distance. The sharpness of the lines is moderate.

Magnesium, No. 2143—Exposure, seven minutes (width and slit exceptionally only 0·030 m.m). Three new lines are only distinct, coinciding with the more refrangible component of No. 31. Nothing visible beyond 185·2.

Zinc, No. 2144.—Exposure, thirty-two minutes. Seventeen new lines, one beyond 185·2. One of the two most efficient lines again coincides with the more refrangible component of No. 31; the other, more strongly deflected, lies closely to the same component. The entire region appeared very pale.

Hydrocarbon, No. 2152.—Luminous in an electric discharge tube closed with quarts; pressure = a mercurial column of 3 mm. Exposure, twenty-five minutes. Ten new bands, decreasing very regularly in efficacy and intensity with its wave-lengths; the last band appears as a faint shadow between the two components of line No. 32.

Another proof with the same tube (No. 2153) gave, with a double width of slit (0·080 mm.) and two and a half hours' exposure, the entire spectrum stronger, but still very clear, and traces of two new bands beyond 185·2.

All these spectra, I must add, like the spectrum of aluminium, have acted much more feebly in their more refrangible half than in the rest of the ultra-violet. As far as the region of the most refrangible cadmium rays they consist of a deep black band, interrupted at most by single, solarised lines, which stand clear as glass. In the other part, even on the most prolonged exposure, I have never seen such a confluence of the lines, still less solarisation.

As results from the above conspectus, it is common to all the proofs that they develop a greater or less abundance of rays in the most refrangible part of the spectrum, where hitherto only the few lines of aluminium had been known; that most of them overstep the previous limit of the ultra-violet, and, further, that they finish with almost the same wave-length.

I next hoped to attain more by prolonged exposure, and by sparks of still greater energy. I increased the number of the immersed elements, as also the number of the Leyden jars; substituted for the inductorium an influence machine, which, in combination with the Riess battery, gave very energetic sparks; altered the composition of the coating of my plates, increasing the proportion of iodine, so as to heighten the sensibility; sensitised my plates by fuming with ammonia; in short, I sought, by all means, to penetrate further into the ultra-violet. But what I gained was scarcely worth mentioning. In some spectra there was a slight increase in length, but beyond the wave-length, 182 $\mu\mu$, not the trace of a line.

It is a phenomenon universally observed in spectral photography that the photography of greatly enfeebled rays involves extraordinary difficulties, and that exposure, however prolonged, does not yield clear images. I have regularly encountered this evil at the limit of the transparency of the material of the prism: in heavy flint glass at the very beginning of the ultra-violet, in light flint glass near the Frauenhofer line O, and in crown glass near R. It is the same at the limit of the trans

parency of the air, the position of which, as appears sufficiently from the foregoing, depends on the thickness of the stratum of air. That the result, at any rate to a small extent, depends also on the degree of sensitiveness of the photographic plate, is proved by the fact that I obtained the spectrum of the June sun (from my laboratory, about 120 metres above the level of the Baltic), beyond the Frauenhofer line U, upon Zettnow's plates, whilst the same line could not be obtained upon other plates at the same time. Still the photographic result in the most refrangible ultra-violet would have fallen out far better if the light which originates on the refractive phases and in the interior of the prisms and lenses had not regularly illuminated the visual field so strongly that on prolonged exposure the whole plate is coloured more strongly than the spectrum itself. We might, indeed, as I observed in 1888, with the photographic spectrum apparatus of Simony, considerably reduce the diffused light by shortening the slit length to a minimum (0·2 mm.); but even here, on proloned exposure, it overpowered the delicate impression of the most refrangible rays to total invisibility.

The contraction of the length of the slit was the last expedient which had opened up the prospect of better results as long as I was limited to the apparatus employed.

If we collate the results of the proofs obtained with a short focal distance, it follows:—

1. That, on sufficient diminution of the absorption of the rays by the air, nothing further stands in the way of the exploration of the spectral region between the wave-lengths 200 $\mu\mu$ and 185 $\mu\mu$, and that the existing means of observation are fully sufficient.

2. That nearly all the electrodes tried emit photographically effective light beyond the limit of the ultra-violet, as hitherto observed.

The appearance of rays beyond the wave-length 185·2 $\mu\mu$ gave an altered direction to my work; instead of the known spectrum, it now referred to the opening up of the unknown luminous region between the wave-lengths 185·2 $\mu\mu$ and zero.

The following portion of my report treats of the means for this purpose and the present position of the solution of this problem.

The Photograph of the Spectral Region beyond the Wave-length 185·2 $\mu\mu$.

According to the foregoing proofs, the most refrangible rays of aluminium had entirely lost their energy in a stratum of air of seventeen metres in thickness; at two metres of air they had left upon the plate an impression capable of being developed, and at a distance of the spark from the plate a good photograph. Their photographic action and its intensification were not in consequence of a heightened intensity of the spark, but of the diminished resistance which the rays encountered on their way to to the plate. The spark was quite sufficient, but the energy of the rays was defective. When they had passed through a great length of air, their photographic efficacy at its entrance into the silver particles of the plate was no longer strong enough to set up its decomposition to a sufficient degree. The preservation of the energy of the rays was therefore the point upon which a better result must be founded.

In all probability, even at the smallest focal distance which I have employed, the loss of energy of the rays was very considerable, in consequence of various hindrances which they encountered on their way. If this loss could be diminished, further success was in view. That such diminution was possible was beyond all doubt. Even the removal of the air which still intervened between the spark and the plate (though only in a stratum of moderate thickness) promised appreciable advantages. But the air was not the sole obstructive absorbent which the rays encounter on their way. Quartz absorbs the most refrangible rays to a perceptible extent (L. Soret, *Arch. des Sciences Phys. et Nat.*, lxi. 332—334, 1878); also glycerine (W. A. Miller, *Phil. Trans.*, clii. 871, 1862), with which the halves of my quartz prism were corrected; and also gelatine, even in a thin stratum, obstructs them visibly (Soret, *Arch. des Sciences Phys. et Nat.*, III. Period., x. 453-455, 1883).

If these hindrances existed, and if their renewal or their great reduction was possible, a further increase of photographic energy would be secured.

The photographic effect is not merely a function of the energy of the rays—it depends, above all, on the behaviour of the sensitive plate. The more unstable the chemical combination of the sensitive constituents of the coating of the plate, the more its loosening during the action of the rays is assisted ("Sensitiveness," H. W. Vogel, *Handbuch der Photographie*, 4th ed., 1890, pp. 172, 193, 208), the more rapid is its decomposition on exposure. If it were possible to assist in this manner the more refrangible rays, the prospect of success would become more favourable.

Delicate details in a photograph, faint luminous impressions, require a plate quite free from any veil. They become turbid, doubtful, and often disappear again if the ground issues from the developing bath not clear as glass, but covered with a grey layer.

As already mentioned, this case occurred regularly in my proofs on prolonged exposure. The dispersed light from the interior of the apparatus, the cause of this veil on the plates, is composed of rays of all degrees of refrangibility; but only those for which the plate is most sensitive have a veiling action. These, with gelatine plates and spark light, are the rays of less refrangible ultra-violet—those, therefore, which are not wanted for my purposes. If I could keep them out of my apparatus, my proofs would be still further the gainers. Not merely was there secured greater clearness for the more delicate impressions, but the design of the entire proof was improved.

This consideration led to a series of researches which had to precede the resumption of my original work. These preliminary operations consisted:—

1. In ascertaining the influence of all absorbents which come into play in the photographic action of the most refrangible rays of spark light.

2. In the utilisation of the results thus obtained for the creation of better means of observation for the spectral region in question.

The only exception here was glycerine, which could be disregarded, since the double prism of the apparatus works correctly without being cemented together. The glycerine was only to prevent the loss of light occasioned by the reflection which arises on the planes of the two single prisms if left uncemented.

The absorptive behaviour of quartz and gelatine with the most absorptive rays of aluminium has certainly been very carefully determined by Soret. But he has only employed the eyepiece. His results do not, therefore, necessarily agree with those of the photographic plate.

The relations of brightness of the wave-lengths, as ascertained by Soret, according to the fluorescence have always a relative value.

They are certainly comparable among themselves, but not with the relations of sensitiveness of the photographic plate. They are this just as little as the behaviour of one kind of plate can be decisive for the behaviour of another kind. Between the ocular and the photographic method of determining the luminosity, in particular of the ultra-violet rays, there is certainly an internal connexion, that of absorption; but how little decisive this is for the case in question is best proved by the fact, that every substance has its own absorption spectrum. It must be also remarked, in passing, that ocular determinations of luminosity, even when they refer to light of the same quality, afford only a very imperfect guide to the objective luminosity.

It was, therefore, absolutely necessary to re-examine quartz and gelatine in this respect. In the same manner I was restricted to my own resources in determining the absorptive action of the air.

A medium has still to be considered which is much more important for my proofs than the substances just named—the sensitive constituent of the photographic plate, silver bromide. The success of the photograph depended in the first place on the behaviour of this substance. If it was in reality so feebly sensitive to the most refrangible rays as my proofs seemed to indicate, there then came up the further problem, to find a suitable substitute for silver bromide.

The determination of the sensitiveness of silver bromide turned likewise in the first place in an absorption experiment. For it could possess higher sensitiveness only if it absorbed the rays with sufficient energy, preferably in the modification used in photographic dry plates. On the manner of the extinction of the rays, whether photo-chemic or photo-thermic, could be decided only by the photographic behaviour of a silver bromide free from any admixture of foreign constituents. It might appear as if a proof with pure silver bromide would alone suffice for this purpose, and as if a knowledge of the absorption might be dispensed with. But this view is contradicted by certain facts of that part of my preliminary researches concerning the production of a new photographic plate, of which below.

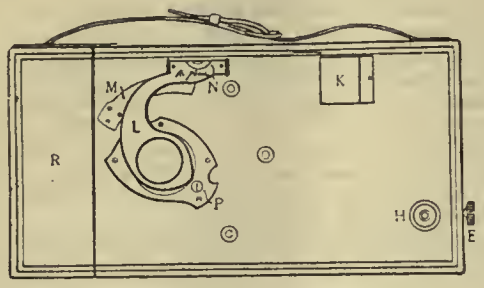
In this manner I might anticipate better results in the region of the smallest wave-lengths than heretofore, but always with the apprehension that the hoped-for rays beyond the limit of activity already reached might indicate a quite different behaviour that those on which my previous experiments were founded. I commenced my preliminary researches with quartz, followed in succession by gelatine, silver bromide, and air.

VICTOR SCHUMANN.

(To be continued.)

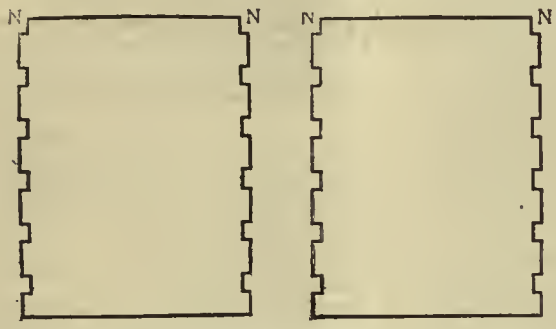
THE NO. 2 FRENA FOR QUARTER-PLATES.

Our former account of the new Frena was necessarily very brief. We now give a detailed account of its construction, aided by diagrams. The first of these shows a side external view of the instrument.



The new size Frena camera is a sure indication that the firm of manufacturers who placed upon the market the first camera for changing cut films do not intend to stand still.

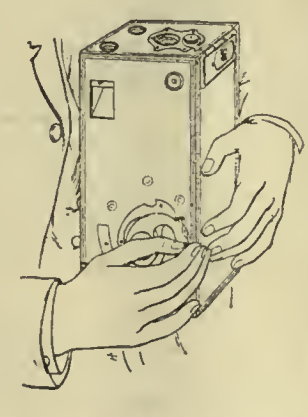
The quarter-plate Frena in every detail has been improved, and, al-



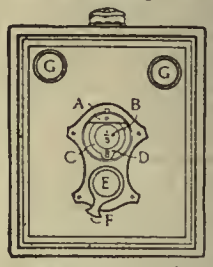
though the lantern-plate size still continues to hold its own, the new size has points which extend its scope of usefulness.

The film-changing mechanism, by which one film is selected from the pack of forty and automatically deposited in the receiving chamber, has been rearranged. Films and card-backings with notched edges are used as in the Frena No. 1, but they are all cut to an exactly identical shape. The alternating notches in the Frena pack, which are necessary to the working of the Frena system, are obtained by packing the consecutive films in opposite directions.

This method of cutting all films and cards of the same shape gives two advantages over the previous system. First, the film and its backing card can be cut together as if they were one backed film. Second, it will be possible to place a larger number than forty films in the camera as soon as the ingenuity of the film-maker has produced a backed film. It will also be readily understood that the mechanism of the camera is rendered by this change even more simple than before.



The chamber which receives the film after exposure is at the back end of the camera, and the Frena is held with its lens end pointing upwards when the film is changed. One motion only, that of turning the handle 180 degrees, and back drops the foremost film of the pack into the receiver, leaving the next ready for exposure.



The lens of No. 2 Frena is a Beck's autograph rapid rectilinear of five-and-a-half-inch focus, and is provided with diagrams, giving the aperture of *f*-8, *f*-11, *f*-16, *f*-22, and *f*-64. The shutter gives accurate exposures of $\frac{1}{5}$, $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$, and $\frac{1}{80}$ of a second, as well as time exposures. It revolves in the diagram slot, and the engraved figures indicate both the speed of the shutter and the stops in use, are read through the lens aperture, and can be rapidly altered. By unscrewing a single knob, the lens, finders, and whole mechanism of the shutter can be laid open to view, and may be easily removed for the purpose of examination or cleaning. The shutter is dependent for the variation of speeds upon no brakes or retarding springs, but always runs at the same speed, the size of the aperture which passes over the lens being varied to give the different exposures. For instantaneous exposures the set-off bolt is pushed in. For time exposures the same set-off bolt is pulled out, which opens the lens until such time as the set-off bolt is again pushed in.

The addition of stops in No. 2 Frena greatly increases the value of the swing back, which, with the smallest aperture, can be used 25 degrees from its normal position and has the advantage over a rising front in that, whatever be the position of the camera, the finder gives an image corresponding with the image on the film which is being exposed, and it also always uses the best corrected portion of the lens.

The No. 2 size Frena, like No. 1, has a fixed focus, and is so carefully adjusted that objects from twenty feet to the horizon are sharply defined on the film with the *f*-11 aperture.

For the purpose of bringing objects nearer than 20 ft. away into focus a set of supplementary lenses are provided, called Frena magnifiers. These form a new and simple method of altering the focus for near objects. One of these can be instantly introduced into the aperture in front of the normal lens, and thus objects as near as 3½ ft. can be photographed, and an absolutely sharp picture is obtained.

The finders are upon a new design. In most finders the mirror is below the ground glass, and the ground glass being thus close to the top of the case, requires very elaborate shields to keep off extraneous light. The images, therefore, on these finders are more brilliant than is usually the case.

The camera is provided with two sockets and a screw, so that a tripod can be used when it is desirable to give time exposures. The whole is neatly covered in leather, and weighs but 4 lbs. when fully charged.

Our Editorial Table.

Photography Indoors and Out.

By Alexander Black.

This book, published by Houghton, Mifflin, & Co., Boston and New York, is essentially one for amateurs, whom it pleasantly informs of much that is known of the early history of photography down to more modern times. In his description of the lenses employed in photography our author is rather weak unless when he acknowledges inspiration from other sources; otherwise, and when left to himself, he gives us Ross's cemented doublet as the orthoscopic lens, and makes Dallmeyer's triple achromatic with a double convex back combination. But it is fair to state that the book is written in a popular style for those ignorant of the art and makes no pretensions to scientific or technical accuracy. In the home gallery, that is when taking portraits, especially those of babies, in a private room, he gives directions for softening the shadows by suspending reflecting screens. He has improvised reflectors for an impromptu window portrait by covering the floor about the sitter with newspapers, hanging newspapers or other white sheets of paper or muslin under the nose of the camera, or holding up other white material opposite the window and just out of range of the portrait. This portion of the book is suggestive, and must prove useful to the inexperienced aspirant after portraiture. We are quite in sympathy with the author when in speaking of flash-light photography he says: "Nothing in home photography is more delightful in the interest and amusement it gives at the time, and in the pleasure it affords in after-years than the picturing of familiar groupings in domestic life, in parlour and in kitchen, at the evening

lamp, at the piano, and at the Christmas tree." He cautions the amateur who uses the hand camera not to expect it to do marvels, to take pictures when or where there is not sufficient light, but to give the plate a fair chance by not setting the shutter for a high speed when there is little light and little movement. This caution is applicable to others than green hands in America. Who has not heard of the button-presser who bestowed a look of pitying contempt upon the experienced veteran who had been exposing four minutes in the interior of Canterbury Cathedral one dull afternoon, with the remark, "I have just taken a snap-shot at the same view, but I only gave it the hundredth part of a second and I hope I shall get a good negative." "I hope you will," dryly remarked the veteran. Ample directions are given for developing the negative, for printing, toning and fixing the proofs, and taken altogether it is an excellent book for a young amateur.

It contains photographic illustrations, which, together with the text portion, are well printed on good paper.

The *Photographic Times* Christmas Number.

We congratulate our contemporary upon having in this Christmas number quite excelled itself. What with landscapes, seascapes, astronomical, *genre* and portrait subjects, it comes in an easy first over anything hitherto attempted in the way of illustrating a magazine selling at fifteen cents (7½*d.*). Of these there are over sixty half-tone pictures, several whole-page ones among them. The text matter, too, is considerably above its average. Among this is an article on Astronomical Photography at the Lick Observatory, by Prof. E. S. Holden, illustrated by sun spots, lunar craters, and by three views of the moon. There is too an article, "The Story of the *Photographic Times*," well illustrated by portraits of past and present editors and contributors. The chapters on the Fathers of Photography is in this number devoted to an appreciative article on Walter B. Woodbury, whose lamented death in 1885 has been recorded in our columns of the period. We notice that the writer mentions him as "the pioneer of balloon photography." It is not detracting from the fame of Mr. Woodbury to say that this honour belongs to H. J. Luff, who had patented this application of photography in this country in 1854, or more specially to M. Nadar, whose patent for photographing from a captive balloon dates from 1858, that of Mr. Woodbury being nineteen years later. This Christmas number reflects the highest credit on the proprietors and all concerned.

Southern Studies.

By A. G. Tagliaferro.

If there ever had been any doubt as to Mr. Tagliaferro's skill as an artist, this fine collection of Southern Studies must effectually dispel any ideas to the contrary. The series of twelve begins with *An Uninvited Guest*, in which a man, whose nationality may be guessed at from his swarthy complexion and the guitar hanging on the wall, while engaged with his dinner becomes aware that he is not alone, but that a young jackdaw, who has escaped from a cage overhead, is occupying himself in actively discussing some viands at the farther end of the table, the rightful occupant surveying the scene with grim interest. In the picture *All's Fair in Love and War* we have two men of the mechanic class playing at cards, one of them oblivious of the fact that the maiden behind him, who is pouring out for them the wine from a flask, is telegraphing to the other by her fingers the nature of the cards held by the opponent. This picture, like the former—nay, like all of the series—displays masterly skill in posing and lighting. In *Forty Winks*, the good father, having finished his tea and fallen asleep in his chair, is about to have his temporary oblivion terminated by the mischievous damsel who, with feather-duster in hand, is leaning over the screen behind, intent upon tickling the nose of the victim of Morpheus. *A Humble Offering:* Here we have a roadside shrine, with an image of the Madonna, to which a peasant-girl is devoutly making an offering of, doubtless, carefully selected flowers. The technique, equally with the art, in these and the others of the series is of a high order of merit. They are all of considerable dimensions, the prints being fourteen inches by eleven and a half inches. They are well printed in photogravure, on India paper, by R. Paulussen, Vienna, by whom they are published, and also at 215, Shaftesbury-avenue, W.C.

News and Notes.

Photographic Club.—January 3, *Clouds*, by Mr. Birt Acres.

West London Photographic Society.—January 2, Technical Meeting—Lantern.

Lewisham Camera Club.—January 5, Demonstration of *The Paget Prize Lantern Slides*, by Mr. S. Herbert Fry.

Mr. Francesco Duran intimates that his address is now "Ravenswood," Trinity-road, Birchfields, Birmingham.

Woodford Photographic Society.—January 4, Members' Lantern Slides. 18, *Platinotype*, by Henry W. Bennett.

Central Photographic Club.—On December 29 Mr. Lamond Howie, of Eccles, will deliver his lecture, accompanied by slides, on *The Passion Play at Oberammergau*, and on the following Friday Mr. Burdick, of Chicago, will give a demonstration of the use of the air brush.

Photography as a Profession.—Here is a case of some interest, as showing the salary sometimes said to be paid to assistants. One day last week, at a London police-court, a photographer, a married man, was charged with robbing his employer, and was sentenced to one month's imprisonment. A detective, who went with the prosecutor to the prisoner's lodgings, said the latter addressed the former as follows: "I shan't work for you again for twelve shillings a week. When I have got a little business on my own account, you turn round on me." If salaries for qualified photographic assistants—and, as the man was commencing business on his own account, it might be assumed he was—have really come down to this, the minimum wage of sixpence per hour for dock labourers, or street scavengers, may be a source of envy to some photographic workers. At only nine hours a day, the remuneration is less than threepence an hour.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 1	Camera Club	Charing Cross-road, W.C.
,, 1	Peterborough	Bedford Coffee House.
,, 1	Richmond	Greyhound Hotel, George-street.
,, 1	South London	Hanover Hall, Hanover-park, S.E.
,, 1	Stereoscopic Club	Brooklands Hotel, Brooklands.
,, 2	Birmingham Photo. Society	Club Room, Colonnade Hotel.
,, 2	Bolton Photo. Society	10, Rushton-street, Bolton.
,, 2	Brixton and Clapham	376, Coldharbour-lane, Brixton.
,, 2	Exeter	City Chambers, Gandy-st., Exeter.
,, 2	Hackney	206, Mare-street, Hackney.
,, 2	Herefordshire	Mansion House, Hereford.
,, 2	Keighley and District	Mechanics' Institute, North-street.
,, 2	Lewes	Fitzroy Library, High-st., Lewes.
,, 2	North London	Canonbury Tower, Islington, N.
,, 2	Oxford Photo. Society	Society's Rooms, 136, High-street.
,, 2	Paisley	9, Ganze-street, Paisley.
,, 2	Rochester	Mathematical School, Rochester.
,, 2	Rotherham	5, Frederick-street, Rotherham.
,, 2	Sheffield Photo. Society	Masonic Hall, Surrey-street.
,, 2	York	Victoria Hall, Goodramgate, York.
,, 3	Edinburgh Photo. Society	38, Castle-street, Edinburgh.
,, 3	Leytonstone	The Assembly Rooms, High-road.

,, 4	Oldham	The Lyceum, Union-st., Oldham.
,, 4	Tunbridge Wells (Annual)	Mechanics' Inst., Tunbridge Wells.
,, 5	Brighton and Sussex	Librarian's Room, Public Library.
,, 5	Cardiff	Castle Arcade, Cardiff.
,, 5	Central Photographic Club	Coleman's Hotel, Henrietta-st., W.C.
,, 5	Croydon Microscopical	Public Hall, George-street, Croydon
,, 5	Holborn	100, High Holborn, London, W.C.
,, 5	Leamington	Pump Room, Leamington.
,, 5	Maldstone	"The Palace," Maldstone.
,, 5	North Kent	Gravesend.
,, 6	Hull	71 Prospect-street, Hull.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

December 21.—Mr. W. E. Debenham in the chair.

Andresen's Developing and Fixing Cartridges.

Mr. E. A. Leblanc prefaced a short demonstration of Dr. Andresen's preparations by remarking that they were useful for tourists. The metol cartridges could be used for developing bromide paper as well as negatives. Speaking of the new "bars" of acid hypo for fixing purposes, he said they were packed with the powder in the uncompressed form. A great advantage of the bars was, besides their portability, that they dissolved very readily. The tone-fixing cartridges could be used for albumen as well as gelatino-chloride paper, toning in the former case, however, taking somewhat longer. Speaking of metol, he said it was more energetic than pyro, and thus saved time, besides being cleaner with sulphite, the general stain being less.

Several prints were then toned and fixed and a Wratten plate developed successfully, and after a few observations of a conversational nature from members, Mr. Leblanc received a vote of thanks.

The Fountain Air Brush.

Mr. Charles Burdick, of Chicago, demonstrated the new air brush, pointing out that it was of pencil shape, and had not many pieces. It gave a good quality of spray, and great control could be obtained over the amount of colour used. Held close to the work, a fine spray was given; at a greater distance, a broader effect. The quality of the shading was excellent. If the colour were rubbed in or washed on, a close texture was obtained, but this was overcome by the use of the brush, which threw the colour on in little specks, virtually a very fine stipple. The frictional wear of the tool was not two per cent. The reservoir of the brush could be filled with colour, but eight to ten drops were sufficient. It could be used for working up the shadows of an ordinary negative, but not for retouching. In landscape work it would be especially useful. It could also be used for lithographic work or finishing bromide prints. The spray is actuated by air pressure, and the brush is held just as an ordinary pencil is held. Its cost is about 6*l.* 10s. complete. Mr. Burdick gave a practical demonstration of the use of the tool, producing one or two freehand heads and eyes. Several specimens, plain and coloured, were also on view. He said the standard water colours could be used. With an hour's practice, background work could be done by a photographer, but the further use of the tool was a matter of practice.

The Chairman, in moving a vote of thanks to Mr. Burdick, remarked on the fineness of the lines produced by the brush.

Croydon Camera Club.—December 20, the President (Mr. H. Maclean, F.G.S.) in the chair.—An unusually complete and well-arranged lecture was given by Mr. John H. Gear on *Various Methods of Lantern-slide Making*, in which the leading processes were graphically described. As the above will, no doubt, be in due course printed *in extenso*, we shall not attempt a condensation; but attention should be drawn to the admirable way in which, by means of especially prepared slides, the method of slide-making by reduction was illustrated on the screen. Thus, (1) showed the apparatus in position; (2) the same during exposure; and (3 and 4) the procedure necessary for printing in of skies. The discussion, amongst many other points elucidated, elicited that there is much room for improvement in the manner in which slides are shown by many Societies whose status would make one think them to be incapable of any shortcoming in this respect.

Hackney Photographic Society.—December 19, Mr. E. Puttock in the chair.—An entertainment was given to a large gathering, entitled *Chicago Exhibition*, by the Society's Hon. Lanternist (Mr. Albert Rose). A number of slides of excellent quality was shown and proved very interesting, as they gave the audience a good idea of the size of this gigantic exhibition. Members were particularly requested to attend on January 2, when Mr. Burdick, of Chicago, will give a demonstration upon *The Air Brush*, also a demonstration by Mr. Howson on *Matt-surface Paper*.

South London Photographic Society.—December 18, Mr. F. W. Edwards in the chair.—A demonstration was given by Mr. S. H. Fry of making lantern slides on gelatine plates. One good rule, he said, in making slides was to make the exposure suit the developer, and not to alter the latter to meet the exposure. Hydroquinone he recommended as a developer, but, if it was desired to use one of the newer developers, metol was the best for the purpose. The use of an acid fixing bath assisted materially in the production of clear slides. The continued use of one quantity of developer for a number of slides militated against the attainment of the best results. A series of slides made from one negative on Paget slow plates were projected on the screen to show the variety of colour obtained by exposure, and the use of varying quantities of carbonate of ammonia in the developers. A number of slides, exposed, developed, and fixed during the meeting were shown in the lantern. The new lantern awarded to the Society in competition at the Stanley Show was on view. Attendance, forty-eight.

Birmingham Photographic Society.—December 19, Mr. J. T. Mousley in the chair.—The series of one-man exhibitions was continued by Mr. Underwood, who had a large number of prints on view. They comprised all kinds of subjects, while the interiors, perhaps, showed especial skill, the detail being so clearly defined, and no hardness in the shadows. Mr. Underwood also showed a great variety of good tones on gelatino-chloride paper.

Leeds Photographic Society.—A meeting of the newly elected Committee for the ensuing year was held in the Society's Rooms at the Mechanics' Institute on Monday, the 18th inst., for the purpose of electing the officers and settling the syllabus for the year. The officers elected were as follows:—*President:* Mr. J. H. Walker.—*Vice-Presidents:* Messrs. S. A. Warburton and Godfrey Bingley.—*Librarian:* Mr. T. Butterworth.—*Lanternist:* Mr. H. P. Atkinson.—*Treasurer:* Mr. Herbert Denison.—*Secretaries:* Messrs. Herbert Denison and Mr. H. L. P. London. These gentlemen, together with Messrs. B. A. Burrell, F.I.C.; R. Steele; and Dr. E. H. Jacob, M.A., M.D., form the Committee. The Society's Annual Lantern Exhibition, which has hitherto been held in November, has been omitted for the present year, but will be held on January 18 next in the Albert Hall, when a novelty will be introduced in the use of the electric light in the lantern. The syllabus for the coming year comprises many interesting papers and demonstrations on subjects connected with photography.

Lincoln Camera Club.—On the 20th inst. Mr. Howson (of the Britannia Works Company, Ilford) gave a demonstration on *The New Ilford Matt P.O.P.* The lecture was practically the same as given before the Central Photographic Club on the 15th inst., so need not be given in detail here. After describing the paper, Mr. Howson at once proceeded to demonstrate the use of it, showing how different tones, ranging from almost a pure black to sepia and brown, could be obtained with the greatest ease. Judging by the specimens exhibited during the evening, the paper leaves nothing to be desired, such exquisitely soft and beautiful pictures surpass anything before attempted. The members of the Club are to be congratulated upon being first in the provinces to have this most easy and beautiful process demonstrated before them.

Brechin Photographic Association.—December 20, Mr. William Shaw Adamson, of Causton Castle (President), in the chair.—Public Lantern Entertainment.—An audience of about 1000 assembled to hear an illustrated lecture entitled *A Scamper through the States, with a Visit to the Chicago Exhibition.* This was followed by the exhibition of about 100 slides of the members' work, and humorous and effect slides. Mr. James Bruce read the descriptive lecture, and Mr. D. Lamb, late of Lamb's Diorama, presided, with much acceptance, at the lantern. The expenses were defrayed by a collection, which amounted to over 7*l.*

EXHIBITION OPEN.

1893.
Dec. 29–Jan. 22, 1894 *Bristol Triennial International Academy of Arts, Bristol. Hon. Secretary, F. Bligh Bond, 36, Corn-street, Bristol.

* Signifies that there are open classes.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

PHOTOGRAPHIC COPYRIGHT.

To the Editor.

Sir,—In your last number, on page 814, is a paragraph headed "On Things in General," relating to photographic copyright, and which is calculated to mislead the photographic public if not corrected. The law is as follows:—

When a sitting is given to a photographer WITHOUT PAYMENT, the copyright vests in the photographer, for "from the moment when the negative is taken it is the copyright of the photographer." It is true the requirements of the Act are not complete until the work has been registered at Stationers' Hall, but this may be done at any time AFTER publication.

Upon registration, the owner of the copyright is entitled to avail himself of all the statutory remedies against any person reproducing the photograph—that is to say, he may get damages or penalties, an injunction to restrain the producer from using the copyright in any way, and an order for the delivery up of reproductions unlawfully made.

I admit it is advisable to register a copyright picture as soon as possible after the photograph has been approved by the sitter; but I can vouch for the accuracy of my statement, that it may be done at ANY TIME.—I am, yours, &c.,

Joseph J. Elliott.

Talbotype Gallery (Elliott & Fry), 55 and 56, Baker-street, W., December 27, 1893.

[The opinion quoted by Mr. Elliott is that of a gentleman qualified by considerable experience to advise as to the law of copyright as applied to photography.—Ed.]

THE SPEED OF PLATES: A CRITICISM AND A REPLY.

To the Editor.

Sir,—The letter from Messrs. Hurter & Driffield in your last issue calls for some reply from me, although, I think, considering its tone, I should be perfectly justified in leaving it unanswered. I have carefully re-read my paper, and I cannot see any reason to alter anything that I have said. Neither do I see any justification for Messrs. Hurter & Driffield's assertion that I am angry. If any impartial reader can find any thing of a personal or angry nature in my paper, I am ready to withdraw it and to apologise. I have spoken strongly and to the point about Messrs. Hurter & Driffield's work because, in my opinion, some plain speaking was needed, and I think that if any justification were required of the course I took, it is supplied by the personalities of Messrs. Hurter & Driffield's reply. Their position seems to be defined by the old legal gibe: "With a bad case abuse the the plaintiff's attorney." However this may be, kindly permit me to take up the few points raised by them last week. They lay some stress in their opening paragraph on some supposed rules of the Camera Club. I need hardly say that no such rules exist, and if they did they could hardly be supposed to apply to Messrs. Hurter & Driffield. My object in giving the widest publicity to my paper was to give these gentlemen the most open field for their reply. Had I not done so, they would have had most just reason for complaint. I may remark, also, that pressing invitations were sent to them to be present at the meeting of the Camera Club at which my paper was read, both by myself and, I believe, by the Secretary of the Club.

Messrs. Hurter & Driffield's assertion that they can produce two

identical negatives on two different plates does not in the least meet my statement that this cannot always be done. Even granting that it could be done by a *tour de force*, it does not follow that either negative would be the best producible on the plate. Still I think I may safely leave this to the judgment of those who do me the honour to read my paper.

I may do the same with their next statement, viz., their denial that they ever asserted that the ratio of gradation of a perfect positive must be the same as that of the object portrayed. I need only refer to the opening paragraphs of their *Photo-chemical Researches* for proof of this.

The next paragraph of their letter contains a fine example of the logical fallacy *suggestio falsi*. Captain Abney has never abandoned his method of speed determination, although he perfectly agrees that it, and any other method that expresses the speed by a single number, can never be more than a roughly approximate one. I presume, then, that Messrs. Hurter & Driffield will withdraw their statement.

The next paragraph contains the old confusion that I drew attention to in my paper; they seem utterly unable to distinguish between a complete statement and an approximate one. My assertion that the printing value of a negative is through a certain range proportional to the negative logarithm of the exposure is an approximate statement, and is perfectly consistent with the fact that through a greater range the law of error formula fits the curve of a plate. Messrs. Hurter & Driffield are here on the horns of a dilemma, they must either be supposed ignorant of the principles on which approximations are made or must be thought to be confusing the issue.

A similar dilemma arises in the very next paragraph. As I am away from home, I have not before me the copy of the *Camera Club Journal* to which they refer, but I have the unpaged reprint of Captain Abney's paper, and in it I find the following words:—"The curve of error has what is called a singular point, that is, a point where it is neither convex nor concave," &c. If, in the face of this, Messrs. Hurter & Driffield continue to say that "the point of inflexion was not mentioned, and is not meant," there is only one inference to be drawn, and that is that they do not know what a point of inflexion is. At least, if they do, their ideas of scientific honesty differ greatly from mine.

In conclusion, I would say that abuse is not argument, and I fail to see that Messrs. Hurter & Driffield have met a single one of the points raised in my paper; in fact, the very tone of their letter shows that they have felt the force of my arguments. As for the quotations from my paper that they have taken from the context which justified them, and used against me, I can only say that their attitude reminds one of that of the quack medicine vendors, who, in reply to an analyst's declaration that their nostrums contain nothing of any medicinal value, boldly answer, "Our medicine is of so subtle a nature that it defies the most searching analysis."—I am, yours, &c., HARRY M. ELDER.

Brighton, Dec. 20, 1893.

GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—I have had some experience with gelatino-chloride paper, and have had similar experiences with the sulphocyanide bath as your correspondents, "J. H. Smith" and "Scribbler." All the defects they enumerate have been common with me until I acted on the advice given in your issue of (I believe) October 27, viz., to treat the prints after the first washing with a bath of common salt and water before toning.

The effect has been magical, and I may say I find I can now tone with more certainty and equality of results, and without the extravagant waste of gold to which your correspondents refer. Moreover, the prints are best judged by their surface tone, and when just a shade warmer than you intend them to be should be taken out of the bath.

I consider your suggestion the most valuable one that has yet been made in the controversy on the use of the sulphocyanide bath. Perhaps users of this paper will act on your suggestion before they condemn gelatino paper altogether.—I am, yours, &c., G. E. ARNOLD.

Knaresbro'.

To the EDITOR.

SIR,—I trust that no reader of this JOURNAL will accuse me of any desire of "rushing into print," for such is not my wish; but, as so many other workers have written a few remarks on the above subject, let this be my excuse for adding my experience. I may at once state I am not referring to any particular make of paper, for I notice that directly a complaint is made against any particular brand, the manufacturers of the said brand immediately insinuate partiality, trade interests, &c. It is to be lamented that, in almost all complaints made against commercial photographic products, the *manufacturers are never in fault* (?) This, I am sure, prejudices their cause. After all, is not photography in every branch a series of compromises? No part of the art-science is perfect. The same faults which I notice urged against certain brands of paper I maintain apply equally to all brands. With regard to the quantity of gold used in toning, undoubtedly the prints on gelatino-chloride papers may be toned with the same quantity of gold as used in albumenised paper. But what kind of tone do we get? Not such as would be considered a rich purple on an albumenised silver print; therefore, I contend that much more gold is required to bring about a similar result.

Now, as to the assertion in certain instructions issued that the "prints lose little in toning and fixing." This is indeed a delusion and a snare, and the merest tyro in printing will immediately discover his error if he only slightly overprints his proofs. The prints undoubtedly do lose a great deal in after processes of toning, fixing, and washing.

With regard to double tones, it seems that some papers show this defect more than others; but when we consider that the deeper a print is when it leaves the printing-frame, the richer the resulting picture when toned, it seems somewhat a natural consequence that where a print is softened off in vignetting, and the reduction of silver is so much less, that it can hardly take the same tone as in the fully printed parts; this, however, I leave to those better qualified than I am to deal with. I feel sure that, if manufacturers would only meet the users of their wares in a more friendly and impartial spirit, the benefits would be mutual, and the amount of written controversy would be less bitter and unfriendly, and far better employed in an honest endeavour to finally reach that estimable quality—*the truth*.—I am, yours, &c., FREDERICK W. MUNCEY.

Kilburn, London, N.W.

THE BRADFORD CYLINDER ACCIDENT.

To the EDITOR.

SIR,—I fully expected that Mr. W. I. Chadwick's letter, so prominently published in your issue of the 1st inst., would have been answered sooner. As no answer has yet appeared, I would like, with your permission, to reply to some of the statements made in the letter, fearing that they might mislead persons not well acquainted with the facts.

With reference, first of all, to the very sad accident at Bradford, perhaps even Mr. Chadwick will grant that if it tends to create nervousness among the users of gas cylinders, it tends in a hundredfold degree to breed it among persons who fill and distribute them. Therefore, I should very much like to know on what grounds he bases his opinion that "we may expect these explosions much more frequently from now." Has he any grounds, or is it just an "alarmist's" assumption. I should rather anticipate that the result of the accident and the attendant inquiry would be an amount of caution and enlightenment which would still further reduce any risk.

Through the whole of Mr. Chadwick's letter there seems to be an implied censure on the Compressing Companies. How the Bradford accident can be made a peg for such a censure, I do not see. The accident does not appear to have been owing to any neglect of prescribed tests on their part—the cylinder which burst was not even supplied by any of them. Probably, Sir, you have already received a copy of Professor Goodman's report, and will doubtless publish it for the information of your readers. I would commend it to Mr. Chadwick's notice. It verifies completely the fact that cylinders properly made, annealed, and tested, are absolutely safe under all the conditions of ordinary transport and use. It also proves that the best makers of cylinders are perfectly acquainted with the requirements of the trade, and that in spite of Mr. Chadwick's opinion the conditions of safety laid down by the best makers and compressors have been sufficient (see Mr. Howard Lane's letter in *Engineering*, of December 9, and Mr. K. S. Murray's *Handbook on Compressed Oxygen*).

According to Professor Goodman, by whose kind invitation I was present when he made his tests of the Bradford cylinder, the defect of that cylinder lay in the fact that it was constructed of a high carbon steel, too hard and brittle for the purpose, and also that the annealing process, which is necessary to soften and toughen the metal after the manufacture of the cylinder, and which was specially requisite in this case, had been entirely omitted. On these points, in the absence of satisfactory tests, it has been customary to accept the maker's guarantee. It is now proposed that the Compressing Companies should anneal all cylinders themselves, and thus become themselves responsible for the proper ductility as well as for the tensile strength of cylinders. Of course, from a public point of view, this would only shift the responsibility from the makers to other equally interested and fallible persons. Hence the further suggestion for Board of Trade interference. So far as outside interference would secure an independent guarantee that every cylinder which was passed into use had been properly made and tested, without introducing repressive restrictions, I am sure it would be welcomed by the Compressing Companies as much as by the public. Such interference might take the form of Board of Trade inspection, or, what would be perhaps preferable, inspection and insurance by a first-class insurance company, as is the case with boilers.

There are two or three statements in Mr. Chadwick's letter which I believe he has made before, and which have been replied to elsewhere.

There may be imperfections in the management of the Compressing Companies, but I cannot think they are such as he indicates. He speaks about cylinders being over-charged to 130 and 135 atmospheres. Quite possibly. These are not dangerous pressures. They are meant to allow liberally for the cooling, and consequent reduction of pressure, after leaving the compressing pump; and, indeed, incidentally serve as a modified test of the soundness of a cylinder each time it is filled.

Then there is the sensational revelation about "interchangeable adaptors." I do not know what Mr. Chadwick refers to, unless he means certain fittings which have been supplied, from time to time, to customers to enable them to connect old types of fittings with new types of valves. But with the mechanical knowledge he possesses, he should know that it would be possible to make a connecting piece for attaching a coal-gas cylinder to an oxygen compressor, or *vice versâ*, whatever form of valve outlet were adopted. The object of altering the valves and connexions of coal-gas cylinders was to render it impossible for a workman to fill a cylinder *accidentally* with the wrong gas. He can be trusted not to do it intentionally, unless he wishes to commit suicide, and there are easier ways of doing that. I certainly cannot agree with Mr. Chadwick that "the security which was paid for is *gone*." It exists, and is a very real security, I can assure him.

Excuse me, sir, if I refer to another point. I understand Mr. Chadwick to state that, if the Bradford cylinder had burst in the room where the Ilkeston gas-bag explosion occurred, it would have blown out the walls and brought down the roof on the heads of the audience. Now, I do not wish to under-estimate the consequences of a cylinder explosion, but I would like to remark that I visited the scene of the Bradford accident, and, though it occurred in a narrow subway about twelve feet wide and eight feet high, I could not find a mark on the floor or wall to indicate that anything had happened. Indeed, the glass panes of a lamp which hung on the wall not above eight feet from the spot where the cylinder burst were not even fractured. And yet Mr. Chadwick says he is not an alarmist. Well, sir, I don't like to be rude, but I should like to call him one.

Perhaps the term explosion, as applied to the Bradford accident, has caused some confusion of thought. It was not an explosion in the usual sense of the word. An explosion of twenty cubic feet of mixed oxygen and hydrogen gases in a cylinder would be even a more serious thing, and I am glad that the chance of such an occurrence is so satisfactorily remote. Neither did the Bradford cylinder burst owing to an excessive internal pressure. It was strong enough to bear for an indefinite time much greater internal pressure than it did contain, so long as it was not subjected to any severe shock. It was broken by the shock of its fall, because it was brittle; and, of course, when it broke, the expansion of the gas it contained caused the pieces to fly violently apart—just as a charged soda-water bottle would fly apart under similar circumstances.

In conclusion, sir, I must express my surprise that Mr. Chadwick should seize every opportunity to discount the efforts, and discredit the instructions of the Compressing Companies. I might remind him that even a Government inspector would have to study the subject in the light of their experience before he could afford much protection to the public. Cylinders have been filled and distributed many hundreds of thousands of times during the last few years, and the accident at Bradford is the first which is traceable to the failure of one of them. Surely even Mr. Chadwick will admit that those responsible for the growth of this business must have exercised great care and forethought to have developed it with so small a record of accidents. And if he will calculate the reduction of risk which the cylinder system has effected for users of lime-light since cylinders took the place of bags, I think he will acknowledge that lanternists, at any rate, have no cause for complaint. There are lessons to be learnt from the accident at Bradford, but we can learn them without getting into a panic.—Apologising for the length of my letter, I am, yours, &c.,

W. Morton Jackson.

Manchester, December 18, 1893.

Answers to Correspondents.

Bucks.—Without seeing an example or two, and having some details of the system pursued, it is impossible to offer an opinion.

J. Westlake.—The background may be very good as a work of art, and well executed, but it is far too pronounced for photographic use. Scenic backgrounds for portraits should be suggestive rather than pronounced.

D. E. L. A. Y.—Probably press of Christmas orders is the cause. As a rule, the firm are prompt in the execution of orders. We cannot assist in the matter, though we shall be sorry if you lose a profitable commission.

C. J. R.—There is no reason why a metal cast cannot be obtained from a Woodbury relief. Send the relief to a stereotyper, he will supply a metal replica. It will be advisable to send the relief on the glass upon which it is developed.

T. Morris.—The cause of the "sparkling points" in the enamelled prints is simply air bubbles enclosed between the print and the gelatine. The method of procedure is quite right; the only thing necessary to success is greater care in the manipulation, so as to avoid the air bells.

A. Karl (Cologne).—Yellowness is no more general on gelatino-chloride prints made on paper of British make than on that manufactured abroad. It is simply a question of manipulation. We cannot account for your getting whiter prints on one paper than the other. They should be pure in either case.

Churlish.—If the owner of the historic mansion refuses you permission to photograph its interior for publication, we cannot see that you have any cause for complaint. Surely every man has the right to say what he will, and what he will not, permit in his own house. We must decline to publish the letter even if you did not desire your name to be suppressed.

B. B. H. asks if negatives that are developed with a somewhat discoloured pyro developer, and have a yellow colour, are likely to be less permanent than others which are produced with a colourless developer, and have only an indication of a yellow tint.—We see no reason why, other conditions being equal, the negatives should be more permanent in one case than in the other.

G. G. R. asks what is the best mountant for carbon prints, and also for collotype prints with a glazed surface? Any ordinary cement that will secure the prints to the mounts may be employed for pigment prints, as they, unlike those in silver, are not liable to be affected by the mountant. However, nothing is better or more convenient to use than starch paste.

R. Wenman.—None of the developers given in the Almanac for dry plates are of any use with wet collodion. We don't see how this process is to be rendered, as you term it, "less messy." After all, the "messy" rests very much with the manipulator. Some workers get their hands much stained in working, while others, more neat manipulators, scarcely stain their hands at all.

Detector.—It is more than probable that the "fixed focus" lens is not at fault, but that it is "fixed" at the wrong focus for such purposes as you have been employing it. If it is rightly adjusted for outdoor work, it will certainly be wrong for portraits in rooms. The only thing to be done is to have the camera altered, so that the focus of the lens can be adjusted to suit its requirements.

A. N. Blake.—The only suggestion we can make as to your going wrong is that the directions given by the author of the article have not been followed, otherwise the result would have been different. By merely seeing a print, with no other data, it is impossible to say why the failure. Read the last paragraph of the article carefully and try again. Perfection is rarely arrived at in the first essay.

T. Blackman.—The process could not be patented, or, to be more accurate, a valid patent could not be obtained for it. Vignettes with hatched backgrounds were used and patented, and the patent lapsed, and the thing often advocated by us years ago. Do not be deterred from working by any threats. No patents in connexion with this subject have been applied for of late. Simply a case of "bluff."

A. Davies.—In taking up the carbon process as a beginner, we certainly advise you to purchase the tissue ready for use. Although in extreme cases (abnormally thin or dense negatives) an advantage is to be gained by sensitising the tissue for oneself, it is not to be recommended to beginners, inasmuch as they can ensure obtaining it in the best conditions for average purposes as supplied commercially, a state not always secured by a novice when he sensitises for himself.

Death of Mr. P. D. Coghill.—With much regret we have to announce the death of Mr. Peter D. Coghill, the Honorary Secretary of the Northern Photographic and Scientific Association, which meets at Wood Green, N. It was in a large measure due to the energy of Mr. Coghill that the Association was formed, and achieved such rapid success. To his influence was owing the admirable lectures which have lately been delivered by professors of various departments of science. He was a skilful microscopist, and excelled in the production of photographic enlargements of bacilli and similar objects. He was professionally connected with the Royal College of Veterinary Surgeons, to which he came from the laboratory of the Royal College of Surgeons, Edinburgh. He was a genial, talented man, and will be much missed. He was lately seized with influenza, on which pneumonia was said to have been grafted. He died on the 20th inst., at his residence in Hornsey, N.

THE LANTERN RECORD.

CONTENTS.

THE DILUTION OF OXYGEN.

The suggestion from a correspondent, as given in a communication to the November "Lantern Supplement" that oxygen under pressure, whether in cylinders or in the gas-manufacturers' holders, deteriorates so that it becomes "little more than atmospheric air," met, as it was only reasonable to anticipate it would, with several rejoinders pointing out the extreme unlikelihood, if not impossibility, of any such deterioration taking place. A little reflection indeed must show that, were compressed oxygen likely to be changed, under pressure, very largely into nitrogen—for that is the extraordinary reaction which our correspondent implies takes place—the retailing of compressed oxygen, to say nothing of its employment for illuminating purposes, would be entirely out of the question.

As to any "corrosive influence" being at work on account of the gas being kept for a considerable length of time in the cylinder, we can recall no experiences either of our own or of our correspondents bearing out such a theory. Possibly our correspondent was confusing oxygen with coal gas, the latter undoubtedly when kept for several months in the cylinder being sometimes liable to react on the metal to form various compounds which have a detrimental effect on the lime and the quality of the illuminant. But even this is, we believe, largely governed by the qualities of the hydrogen, tolerably pure varieties of the latter, that is, free from a large excess of hydro-carbons, keeping on the whole very well indeed.

There seems little room for doubt, however, that of the varieties of commercial oxygen now available, some kinds are less pure than others, that is, they are more or less diluted with nitrogen beyond the theoretical standard of five or six per cent. Nitrogen has been termed in this connexion an "inert" gas, but this is an obvious misnomer when it is present in large quantities, inasmuch as in the measure of the amount of nitrogen present so is the illuminating power of the oxy-hydrogen light decreased. Other considerations of an economic nature will also serve to establish the fact, that nitrogen in large quantities is the reverse of inert in a mixture supposed to consist of practically pure oxygen.

This subject of the dilution of oxygen and its consequent effects in lantern work has recently received attention in several quarters. The results of some experiments mentioned by Mr. Grundy of the Royal Naval College, Greenwich at a meeting of the London and Provincial Photographic Association, quite bear out the experience of many who have found commercial oxygens vary in purity. That gentleman stated that he had recently analysed a sample, and found that it contained nearly forty-five per cent. of nitrogen; others had up to fifteen per cent., while another of a special make only contained about eight per cent. In no case had he been able to obtain so low a percentage of nitrogen as five.

If Mr. Grundy's results are typical of the qualities of commercial oxygens in use by lanternists, it is highly desirable that some simple means of ascertaining the purity of the gases with which they are working should be placed within their reach. Such a test should be one which those comparatively ignorant of chemistry and physics should be able to apply; and such a one is that, we conceive, which was promised by Mr. A. Haddon to be given at a future meeting of the Association. Tests of the kind doubtless already exist, but we shall not anticipate Mr. Haddon's promised method, which we are sure will be simplicity itself, and therefore welcome to all lanternists.

LANTERN NOTES AND NEWS.

Adverting to our remarks of last month as to the utilitarian applications of the lantern in practical photography, a recent lantern night of the London and Provincial Photographic Association supplied an apt illustration of our meaning. At that meeting, among the slides shown, were several by Mr. H. E. Davis, which exhibited the peculiarities of the amidol developer in various modifications, as expounded by that gentleman in the course of his able article on the subject in the Almanac just published.

* * * * *

In the same connexion it will be remembered we spoke of the practicability of projecting upon the screen the negative image while undergoing the process of retouching, in order that an audience might gain some idea of the retoucher's method, especially in regard to the kind of strokes employed to produce various effects. When thus writing we had overlooked the fact that recently partly the same end had been secured in another way, namely, by the projection of untouched images upon cartridge-paper screens, the retouching upon the projected images being accomplished by a stick of charcoal.

* * * * *

One of the *desiderata* of the lantern which we anticipate will be generally called for in the future will doubtless be the means of obtaining a uniform standard light; so that, given the focus of the objective and similarity of screens, it would be possible for different audiences to see the same set of slides under practically identical conditions. At present this is not often practicable; indeed, as is well known, the character of the light exercises such a remarkable influence over the quality of the pictures shown on the screen, that it is no uncommon thing for a set of slides to be well received when shown by means of one lantern, and to be quite otherwise regarded when exhibited in

another, although, possibly, the conditions of light, condenser, and screen are considered to be tolerably uniform in both cases. Irregularity of illumination is far from being unknown, even in double lanterns. A method of standardising lantern illuminants would be welcomed by all slide-makers.

* * * * *

THE slides, prepared by the Devon and Cornwall Camera Club, of Plymouth and its environs, where the Photographic Convention of the United Kingdom is to foregather next summer, are to be shown this week before the members of the Photographic Section of the Croydon Microscopical Society. We trust that they will go the round of the principal London and country societies. Would it not be a politic move to send them up to one or two of the Glasgow and Edinburgh societies, in order, if possible, to render nugatory Mr. William Lang's dismal forecast of the number of Scotchmen likely to come south to the Convention?

* * * * * *

WE publish in another part of the Supplement the first report of the Charitable Lantern Society which, during the months of November and December, has given a series of lantern entertainments to the inmates of several London hospitals. We gather that those entertainments were highly appreciated, and we applaud the Society in its kindly mission. It appears, however, that its operations are somewhat restricted by the lack of a sufficiency of apparatus and helpers, for which and to whom we venture to appeal on its behalf. We are confident that many of our readers will be glad to help in the good work, and we ask them to send either offerings of lanterns, fittings, gas bottles, or slides, or of their services, to the Hon. Secretaries, Mr. B. Foulkes-Winks, 2 Pretoria-avenue, Walthamstow, and Mr. F. Simmons, 158 Frances-terrace, Herne Hill, S.E.

PRINTING COLLODION TRANSPARENCIES BY CONTACT.

To many of the users of collodion plates for transparencies and lantern slides the extreme tenderness of the film presents considerable difficulties, owing to the ready manner in which it suffers mechanical injury. This is more especially the case where contact printing is adopted, although, even when used in the camera, these films are liable to suffer from carelessness arising out of our modern familiarity with the tougher gelatine surface. But to the collodion workers of anything over a dozen years ago this delicacy of surface gave no trouble, since they were prepared for it, and consequently took the necessary precautions. A few hints as to the best modes of avoiding the danger may not be out of place, and may be specially useful to makers of lantern slides at the present season.

The injury that takes place in the printing frame is of a twofold nature; it may arise either from over-pressure, or from abrasion, or rubbing of the two surfaces together while in contact. This distinction may seem a trivial one, but it is not really so, for the precautions that will prove effective in the one case will not necessarily do so in the other. The methods of combating the trouble may also be divided into two classes, chemical and mechanical, the former being only available to those who prepare their own plates. This side of the question I will take first.

The most obvious way out of the difficulty is to render the film harder and tougher; but, of course, this can only be done in the course of the preparation of the plate or of the emulsion. Those who prepare their own emulsions may often confer a certain amount of additional toughness on the film by a careful selection of pyroxyline; but, as modern samples of a suitable kind are so few and far between, it is scarcely worth while trusting to that plan. But, by the use of a protective material, either added to the emulsion or applied to the surface of the film, a degree of hardness may be secured which, if it is not equal to that of gelatine, is at least quite sufficient to save the plates from injury under anything like ordinary treatment.

To my own knowledge there are many amateurs who still continue to use unwashed emulsion for transparency purposes, for which it has many advantages that the washed emulsion does not possess, amongst them being the possibility of applying a protective or preservative coating such as I have alluded to. This need not interfere in any way with the general character of the emulsion, or affect its working in the slightest degree; it is not, in fact, a "preservative" in the sense in which the term used to be employed, *i.e.*, a substance which, while it kept the pores of the collodion open and permeable to an aqueous developer, as well as to a less degree "preserving" the sensitive film from atmospheric influences, had usually also a more or less important action upon the working of the sensitive material. In our present case we require no such chemical action, as the emulsion, so far as its working properties are concerned, should be complete in itself, the preservative consisting of a substance practically inert chemically, but forming a varnish-like coating on the surface of the collodion.

Of the materials applicable to this purpose only two or three need be mentioned, though many of the old preservatives may be used. Tannin may be taken first, as this, while forming a protective coating, may also have an appreciable or even a very decided action upon the sensitiveness of the emulsion, as well as upon the colour of the image. For this reason it may be in some cases objectionable. For the benefit of those who decide to use it, I may say that the strength of solution should be fifteen grains to the ounce of water, and the same quantity of best *English* loaf sugar may be added with advantage. The solution must be perfectly clear and bright before use, and as even nowadays a sample of tannin is occasionally met with that will not filter bright, and only becomes so after many days' keeping, I may add a rapid method of clearing the solution.

This consists in adding to the tannin solution a small quantity—say, from one to two drachms to each pint—of albumen previously mixed with its own volume of water, and shaking the whole vigorously for a minute or so in a bottle of much larger capacity than the quantity of liquid. Upon allowing this to settle, the coagulated albumen will carry down with it all the turbidity; or the solution may be at once filtered, and will pass perfectly clear and bright.

The best preservative, however, in my own opinion, is albumen, because, while it is practically without influence on the working of the emulsion, it gives a beautifully hard coating, which is easily removed in the course of development owing to its solubility in water, and especially in alkaline solutions. The strength of the solution may be about one to three or four, or say the whites of four eggs made up to a pint with water. The method of mixing is important in order to obtain a clear solution. If the eggs be beaten and then diluted, the solution will be of an opalescent character, with a quantity of fibrinous particles held in suspension. The latter may be filtered out, but the turbidity will only disappear after many days' keeping, when the solution will have lost some of its value as a protective agent.

If, however, ten or fifteen drops of ammonia be added to the albumen in a capacious jar or glass measure, and the requisite quantity of water be added, and then gently stirred until the whole is thoroughly mixed, the solution may be at once filtered through bibulous paper, and will pass perfectly clear and bright and ready for immediate use.

Gelatine may be used instead of albumen if preferred, and will be cheaper, but it is not so easily removed, if that be a desirable point, as I think it should; and it requires to be applied hot, the plates being warmed also. Any good white gelatine may be used, and the strength should be about ten grains to the ounce of water, very carefully filtered before use.

Any of these solutions may be applied to the plate after the soluble nitrates have been thoroughly removed by washing, a small quantity being first flowed over the surface, and thrown away or returned to a separate vessel to be refiltered; a second quantity should then be poured on and allowed to remain for about half a minute, when it is poured off, to be refiltered before being again used, and the plate reared up on edge to dry. In the case of gelatine, the solution itself should be warm, and the plate, just before its application, should be dipped for a moment into a vessel of hot water in order to avoid chilling the gelatine, which would conduce to irregularity of coating.

I anticipate, however, that the great majority of those who prepare their own plates—even of those who make the emulsions themselves—use the washed emulsion, the convenience of which is undoubted. Here the preservative solution is useless, although the application of the preservative is still possible by dissolving it in the emulsion itself. If the latter is in perfect condition, there need be no fear of injuring

its working properties or of materially affecting the character of the results. In years gone by preservatives, or "organifiers," were commonly added to washed emulsions, in the vain hope of imparting qualities they did not originally possess, but the advantages of such additions, or any change of a chemical nature they produced, were, I fancy, more imaginary than real. Their mechanical action, however, cannot be disputed; in fact, it is a very easy matter to overdo the thing and render the films so hard that they will not develop.

Here, again, tannin proves a useful agent where but a slight hardening of the film is required, and it will be found also a most convenient one on account of its ready solubility both in the collodion and in water. It may be added to the emulsion in the proportion of from three to five grains to each ounce. Though before solution it presents a powdery and somewhat crystalline appearance, it dries up to a smooth varnish-like film, and gives to the collodion surface a hardness it does not possess alone.

Balsam of tolu is another useful addition for the same purpose, and in the same proportion as tannin. It gives greater hardness, but it is far less easily soluble, and consequently renders a longer application of alcohol to the film before development absolutely necessary. The alcohol, too, may with advantage be used undiluted, instead of mixed with water. This point attended to, no trouble will be experienced from want of penetration of the developer.

W. B. Bolton.

LANTERN MEMS.

There is so much already known about the optical lantern and its manipulation, that it is difficult to give information that shall be of service to the "old hand" at operating; at the same time, many who are not *au fait* may find, now and then, a hint in these paragraphs that are useful. They are, as a rule, the results of queries asked by lanternists during the month, or items of novelty or interest.

* * * * *

A popular error, or one I have found to exist in several instances when compressed gas and automatic regulators have been used, is to leave the taps of jets turned on, as one did when the gas was used direct from the cylinder, and regulate the light by the screw valve of the cylinder. This plan is altogether wrong, for it neutralises the value of the regulator. The course to adopt is exactly the same as if the large gas-bags of old were employed, viz., to have all taps of apparatus turned off, then turn on the valve of cylinders (half a turn or so), and turn on the hydrogen tap a little, light it, and after lime cylinder is warm turn on the oxygen slowly, then more hydrogen, and again more oxygen alternately, until the best light is obtained without hissing or roaring.

* * * * *

The conditions in respect of the use of compressed gases from cylinders and that from bags is so opposite, that the jets constructed for the latter are not nearly so good as the modern ones for the compressed gas system. With bags, the key-note of experts was, "A free way," without obstruction of any kind, in the jets, pipes, or india-rubber tubing, which was preferred large. Now it is found necessary to interpose something in the mixing chamber of jets that shall cause the gases to intermingle, and so either alternate discs and gauze, or particles of pumice, are fitted under the nozzle, so as to stop back or check the flow for the moment, to ensure proper mixing.

* * * * *

This will be understood when the difference of working pressure is considered, for the maximum with the bags usually represented ten or twelve inches of water pressure, while that from the regulator or gas cylinder is about thirty-six inches of water pressure. As this extra pressure, properly utilised, means an increased light, it is natural that operators should desire to avail themselves of it. A jet with a good mixing chamber and coned nozzle, or one with a long, swan-like neck, can be used with a larger nipple without noise, and consequently a better light obtained.

* * * * *

The incandescent "focus" electric light lamps have now been in operation four years, and I recently heard from one professor who finds this system of demonstration so satisfactory that for ordinary class work he never thinks of using any other source of light for his optical lantern; and, moreover, where the electric light is laid on, and only ordinary photographs or temporarily prepared transparent dingrams or formulæ required to be shown, it is quite powerful enough, requires no special attention after once setting, and the light is switched on and off the lantern, or the class room darkened or lighted at will.

* * * * *

When one reflects how readily the whole system of electric lighting is controlled in such places as the Royal Institution, the Society of Arts, and our large theatres, one can only hope that the day will soon come when the generation and distribution of electricity will enable every private householder to take advantage of the current at no greater cost to himself than the same amount of illumination derived from gas now costs.

* * * * *

A little bird whispers there is to be a new and simple arc lamp placed on the market shortly that will answer nearly as well, if not quite, for all lantern purposes, as the comparatively expensive ones that have, during the past few years, proved successful in the higher class of optical projections.

* * * * *

Those who saw and were delighted with Muybridge's Zoopraxiscope should not fail to "put a penny in the slot" of the machines at the Electric Wonder Exhibition in the Strand, near Bedford-street. The remarkably natural movements of the various figures showing ladies dancing, horses jumping, men vaulting, cavalrymen trotting, infantry marching, &c., as seen visually through an eyepiece (in some cases aided by magnifying lenses), only makes one desire more to see this principle of Anschütz's Tachyscope developed so as to be optically projected on a large scale.

* * * * *

There is, no doubt, a splendid field open to photographers and lanternists in the way of perpetuating and reproducing lifelike movements, and, if our scientific men and mechanicians set their brains and hands to work, possibly before very long, an instrument will be designed and constructed that can be used in the ordinary optical lantern to show photographic moving figures, to the delight of the audience far in excess of that created by the old zoetrope, or wheel of life, and the chorentoscope, which, however, are both pleasing and interesting still in their way.

* * * * *

The modified form of zoetrope has some of the designs from life, and being reproduced on a film instead of glass are not likely to break. The necessity of photographing these figures small, on account of the number to be included in the three-inch circle, renders them a little less effective perhaps than if they could be larger, but they are, nevertheless, very entertaining; besides which, the mechanical slide and designs are sold at a moderate price. If one could preserve the successive motions of the figure moving with about half the number of separate reproductions of the design, they could then be larger, for now there are something like twenty-four figures of, for instance, the hoarhound running, to illustrate the movement in its entirety, and showing apparent progression.

* * * * *

Something on Mr. Muybridge's plan would do capitally, for he could alter it at will by the slotted disc used with the disc having on it the photographic designs, and make the figures apparently progress or go through their movements in one position, or make a retrograde movement by having a similar number of slots to designs, or one more or one less. If Mr. Muybridge could now see his way to let some good house in the optical world reproduce his patent apparatus, I feel sure it would not only develop a new field of work for photographers, but also make a distinct novelty for many entertainers.

G. R. Baker.

ON THE VENTILATION OF OPTICAL LANTERNS.

Perhaps at no former time has the optical lantern been so largely taken advantage of for the purpose of illustrating lectures as at present. The extraordinary increase of photographic societies has

brought out so many amateur lecturers in nearly all large towns and cities, until it may be said they are as plentiful as blackberries. With this addition has come some new features in the way of lecturing, or, as some choose to term it, lantern entertainments.

For a long time it was generally considered that the proper duration of time for a lecture or entertainment to occupy was from one hour to one hour and a half, less than this being looked upon as insufficient to satisfy an exacting audience; while, if the longer period was exceeded, the audience began to tire, and show signs of impatience on the score of having too much of a good thing. To fill up such a period of time, a subject embracing somewhere from sixty to eighty slides was considered sufficient in the way of illustrating a lecture, so as to permit of a well-arranged description to each representation, or slide shown. With such a number of pictures to put through a lamp in such a space of time, and working into the hands, or to the call of a lecturer of experience (who knows how essential to success it is to frame his remarks so as to give a convenient time on each slide), an operator used to find the manipulation of a biunial lamp a work of pleasure, and had no difficulty to dissolve off and on from top to bottom. Somewhat recently however, out of the ranks of so many amateurs who consider they know all about lecturing and the working of a lamp, "but who, in reality, would cut a sorry figure were they called upon to officiate at the jets," has sprung up a number of those who entirely ignore the necessity of giving an operator a sufficiency of time on each slide before they call for the next; and hence it is now by no means an uncommon occurrence to find lectures embracing a series of two hundred slides over a space of close on two hours' duration.

The outcome of this is that a new method of working a double lamp has come into vogue, and now, instead of the old practice of a somewhat slow method of dissolving, it has become necessary by experienced operators to resort to the expediency of keeping both lamps full on, and making the change from one picture to another by means of the hand and the cap of the lens, the hand being slowly moved across the lamp that is showing, and finally blinding off by placing the cap on the lens. By this means a great many slides can be run through a double lamp in the course of an hour and a half or two hours. Of course, the method means the consumption of a much larger quantity of gas, but nowadays it is cheap, and an extra quantity is seldom grudged. The method works exceedingly well where a large number of pictures have to be shown; but it has one great drawback, viz., the excessive heat generated by both jets burning full on simultaneously for such a great length of time, and therefore, in course of a short period, a lamp of the modern type gets pretty well knocked up, not to speak of the damage to condensers and slides.

Opticians, as a rule, are never slow at keeping pace with the times, and, in the near future, we are likely to see more attention paid to the ventilation of biunial lamps, for that much may be done in the way of causing a continuous flow of air to pass in and out of a lamp when being so used is already a *fait accompli*.

Quite recently I had the pleasure of inspecting a lamp on the premises of that veteran optician, Mr. M. Edwards, of 200, Sauchiehall-street, Glasgow, so long the senior partner of the business firm of James White. In this matter Mr. Edwards is likely to be the pioneer of a new system of ventilating optical lanterns. Being anxious to test personally the efficiency of the ventilating arrangements as applied to this lantern, Mr. Hassard, the manager of the firm, at once placed the lamp at my disposal, and made the fullest arrangements for a severe test. I have seen this lamp burning two blow-through jets continuously for two hours straight away, and at no time could it be said that the heat was excessive, but, on the contrary, showed a marked improvement over the common form of lamps. Mr. Hassard speaks in glowing terms of the comfort of working with such as against his experience with what he terms other furnaces.

In outward appearance and size this lamp differs but slightly in form from an ordinary biunial lantern; it is supplied with doors at both sides, and the top compartment is entirely separated from the bottom by means of a metal plate, which cuts the lamps into two chambers, *i.e.*, a metal plate divides the lantern in the centre. The ventilation is derived by the insertion of gutters running the entire length of the lamp. These gutters are light tight, but the bottom one takes in air, and by the top one passes it out in a heated form.

The top gutter on the bottom lamp is placed just below the dividing plate, and the heated air from the bottom jet is thus carried away outside the lamp, and never gets into the top lamp at all. Any one placing the palm of the hand up against the outside of this gutter would be surprised to feel the amount of heated air which is thrown out by means of it.

Immediately above the dividing plate of the top lamp is a similar intake gutter, and this is constantly taking in cool air, tending in a wonderful degree to keep the top lamp cool, the heated air passing out by another gutter and by the ordinary top of the lamp.

This arrangement works most admirably, and seems a distinct step in advance in the matter of ventilating optical lanterns.

T. N. Armstrong.

ETHER SATURATORS.

Mr. E. Purton who, in a letter published on page 24 of the Lantern Supplement for December 2, speaks of "snapping and hissing" as "troubles with which all users of the ether light are, unfortunately, only too conversant," and describes a single tube saturator as an improvement upon forms in use, may be informed that a single tube saturator, the construction of which I patented five years ago, was used in illustrating all of the lectures at the Franklin Institute for two years, during which time not a single "snap" occurred, and the smoothness and reliability of the light was so remarkable that the lantern service received special official commendation.

The gas passage in the instrument described by Mr. Purton is no longer than would be possible with my own much simpler construction in a tube of the same diameter and is therefore distinctly retrograde, because more complicated and expensive. The absence of means for removing the filling to dry it out occasionally is also a fatal defect if anything but purified light petroleum ether is to be used in it.

F. E. Ives.

CHARITABLE LANTERN ENTERTAINMENT SOCIETY.

This Society, which was inaugurated last October for the purpose of giving free lantern entertainments to the inmates of our hospitals and similar institutions, has recently given entertainments at the following London hospitals:—

November 15, Temperance Hospital, Hampstead-road, N.W. (Women's Ward; Men's Ward). November 26, Victoria Hospital for Children, Chelsea (Girls' Ward). November 30, North East London Hospital for Children, Hackney. December 3, Victoria Hospital for Children (Boys' Ward). December 9, Children's Hospital, Great Ormond-street. December 12, Paddington Infirmary (Female Ward). December 15, North East Hospital for Children.

In every case the entertainments were very successful and much appreciated, a request for another "show" later on usually following the conclusion of each. As a rule a little music is given between the different sets of slides. The society gives, thus early in its career, two to four entertainments each week at London hospitals, and has dates fixed for infirmaries and ragged schools, and it is intended to generally extend the scheme in similar directions, but at present it is somewhat hampered in its work owing to lack of sufficient apparatus and workers. Two biunial lanterns and fittings and oxygen gas bottles are urgently needed, as well as slides.

In laying this first report of the Society before the public it is hoped that those readers who sympathise with the objects of the Society will do what they can to assist it, either by becoming members or making a donation to the funds, or by the gift of apparatus, or the loan of slides.

The joint secretaries are: Mr. B. Foulkes Winks, 2, Pretoria-avenue, Walthamstow; and Mr. F. Simmons, 158, Frances-terrace, Herne-hill Hill, S.E., to either of whom communications should be addressed.

MR. W. I. CHADWICK ON "LANTERN EXPERIMENTS."

Before the South Manchester Photographic Society, on Monday, December 26th, Mr. Chadwick read a paper and gave a demonstration of the capabilities of the optical lantern, which instrument, Mr. Chadwick said, was now recognised by all science teachers as one of the most valuable at their command. But, of the thousands possessed by amateurs for private and home use, few were ever used for any other purpose than showing slides on a screen. "We may entertain our friends at home with a miscellaneous collection of slides—holiday reminiscences, or wanderings in a foreign land—and when our store of slides has been exhausted there are scores of thousands of others to be obtained by purchase or hire. Indeed, so many are there, of all places and all subjects, that it is not surprising to hear of people becoming confused with the variety when looking through some trader's catalogues, and in not a few cases people had been known to become quite demoralised in their selection, and to finally decide upon, say, five or six dozen comic slides.

A Ragged-school Entertainment.

"Not very long ago the superintendent of a ragged school called upon

me, and I promised to give a lantern exhibition at his school. We had some talk about the class of audience and the nature of the entertainment. 'Bring plenty of comic slides, something to laugh at,' said he. But I had my own ideas about that, and persuaded him to leave the selection to me. When the time arrived I found that my audience consisted of about 300 to 400 boys and girls, from twelve to twenty years of age. I told the superintendent and some of his committee who were present that I intended to test the taste of the boys and girls, and to educate them, if possible, to a higher standard, and I started with 'Half an Hour at the Seaside,' a popular scientific lecture.

"'Half an Hour at the Seaside.'

"The slides were very pretty pictures, and I talked to them about the seashore, the clouds, and the sky, the salt water and the seaweeds, the pebbles and the shells, cockles, mussels, the crab and shrimp, and so on; and then we went to sea in a fishing smack, and, after landing our fish, we saw it being sold by auction at Grimsby Docks, then packed in boxes, and finally we found ourselves at the Manchester Wholesale Fish Market. I then told my audience that the next few pictures would speak for themselves. They were of two distinct kinds, and would be shown two of each kind together alternately. The first two were most beautiful photographs of snow and frost, the second two comic pictures, followed by two statuary slides, and then came two more comic, some things to laugh at, but nobody did laugh. I further explained that they could have plenty of either kind, and it was for them to say which they liked best, the pretty pictures or the comic. They decided by an overwhelming and almost deafening majority in favour of the pretty pictures and 'more seaside.'

"'More Seaside."

"Then I gave 'Dick's Dive in a Duck-pond,' and concluded the exhibition with a few photographs of trotting horses and other animals in motion, shown by a wheel-of-life adapted to the lantern, and I have every reason to remember that audience as a most appreciative one. When all was over I asked the Superintendent what he thought. Here, I said, I have given two short scientific lectures, shown over eighty scientific slides, and only six comic slides, which latter were not appreciated. Now this is a lesson that might be carried away in hundreds of cases. Science need not be dry, nor uninteresting, nor difficult to understand. On the contrary, it could by aid of the lantern, be made a source of endless entertainment and instruction, and the lantern, when properly constructed, lends itself to almost every branch of science. By it experiments and demonstrations to our friends at home may be conducted with far less expenditure in apparatus and material than by any other method. It would be out of the scope of the present communication to enumerate the home experiments that may be performed even with an oil-burning lantern and a few accessories that are easily made or purchased for a few shillings.

Books on Optical Projection.

"But, How to begin? Well, there are plenty of books published on the subject of optical projection, and a new one, just published, *Sunshine*, by Amy Johnson, L.L.A., F.R.A.S., is a delightful lantern book, comprising a series of about forty popular experimental lectures on science delivered to young people, with special considerations for optical projections. Indeed, there is a section of the book devoted to lantern projection, with practical hints and home experiments. Another charming little book is *Soap Bubbles and the Forces which Mould them*, by Professor C. V. Boys, F.R.S. This book also contains a section of practical hints to the lanternist for making and projecting those interesting and fascinating playthings of our boyhood, soap bubbles. The author also describes other experiments, 'so wonderful and yet so simple that, if they had been performed a few hundred years ago, the rash person who showed them might have run a serious risk of being burnt alive.' Lastly, *Science at Home*, a pamphlet by the late W. B. Woodbury, is recommended as containing a number of beautiful lantern experiments, all of which may be easily performed in our own family circles by the merest tyro.

The Lantern Itself.

"Respecting the lantern itself, much might be said in favour of limelight, though for home use a good oil lamp—one that does not smell or burn like a roaring furnace—is very convenient, and answers most purposes if the screen be not too large. A good opaque screen, about four feet six inches square, was generally large enough for home use with an oil lamp; but in a large room—still using the oil lamp—a translucent screen of about the same size would be better; and it might be worth while to mention that only a few days ago a most successful exhibition was given to an audience of over 200 people on such a screen—three feet six inches square—with an oil lamp, and it will be seen that had the pictures been projected to seven feet by the same luminant, the illumination would only have been one-fourth, because seven feet square is four times the area of three feet six inches. By using compressed oxygen in cylinders, as now supplied commercially, there is practically no danger in using the limelight, and it might truly be said to be as safe, or safer, than a paraffin lamp."

Various Experiments.

Mr. Chadwick then proceeded to exhibit a number of experiments. A wire stand was made to support a thin metal plate in a horizontal position (edgeways to the condenser), and under it was placed a spirit lamp. In a few seconds the plate became quite hot, and then a single drop of water was allowed to fall upon the hot plate. The drop of water at once assumed the spheroidal form, and on the screen it could be seen separated from the plate by a film of vapour. The spirit lamp was now removed, and as the plate cooled the drop of water burst into steam and was gone. This beautiful experiment illustrated a frequent cause of steam boiler explosions. From suddenly letting off steam the water in the boiler assumes the spheroidal form, and a thin film separates the water from the boiler, which latter rapidly heats. The engine-driver or the fireman, thinking his water is getting low, pumps in cold water. He thus cools the boiler, destroys the spheroidal form, and the accumulated heat, suddenly converted into steam, bursts the boiler. A long focus lens is best for showing this experiment. The same experiment is often seen in the kitchen, when cold water is put into a hot frying-pan, and the water runs about in 'blobs.' This was followed by experiments illustrating the retention of images on the retina by pieces of perforated card placed in the lantern. White spots were seen on a dark screen. After a minute the light from the lantern was shut off, and the screen dimly lighted from a gas bracket in the room. The audience saw the spots now reversed and quite black on a white screen. When a photographic negative of a portrait was projected on the white screen and looked at for a minute, the portrait was not always recognisable, but directly the light was shut off the image was 'seen' as a positive and at once recognised As some one once said, 'You see it when you don't see it, and then you do.' A number of experiments in colour were next performed, producing the complementaries, followed by some most interesting optical, chemical cohesion, and adhesion experiments. By what is known as the vertical attachment applied to a lantern other experiments were produced, including the motion of camphor upon the surface of water. A number of thin shavings of camphor were delivered to the water surface and projected on the screen, when they were seen, much magnified, rotating and twirling about in manner extremely interesting, but not unaccountable, for the motions of camphor are now well understood by scientists. It was also shown that camphor was not the only substance that produced similar motions under similar conditions. The lecture was brought to a close by a number of ingenious mechanical arrangements. A chameleon was made to show changes of colour; primary colours produced white light; and, by a wheel of life adapted to the lantern, the motions of trotting horses, birds on the wing, and other animals in motion were shown upon the screen.

A VARNISH FOR COLLODION LANTERN SLIDES.

A correspondent writes: I have been making a series of experiments to find out the best varnish for collodion lantern slides. I have tried nearly all the published formulæ, including Mr. Armstrong's acetic solution of gelatine, but the best one which I have used is as follows:—

Tunny's impervious varnish	1½ ounce.
(This is a saturated solution of amber in chloroform.)	
Pure benzol	1½ "
Gum damar	¼ "

When dissolved, to be filtered through cotton wool.

This varnish runs on the plate as freely as collodion does, without the tendency to coat your fingers and back of the plates like most other varnishes which I have tried. It dries hard with a gentle heat, and is not tacky, and it renders the film quite bright and glass-like.

LANTERN SLIDES BY THE WET-COLLODION PROCESS.

[Holborn Camera Club.]

Processes for the production of lantern transparencies are almost as numerous and varied as those for positive paper prints.

When we come to reckon up the various adaptations of collodion, with the bath and in emulsion, with the numerous variations in gelatine (as in

commercial lantern plates, carbon tissue), and the photo-mechanica methods (as in Woodbury and Stannotype), even setting aside these latter processes which, owing to their mechanical element, are beyond the ordinary worker's capacity—disregarding these, we may safely assert that there is as great a field for choice of process as in paper printing.

It is not my intention to-night to open a discussion on the merits or demerits of either one of these processes as compared with another, but I shall endeavour to demonstrate one of them here before you—a process that has stood that most severe of all tests, the test of time, one which, as I will endeavour to show you, can be made to something like answer to the will of the operator. It is the wet-collodion process, pure and simple.

Perhaps you may say, Not much of the latter; but I certainly think that, with reasonable and proper care taken in the various operations, and a fair knowledge as to the properties of the chemicals employed, it will be found simple enough; and, as to the quality of results obtainable by its aid, I don't think much need be said, for the characteristic qualities of a good collodion slide are familiar to most of you, qualities which have long since become standards.

Before commencing my demonstration it will, perhaps, be well for me to give you a rough outline of the process and the chemicals employed, so that you may be better able to follow the method of procedure when I come to demonstrate its working.

Cleaning the Glass Plate.

The first thing to be considered is *the glass plate and its cleaning.*

Assuming that old glass (such as spoiled lantern plates) is to be employed, the first thing to be done is to remove the films, and this can readily be accomplished by the aid of hot water and soda. After this operation it is well to weed out the scratched glass, which should be rejected.

The selected plates are now put one by one into an earthenware jar of hydrochloric acid and water, about one part acid to three parts water, and in this they should be allowed to remain at least twenty-four hours.

It is a good plan to make this jar of acid a receptacle for glass for future use, to be drawn upon as required.

To ensure its perfect cleaning, each plate, before the acid is rinsed from it, should be laid on a piece of rough flannel (such as house flannel) on a flat surface, and both sides subjected to a vigorous rubbing with a pad of the same kind of material. It can now be well rinsed under the tap, and, having ascertained by means of the finger nail which is the polished side, place it in a rack to drain, putting that side in a certain direction for future guidance.

The Substratum.

Having gone through the batch, they are now ready for coating with a substratum of albumen. This is made up of

The white of	1 egg.
Water	1 quart.
Ammonia	5 drops.

which must be beat up to ensure perfect desiccation of the albumen, and then filtered.

After draining, and while still wet, this preparation is flowed over the polished sides of the plates, and they are again racked to dry, care being taken to place the albumenised surfaces in one direction, for, if this operation is properly performed, it is very difficult to distinguish one side of the glass from the other.

Dust being the greatest enemy to successful working of the wet-collodion process, very great care is needed to guard against it, and at this stage (a drying cupboard not being at hand) the precaution necessary is that the rack be carefully and completely covered over with tissue paper, and the place on which it stands well wiped with a damp cloth.

The drying should be done as quickly as possible, that is to say, within an hour or two. It is even convenient at times to use an oven for this purpose, so that it can be done in a few minutes when plates are wanted quickly.

Coating the Plate.

The plates are now ready for use, and can either be packed film to film or stored away in grooved boxes until required.

The next operation being coating with collodion and sensatising, which has to be performed in the dark room, and here I would say by all means have plenty of light. This sounds paradoxical; but, as photographers are becoming used to this seeming absurdity, I need not excuse it here, especially as it is sound advice, but as oft disregarded as given.

Before, however, saying anything about the operation of coating the plate, we have to consider the very important question of the collodion to be employed. My advice is, to begin with, Buy it. You may be led on to make it at some future time, but this is best for a start under any circumstances. Either Mawson's or Thomas's plain collodion are good and reliable.

Before use, these, of course, have to be iodised—that is, iodide and bromide salts, usually of ammonium and cadmium, are mixed with it. These salts being acted upon in the film by the silver bath are converted into iodide and bromide of silver, thereby making the plate sensitive to white light.

A suitable iodised collodion for transparency work from a negative o medium density is made as follows:—

Ammonium iodide	3 grains.
Cadmium iodide	½ grain.
Ammonium bromide	2½ grains.
Plain collodion	1 ounce.

This should be made up several days before use, and will keep good for perhaps a couple of months. Upon first mixing it will probably go to cherry colour, but will become paler in a day or so, straw colour indicating its fit condition.

Coating the plate is much easier demonstrated than explained, so I shall say but little upon it further than that it is done in exactly the same way as varnishing (without, of course, warming the plate), and is as easy to perform.

I might, however, mention one or two of the precautions generally used in connexion with this important operation. (1) Pour the collodion from a bottle with a broad lip. (2) Do not have the bottle more than half full. (3) In pouring hold it so that the lip nearly touches the surface of the plate, and (4) pour as little more than enough to go over the surface of the plate as possible. A separate bottle should be used to receive the drainings from the plate, for the same reason as in varnishing a negative.

When the collodion ceases to drip from the corner of the plate (which, by the way, should not be rested in the mouth of the bottle), the plate should be brought to nearly a horizontal position and slightly rocked till the film is set by the evaporation of the ether. The time required for this will, of course, vary according to the temperature of the room, say, from half to one minute.

Sensitising.

The plate is now ready for sensitising, and the silver bath for this purpose is made as follows:—

Nitrate of silver (recrystallised)	1 ounce.
Distilled water	12 ounces.
Potassium iodide	1½ grains.

This should be kept in a clear glass bottle and well sunned before being brought into use, or, in other words, exposed to sunlight for some hours. This will cause any impurities in the form of organic matter to precipitate, so that same can be filtered out, which must be done.

The bath has now to be made slightly acid, if not so already, and this can easily be ascertained by testing with blue litmus paper, which should slightly redden in about one minute. If it does not, add two drops of pure nitric acid to the bath. The bath improves with age for this kind of work, and can be strengthened when required by the addition of a forty grain solution of silver nitrate. The strength of the bath itself should not exceed this.

Sensitising the plate is the next operation, and this will take from three minutes in summer to five minutes in winter. With regard to apparatus, I would here recommend that the dipper be a broad glass one, so that the plate on immersion can be freely moved about for the first minute or so without the chance of its falling off. This movement is absolutely necessary to prevent uneven sensitising.

The plate should be withdrawn slowly, drained on a pad of clean blotting-paper, and the superfluous solution wiped off the back. It is now ready for the dark slide, into which it should be put in a nearly vertical position, the corner from which the collodion was drained being downwards.

I might here mention that this particular corner must always be kept down, that is to say, during the sensitising and draining of the plate after exposure till development.

About exposure I do not intend to say much, as it is such a thing of circumstance; but, as a guide, I might say thirty seconds will be found about right for a negative of medium density, using stop *f*-8 at mid-day this time of the year, that is against a clear sky, reducing from half-plate, and using the collodion as I have given.

Development, &c.

With regard to developers and development a volume might be written, but I think the present case will be better met by my giving you but one formula and a few hints on working than by going deeply into this very

controversial matter, especially as my purpose this evening is more to demonstrate than talk.

The developer which I shall give you is the one I am about to use to-night. It is made as follows:—

Ammonia sulphate of iron	15 grains.
Glacial acetic acid	15 minims.
Water	1 ounce.
Alcohol	*quant. suff.*

This compound salt of iron and ammonia keeps well, made up, and gives a very fine, rich, and transparent deposit—qualities so essential for this work.

In developing, the plate is held in the hand, as in coating with collodion. I might almost say that this itself is a coating operation in which you eventually wash the coating off again.

About a drachm of developer is sufficient to cover the plate, and this should be flowed from side to side by gentle rocking, and without letting any go over. This, of course, will require a little practice at first. To cause the developer to flow freely over the plate it is necessary to add a drop or two of alcohol an ounce to it. This will have to be increased as the bath gets older.

When the image has attained sufficient density by transmitted light (by which it should be viewed during development), wash off the developer without delay, and after a good rinsing fix in a bath of—

Cyanide of potassium	25 grains.
Water	1 ounce.

Being a deadly poison, this, of course, has to be used with great caution. The method I adopt is, I think, a good one. The cyanide pour out into a lantern plate (dry) developing dish and immerse the plate in a metal holder, which grips it by the edges, and in this holder I subsequently wash the plate under the tap after fixing is completed, so that I have no need to touch the cyanide with my fingers at all.

Fixing is complete in a few seconds, after which the plate must be washed immediately, or delicate detail may be eaten away.

If the tone of the resulting picture be not to your liking, it can be toned to a simple black in a bath consisting of—

Chloroplatinite of potassium	2 grains.
Water	5 ounces.
Nitric acid	5 drops.

I think I have detailed to you a fair outline of this process, so will now, with your kind permission, do my best to demonstrate something of what I have been telling you, filling in details here omitted as I proceed.

You will see even from this outline that there are no instructions on the box with the wet-collodion process. Nevertheless, with careful working, perseverance, and Captain Abney's Instruction-book, all of which are indispensable, it will be found by no means so difficult to master as a good many have been led to suppose. J. F. Stavens.

RECENT NOVELTIES IN LANTERN APPARATUS.

The Blackfriars Photographic Company, of Surrey-row, are represented in lanterniana by a variety of lanterns, extending from the cheap tin variety, which may be had complete at a cost calculated to accommodate the most exiguous purses, through various grades of quality, to the most handsome and serviceable single and double mahogany-body instruments, suitable for either oil or limelight. The Company, who are agents for Griffiths' lantern slide making camera, also include slides and accessories of all kinds in their lantern department.

We have received the Lantern Catalogue of Mr. W. I. Chadwick, of Manchester. Therein the lanternist will find particularised a considerable variety of lanterns, details as to cylinders, regulators, gauges, objectives, condensers, carriers, lantern-slide accessories, saturators, oxygen generators, screens, desks, tripods—and, in fact, the entire paraphernalia of the modern optical lantern, selected with the skill and judgment which we are entitled to expect from Mr. Chadwick's long practical acquaintance with all that concerns the lantern. In addition to the lantern proper, the lantern microscope and polariscope, and apparatus for scientific projections generally are dealt with. To the purchaser, Chadwick's catalogue should be a useful guide; to the student, a fund of information, as it includes reprints of many of Mr. Chadwick's lantern papers.

LANTERN-SLIDE MAKING IN FOOCHOW.

At a recent meeting of the Foochow Camera Club, Mr. Menearini, the Hon. Secretary, gave a lecture on this subject, in the course of which he said:—Lantern shows, or, as commonly called, "magic lantern exhibitions," have become so very popular, that I thought a demonstration of how these entertainments were made would be interesting to you. I have therefore come forward not as an inventor of some "Menearini patent," but simply as a narrator of what I have learnt myself of this fascinating pastime from books, periodicals, and a little experience.

We all remember our younger days, when to be taken by our parents to a magic lantern show was as great a treat as to be given a piece of "butter-scotch." How many times have we gazed delighted on those large pictures, shown us on a white sheet, and wondered how they were done, and what a respectful admiration we had for that man who could show us such wonderful things? Well, now, any one, with but little work, can produce those "magic pictures."

Great are the advantages of a "lantern show;" it delights and instructs the juveniles more than at first thought would seem. And so much am I convinced that it does instruct that, if I should have it in my power, I should make it compulsory for every schoolmaster to have a magic lantern, and give, at least once a week, an exhibition, showing some of the superior slides which can be purchased on any subject required at a very small cost. By further explaining the subjects, geography, natural history, astronomy, &c., could be taught, and be impressed more on young minds than by hours of poring over books, which, in many cases, are not understood, and which are repeated as by parrots.

Very much has certainly been done in this line; scientists and public speakers have been convinced of the enormous advantages there are in using the lantern to illustrate their papers. What would require a long explanation, and then would not convey to the mind a perfect idea of the subject, with the aid of a magic lantern and a photographic lantern slide, can be shown to a large audience one hundred times larger than nature, and with all its details.

Photography has been rendered so very simple that I cannot understand how every man or woman having a spare moment does not make his or her own pictures. How many are the occasions when, if you had been able to take a photograph, you would have had pictures of places dear to you, and which are bound to bring agreeable recollections in days to come.

For a comparatively small sum you can purchase an outfit, and surely you can always find a kind friend who could explain the mysteries of this most entertaining and useful of pastimes? and I can assure you that, although it is many years since I dedicated my spare moments to photography, still I find there is such a fascination when watching the exposed plate being developed, especially if the negative has been correctly exposed, and the development proceeds gradually and the result is a good brilliant negative, I know not how to express the intense satisfaction it produces.

But I observe I have deviated considerably from the object of my theme. I shall now come to the point.

Of course, the principal thing you must have for slide-making is a good negative; this can be of any size desired, but should be, to give good results, clear, crisp, and full of detail.

There are two ways to produce lantern slides, one is by contact—that is, the film side of your negative and the film side of the lantern plate are placed back to back in a printing frame, and exposed either to day or lamplight. Usually for this kind of work the negatives are on quarter plates; but I have seen lantern slides made from other sized plates when only part of the negative was required.

The other way is the most used, and this is by reduction with a copying camera. Better results are given in this form.

Most complicated and expensive apparatus are catalogued by home manufacturers, but, as you may see, my only appliance is simplicity itself. A board, four feet long by twelve inches wide, to this is screwed on perpendicularly another board eighteen inches high, which has an aperture large enough to hold a negative. Opposite this I place the same camera I usually take my photographs with. This is an "Optimus" full-plate, long-focus instrument, to which I attach a Voigtländer rapid wide-angle Euryscope, using a required size carrier in my dark slide.

Having determined on the focussing screen the proper distance between the negative and the lens, I firmly screw the camera on the board, marking the place, and so am saved the trouble of readjusting the camera every time it is required.

I prefer doing my slides in the evening when I am at leisure. The plates I use are Ilford Special lantern plates. I find these and the same manufacturers' white labelled dry plates the best suited for our climate. Wet-collodion lantern plates are preferred by some, and certainly they possess their charms; but dry plates have the advantage to be ready prepared, economising much time, and are so cheap (one shilling a box of a dozen plates) that I do not think it worth while messing about as in old days with collodion, silver baths, &c.

The exposure varies, of course, according to the density of the negative, the light, &c., but the average exposure is about two minutes by lamplight.

To develop, any of the recognised formulæ can be used, my advice being to use the developer specially recommended on the box by the maker. I personally use Ilford hydroquinone developer, and I am very satisfied with it.

After developing and washing, a few minutes in an alum solution hardens the film and clears somewhat the high lights. Do not make the hypo bath too strong, and wash finally for about half an hour.

The slides can be finished by toning with either gold, platinum, or

nranium nitrate, but this is not necessary if the exposure and development are correct. Clouds are printed in whilst exposure is carried on, but are very difficult to work. When the plate is dry it is mounted with a cover glass, placing a lantern mask between the two glasses, and binding them together with specially prepared lantern slide binding strips.

The magic lantern, or, as it is more pompously called, "the optical lantern," can be lighted either with kerosine oil, oxyhydrogen limelight, or by the new Aëro Carbon Incandescent lamp. The picture is better shown on a white wall, but fairly good results can be shown through a thin shirting screen, as I shall presently do myself, showing you first practically how to make a lantern slide, with the flashlight picture made by our esteemed Vice-President, Mr. Rentzsch, and then, after exposing the resulting slide through my lantern, I shall follow on with other slides, some of my own making, others purchased from home makers.

SHIPPING ON THE SCREEN.

Last month, Mr. John Adamson, jun., says the *Yachtsman*, so favourably known to all readers of the *Yachtsman* through the instrumentality of his splendid photographic yachting pictures, lectured in the Queen's Rooms, Glasgow, on "The Rise and Progress of Shipbuilding on the Clyde," for the behoof of the funds of the local branch of the Royal National Lifeboat Institution. The lecture was illustrated by means of something like 201 beautifully prepared transparencies. Many of these were made from negatives of his own, which have now become famous far and near—that is, direct negatives—while others were prepared from copies of carefully kept and faithfully cherished old pictures and prints kindly placed at Mr. Adamson's disposal for the purpose by our leading ship and yacht builders and owners. Shown on a very large screen, and illuminated by a very powerful limelight, they made as interesting objects of the kind as the eye could well rest on, while Mr. Adamson's neat and apposite remarks as the views passed before the audience, supplied all the information necessary for the purpose in the most agreeable manner.

The Clyde folks are very proud of their splendid river-steamer service and all pertaining to it, and this seems to be well-known to Mr. Adamson, for he showed an almost unique collection of views, setting forth their history from the time of the *Comet* and *Industry*—the latter built nearly eighty years ago, at Fairlie, by the father of Mr. William Fife, sen.—to the *Columba* and *Lord of the Isles* of the present day. Great attention was also paid to the ocean greyhounds, both past and present, and few hits of the entertainment seemed to take better than the exhibition of some most perfect views of some of the sumptuous interiors of the marine palaces of the present moment. Mr. Adamson is very strong also in pictures of the huge sailing ships which the Clyde builders have been so busily engaged turning out recently. Several views of one of these—the negatives concerning which were taken when the ship was bowling briskly to sea under full sail some fifteen miles westward of Ailsa Craig—indicated a veritable triumph of the photographer's art. The yachting pictures were simply delightful, and our entertainer is to be complimented on his selection in this department.

Lord Provost Bell, one of Clyde's most accomplished and popular yachtsmen, presided, and earnestly and eloquently he pleaded the cause of the Lifeboat Institution, showing, as he went along, that Glasgow, while a generous giver in connexion with many things, did not subscribe nearly so liberally as she ought to this good cause.

The attendance was flatteringly large, and amongst the goodly gathering were to be seen many of our foremost men, both in shipping and yachting circles; and Mr. James A. Small (a leading Clyde Corinthian), the Hon. Secretary of the Glasgow branch of the R. N. L. I., must have been very pleased at the success which attended the entertainment designed and carried out for the benefit of the cause he loves so well.

Lantern Queries.

A. Rix.—Spent limes are useless.

V. Thring.—Reflectors are not often used for the purpose.

Alfred Peel.—The electric lantern we then described was asbestos-lined.

L. Arbour.—Mr. R. R. Beard of Alscot Road, Bermondsey, would probably be able to make you a lantern to a special pattern.

Seneca.—The position of the light in relation to the condenser can easily be ascertained by practical experiment.

C. Primmer.—You mean, no doubt, a vertical attachment. Apply to a lantern optician.

W. A. Rawson.—Celluloid slides can only be shown by means of a suitable holder or carrier.

Doubt.—Light the hydrogen jet to warm the lime and the lantern before admitting the oxygen.

Lime.—Hard limes for mixed jets and soft limes for blow-through jets are generally employed.

F. Peters.—Possibly your dealer would be able to supply you with coloured lantern masks and binders.

A. J. Fuller.—Better consult your local gasfitter, who would probably be able to supply you with what is required.

S. R. Fenwick.—Yes; printing-out lantern-slide plates are articles of commerce. The Paget Prize Plate Company supply them.

Exchange.—Yes, we shall be pleased to throw open the columns of the Supplement to announcements of articles for exchange in connexion with the lantern.

Oxide.—The only "impurity" likely to be present in the oxygen is nitrogen—which means that you would be burning a mixture of oxygen and atmospheric air. See leader on the subject elsewhere.

Collo.—Yes; the wet collodion process is still extensively employed in the production of commercial lantern slides. Possibly Mr. J. F. Stevens's paper in the present Supplement will meet your desire to know how it is worked.

M. Smiley.—There is certainly no advantage in the use of a seven-inch condenser for showing lantern slides on the screen; but if, as you say, you propose using the same optical system for both projection and enlarging, by all means select the larger condenser.

L. Neighbour.—Special tests for the flatness of field of the objective are unnecessary for the expert professional photographer, who can tell by a glance at the image on the screen whether the objective defines as well as he requires.

Ilex.—The slides may be masked down to a very great extent—a picture of, say, an inch square being quite large enough for projection under the circumstances you mention. The outside dimensions of the plate—that is, $3\frac{1}{4} \times 3\frac{1}{4}$—is the only arbitrary size in connexion with lantern slides.

Rev. P. N. W.—A complete exhibition with an oil lantern and, say, one hundred to two hundred slides of general subjects might be arranged for with the nearest lantern dealer for probably about two pounds. The limelight might be possibly double the amount, but all would of course depend on circumstances. Write to a selection of the firms whose announcements you will find on the outer pages of the Supplement.

We have received the price-list of Messrs. S. & J. Mitchell, of Blackburn. Therein the lanternist and those organizing lantern entertainments will find information of much value.

Messrs. Sharp & Hitchmough, of Liverpool, have submitted to us samples of their "Opaque Lantern Screens," which are prepared with a special flexible waterproof material, perfectly white and opaque. They are cheap, and should answer the purpose admirably.

The agency for the Askew oil lantern, one of the remarkable features of which — as many of the members of the Photographic Society of Great Britain, the Photographic Club, and London and Provincial Photographic Association will remember — was the extreme celerity with which it could be set up in readiness for the first slide, the feat being accomplished by Mr. Askew on one occasion in less than five minutes, has passed into the hands of Messrs. Newton & Co., of Fleet-street.

The Charitable Lantern Entertainment Society meets on the second Thursday in each month at 186 Aldersgate-street (Y. M. C. A.). The following are the officers:—*Vice-Presidents:* J. T. Helby, Esq.; Rev. F. E. White, M.A.; Walter Chetwin, Esq.; Rev. S. F. Bridge, M.A., Surrogate; William Roberts, Esq.; Edward Woodger, Esq., M.R.C.V.S.; William Dixon, Esq.—*Committee:* Messrs. S. G. S. Dicker, G. N. Foot, J. H. Noel-Cox, A. H. Benham, H. Granville Dicker.—*Hon. Secretaries:* Frederick Simmons, 158 Frances-terrace, Herne Hill, S.E.; B. Foulkes-Winks, 2 Pretoria-avenue, Walthamstow, Essex.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*February* 3, 1893

THE LANTERN RECORD.

CONTENTS.

THE SHAPES OF LANTERN-SLIDE MASKS.

The effective appearance of a lantern slide on the screen is so largely dependent upon the exact shape which the picture itself is permitted to have, that we are surprised that this point, unimportant though it may at first sight appear, does not engage the thought and the attention of slide-makers more than is the case. We use the phrase "permitted to have" designedly, because not only is it evident to us that, in numerous instances, a picture is spoiled by the unsuitable shape of the mask, but that those shapes are chosen a great deal at hap-hazard, while we are inclined to think that frequently the picture is selected to suit the mask instead of the mask being chosen to harmonise with the picture, as mounts and frames are.

The shapes of slide-masks in use include the circle, the square, the oval, the vertical and horizontal oblong, the cushion, and the dome. The openings of these shapes vary somewhat in size, especially the purely symmetrical sizes. Indeed, the variation in the sizes of the openings is so great that occasionally, when looking at a slide on the screen and noting the proportions of the mask to the image, we are reminded of the immortal Falstaff's remark as to the halfpenny-worth of bread and the intolerable quantity of sack. And this without reference to the question whether the slide be made by reduction or not.

Certainly large masks are useful as concealing the uninteresting or non-pictorial margins of a slide, but, taken in relation to the full dimensions of the plate, they are an obvious sign of weakness. The shape of opening most generally employed is, perhaps, the complete circle, which, however, to our thinking, is not the most suitable shape to give a lantern picture, inasmuch as one is not conscious of looking at a landscape, a building, a street scene, or, indeed, any view in circular form. Painters seldom paint their pictures in circles, and circular illustrations are not common, so that the slide-maker has little or no artistic support on his side for circular masks.

In looking at a large number of slides on a screen, we have heard people affirm that their eyes are less strained the more the screen is illuminated, and this, if generally the case, would seem to indicate that square or cushion shapes, with the largest possible openings, are the better for common use. As a rule, we should say that, for this and other reasons, the more of a picture that could be shown the better. It may be urged that the use of different-sized masks, permitting of the deletion of uninteresting or inartistic portions of a slide, is a positive advantage. This is undoubtedly so in contact work; but by other methods of exposing the lantern plate the subject can be selectively treated, so that unsuitable parts thereof need not be included in the slide, and masking down obviated. Hence the circular opening need not be a *sine-quâ-non*.

The same objections to circular openings appear to us to apply to the upright oval, although, used horizontally, it accords more with the way in which a view is naturally seen. For landscapes the horizontal oblong accords with the common usage as to the shape of views, and to this, as well as to the upright oblong, the square, and the cushion, there can be little objection. We, however, reiterate our opinion that large openings are, where obtainable, to be preferred to small in the interests of audiences, especially popular audiences, to whom plenty of illuminated screen area is, we have noticed, more acceptable than much-masked-down pictures.

Naturally we are far from saying that, where the use of a circle instead of a square can save a good slide which may have some marginal defect, it should not be used; on the contrary, this strikes us as a legitimate use for such shaped openings. But defects at the edges of a slide are not more frequent than central defects, hence we consider that the circle is used more from want of thought as to its suitability for the purpose. The dome is a shape which we seldom see used by artists and illustrators; and for lantern slides, and, as regards what we should call naturalness of effect as applied to the shape of a screen picture, we might class it with the cushion, the circle, and the oval as merely assuring variety of effect. Whether this is a *desideratum* is open to question. Speaking from our own experience, we should give preference to purely rectangular openings, as fulfilling every artistic requirement and selected with due regard to the composition of the picture. This would imply that the slide-maker, when making his slide, should pay some regard to the shape that would best suit it on the screen instead of, as at present is chiefly the case, leaving that point to be settled at the moment of mounting it.

LANTERN NOTES AND NEWS.

We are often asked for a quick and simple method of preparing an illustration—say, a writing or drawing—for the lantern, without the necessity of having to copy it, and make a lantern slide. We have given the method before, but for the information of recent inquirers we here repeat it. Coat thin glass with benzole varnish to which a few drops of indiarubber solution have been added. The film dries transparent, but it admits of the finest writing being made on it by means of a steel pen and India ink. By superposing the coated glass plain side on to an engraving or picture, an accurate copy of the outline may be made in a few minutes. This plan was originally published by the late W. B. Woodbury.

Instances have recently come to our knowledge where, at lantern exhibitions, slides have been shown which were made from negatives not taken by the individuals who had prepared the slides. We believe it is generally understood that, where lantern slides are shown, the exhibitor, by the fact of the case, is also supposed to be responsible for the negatives. But where this is not so the fact, in our opinion, should always be stated, otherwise great risk of not unreasonable charges of sailing under false colours is run. Lantern-slide making is a fine art, of which the production of suitable negatives for the purpose is certainly not the least important part; and therefore, independently of other considerations, the author of a negative has a clear moral right to recognition by name where a slide made from his negative by somebody else is shown.

* * * * *

Mr. Howard Benham is apparently the owner of several skeletons which he has turned to account by grouping them in amusing attitudes, such as boxing, taking tea, singing, &c., and photographing them. Lantern slides from his negatives were shown at one of the Photographic Club's ever-delightful lantern nights a few weeks ago, and we well remember the mirth and amusement they caused. Singular to relate, when they were afterwards shown at the London and Provincial Photographic Association, they did not raise many smiles, and on Wednesday week, when they formed part of the programme at the Photographic Club's Annual Ladies' Entertainment, they (unless we were greatly deceived) scarcely gave unmixed delight to a majority of the many ladies present.

* * * * *

By the way, at the entertainment in question, the accomplished pianist, Mr. Kepps, as the slides were projected on to the screen, kept up a running accompaniment of music in unison, as far as was possible, with the nature of the subject. Thus, when some views of Newhaven Fishwives were shown, "Caller Herrin" was played, and so on. Messrs. E. W. Parfitt and R. R. Beard worked the triple lantern used on the occasion with the skill we should expect from the conjunction of a clever amateur lanterniist with a skilful professional.

* * * * *

Small tracings on paper or linen are occasionally utilised for projection in the optical lantern, and it may be useful to some to know how paper suitable for the purpose may be prepared. Stout tissue paper is brushed over with a mixture of equal parts of mastic varnish and oil of turpentine, and hung up to dry spontaneously. Canada balsam, thinned by turpentine, also answers the same purpose.

* * * * *

To those lanternists who make their own oxygen by the chlorate method, the following hints for obtaining it chlorine free, which were recommended some years since by a contributor to the Almanac, Mr. W. F. K. Stock, may be of service:—1. The mixture should be finely ground. 2. Not more than one-tenth of manganese dioxide should be used. 3. The gas is made to come off not faster than six feet in twenty minutes. 4. Two wash-bottles of forty ounces capacity each are used. 5. An ounce and a half of dry hypo to be dissolved in the water in each bottle. Mr. Stock said that an old fixing bath, somewhat diluted, could be used for the latter purpose.

* * * * *

In connexion with the foregoing hints, recent analyses of commercial oxygen in cylinders have proved that gross frauds or culpable carelessness are habitually practised at the expense of lanternists by some of those who retail compressed oxygen, so that, unless some improvement takes place in commercial gases, we shall not be surprised if lanternists find it worth their while to prepare their own oxygen more largely than is the case at present. Our report of the meeting of the London and Provincial Photographic Association, at which Messrs. Grundy and Haddon's paper on the estimation of oxygen was given, contains a great deal of instructive reading, which we hope will not be without profit to those who have been indulging in the system of adulteration which those gentlemen exposed in the course of their demonstration.

* * * * *

As illustrating the strange ideas which prevail in some minds as to the manipulation of compressed gases in lantern entertainments, Mr. Birt Acres tells us that not long since, being about to give a display with the lantern in the country, the Secretary of the Society informed him that one of the cylinders to be used contained a mixture of hydrogen and oxygen, and asked, most unconcernedly, whether it mattered? Mr. Acres said (no doubt grimly enough) that it did not matter at all, so long as the cylinder were taken into the open air and the contents thereof set free, which we believe was done. Perhaps it would be well, as Mr. Acres suggested to us, if lanternists about to give entertainments in strange places, and with gases provided for them there, always took means to test cylinders and bags for the nature of their contents before turning the gases into the jets.

* * * * *

Why do not amateur slide-makers take more notice of the minute defects which so often appear in their slides, and endeavour to remove them ere encountering the "fierce light which beats upon" a screen? An enormous proportion of the great many lantern slides we have recently sat under would have been all the better if the negatives from which they had been made had had their imperfections touched out, a remark which also applies to the slides themselves. Recently, at a lantern exhibition where Mr. Redmond Barrett was present with us, that gentleman waxed eloquent over the wide field for the friendly offices of the retoucher which the slides shown presented.

NEUHAUSS' LANTERN WITH PETROLEUM LIGHT AND ALCOHOL CONDENSERS.

Most commercial lanterns, says Ki-Non in *L'Amateur Photographe*, are defective on account of the exiguous dimensions of the condensers. They only illuminate an image three inches in diameter, while the alcohol condensers invented by M. Neuhauss, having a diameter of six and a half inches, project a much larger positive. A pair of lenses of that dimension would cost at least fifty francs, and often have surface defects, without mentioning the greenish colour of the glass, which absorbs a great deal of the light. M. Neuhauss makes his condenser as follows:—To a curved glass vessel of six inches diameter he secures a plate of glass by means of an alcohol-resisting cement (such as the "Crystal Palace" cement), and makes an opening in the curved glass in order to fill the vessel with alcohol, reclosing the opening with a piece of gummed taffeta, which admits of the escape of the gas formed by the changes of atmosphere, and also prevents the loss of liquid during the movement of the condenser.

M. Neuhauss prefers alcohol to water on account of its higher index of refraction, which approaches to that of the glass; besides, the alcohol keeps clear, and does not form air-bubbles even at a high temperature. With water the bubbles adhere to the sides of the glass and absorb a great deal of the light. Besides the two alcohol condensers, he employs a small plano-convex condenser, placed near the lamp so as to shorten the focus of the former, and augment the brilliancy of the light. To avoid the heating of the alcohol the condensers are placed in a box, and the plano-convex lens is secured to the near side of the lamp. Experience has shown that the temperature of the alcohol is only increased a few degrees even after the lantern has been several hours in use. An ordinary petroleum lamp with a reflector suffices, and for objective a portrait lens.

M. Neuhauss recommends for the screen one of paper of the kind used for copper-plate printing, which he prefers to cotton or calico screens. He adds that the whole lantern might be put together very cheaply, as, with the exception of a suitable case and a few sundries, the amateur already possesses the two most important parts of the system—the objective and the petroleum lamp.

Although there is no novelty in the construction of the condensers "invented" by M. Neuhauss, perhaps the few particulars of them here given may be of service to those desiring to make such for themselves.

LANTERN MEMS.

The new railway rates are at present affecting lanternists in the matter of charges for carriage altogether out of proportion to the weight and value of the steel gas cylinders conveyed by the railway companies, and it is a curious anomaly, that if sent by goods train a forty-foot cylinder incurs the minimum charge of 5*s*. for carriage

and 5*s.* for delivery, in all 10*s.* for any distance, as against 3*s.* 3*d.* for the same size cylinder sent by passenger train, even if the journey is 200 miles. In another instance the rates for a cylinder were 1*s.* 8*d.* only by passenger, and 5*s.* for goods (without delivery).

* * * * *

It is sincerely to be hoped that some modification will soon be made in the new rates, for the compressed-gas system has "caught on" to such an extent that it is no longer a luxury to the few, but indispensable to the majority of scientists, lecturers, and entertainers, and, if the railway companies do not arrive at a reasonable "mean" of charges, it will be incumbent on those primarily interested to take up the case and make a collective or representative protest, or present a memorial setting forth the advantages to the community at large and the encouragement of commerce the more extended use of compressed gas is, while prohibitory rates will seriously hamper development and be suicidal as regards their own interests.

* * * * *

The comparatively high price of chlorate of potash gives the companies who produce oxygen gas by the patent process a distinct advantage at the present time, and which is not likely to be modified if the cost of carriage is only reasonable; but if forty feet of gas, costing 8*s.* 4*d.* retail, is to be charged 10*s.* for carriage, the advantages of invention and the development of the compressed-gas industry are likely to be crippled, for the cost of distribution of the gas from the centres (works or agents) will be more than the gas itself—in fact, in the case mentioned, makes the total cost 5½*d.* per foot, without reckoning the return of empties.

* * * * *

Fortunately, a loop-hole is left, and if all who send cylinders by rail will for the present label them to go by "passenger train" the high charge will be avoided. At the worst, however, the consumer will not be paying so much as he used to in the early days of compressed gas; but, as it is a retrograde step, it must be, if possible, altered at all hazards.

* * * * *

This little difficulty with the railway rates sets one thinking as to what could be done if, by some such arbitrary action of the railway companies, compressed gas was not available in the country, and one's thoughts naturally revert to the various methods of using oxygen after making it from (for amateurs) the simplest of all plans—viz., heating chlorate of potash and oxide of manganese. Gas bags are far too cumbersome, inconvenient, and risky, ever to be reinstated, if they can possibly be left where they are—"shelved."

* * * * *

Now is the time for designing a simple gas-compressing machine which should be capable of filling our cylinders to a reasonable pressure—say, thirty to fifty atmospheres—and which any one could use, and which did not require steam or other power beyond manual. If one had a cylinder holding twenty-five feet of gas at 120 atmospheres, he would, at thirty atmospheres, have six feet available for an entertainment, and, if a forty-feet size, then ten feet of gas at thirty atmospheres' pressure.

* * * * *

This machine would be invaluable in the colonies, India, and out-of-the-way places, and also for institutions at home, where assistance is at hand and the necessary time could be devoted to the preparation and compression of the gas, but for the ordinary, and, to a large extent, new class of lanternist that have sprung into existence since the introduction of *cheap* compressed gas; nothing short of the purchase of ready-compressed gas at a reasonable price, delivered by rail or carrier at their houses or place of entertainment, will suffice.

* * * * *

If operators find the limes discoloured after using compressed coal gas, they may know that the gas is not so pure as it should be. The impurity is due to the chemical action on the inside of the cylinder, which produces a reddish rust or deposit, and this, when very bad, is driven through the jet on to the lime. It will sometimes cake in the nipple of the jet and clog it up. Should there be any signs of discolouration, instructions had best be given, when the cylinder is sent to be refilled, to have it "burnt out" before the fresh lot of gas is compressed in it. It is a good plan, on receipt of a cylinder of gas—especially hydrogen—to turn the cylinder upside down, and open the valve of the cylinder for a second, so as to let the gas drive out any water; of course, the key must only be turned on a quarter of a turn, and off again *at once*.

* * * * *

Beard's small-size automatic regulators have now been on the market four years, and they enjoy at the present time a unique reputation for satisfactory working. That they are consistent in their action, and are reliable, may be understood when it is stated that, of over 4000 sold, and in most cases continually used, only about one per cent. have ever failed, and these in most cases from causes outside the control of the inventor. In one instance the whole of the working part was choked up with dirt or mud, presumably from the fact that the cylinder had been stood head downwards, and, when the regulator was fixed in afterwards, care had not been taken to wipe it or get the dirt out. If the same plan was adopted in this case as mentioned in previous paragraph *before* fixing on the regulator or connexions, the dirt would have been blown out where it could not do any harm.

* * * * *

From time to time during manufacture, and as the result of experiment, certain little improvements are invariably made in inventions, and this regulator is not an exception to the rule, for the levers of lazy-tong pattern connecting the top of bellows with the eccentrics that close the valve are now considerably improved and made stronger, and with almost mathematical accuracy. In its construction it has also the merit of being easily inspected by unscrewing the cover.

* * * * *

Regarding the bellows of these regulators, users must remember that everything has a certain life, and, as the bellows are made of indiarubber, *some day* they will get weak and want renewing. I would advise all who have had regulators over two years to order through their optician or the agent who supplied them a reserve bellows for each regulator, so as to have by them, in case of the one in use hardening or perishing from the action of the gases used or the temperature and climate to which they are exposed. If in any doubt about the old one, on inspecting it by removing cover, have it replaced at once with a new bellows, for the cost is a trifling matter, something like two shillings each, while the feeling of security thus obtained more than compensates for the trouble and expense.

* * * * *

Opaque screens are getting more and more into favour, and where they are placed permanently in a suitable position nothing could be more convenient than the roller and lathe plan, as employed for the drop scenes at theatres, the roller being, of course, at the bottom. The whiteness, opacity, and smoothness of these screens enhance the beauty and brilliancy of the photograph or picture projected on them to a considerable extent.

* * * * *

The mahogany-cased opaque screens recently introduced, in which the top of the box is nicely made in two parts, form when turned up the upright and support for the screen. It is most convenient for small and moderate sizes; the former, from four feet to six feet, are made with spring rollers, and the latter, up to twelve feet pull up by means of cords and pulleys, the former being fastened to catches low down on the outside of the supports. The screen is stretched quite firm by a wind-up handle, and the same handle, when the cords are free, wind the screen down (round the roller) into the box.

G. R. Baker.

LANTERN SLIDE METHODS.

[Hoboken Camera Club.]

[Since her return to the United States, Miss Catharine Weed Barnes has, we believe, made a large number of lantern slides from her English negatives, and is exhibiting them before various Societies. The following paper, which she read a few months ago, will therefore be of interest as indicating her method of working.—Ed.]

There is a solid substratum of common sense in the prevailing favour with which lantern slides are received. They have become

an almost essential requisite in these days to any lecturer whose words admit of being made more impressive by adding the evidence of sight to that of hearing. Strangely enough, people will believe their eyes who doubt their ears. This fact being conceded, it remains for me to give some faint idea to-night of the great stature to which this work has grown, what it can be made to mean, and a little—only a little—about how it is done. The old idea of the magic lantern impresses those who give little thought to camera work with an almost absolute conviction of its being a kind of trick, really sleight-of-hand or magic. And when they are told that lantern-slide work is a well-defined and not over and above easy branch of photography, requiring constantly growing experience and thoughtful care to accomplish good results, they smile indulgently, if they do not actually say they doubt your statement. One of the strongest reasons for slides being so popular is that so many more people can thus enjoy a picture than when it is in the form of a print, and still more that, with great care and trouble, it may be, one can sometimes obtain from a poor printing negative a respectable slide. This in many cases is valuable, as from it, if made by reduction and properly strengthened, a good negative of any size can be made. The objection that such negatives are usually blurred and indistinct in outline can be largely overcome by making the image on the slide as small as is consistent with clearness, focussing as sharply as possible, timing very carefully, and using special pains in development. The advantage is that, if such a negative is broken or injured, another can be quickly made from the slide, and where it is difficult to photograph the object over again—always best when that can be done—a camerist need not be at the risk of losing a valuable picture. This often means much trouble, but not necessarily great expense, and to lazy, trust-to-luck photographers who seem to expect their pictures to appear, like that described by Sam Weller, with "the frame and glass on complete, with a hook at the end to hang it up by, and all in two minutes and a quarter," I have nothing to say. It is always the workers who are most anxious to learn, and trouble to them is of little consequence when aiming at good results. In a recent volume by A. R. Dresser, the distinguished English slide-maker, he strongly advocates making slides in a copying camera, and it is gratifying to have my own opinion confirmed by such an able worker, for I do not like contact slides as a general thing. He goes to the extent of recommending the process even with negatives as small as three and a quarter inches square. Some of the advantages in this way of making slides are that you can overcome defects in the negative, leave out any part if wished, enlarge or reduce as desired, and, what always seems miraculous to the uninitiated, make an exposure, develop the plate, and make a slide from the wet negative in a very short space of time, which is, of course, impossible by contact. It is not necessary to have an elaborate outfit if you only have a good short focus lens, but you must supplement it with a greater output of brain force to devise expedients for overcoming deficiencies in the camera, &c. In visiting a celebrated slide-maker's workroom lately, I was ashamed of my own expensive apparatus when examining the simple means he used. An old, discarded wet-plate camera, slightly altered, an ingenious arrangement for using any size negative, and a fine lens—the whole was simplicity itself, and yet his slides are known wherever photography is—and that is saying a great deal. A somewhat similar apparatus is described in Mr. Dresser's book. I fully agree with the latter in laying stress on the position of the apparatus in the room, and noting accurately the actinic force of the light at the time. It is not understood by some how much exposure is hastened when snow has fallen, and how very useful is a ground glass behind the negative, or the reason for placing the negative film side to the lens (otherwise the image on the slide would be facing the wrong way), or the absolute necessity for having the front of the camera square with the negative —in other words, how very easy it is to fail and then blame instruments, chemicals, maker or dealer, and not the worker. One special object of blame is the plate, and each camerist has his favourite one, not that it is necessarily in itself the best, but with it he accomplishes the best work. It is, however, with some workers a case of Love me, love my plate, and your judgment is sharply questioned if you are not able to do so. On my saying to a friend once that I did not like a certain make of plates, as the slides were too black and white, the statement was positively, very positively, questioned, and I was obliged to explain in detail that, whatever my informant's experience was, mine differed from it.

English plates are much slower than our own, four or five times as long an exposure being requisite, which seems to bear out the theory that in slide work rapidity is undesirable, as the average of English slides are remarkably fine. As a rule, theirs are denser than ours, but the shadows are generally clear. The American size, $3\frac{1}{4} \times 4$, has been adopted by some English plate-makers, but the majority of their plates are inconvenient for our lanterns, being both for plates and cover-glass square, solid, very substantial, and apparently made with a glorious disregard of whether they suited any slide-carriers but English ones. We claim our way is more convenient, as it allows title and name of maker to be placed prominently on the cover-glass, and gives more latitude in matting. We also mount our slides differently from foreign workers, and it would save much trouble if some general agreement could be arranged in these and other photographic matters. I spoke recently in Brooklyn on certain slide developers. It does not matter much which one is used if it is used intelligently; each has good qualities, but those are the best which are simple as to formula, cleanly in working, and reliable in action. I do not like the caustic alkalies, as they are too severe on the film and utterly preclude anything like prolonged development, so essential to a good slide. With eikonogen, my favourite developer, I use carbonate of potash, saturate solution, and sulphite of soda in the eiko, which seems to keep well, if it does darken a little. The suggestion was recently made to me of using the new developer, rodinal, otherwise para-amidophenol, as an accelerator in eikonogen, and it was a success. Let me urge putting acid sulphite in the hypo bath, and always have a dish with saturated alum and a little sulphuric acid near it. Keep the bromide bottle "convanient," but not too much so, and use a dropper in the cork. See that for all solutions and washings either distilled or, at least, well-filtered water is used. It is my custom to keep a piece of muslin, filled with absorbent cotton, tied over the rose sprinkler on my faucet, and it requires renewing every few days, as it gets black with sediment. In cold weather the water from the pipes should be warmed before use, else the chill will seriously retard development. In my dark room is a gas-stove, and I generally, in winter, heat water and put a little in the developer, but only just enough to slightly raise the temperature, remembering one sad experience when I saw the whole film slip off the plate. Over-timing, development only for detail and subsequent intensifyings, keeping the lights pure and the shadows clear, by judicious use of the alum bath mentioned, will give an interesting variety of tones, which is a relief from the monotony of the usual colour of slides. Uranium and other salts are also employed in gaining variety of tones, but hand-painted slides must be exceptionally well done to be even tolerable. It is a curious fact that some pictures show much better as slides than as prints, especially where there are good distance effects; and at a recent exhibition a competitor who showed slides and prints from one set of negatives, received a prize for the former in preference to the latter. During my proposed photographic trip to England and Scotland this spring and summer, when I expect to attend the annual Convention at Edinburgh, I shall make a study of the English method of work, and try to ascertain its true inwardness. But there is no earthly reason why, with proper patience and perseverence, any one who can make a good negative should not make a good slide. If prevented from using a copying camera, he certainly can make them by contact in any ordinary printing frame, but should back his plate with dark material, as frames generally are lined with white canton flannel. I would then advise their being made by gas, magnesium, or electric light, which can be readily controlled. Some workers prefer artificial light in any case. Many of the societies provide facilities for this work, and I constantly wonder that it is not more widely taken up; but it is sadly evident that in every society a few members do the most of this work. While the claim is made still, and very positively, that a wet-plate slide is the only true one, all others being unworthy of consideration, yet high authorities all over the country are beginning to believe that just as good effects can be gained with dry ones. I do not offer those shown to-night as examples to be followed in every particular, but as illustrating certain artistic and technical points. The amateur, however, after going through all stages of the slide fever with ready-made plates, sometimes becomes fired with an ambition to coat his own plates. There are several ways of doing this, and all, though not expensive, are more or less troublesome; but the genuine camerist devoted to his work never knows when to give up and, as I can testify, never likes to own a positive defeat. It is a source of regret to me that I am prevented by urgent editorial duties from using my own emulsion closet. At present it is occasionally used to dry carbon tissue, and then only at intervals. I cannot understand those good people who wonder what there is in photography to make its devotees so very devoted, when discoveries and improvements are being made almost every day in its already wide field. Perhaps this is the more strongly impressed on me from the fact that so many instruments, chemicals, &c., are sent to an editor for testing, and the various photographic periodicals, foreign and American, fairly bewilder the novice with the extent to which the work is being carried. One very tempting path is in the direction of different printing methods, experimenting with new printing surfaces and developers, and here is where there is boundless capacity for im-

provement, while with slides there is less variety in the material used, but a great deal in how it is manipulated. Success is, however, impossible, unless one thoroughly believes that what he is doing is worthy of his best energies, no matter what the line of endeavour, but that blindly sticking to it will never accomplish anything really valuable. What is required is steady, wide-open-eyed perseverance and cultivation, not merely of one's artistic and technical vision, but a perpetual post-graduate course in accurate reasoning. The scales and weights on one's shelves then become something more than senseless machines, and are as symbols of the wonderful balance and delicate adjustment of the human brain. You will only get from photography that which you give it; but one can give a great deal, and, if you make yourself believe that in it no art is possible, you will certainly never find any. He who seeks will find. To succeed, you must read intelligently, study carefully, believe it is worth while to give your best attention to camera work and then translate your study into practice, watching critically every step and cutting places for your feet as do the climbers on the Alpine glaciers. No sudden flights of inspiration will carry you very far, although inspiration is needed sometimes to keep up one's courage. I wish to urge at the same time the never being satisfied with one's work. Avoid that as you would a pestilence; it is fatal to further progress. Your satisfaction will be like that of the five little green peas in Hans Christian Andersen's story, whose own tiny pod was all the world to them. While measuring yourself against others and learning to realise your own shortcomings, you will often find, by the great law of compensations, an unexpected balance on the credit side of your account, but it must be fairly earned. This talk has not been intended for a strictly scientific one, but only to show these of you who have paid little, if any, attention to this subject, that it is worth being well considered for the sake of the future before it and what can be made of it. Such associations as the Lantern Slide Interchange are doing much in this country and abroad to disseminate a great amount of knowledge, scientific, artistic, and historical. The work can be made a valuable adjunct in educational training if used to instruct as well as amuse. It is fascinating work, and from personal experience I recommend it to all camerists, men and women, believing there should be no sex in photography, that each should bear the burden and heat of the dark room, do the same work throughout, share equal criticism, and receive the same reward.

CATHARINE WEED BARNES.

THE LANTERN SLIDE AND ITS RELATIONS TO ART.

[Photographic Section of the American Institute.]

THE subject which I shall treat this evening will be, in the main, the relation of art to the lantern slide. That there may be no misunderstanding of what I may say, or misinterpretation of terms used, I will, in the first place, define, as fully as seems to me needful, what I mean by the term artistic in relation to, and bearings on, the subject.

"A DEFINITION OF THE TERM ART IN RELATION TO THE LANTERN SLIDE."

I shall try to avoid assuming a dogmatic position by asserting that my way is the only way; that all who may differ from me are ignorant and idietic.

The fact is, that the interpretation of the word art is very flexible, and becomes quite apparent when we attempt to compare it with the interpretation of the word science. In the latter we must have certainty by demonstration. In art, the element of certainty can hardly be said to exist, except in the minds of the advocates or leaders of certain schools. Modern art, in civilised countries is, in the main, the product of educated and cultured sentiment, and sometimes, when at its best, compares unfavourably with the artistic work of so-called Pagan nations.

In metallurgy the Japanese surpass, in artistic work, that of any European nation or people, but in landscape drawing they are as conspicuous as a failure as they are a success with metals, pottery, porcelains, and textile fabrics. This is due to their ignorance of a scientific principle in nature, which is the arbitrary law of linear perspective; and this is about the only point where science and art clasp hands.

It seems to me that, in defining art, it should, as a rule, be done in general, rather than in specific terms. There can be no specific rule for colouring a landscape. A rule which would dictate to every landscape artist precisely the same pigments, or compounds of pigments, to be used invariably in colouring specific parts of the same view, would be impracticable.

The reason why this is impracticable is because one of nature's immutable laws forbids it. Nature seems to possess the omnipotent capacity of producing infinite variety in the same species, and she exercises this power to the fullest extent in her production of the optic nerve in the human being with sensation and perception. No two artists see or depict with precisely the same colours the same view.

The methods of each are as distinct from the other as their handwriting, and is as difficult to counterfeit. The artist who succeeds in representing form and colour as the cultured majority see it, becomes the popular artist.

The senses which respond most readily to the allurements of art are seeing and hearing. Such artistic effects are usually distinguished as "fine arts," to separate them from the "mechanical and useful arts." The sense of seeing is the one involved mainly in the subject before us this evening. What charms the tympanum, is the harmonious blending of atmospheric waves.

"THE SENSE OF SEEING."

At the present time I am not trying to interest you through the avenue of sensation, and am making no effort to produce pleasurable artistic sensations by draping my thoughts in eloquent language, and presenting them through an expert elocutionist, which would produce artistic effect, but shall address myself to the sense of seeing, which sense is the result of waves of a much more subtle agent than the atmospheric waves, and the sensation of colour is largely the result of the blending of these ethereal waves, and whether the effect on the nerves be one of pleasure or pain depends upon whether the blending be harmonious or inharmonious, the same as results to the sense of hearing when musical notes fall upon the ear, and whether the sensation be pleasurable or painful will depend upon the fact of whether the atmospheric waves unite harmoniously or discordantly.

I hold that anything which produces unpleasant or disagreeable sensations cannot be artistic, and further, that which produces pleasurable sensations without producing weariness is the most artistic.

POPULAR LANTERN SLIDES AND THE OPTIC NERVE.

There may be artistic sensations produced by a loud clanging and banging of musical instruments, but the senses soon tire of it and seek relief. The popular and orthodox lantern slide has just the effect on my optic nerve which noisy music has on the nerves of my ear, and under an hour's strain my optics become tired and rebel. This should not be so. The fault is of long standing and originated in the early days of photography in consequence of certain notions entertained by professional photographers. Artists of that time treated photography with ridicule and contempt; a petty warfare was kept up between the artist and the professional photographer. The photographer who could make a photographic picture became inflated with exaggerated notions of his importance, and just in the degree of popular favour awarded to photography the artist's jealousy was increased and expressed.

"CLEAR GLASS A FATAL DOGMA."

The mistake which the early producers of lantern slides made was the ignoring and ruling atmosphere from the slide—absolutely clear glass was the fatal dogma. This was purely a photographic notion and unartistic to the last degree. Aerial perspective is almost, if not quite, as potential and necessary in a landscape painting as linear perspective. The supreme effort of a landscape artist is to reproduce nature, and to do this he must paint atmosphere. No photographer can make a perfect negative of an out-of-door view without photographing atmosphere; the longer the distance photographed the more atmosphere. If a negative should have atmosphere represented in order to be perfect, it follows that a lantern slide made from such a negative to represent it should represent *all* the atmosphere in the negative. If this be so, it follows that a dry plate which will make a *good* negative will, with the same careful manipulation, make a good lantern slide. This seems quite a rational theory, although it is radically heterodox. Yet dogmatic notions, whether antique or modern, have to, in the long run, submit to modification and change when assailed by *demonstrated facts;* and the slides which I shall exhibit this evening will mainly be for the purpose of demonstrating the correctness of the theory just advanced. These slides have been made, as a rule, on the most sensitive plates in the market. Special plates usually used I shall only exhibit for the purpose of illustrating the point at issue.

I will not deny that there may be cases where a very thin negative without much contrast is used that a special plate would succeed better than a quick plate; but my way would be to strengthen the negative and use the quick plate. The modern lantern slide has become one of the most useful products of photography, and in its adoption to illustrate lectures almost a necessity.

There is scarcely a limit to its use in this field, and it frequently happens that the viewing of slides used on such occasion produce more pain than pleasure because of defects in their production.

"LANTERN-SLIDE MAKING A HEALTHY MENTAL EXERCISE."

The amateur photographer of the present is a devotee of the lantern slide; after becoming able to make a respectably good negative his effort

is to make with it a good slide, and I would not say a word to discourage him or her. Working at any photographic problem, in my opinion, is healthy mental exercise. It necessitates contact with scientific problems, which creates a thirst for more light, and inspires a longing and desire to become more familiar with nature and her methods. The negative and the positive are alluring lights that beckon the student on; torches that illumine the way; prophetic voices that promise reward for diligent labour and patient toil. They are nature's representatives and they bring you in close communion with some of her mysteries, and you are led to realise that just out of your reach nature conceals a golden key with which you could unlock some of her secret chambers if obtained; and she points to the past and shows that the ones who have obtained the magical keys have been the diligent ones, who by toil have earned the privilege of culling a few jewels from her great storehouse. I believe there is nothing better for the ethical and intellectual growth than to become interested in scientific and artistic studies. I would not say a word which would tend to cool the ardour or enthusiasm of the investigator of nature, but would use my influence, as far as possible, to inspire and encourage.

The wonderful advance made in the present century causes the question to be frequently asked, in reference to the future, whether we have not obtained about all of nature's most valuable secrets; and if there is any probability that the next century will, in any respect, be as wonderful as the one that is passing away. From my point of observation my answer would be that we have just commenced; we have not as yet learned the first letters of the alphabet which tells of the possibilities and powers of human reason, and have not even entered the vestibule of the great temple of knowledge.

There is everything to encourage those who are enamoured with the investigation of the great problems that surround us on every hand. What we know when compared with the unknown, is like a few grains of sand compared with the sand on the shores of all the seas and oceans—so to the young or to the old I would say, *go on*, an infinite field is before you.

HENRY J. NEWTON.

MOUNTING LANTERN SLIDES.

[The Beacon.]

WHY is it that while everything else in connexion with photography has been advancing and improving, almost revolutionising, the mounting of lantern slides is carried on to-day exactly as it was some thirty years ago, when the method of mounting each slide in a separate wooden frame was discarded, that is, discarded so far as photographic slides were concerned, for I believe that the finer variety of hand-painted sets are still framed? The present form of mounting, when skilfully done, and before the paste begins to give way, certainly looks well, and the mounter who makes a trade of it is able to do it skilfully; but the amateur who only mounts a few now and then rarely makes a neat job, and is anything but an amateur in the true sense of the word, and would rather make two than mount one any day.

I believe that the disagreeabilities incident to the present method of mounting, rather than any difficulties in the way of making good slides, deter many from turning their attention to that most delightful branch of photographic work, and my object in this article is to urge the adoption, not of a new method, but of one that has been again and again proposed, but rarely adopted—one that will, when we get used to it, look as well as the present method, be much more convenient in various ways, and at the same time as simple as putting a letter into an envelope. It is one also that only needs to be generally seen to be universally adopted, and I have a strong hope that it will soon be so, as several of the British dealers in lantern material have at length seen their way to make and supply the mounts or wrappers, a step likely soon to be followed by those on this side. But we need not wait for that, as the cutting of what I would fain term the modern mount is such a simple matter that any one can do it for himself.

The material and tools necessary for the making of the mounts is some thinnish, tough paper—white writing, or "manila," will do—a pair of scissors and a slide cover. Paper of a white or light shade is best, as the slides so covered are easily seen in dim light, and suitable for writing on. The paper is first cut into pieces of $4\frac{5}{8} \times 3\frac{5}{8}$ inches, and then the clear or opening is cut of any desired size or shape. This is probably most easily done by folding the paper across the middle twice, first in the direction of its length and then of its breadth. This slide cover is employed as a straight edge, laid on the folded corner so as to permit two straight pencil lines to be drawn, making, with the two folded edges, a square, either upright or horizontal, of just half the size of the opening desired. Two straight cuts along the lines, stopping of course at the point where they join, will give, when the paper is unfolded, the desired opening; or, if rounded corners, cushion shape, be preferred, they are easily made by making the cut continuous, simply turning the scissors round the corner, cutting the while. Before unfolding the paper, it is well to snip off the four open corners, diagonally across from the folded corner, so that, when the flaps are folded over, the joints will have a mitred appearance.

On opening the paper thus cut—and two or three dozen might have been made in the time it has taken to explain it—a compound mat and binder will be found ready for use. It is only necessary to paste it, lay the slide and its cover, without anything between, in the centre, and fold over and rub down the flaps. A single trial will show how easy it is to both cut the compound binder and apply it, and after one or two trials, with a tithe of the trouble, to mount as neatly and more conveniently than in the ordinary way.

I have mounted slides in this way for years, and they were admired by all who saw them; but fashions, like facts, are stubborn things, and ill to ding. But, according to the wise man, there is a time for all things, and perhaps the time for the combined mount has at last arrived.

JAMES ROSS.

PRINTING-OUT LANTERN SLIDES.

[Manchester Amateur Photographic Society.]

A FEW words from one who has put to the test the latest addition to the many inventions for the benefit of the amateur may not be out of place. I understand that print-out plates have been manufactured before, but for some cause or other (which I have not been able to ascertain) they were either not a success or were not sufficiently taken up to warrant their continued manufacture.

Some nine months ago the present writer and Mr. Lees of this Society had a conversation as to the possibility of coating a lantern plate with the same emulsion as chloride printing-out paper, the outcome of which conversation was that I wrote a letter to Mr. Howson, of the Ilford Company, pointing out the advantages to amateurs to be obtained from a lantern plate so coated.

In reply that gentleman pointed out that the course suggested was impracticable, and that all advantages claimed for such a plate could be obtained by using the Alpha lantern plate.

It is now, by the enterprise of the well-known Paget Prize Plate Company, not only proved to be not impracticable, but actually an accomplished fact, and my friends may judge of the enthusiasm with which I got hold of a sample of the new plates to put their capabilities to the test.

On proceeding to open my first box, I must confess to a feeling of fear that there was too much white light knocking about, and I very nervously looked around—by force of habit, I suppose—to see that everything was safe. Of course, this was totally unnecessary, as the emulsion is so slow that the plates may be treated just exactly as if they were chloride paper; in fact, the only difference between the two is, that with an ordinary printing frame the lantern plate must not be disturbed, but should be judged by looking on the back instead of on the front, as with paper.

This difficulty, however, will soon be removed, as the same company have in course of manufacture a printing frame specially designed for printing these plates and print-out opals.

The plate is very transparent; so much so, in fact, that you have to resort to the old dodge of breathing on it, to ascertain which is the correct side.

In the printing frame, in this December light, it takes a fearfully long time to print, even when printed in the sun, which, it is interesting to learn, it is advisable to do.

In the comparatively short time I have experimented with the plates, I find they must be printed more deeply than paper.

They come out of the printing frame a bright red, something like a correctly exposed and developed alpha plate, the high lights having a bluish cast.

Two formulæ are given for toning: one a combined bath, for which the plates must not be previously washed; and the other, a bath, followed by fixing, before which the plates should be put in running water for fifteen minutes, to prevent uneven toning.

I preferred the second of these for simplicity, as follows:—

Sulpho-cyanide ammonium	30 grains.
Chloride gold	2½ grains.
Water	16 ounces.

Fixing—

Hypo	3 ounces.
Water	1 pint.

Toning proceeds very evenly, and may be stopped at any time when judged to be a satisfactory tone by looking through the plate.

It must not be forgotten that these plates are intended for warm tones, and I am not sure that a deep black can be obtained; but of that we shall soon learn.

There can be no doubt that the path of the amateur will be made considerably smoother by this new candidate for our favour, and I can confidently recommend our members to give them a trial.

I see a decided advantage in a printing-out plate, for the facilities it offers for printing in clouds, all that is necessary being to print the landscape, and then cut out a paper mask to cover same during the printing in of a cloud; we shall thus gain in two ways:—(1) our results will be more certain, wrong exposures being practically done away with; and (2) the same plate will do for landscape and cloud.

The dark room and its accompanying disadvantages entirely removed, and other advantages which such a plate must possess prompts me to prophesy a great future for the Paget printing-out lantern plate, and a greater addition to the already numerous ranks of good lantern-slide makers. W. H. Shirley.

FARM LIFE ON THE SCREEN.

The Edinburgh Photographic Society held their first popular evening for the session on Friday evening, January 27, in Queen-street Hall. Mr. J. C. Oliphant, Vice-President, occupied the chair, and, in addressing the meeting, said the audience would have the advantage of seeing among others on the screen—on a much larger scale—the picture which had so deservedly gained the silver medal at their recent Exhibition. The lecturer, Mr. James Patrick, of Comiston-road, read the paper which had been prepared by his sister, Jessie Patrick Lindlay, the well-known authoress, which was entitled "Round about the Farm," and which comprised about sixty views taken during the currency of last year, from early spring to mid-winter, of the scenery, with the picturesque backgrounds of the Pentland Hills, and the surroundings of Swanston village and farm, one of those cosy old-world clachans where thatched cottages and homely kail-yards yet exist, almost within "a mile o' Edinburgh town." The pictures were of the highest class indeed, in artistic choice of subject, in the introduction of dogs, horses, cattle and sheep, still life and figures; they displayed that true power of seeing and selecting subjects which is not so widely diffused as is the capacity of making a good negative and the transparency therefrom.

A departure was also made from the usual, or rather a reversion to what used to be the usual, method of showing the pictures by keeping each subject on the screen continuously during the sometimes lengthy description and necessary annotations on the various subjects. The pictures were all untouched in negative or transparency, and the aerial effects happily caught, save in one solitary instance, where to a sunset subject there had been printed in a morning "mackerel" sky of a kind rarely or never seen in the very early part of the day. One of the most difficult of the series, the autumn portion, rendered the stack-yards and straw with a truth of local colour that was almost deceptive. The winter scenes were also exceptionally fine, and some of them, with the dense loading of snow, gave a fine idea of the heavy fall. The Council had for the first time in the Society's history imposed a charge for admission; but, contrary to expectation, the large hall was quite comfortably filled. Several appropriate songs were sung during the evening, and, as indicative of their quality, were called for again.

At the close of the lecture, which was throughout deservedly cheered, Mr. J. Barclay, Secretary, in the name of the Society, heartily thanked Mr. Patrick and the ladies and gentlemen who had contributed to carry through so very pleasant an evening. The lantern was worked admirably and without a hitch.

ZOOPRAXOGRAPHY ON THE SCREEN AT THE CHICAGO EXHIBITION.

We have received the following official communication:—

By invitation of the Fine Arts Commission of the World's Columbian Exposition, Mr. Eadweard Muybridge will give at intervals, from May to October, 1893, in the Zoopraxographical Hall of the Exposition, a series of lectures on the *Science of Animal Locomotion*, especially in its relation to *Design in Art*.

These lectures will be given under the auspices of the United States Government Bureau of Education, and will be based on the elaborate work—*Animal Locomotion*—containing the results of the electro-photographic investigation of the movements of animals, made by Mr. Muybridge for the University of Pennsylvania.

From the investigations of Mr. Muybridge—which were commenced in 1872—originated the science of *Zoopraxography*, and lectures and demonstrations on this subject have been given by the author at nearly all the principal institutions of science, art, and education in the United States and in Europe.

It is a subject of the most profound importance to the scientist and the artist, and has been universally recognised as of the greatest interest to the general public.

Although it is probable that the present series of lectures may not be unworthy the attention of the philosopher, they will be free from technicalities, and adapted not merely for the instruction, but also for the entertainment of popular and juvenile audiences.

The illustrations will comprise a selection of consecutive phases of movements by men, women, children, horses, dogs, cats, wild animals, and birds, photographed while they were running, jumping, boxing, dancing, galloping, trotting, kicking, flying, or engaged in other muscular exercises. They will be projected by the electric light on a large screen, and, after an analysis, the successive phases will be combined, and put in motion with the semblance of actual life by the zoopraxiscope.

The differences between a true and a false impression of animal movements will be demonstrated by illuminated projections of the works of many eminent painters and sculptors of ancient and modern times.

LANTERN SLIDES OF NORTH WALES.

Before the Putney Photographic Society, on January 23, Dr. J. F. Farrar in the chair, Mr. John A. Hodges, President of the West London Photographic Society, read his lecture (illustrated by lantern slides) on *Rambles with a Camera in North Wales* to those members and their friends—about one hundred—who were present. No doubt this large attendance was mainly due to the pleasing recollections of his lecture on *North Devon* given before the Society last year. Mr. Hodges' graphic powers of description, marked enthusiasm for Welsh scenery, together with his quiet, dry humour, were thoroughly appreciated by an attentive audience. It is quite unnecessary to say that the hundred slides illustrating his remarks were of the best quality, showing true artistic feeling as well as perfect technique. For the information of any brother photographers who may wish to do good work in Wales the following particulars of the route taken by Mr. Hodges may be acceptable:—Start from Llangollen, and follow the course of the Dee, past Bala, to Dolgelly; thence, down the estuary of the Nawddach, to the sea at Barmouth, continuing the journey by the Cambrian Railway to Harlech and Portmadoc. Leave the train there, and proceed by coach to Beddgelert, changing there into the Bettws-y-Coed coach. From that quaint and picturesque village go by the North-Western Railway to Conway, Penmaenmawr, Bangor, and Carnarvon. By taking this route no doubt much of the finest and most beautiful scenery in North Wales could be visited in a tolerably short trip of about a week or ten days.

MOUNTING PASTE FOR LANTERN SLIDES.

For attaching lantern slide bindings to the glass nothing is better than bichromated paste, which is used for attaching paper to glass in the manufacture of electric instruments, and which is a most useful paste for many purposes in damp climates. It is made as follows:—

Flour	2 teaspoonfuls.
Water	4 ounces.
Bichromate of potash	5 grains.

The flour must be rubbed to a smooth paste with the water, then placed in a saucepan over the fire and kept stirred until it boils. Add the bichromate slowly, stirring all the time; then stand to cool.

This paste must be kept in the dark, and used as soon as possible. Soak the paper in it, and attach to the glass, then place in direct sunlight for a day. This sets up a chemical change in the bichromate, and renders the paste insoluble.—*Journal of the Photographic Society of Japan.*

MAGNESIUM FOR LANTERN SLIDES.

[Minneapolis Camera Club.]

There is certainly no better or more pleasing way of showing our work than by the use of the stereopticon and lantern slides.

A proof of this is that an announcement of a lantern exhibition will nearly always draw a good-sized audience, and it is almost actually necessary nowadays for a lecturer to make use of this means of illustrating his ideas.

A number of our members have never made lantern slides. They have probably never investigated the process far enough to see how exceedingly simple it is, and I will endeavour to show you this evening one of the methods used. Lantern slides are made either by "contact" or by "reduction" from the negative by means of the camera.

The contact plan is most generally adopted by amateurs because of the ease with which it is done, and also from the fact that it can be done a night. This plan is all very well when you have small negatives; but, even with 4 × 5, it would be better in the majority of cases to make the slide by reduction, and with large negatives this is absolutely necessary. The ordinary way of making slides by reduction is to place the negative (film side toward the camera) in a north window, with a piece of ground glass behind it; then put a lantern plate in your plate-holder, and, after getting the proper-sized image on your focussing screen, make the exposure, and develop the same as if made by contact.

An advantage obtained in reducing is that a soft slide may be made from a harsh negative, and by proper exposure and development a good slide may be made from a negative so thin and flat, that it will not yield a passable silver print. Another reason is that it is practically impossible to get perfect contact in a printing frame with the ordinary lantern plates, while by copying in the camera it is a very easy matter to make the slides absolutely sharp. But in order to make slides by reduction we must have daylight—at least, that is the general supposition. Not many amateurs—in this city, at least—have much time to devote to this kind of work in daylight, and I will demonstrate to you this evening how I make slides by reduction at night, using magnesium ribbon for illumination. I have constructed a frame consisting of two uprights with two grooves on the inside. The uprights are just far enough apart so that a glass ten inches wide will slide between them, and they are twelve inches high. In one groove I slide a 10 × 12 ground glass, and in the other I place the negative. If it is 10 × 12, it just fits; if it is smaller, I put the lower end in the groove at the bottom of the frame, and lower a strip that slides in the side grooves down until it reaches the top of the negative. I place this frame on the table, and draw the camera stand up facing it. After once adjusting the height, it is hardly ever necessary to change it for the same-sized negatives. I then focus as usual, using a candle behind the ground glass to illuminate the negative. When everything is ready, I cut off from three to six inches of magnesium ribbon, according to the density of the negative, and hold it in a pair of pliers, light it at the candle, and pass it rapidly back and forth behind the ground glass and negative. The secret of success in this is to be rapid and give the whole negative equal illumination.

I made a few failures in this before I succeeded in getting the negative evenly illuminated, but after a few trials it is very easy.

A. L. Eidemiller.

SLIDE MAKING BY REDUCTION.

Before the Croydon Camera Club, on January 30, Mr. Gay Wilkinson gave a lecturette, with demonstrations, to a numerous gathering of members on *Slide Making by Reduction*. Apart from the engaging readiness with which the lecturer made clear all doubtful points raised by inquiring auditors, the proceedings were chiefly notable for the primitive character of the appliances used in obtaining those brilliant results for which Mr. Wilkinson is so distinguished, and by his demonstration of how, with very simple manipulatory means, he obtains the much-to-be-desired skies in his slides.

Lantern Queries.

B. Simpson.—An article on lantern slides by printing out appears in another part of the Supplement.

W. Tressle.—Why not use a saturator? This will do away with the use of cylinders and bags altogether.

A. Pryce.—A table in the current Almanac supplies the information requisite for calculating the distances. You do not state the length of the hall.

P. C. R.—Possibly through condensation of moisture upon the condensers or objective. Always let both be warmed before commencing the entertainment.

S. Welsh.—The samples of cover-glasses sent are slightly yellow, and are, therefore, hardly suitable for the purpose. The more colourless they are the better.

E. L.—Gas cylinders are made by the Projectile Company. They, however, only supply wholesale. The valving is done by the gas compressers.

Binoxide.—It is considerably over twenty years since electricity was employed for lantern illumination. Mr. Browning introduced a lamp of that nature in 1868.

Mica.—Yes, mica plates are now available for lantern-slide supports—they might be used for pictures by the carbon process. They are, however, rather expensive.

Gas.—Certainly not more than five feet of oxygen an hour should be necessary for your double lantern, and thus a twenty-feet bottle should last for two evenings' entertainment of two hours each.

J. F. Young.—The addresses of the Hon. Secretaries of the Charitable Lantern Entertainment Society will be found in the last Supplement in which you will learn all particulars of the Society's objects.

Beginner.—The slide sent is not clear enough in the lights for projection purposes, while the detail in the shadows is not sufficient. Join a Society, and endeavour to learn what is required from the examples shown.

C. Winsrone.—By using an alum trough to absorb the heat rays, the inhabitants of your various samples of pond water will not receive their quietus so quickly, and thus you will be able to keep them moving about a little longer.

Mark Layland.—Hydrogen or common house gas is so easily obtainable, that it is rarely worth one's while to generate it for one's self. However, as you ask us "merely as a matter of curiosity, and not because you intend trying it," how it may be obtained, we reply: By the old experimental zinc-sulphuric-acid method.

Di-chroic.—Special tinters for imparting sunset or moonlight effects to slides may be obtained of lantern dealers. Usually, they include a selection of colours, and are made to fit on the lantern front. The coloured effects with the limelight as seen on the stage are produced in a somewhat analogous manner.

N. Ormish (Liverpool).—The gas to be rendered suitable for lantern purposes should be enriched by a hydrocarbon, which may be effected by allowing the hydrogen to pass through a metal vessel holding some fibrous substance saturated with naphtha, turpentine, or benzole. Two flames so enriched will form a light of great brilliancy. There is not, so far as we are aware, any commercial appliance of this nature on the market; but, having given you the necessary conditions, any gas-fitter would be able to work out a suitable plan from this description.

We have received the new Lantern Catalogue of Messrs. Archer & Sons, of 43-49, Lord-street, Liverpool. It is a complete and comprehensive guide for purchasers of lanterns and their numerous accessories, various kinds of singles, biunials, and triples being described and illustrated. Special prominence is given to the "Ideal" single, which has met with great success among lanternists. Some of its advantages are that it has interchangeable lenses, and will show either in the smallest room at home or across the largest hall, being equally suitable for the drawing-room, schoolroom, lecture-hall, or microscopic, scientific, and experimental work, also for photographic enlarging. The body is of polished mahogany, lined with iron, and thoroughly ventilated. There are walnut-panelled doors both sides, fitted with brass shutter sight-holes. The front is connected with the slide stage by means of a leather bellows, same as on a photographic camera, which is much better than the usual brass tubes, because (1) it is lighter, (2) more portable, (3) cheaper, (4) easier to extend to and fro. This allows the use of lenses from the shortest to the longest range, so that pictures can be shown either close to the sheet or across the largest halls. The whole of the front removes clear away for the use of scientific apparatus. The bellows front is worked by a rack running the whole length of the lantern (in addition to the short rack on the object lenses). The object lenses are mounted in cylindrical tubes, which slide in the rack mount, so that they can be changed from one foci to another in an instant. They are fitted with double pinions, flashing shutter, and groove for tinted glasses. The rack front is mounted on a loose wooden board, so that photographers can use their own lenses for enlarging. At the end of the Catalogue, which omits details and prices of nothing required by lanternists for ordinary as well as scientific projection purposes, will be found useful directions for working lamps and lanterns, cylinder notes, hints on mixed jets, the lantern microscope, &c. Messrs. Archer have the advantage of practical acquaintance with the lantern. Incidentally we learn from their Catalogue that they supply a special biunial to the Sunlight Soap Works for projecting a picture ninety-two feet from the screen, the lenses being capable of showing at a distance of 200 feet if required.

Exchange Column.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*March* 3, 1893

THE LANTERN RECORD.

CONTENTS.

ANNOUNCEMENT.

Last autumn, when we instituted this Monthly Lantern Supplement to The British Journal of Photography, it was our intention to restrict its appearance to the winter months, but the remarkable appreciation which this new feature has obtained from readers and advertisers alike has decided us to make it a permanent addition to the Journal, so that we have now the pleasure to announce that a Lantern Supplement will appear with The British Journal of Photography on the first Friday of every month throughout the year, without intermission.

There are other, and perhaps equally important, reasons for this step. Observation has shown us that while, among photographic societies and at public entertainments the optical lantern during the summer months is not so largely availed of as in the winter, its uses for enlarging by photographers generally, for projection purposes among many sections of modern scientists, as well as for private and individual employment in regards too numerous to specify here, are so slightly diminished as to confirm our opinion that the lantern and its cognates, with all the manifold points of practical and theoretical interest appertaining to them, are entitled to unremitting recognition and discussion at our hands. Mechanical, scientific and artistic progress in lantern work may be expected to produce constant development at all seasons of the year, which would assuredly suffer if it did not find early representation in these pages.

We take this opportunity of removing a misconception which has arisen in regard to the "Lantern Supplement." It was, as we have previously pointed out, projected a considerable time ago, but circumstances delayed its appearance until last October, when its immediate success not only provoked imitation but instigated our contemporaries to devote more attention to lantern matters than they had hitherto done. The "Lantern Record," therefore, may claim to have stimulated increased interest in lantern work—an interest which it will be its aim in future to sustain, support, and augment.

A VISIT TO BRIN'S OXYGEN WORKS.

A Talk with Mr. Kenneth S. Murray on Oxygen.

Recent discussions and experiments relating to the purity of the oxygen commercially supplied for limelight purposes have invested the subject with great interest in the lantern world, not only as concerns the methods by which it is prepared, but also as to the sources whence it emanates and may be obtained. We have, therefore, thought that some brief account and details of the method by which oxygen is produced on a large scale would be welcome to our readers. It must be remembered that, although this gas is in very large demand for lantern illumination, it has several other uses and applications of an extensive nature—medical, theatrical, industrial, &c.—which combine to render its production necessary on a scale far in excess of what is required in photography, so that oxygen-making at the present time ranks as quite an important industry.

Oxygen, by the chlorate method, is commercially produced to a limited extent, and we believe that other systems are in actual or imminent use, but it is tolerably safe to assume that a preponderating percentage of the gas employed by lanternists is prepared by the barium process. This is the patented process of the Brin Company, which Company has several offshoots in the north of England and Scotland, and to the London works of which we recently paid a visit. Here, under the attentive guidance of Mr. Kenneth S. Murray, the engineer and manager of the Company, we were enabled to gain a very good idea of the elegant system by which the air we breathe is made to part with its oxygen for the wants and uses of art, science, and industry.

The Barium Process.

The chemical text-books (*Fownes*, p. 364, tenth edition, *passim*) inform us that Boussingault, a French chemist, proposed to utilise the property which barium oxide, when heated, has of obsorbing oxygen from the air, so passing into the dioxide, and of yielding up the absorbed oxygen at a higher temperature, for the inexpensive preparation of oxygen on a large scale; but, inasmuch as the barium monoxide gradually lost its power of absorption, the idea seems not to have passed permanently beyond the stage of a laboratory experiment. Messrs. Brin, however, improved upon Boussingault by purifying the air before it was brought into contact with the barium, and by admitting the air under pressure, and exhausting the oxygen under a vacuum. This also allowed of a uniform temperature being employed in the peroxidation and deoxidation of the barium.

The principles involved in the preparation of oxygen by this method are, therefore, exceedingly easy to grasp, and it is in their application to the exigencies of commercial production

that the Brin Company have succeeded in perfecting some highly ingenious machinery, which we saw in operation on Friday last. Properly to appreciate and describe such machinery one needs the acumen of an engineer, and very considerable space, and we must, therefore, herein content ourselves by imparting simply a popular idea of it as we saw it in action. The machinery room, engineer's shops, cylinder-testing department, the compressors, gasholders, furnaces, complete a large installation at Horseferry-road.

The Machinery at Work.

The routine of the process begins with the pumping in of air from the atmosphere, which is passed into a large receiver containing caustic lime, and thence into a second and smaller receiver (of caustic soda), the latter, to quote Mr. Murray, acting as a check on the former in the removal of moisture and carbonic acid from the air. The purified air is then passed into large pumps, where it undergoes slight compression, and finally passes through a chamber for filtering out solid particles, and a distributor placed on top of the furnace, into the retorts. The large furnaces are built at an angle with the horizontal, and contain on each side twelve inclined retorts, of cast iron, of six and a half inches internal diameter, one inch thick and about ten feet long. These hold between 2000 and 3000 pounds of barium in small lumps. A temperature of about 1300° Fahr. is obtained by the admission of primary and secondary air into a coke furnace, the carbonic oxide found being burnt into carbonic acid in the combustion chambers. By means of wall-holes in the sides of the furnaces one sees the retorts at a dull red heat. The heated barium abstracts the oxygen from the purified air, and the free nitrogen escapes up through an automatic valve, whence it passes out into the atmosphere. At the end of five minutes an automatic reversing gear reverses the working, a vacuum is created in the retorts, the air and impure oxygen in the connecting pipes are blown away, and the oxygen passes back through the pipes to a comparatively distant part of the works into the gasholder, which has a capacity of 2000 feet.

In another five minutes the reversing gear is again automatically converted, air passes into the purifiers, as before, thence to the pumps and retorts, and so on, for every five minutes of the day and night, Sundays as well as week days, all the year round. The maximum volume of gas capable of being drawn off can thus be seen to be very large. At the time of our visit only one of the furnaces and one set of retorts were at work. As showing the longevity of the barium oxide, Mr. Murray told us that in some of the retorts they were still using barium which was first employed in 1886, when the Brin syndicate started working the process. After a time the barium is prone to cohesion, when it has to be taken out and broken up.

From the moment when the air is pumped into the purifiers until the pure oxygen leaves the compressor the process is practically automatic, save and except such attention as even automatic machinery must have. Of special value is this, in that, when the air and impure oxygen are blown out of the pipes, the egress of atmospheric air is prevented. In atmospheric air there are, by weight, 23·1 parts of oxygen to 76·9 of nitrogen, and by the Brin process about fifteen parts by weight of the oxygen are taken up by the barium monoxide.

Compressing the Gas and Filling the Cylinders.

The gas from the storage holder passes directly into the compressor. This is of a three-stage type—that is, it has three cylinders, each compressing the gas to a different pressure and is driven by engine power. The gas from the holder passes into a cylinder, in which it is brought to a pressure of eight atmospheres, from thence it proceeds to a second cylinder, where it is further compressed to thirty-two, and finally to a third cylinder, where it is brought to 125 atmospheres. Water is taken up by the gas as it passes into the cylinders for which it acts as a lubricant. It is, however, separated by gravity from the compressed gas before the latter is led into the storage cylinders. The gas, while undergoing compression, is cooled by the compressing cylinders being surrounded by water.

The working capacity of the compressor which we saw in operation is 1000 cubic feet of gas per hour compressed to 120 atmospheres. Here were all sizes of the ordinary storage cylinders being filled by an *employé*, for whose guidance a most stringent set of rules to be observed as regards the working of the compressor, and the Company's test stamp on the cylinders he has to fill, is conspicuously placed; equal rigidness marks the rules which govern the reception of cylinders, from customers, to be filled.

Testing the Cylinders.

The cylinders are tested by the hydraulic method to a pressure of, we believe, about two tons to the square inch, or double the highest pressure the compressed gas with which they are filled is likely to exert on them. Briefly, the testing method consists of holding the unvalved cylinder, inverted, at the top of a well several feet deep, in a collar of indiarubber against an outer surface of water. The hydraulic pressure is then exerted by the usual means, and the expansion of the metal cylinder is registered and read on a recording scale the indicator of which is forced up by the displacement of the water surrounding the cylinder. If upon relaxing the pressure the indicator fails to return to its approximate zero point, the cylinder has permanently expanded and has not stood the test. Hard by, in the same shed, is a small hospital, containing a few cylinders which have failed under the test. All the cylinders are valved on the premises, the lubricant employed being graphite and plumbago.

The Purity of Oxygen.

At our request Mr. Murray allowed a test to be applied to a small quantity of oxygen taken from the bulk actually in the gas holder while we were present at the works. For this test the Hempel method (which our readers will find described in Messrs. Haddon and Grundy's recent paper on the "Estimation of Oxygen") is habitually used. On this occasion the sample of gas drawn from the holder showed, according to the test, that oxygen was present in it to a percentage of 93·4. Mr. Murray informed us that his Company did not profess to supply a gas containing less than seven per cent. of nitrogen, and that the latter was seldom present in a greater proportion than as here indicated. The supply of gas containing a lower percentage of nitrogen than seven or eight—absolutely pure oxygen in fine—would, we understood, add immensely to its cost.

Most lanternists will agree with Mr. Murray and with ourselves that a gas containing only some seven or eight per cent. of nitrogen is everything that is required for projection purposes. Some idea of the large volume of gas sent out from the Horseferry-road Works may be had when we say that the average weekly output is about 35,000 feet, or, annually, 2,820,000 feet.

The Illuminating Powers of Diluted Oxygen.

The frequent supposition that the illuminating powers of oxygen are necessarily much affected by its dilution with a

large volume of nitrogen, appear to have been contra-indicated by the results of some experiments which Mr. Murray made with a sample of gas other than Brin's, containing nitrogen to the extent of forty per cent., and one of their own preparation, having only some seven or eight per cent. Two lanterns were used, the conditions equalised, discs thrown side by side, and other experiments made, with the result that Mr. Murray found himself unable to detect much, if any difference in the brilliancy of the light given off by the aid of the diluted oxygen as against their own gas. The consumption of the former was, however, much quicker than that of the latter, so that the real loss by the use of heavily diluted oxygen would appear to have more to do with the depletion of the lanternist's pocket than with the degradation of his pictures on the screen.

Oxygen, unfortunately, cannot be identified by its trade-mark, and, therefore, when having one's cylinders filled for one by an agent, it is impossible for one "to see that we get" nitrogen-free oxygen. It appears that some of the Brin Company's agents have recently been supplying gases containing large percentages of nitrogen, with the result that the Company have got an undeserved blame in the matter. Mr. Murray, however, philosophically remarked that Brin's had only suffered a little temporary harm, all their agents having come back to them.

We were disagreeably surprised to learn from Mr. Murray that many cylinders sent back for refilling contain oil, &c. By what we could gather from our courteous guide, we have no difficulty in perceiving that the business of an oxygen-maker and compressor carries with it rather above the average number of small troubles, which require sleepless vigilance to obviate and overcome. Mr. Murray is at present supervising the laying down of additional oxygen-producing plant at Huddersfield, Manchester, and Stoke.

LANTERN NOTES AND NEWS.

A CORRESPONDENT inquires if the Lantern Society is still in existence. Not having for many months received any communication from the Secretary, we presume that the Society is no longer doing active work in connexion with lantern matters.

* * * * *

THE slides to illustrate places to be visited during the Photographic Convention of the United Kingdom, to be held at Plymouth in the week commencing July 3 next, are now going the round among the London societies. Mr. Hansford Worth, the Hon. Secretary of the Devon and Cornwall Camera Club, asks for further applications for the loan of them.

* * * * *

MR. WALTER TYLER, of Waterloo-road, for whom, as the "Universal Provider" of Lanternland, we entertain a respect not unmixed with awe, intends to visit the Chicago Exhibition in the course of the summer. No doubt during his stay he will keep an eye on lantern matters in the States, with a view of picking up any unconsidered trifles in the way of novelties for next season.

* * * * *

THAT is, if there *are* any lantern "novelties" to be met with in America. From what we can gather by a study of the literature of the subject, our friends across the water are somewhat behind us here in lantern-slide work, quantitatively and qualitatively, the same remark holding good with regard to the lantern and its accessories.

* * * * *

ON February 14, Mr. F. W. Hindley showed his now well-known series of Irish slides at the Shoreditch Tabernacle. As illustrations of life and character in remote parts of the Green Isle, these slides are both instructive and humorous. To generalise from the bootless condition of many of the figure subjects—men, women, and children—in Mr. Hindley's slides, one is warranted in supposing that the trade of the bootmaker in some districts of the distressful country is hardly less precarious than agriculture.

* * * * *

APROPOS of Mr. G. R. Baker's remarks in the last "Lantern Record" on the subject of the cost of transmitting gas cylinders under the new railway rates, we heard of a case where a ten-foot bottle, which, under the old rates, cost one shilling and threepence for carriage from London to Hastings, was, since the first of January last, charged five shillings and sixpence, an increase of nearly 300 per cent.! The consignee protested against the charge, to the Railway Company, who have asked him to let the matter "stand over," which means, no doubt, that the Company, like other companies have had to do, will revert to the old rates.

* * * * *

THE other day Mr. T. Edgar Pemberton delivered, in the Court Theatre, an anecdotal narrative, entitled, "The Story of the English Stage," before an audience of distinguished actors and actresses. The lecture, we read, was illustrated by a number of portraits of leading actors and actresses from the time of Shakespeare to the present day, which served Mr. Pemberton as the text for a rapid running commentary. "Some of these screen pictures," adds our authority, "were excellent, but a few were marred by the insufficient size of the sheet upon which they were thrown by the lantern, and others were indifferently focussed." When a non-technical reporter is moved to write thus of a lantern-slide display, we must conclude that it was not so skilfully managed as it might have been. As an adjunct to a lecture, good slides and a well-manipulated lantern ensure half its success; poor slides and incompetent lantern management, even to a non-technical audience, detracts to a like degree from the sum of pleasure or profit derivable.

A USEFUL VARNISH FOR NEGATIVES OR TRANSPARENCIES.

IN the course of an article in the December number of the "Record" on "Lantern Slides," I alluded to the use of a varnish composed of celluloid dissolved in amyl acetate, but since that article was written I have succeeded in making a superior varnish from ordinary pyroxyline, dispensing altogether with the amyl acetate, which is not always easy to procure.

The advantage of celluloid varnish over ordinary collodion is that it sets and dries more slowly and gives a more even film, owing to the absence of the extremely volatile ether which is necessary to effect the solution of pyroxyline. Celluloid itself, consisting of pyroxyline in combination with camphor, is more or less soluble in alcohol either methylated or pure, especially if the liquid be heated, but I have not been able to prepare a satisfactory varnish in this manner, partly on account of the imperfect solvent action, though chiefly because the film when dry is opalescent.

The ordinary sheet celluloid employed at the present time as a support for negative films, if digested in common methylated spirit, slowly swells and gradually dissolves, forming a faintly opalescent solution which flows fairly well over glass, but does not give a very even film. The addition of a very small proportion of ether both aids the solution and improves the character of the film as regards uniformity; but, unfortunately, it dries perfectly white and opaque, and the only purpose to which such a preparation could be put would be to form a dead black varnish for wood or brass work, for which it answers remarkably well, requiring no heat on its application.

It occurred to me that, by using ordinary pyroxyline in conjunction with camphor, the solvent action of plain alcohol might be utilised with, perhaps, better results than above stated. Accordingly, camphor was dissolved in methylated spirit, and to this solution pyroxyline was then added. At first it showed no signs of dissolving, but after some little time it began to swell, and became transparent, and eventually dissolved entirely, forming a bright, clear solution, that flowed easily and smoothly over the glass, and dried with perfect transparency, though very slowly, unless assisted by heat. Compared with a coating of plain collodion, however, I could find no great

advantage as a protective agent, while I think the collodion gave a decidedly more even film, though, when examined side by side when dry, there was not much to choose between the two.

The proportions of camphor and pyroxyline employed were one to four, the camphor being first dissolved in a small quantity of spirit in which the gun-cotton was digested until it was reduced to a viscid mass, after which more alcohol was added, until the quantity of pyroxyline was about five grains to the ounce of liquid. The pyroxyline was Hopkin & Williams' ordinary, which, when dissolved in ether and alcohol, forms a beautifully clear and structureless collodion.

Not being satisfied so far with the result attained, I cast about for a better solvent that could be readily obtained of fairly uniform quality; many solvents offer themselves, but they possess no advantages over acetate of amyl, if indeed they are as good. I remembered, however, some years ago experimenting with methylic alcohol, or rather commercial wood naphtha, as a substitute for ordinary alcohol or methylated spirit in the preparation of collodion; indeed, it was claimed at the time that wood naphtha was, in itself, a perfect solvent of pyroxyline without the assistance of ether.

Whether *pure* methyl alcohol does really constitute a perfect solvent or not I cannot say, but it is certain that the crude article known in commerce as "wood naphtha" will dissolve some kinds of pyroxyline entirely and easily, though others are only partially acted upon, while, again, different samples of the liquid itself exhibit varying solvent powers. The truth is, probably, that the solvent action depends in a great measure on the impurities contained in the commercial naphtha, amongst which are acetone and methyl acetate. The former is well known to be a solvent of pyroxyline, and the latter, judging by the behaviour of the corresponding acetates of ethyl and amyl, may with equal certainty be placed in the same category.

Used alone as a substitute for methylated spirit, the wood-naphtha did not prove, on trial, to answer the purpose much, if at all, better than the spirit in conjunction with camphor. But when a small quantity of camphor was just dissolved in the wood-naphtha, it was converted into an admirable solvent, acting with the particular sample of pyroxyline I have referred to both quickly and perfectly. With other kinds of pyroxyline, as well as papyroxline of the so-called "high temperature" kind, that I happened to have about, it worked equally well as a solvent, but the results were not available for varnishing purposes, owing to a certain amount of opalescence due entirely to the pyroxyline.

The same proportion of camphor—or perhaps a little less—to pyroxyline as that mentioned previously answers perfectly, and the strength of the solution may be varied from three to six grains or more of cotton to the ounce, according to the kind of coating required. For lantern slides the smaller quantity is preferable, but for negatives the stronger film would perhaps be better. The varnish is poured on to the glass in the ordinary way, and left to dry spontaneously in a vertical position, or dried by heat, as may be the more convenient.

Under ordinary circumstances I have not been able to discover any ill effect arising from the presence of the camphor in the film. I have applied great heat without producing any effect whatever, beyond causing a smell of camphor; but it may be worth trying whether, when enclosed between two glasses, as in a lantern slide, a high temperature may not cause a gradual deposition of camphor on the covering glass, and consequent loss of transparency.

W. B. Bolton.

LANTERN MEMS.

The obnoxious railway rates are to be amended, and lanternists will be pleased to learn that already the larger companies whose lines run to the north and west have reverted to the old scale of charges for gas cylinders sent by goods train.

* * * * *

By general consent, it seems to be admitted that the lantern trade has been suffering this season, either from the general depression, or over-production, and the increased number of dealers in apparatus. When every store, many of the large drapers, some of the athletic outfitters, map-sellers, toy-dealers, and others of outside businesses, take to buying commercial lanterns, English or foreign, as the case may be and offering them for sale, it stands to reason that the legitimate traders—*i.e.*, opticians and photographic apparatus-sellers—must be affected.

* * * * *

Of course, in these days of free trade, it must not, I suppose, be hinted that business should be in any way controlled, but most people will agree with me that it is not reasonable to expect a hosier or toy-dealer to understand sufficiently the technicalities of the optical lantern and all accessories to be in a position to personally satisfy himself and customers that what he is selling is really a scientific instrument.

* * * * *

In pre-photographic days the magic lantern could hardly be called a scientific instrument, except in special instances; but now, with lantern sections to photographic societies in such numbers, and lantern societies as centres for criticism and demonstration, anything that does not approach perfection is discounted, if not tabooed.

* * * * *

One naturally, with all the varied designs of lanterns as catalogued and advertised, asks the question, Is there a fashion in the optical lantern? If so, has the fashion changed during the last year or two? and, if so, in what direction is the change?

* * * * *

No doubt, with technical education so much to the front, and the optical lantern popular as a means of demonstration, the inquiry for either scientific or practical slides has increased, and also some modifications in design of apparatus become necessary, so that physical and other experiments can be readily made. The change has been somewhat gradual, but, nevertheless, is decided.

* * * * *

Recently a splendidly made jet gave a little trouble by not producing as much light as formerly, and on examination it was found that the mixing chamber had become fused, and the discs and gauze alternately placed had become clogged. It had been used with a great pressure, and the orifice in nipple was the maximum size it was thought could be worked.

* * * * *

In the result it was found that, notwithstanding the mixing box was already large, it was not large enough for the orifice used, and a better light was obtained by a smaller aperture; for as the pressure increases the opportunity for mixing rapidly must also be available, otherwise the gases blow right through the nipple orifice in somewhat separate streams and do not give the best light, in fact approach nearer the principle of the blow-through jets.

* * * * *

In the old days of gas-bags the pressure was nothing like it is now from the gas-cylinder and regulators, and so the conditions of mixing in the chamber were different. I remember the late Mr. Viles designing a very free way mixing chamber and nozzle for use with bags, and with excellent results; but the same form when used now with pressures representing twenty-four inches of water pressure (and in one case I know of forty inches) it would not be at all the best kind.

* * * * *

The end of the month will bring the end of the lantern season within measurable distance, hence it will be wise to give a thought to the condition of the apparatus before it is put by for the summer. All lime-dust must be removed from inside the body of lantern and finger-marks carefully wiped off the brasswork.

* * * * *

Should it not be possible to keep the whole of the apparatus where the temperature will be equable, and above 50° Fahr., the indiarubber tubing should be disconnected, and put away separately, so that it does not get hard and perish. A little furniture polish (or sweet oil and vinegar mixed) should be rubbed on the woodwork with a soft rag, and all steel parts of jet, &c., wiped over with an oily rag, and afterwards by a clean rag.

* * * * *

For class demonstration, however, the lantern can be employed right up to midsummer, if the limelight is used, and the windows of room reasonably screened by blinds, and providing, of course, that photographs and diagrams, &c., or objects not requiring the maximum of light (such as the microscope), are exhibited.

G. R. Baker.

SKIES IN LANTERN SLIDES.

TIME was, when it was not an unusual occurrence to project upon the screen at a lantern show, a transparency in which the sky was represented by the blank sheet. "We have changed all that," as our *pyrogallic* neighbours say in a well-known proverb. Now, perhaps, there is a tendency to introduce skies too strong in character; but, as this article is to deal with the technical rather than the art side of lantern slides, I must let that pass.

There are three methods of introducing clouds, from a separate negative, into a lantern slide, viz.—

1. By printing them upon the cover glass either by contact or in the camera.

2. By combination printing in the camera upon the *same glass as the rest of the picture*.

3. By combination printing upon the *same* glass by contact.

It is my intention only to describe the first method and the last in this article. The first method because it presents the fewest difficulties in practice, the last because I have a little hobby of my own to ride, and because I think I have found a useful and convenient method.

The first way consists in printing what I may describe as the foreground of the picture upon one lantern plate, and the sky portion of the picture upon a separate lantern plate, which latter is made to serve the purpose of a cover glass. This appears at the first blush to be an extravagant way of setting to work, but it will not be found so in practice. It will be apparent that there is a greater risk of failure when two negatives are to be combined into one picture than when all the image is to be secured by one exposure only. By making a separate exposure of each part, the risk of spoiling an already good foreground by adding to it an imperfect sky is avoided. More than this, for, supposing, by way of example, that this misfortune has already happened, it is easily remedied by clearing off the faulty sky image with a strong reducer, and then adding another and a better sky upon a separate plate. So that, in this manner, if the first way be not relied upon as a *method in itself*, it is, at all events, a sort of *pis aller*—a way out of the difficulty in default of some other procedure which has failed. As I am only suggesting methods of working, and not dealing with the routine of slide-making, no instructions for exposure or development need be given, but the following points are of importance, and should be carefully attended to.

First, as to the lighting of the sky negative—I mean the direction from which the sun's light falls upon the clouds at the time of photographing. Be careful to select a negative in which the clouds are lighted from the same direction as is the foreground. A sunset sky, a magnificent effect of its kind, looks ridiculous when there are cast shadows in the foreground indicating that the sun was upon the left-hand side of the camera at the time of making the negative. It may be suggesting too much in these days of the ready-made, that every one should make his own cloud negatives, but it is a most interesting and fascinating study—that of cloud formations—and a pursuit which may often be followed when landscape is out of the question. A naturally lit sky negative secured, a reversed transparency must be made of it if the cover glass system be followed. The two films—that on the foreground portion and the sky on the cover glass—being brought together film to film for mutual protection, it is clear that the latter (the sky) will be looked at from the reverse side to that of the other, or foreground part of the picture.

Being thus viewed from opposite sides, viz., one from the glass side and the other from the film side, one of them, preferably the sky, should be reversed, so that, by being placed film inwards, its appearance when viewed *that way* is correct. This involves the making of the sky transparency by copying in the camera, and not by contact. If the sky negative be reversed in position in the copying camera, i.e., placed film side *away from the lens*, the resulting transparency will be reversed as far as right and left are concerned, and that is just what is required. Sky transparencies for the method by contact, then, are impossible, unless a sky negative be available which happens to be lighted in the opposite quarter to that obtaining in the foreground, in which case it may be used, and being reversed in the transparency, will be suitable for our present purpose. Generally speaking, I much prefer transparencies made in the camera. There is an indescribable quality about them when shown in the lantern, which is, nevertheless, an obvious one. It consists, I think, in the crispness due to the rays of light proceeding from the lens in the copying camera with little, if any, diffusion, whilst in transparency or contact work the light strikes the negative in all directions and produces a mild form of halation or blurring in the resulting transparency, evidenced in the lantern as a lack of crispness, which does not, however, amount to "unsharpness."

Unless the horizon line be very intricate it will be found most convenient to neglect the sky portion of the foreground and the foreground portion of the sky when making the transparencies. After being fixed, washed, and *dried*, those portions which ought to be clear glass may be made so by a strong reducing bath, such as Farmer's ferricyanide of potassium and hypo. I am inclined, however, to prefer for this purpose a cyanide bath containing tincture of iodine, as it leaves the gelatine film a better colour, and acts more energetically. The following works well for this purpose:—

Cyanide of potassium	100 grains.
Tincture iodide of potassium	20 or 30 minims.
Water	1 ounce.

The solution should be applied to the film, *when it is dry*, with a well-shaped sable brush. If found to act too strongly, the proportion of water may be increased. It must be used upon the *dry* gelatine film, for, if it be applied to the film when wet, the solution will be found to run out of control.

I will now pass on to the third method, viz., printing both sky and foreground upon one plate, and by contact. Let me frankly say at once that much more skill is required to work successfully upon the once sensitive plate; and that, whether it be by contact or in the camera, and whether the two exposures be made by careful registration and developed at one time, or whether the way I prefer—viz., of exposing and developing the foreground, and then adding the sky exposure—be adopted, still the technical difficulties remain. I advocate, therefore, the method which I have already described, because it is the easiest, and there is no advantage in choosing the more difficult way; and it is the cheapest, and this is a happy coincidence. If this be not enough, I am also inclined to find it the most perfect from a technical point of view, because the two portions, or rather the sky, can be pared and reduced down to an indistinguishable joint. Yet, with all these advantages, I shall be inconsistent enough to praise the last, or third, method, if for no other reason than its presumed novelty.

But to proceed. In this method the chief factors are the careful and, I ought to add, judicious shielding of the sky portion from the action of light during the exposure of the picture proper, and also of the picture portion—but this is not so important—during the imprinting of the sky. For this purpose a mask must be prepared, and I recommend that a print be made from the picture negative, and that, after mounting it upon a piece of thin card (it need not be toned or fixed), the line of demarcation between sky and picture be carefully cut with scissors or knife. Armed with the carefully cut mask, an exposure by contact of the picture may be made, the sky being judiciously shielded from light.

Development is proceeded with in the usual manner, and the plate carefully washed. Now place upon it a sheet of clear, transparent celluloid, such as is used for cut films, or a piece of Eastman's rolled film. Rub it down into contact, and be careful to remove air bells. Dry the surface of the superposed celluloid, now ready to be placed, with its attached plate, in contact with the sky negative. The function of the celluloid film is simply to prevent the wet gelatine film being brought into contact with the sky negative, which would quickly spell ruin to it. A proper exposure can now be given to the sky, the foreground being shielded or not, according as it is intended to allow the developer to flow over the whole or only the sky portion of the transparency. My usual practice is not to shield it, but to develop the sky with a large camel's-hair brush, tilting the plate and the containing developing dish at a convenient angle to prevent the developing solution covering the picture portion of the slide. This simple expedient of an intervening waterproof film enables skies to be put in by the double development process, which hitherto have involved the necessity of working by the camera method. As it is quite easy in practice, and involves no further cost for apparatus, it is, at any rate, worth a trial, which will, I trust, be as satisfactory to my readers as it has been in my own hands. If the Editor thinks there is any general interest left in it, I may describe the second method "in the camera" in another article. S. HERBERT FRY.

LANTERN MATTERS AT THE CAPE.

WE are enthusiastic here on lantern-slide making. A goodly number of the members of the Cape Town Photographic Club boast an oil lantern, and at every meeting of the Club an exhibition of lantern slides is given. I say at every meeting, but I should say at at least ten out of the twelve ordinary meetings during the year, and we generally have one or two limelight nights, when the public are invited. It is always dark before nine o'clock here, even in mid summer, and before half past nine the discussion has been disposed of, and the slides appear on the screen. A selection of slides will be shown publicly next week in Cape Town, and will then be shipped fo England to go the rounds of the various societies and clubs. I dare say you will find them a very mixed lot, but then we can say much

about the same thing with reference to the sets that came from England to go the rounds here. I have not seen them yet, and have perhaps no right to express even the very natural opinion just given. Good, bad, or indifferent, a little outspoken criticism by the English photographic journals will do us no harm.

Limelight.

We are still in the dark ages here. The old gas bags, and, alas! that it should be so, retrogression to the blow-through jet. Careless manipulation and too many cooks led to a disaster in Cape Town with the mixed jet. The old story—hydrogen in the oxygen bag. Now the proprietors of halls will not let the mixed jet be used. Up country, where coal gas is unprocurable, and it takes a day's work to make eight feet of hydrogen, the ethoxo light has grown into favour. The Cape Observatory, however, is now to the fore. Here we have an electric light installation, and the Philosophical Society recently purchased a Serrin lamp. At a recent meeting, when Dr. Gill exhibited some astronomical photographs, it was somewhat roughly rigged up, and the current from a storage battery of thirty-two cells turned on. With the dynamo, the arc light in the lantern is an exasperating failure; but, with a steady current, the light is fairly free from jumps and of great brilliancy. Altogether, it was a success, and when the lamp is properly fitted to the lantern, with suitable adjustments for centering, we hope to do better things with it. A gentleman here who has his own installation is getting a lantern wtih electric lamp fittings from England. The arc light is to be used, but I was asked by his electrical engineer what incandescent lamps it would be advisable to try with it also. As I hope to be present at the trial, I trust to be able to give you particulars later on. There is this much to be said, that electric lighting is making greater strides out here than in England proportionately to the importance of the two places, and referring also to its general use, and not to discoveries and inventions, for which, of course, we look to you. There are fewer vested interests in the shape of gas companies, &c., in the way. Some small suburbs of Cape Town are already lit by electricity, and Cape Town follows soon, the dynamos to be worked by water power, and electricity supplied to shops and private houses. I venture to think, therefore, that in its adaptation to the lantern we may get ahead of you, and any notes on the subject may be of service.

Harking back to the arc light in the lantern, I have one serious objection to make against it. The heat is great, and add to that changing of slides, and incessant looking to the centreing, the work is warm. Add further, as I experienced recently, the working of thirty or so moving comic and chromotropes in a darkened room, some twenty feet square, on a Saturday afternoon, the thermometer standing at 86° in the shade, and seventy children and adults present, and you will agree with me that Sheol would have been a relief to it. The forty minutes it lasted took more out of me than a walk up Table Mountain. Happily I had anticipated it, and put on *not* my best clothes—they wanted wringing out after the performance.

The Lanternoscope.

This is a handy little instrument, but I fancy that one of our club members, Mr. Gracie, has introduced a very obvious but great improvement. Instead of a little lens, he has introduced a large one, as in the graphoscope, so that two eyes may be used. Of course, the instrument is a little more bulky, but not remarkably so.

Cutting Lantern Masks.

Will this item be new? I have used the method some years, but it is so obvious, that I am afraid it will be new only to the few. I have always cut my own masks, "to make the punishment fit the crime," and made my own templates, but the difficulty arose in getting the opposite curves symmetrical. The template I use is only half a template, and it is graduated (see sketch) for various widths. The paper is folded, and, when cut, the opposing curves correctly balance one another.

C. Ray Woods, *Photographic Assistant at the Cape Observatory.*

FLEXIBLE METALLIC TUBING FOR THE LANTERN.

The United Flexible Metallic Tubing Company, of 96, High Holborn, is the company from whom the flexible metallic tubing recently referred to by Mr. Haes as suitable for use with the lantern may be obtained. It consists of long strips of metal, shaped to the required section by mechanical means and coiled in a spiral form round a core to form the tube. The operations are performed in a single machine, which produces the complete tubing from the plain strip. It may be had of various internal diameters, in steel or bronze, from five-sixteenths to one and a quarter inches, at sixpence per foot upwards. The tubing is gas-tight, does not kink or smell, and is so far flexible as to coil in a circle of eight inches.

A NEW FOLDING LEVER KEY.

Brin's Oxygen Company are just introducing a New Hinged Lever Key, which combines the good qualities of the ordinary "piano," or Tee

Handle Key and the long Lever Key, without possessing their disadvantages. The Company has hitherto discouraged the use of lever keys, because even in the hands of experienced workers such power can inadvertently be exerted in closing a valve, so that the spindle is liable to injure the valve seating.

The new key will render the opening of valves easier, and at the same time permit of finer and steadier adjustment than is obtainable with the ordinary "piano" key. The above sketch explains itself. The *full leverage*, as illustrated at B and C, is obtainable, if desired, for opening

the valve; but, *as the hinge acts in only one direction*, the key, when used for closing the valve, is converted into the ordinary "piano" form, as illustrated at A. The Company recommend the key to be used for medical purposes, or where oxygen is employed direct from the cylinders.

LANTERN SLIDES ON GELATINE PLATES.

[Leytonstone Camera Club.]

Our subject this evening is "Lantern Slides, and how to make them." This is a very wide title, considering the number of processes there are by which they can be made; but I only intend to treat of one of them this evening, and that is the ordinary gelatine plate of commerce, leaving the others, such as the wet-collodion, collodio-bromide, albumen, &c., to abler hands than mine.

Lantern Slides versus View Albums.

It has always been a matter of surprise to me how few photographers, either amateur or professional, go in for lantern-slide work. Personally, I consider it the most fascinating branch of photography, especially for the amateur who may only go in for a quarter-plate camera, as then it is simplicity itself; for the man who works a larger size it certainly is a little more difficult, but not a great deal. But, whether he use a large or small camera, the pleasure is just the same, as he can occupy his winter evenings, first in making them, and then by showing them in his lantern (or some one else's) to his friends, for it is a fact that you can get people to sit a whole evening and look at photographs on the screen when they will get satiated after half an hour with an album of prints. Another thing, he may have a dozen albums of views, but no one will trouble to come and borrow them to look at (except perhaps on a few occasions, for a *conversazione*, when ten to one they will come back dirty and finger-marked, and practically half spoilt), and there they lie from one year's end to another, a perfect waste of money and power. But let him make a lantern slide from each of them, or, say, only the best, and he will soon

find that his pictures, which as prints in an album no one took much notice of, are now in great demand. A friend from round the corner will send a polite note requesting the favour of the loan of a few slides, as he is going to have some friends. Then the schoolmaster hears of it, and borrows them to show the school children; and then the rector of the parish has a turn, and so on. Thus your picture, which only gave pleasure to a few before, now does so to hundreds, and perhaps thousands.

The Slide and its Uses.

What is a lantern slide? It is simply a print upon glass instead of paper, to be viewed by projection from an optical lantern upon a screen of more or less large dimensions, as by this means it is greatly enlarged. A *sine-quâ-non* of a good slide is that it shall be perfectly sharp, in fact, as sharp as needles; no fuzziness, rough paper, or diffusion of focus is allowed here. A judge who would award a prize to a print from a diffused focus negative would be "down on it like a cart of bricks" if you sent in a slide from the same negative. Another condition of a good slide is that it shall have perfect gradation, from the very highest light (which only should be clear glass, and not much of that) to the deepest shadow, so as to produce that softness of effect which, in my humble opinion, is so desirable in a good slide. I think that the days of the hard black-and-white slide, of diamond mounted brilliance, are fast being numbered.

This brings us to the uses of a lantern slide. We have already spoken of the pleasure side of the question, but that is not their only use. It is as helps to instruction that they are already, and will in time become more so, of the greatest use to man. In hospitals, colleges, schools, &c., they are used to illustrate lectures in a maner that was impossible in the old days with diagrams drawn by hand. I believe a good many hospitals and colleges now have a dark room and apparatus attached for the purpose of making slides of objects and diagrams to be used in the class-room. To the lecturer in astronomy, botany, geology, &c., they are simply invaluable.

Contact and Reduction Methods.

There are two methods of making lantern slides, first by contact, and, secondly, by reduction in the camera; the first is the most simple, and very fine results are obtained by it; but it is only applicable to small negatives or small portions of large ones. For the whole of a quarter-plate, or anything over, we must have recourse to our second method by reduction, and it is to this that I shall chiefly refer this evening; but I will give a short description of the method by contact first. In printing by contact, it is as well to have a special printing frame, such as the one I have here (Adams'). By means of this I can print from any portion of a negative, from whole-plate downwards, and, once having selected the portion required, there is no need to readjust the frame, supposing that you want more than one slide from the same negative. There is also no chance of the plate slipping and thus getting scratched, which is very likely to happen with the ordinary frame, it also prevents any light getting in at the side of the slide. A lantern plate is taken and placed in contact with the negative and exposed to the light of a lamp or gas flame for so many seconds, more or less, according to the density of the negative, near to the light if it is a hard one, and some distance off if it is a thin one. There is one good thing about this method, and that is, that you can be pretty sure of getting a good slide at the second shot if you don't manage it at the first, as, the light being nearly a constant factor, it is only necessary to give the next plate a few seconds more or less, according to circumstances.

But to come to our second method, by reduction in the camera. By reduction I mean, to reduce the whole of, say, a 10×8 negative on to the standard $3\frac{1}{4}$ inch lantern plate. Obviously this cannot be done by contact, so we must use the camera. The 10×8 or any other sized negative is placed in such a position that it is evenly illuminated, and then simply photographed on to the lantern plate. The great drawback to this is, that it is almost imperative that it be done by daylight, as the great difficulty with artificial light is to get an even illumination over the whole of the negative, unless you use a condenser, which is an exceedingly expensive item, as one large enough to cover a half-plate would have to be about eight inches in diameter, and would cost about 5*l.*, and one twelve inches in diameter would cost about 11*l.*, and that would only cover a whole-plate, so that for most amateurs is out of the question. But, by using daylight, it is a very inexpensive matter, providing you have the time and the daylight; but that is the rub; most of us have not much time when daylight is available; but for those that have, here is what is required, and those that have not got it should make it by getting up a couple of hours earlier in the morning (I know one man that makes the majority of his slides by this means), it will do them a lot of good in more ways than one. Take a board about three feet long, such as the one in front of me, and attach a frame to one end of it to hold the negative, and a small sliding platform to hold the camera. This is then to be rested on the frame of a window having a clear view of the sky. This length of board is quite long enough to reduce even from 12×10, if a four-inch lens is used. Two pieces of grooved wood cross the frame to support the negative, and these pieces can be adjusted at any angle, so as to be able to correct any lines that are not quite plumb, the swing-back of the camera being also brought into play for the same purpose. This board can also be used for artificial light without a condenser, if magnesium ribbon is used, and we will try a few exposures this evening. A piece of ribbon is burnt behind the negative, and is passed rapidly to and fro, only pausing for a moment where any part more dense than the rest requires more light, or strands of the ribbon can be stretched across a frame behind the negative, having a double thickness opposite the part that requires it; but this does not seem to give such an even illumination as the previous method.

The Plate and its Development.

There is a choice of several varieties of plates to use, and I think they are all as good as one another; but it is better to stick to one make of plate, as then you can get a set of slides all about the same colour and tone. I am speaking now of black tones, but for reds, warm brown, or purple, it is as well, perhaps, to use a chloride plate such as the Alpha or Cowan's. Some of these colours can be obtained on the ordinary plate by toning with uranium for brown sepia or reds, and by developing with pyro and carbonate of ammonia for purple; for good blacks nothing seems to beat hydroquinone, although very good shades of black can be obtained with ferrous oxalate, eikonogen, rodinal or amidol. The formula that I use is the Ilford Universal, as follows:—

No. 1.

Quinol	100 grains.
Potassium bromide	30 ,,
Soda sulphite	2 ounces.
Water to	20 ,,

No. 2.

Soda caustic	100 grains.
Water	20 ounces.

One part each No. 1, 2, and water, and for chloride plates, two parts quinol, one part soda, and four parts water. With quinol there is no necessity to use a clearing bath, as this developer does not stain the plate like ferrous oxalate. The fixing bath, four ounces hypo to a pint of water, is quite strong enough, and a fresh clean solution should always be used. After the slide is fixed it should be well washed in running water for one or one and a half hours, then dried in a place free from falling dust, when it is ready for mounting. When the slide is taken from the tank after washing it is well to give it a final rinse under the tap and gently pass the finger over the surface of the film. This will remove any particle of dust that may have become attached to it.

Exposure.

The matter of exposure is an awkward one to deal with, no two negatives require the same, a very dense one on a dull day in winter at 11 o'clock may require anything from two minutes to twenty on an Ilford Special, Fry or Paget Rapid, but a negative of good quality and proper density, say at this time of the year at 11 o'clock, with a bright clear sky about forty seconds or thereabouts, but it is mostly a case of trial and error, if thirty seconds has been found too little, the next one, at forty-five seconds, will perhaps be right. This may seem somewhat wasteful and extravagant, but it is not necessarily so, you *may* use four plates before you get a right exposure in the first negative that you start with; but this experience will serve you well in the following ones, and you may go on, and, with one or two exceptions, make a good slide at each exposure afterwards. The great difficulty is, that the light is not a constant one, especially when the sun is obscured by clouds, so that, when returning from the dark room, you may not notice that the light is not so good in consequence of a darker cloud than usual having crossed the sky; this means that the next plate will be more or less under-exposed; it is these little things that throw you out and account for the pile of wastes that come in so handy for cover glasses. While we are on the subject of exposure it is necessary to point out that there are very few negatives but what are all the better for a little judicious shading of some part or another—for instance, covering the landscape, while the clouds in the sky print through, that is supposing that the clouds are there to print; if not, it is better to sun the sky down, by moving a piece of card up and down in front of the negative, giving more exposure to the upper part of the sky than the horizon. Again, in the case of an interior view, the window will be much more dense than the remainder; this should be printed by cutting a hole in a piece of cardboard, and holding it so that the light

coming through the hole only on to the window will enable it to print through; then, when it comes to developing, these under-exposed parts may be brought up, by the use of a stronger solution applied by means of a brush, or, better still, by the finger tip, as the heat from the finger helps the action of the chemicals in the developer; this brings us to another point in the matter of under-exposed (or apparently so) plates.

Toning, Reducing, &c.

At this time of the year, if the solutions are kept in a cold room, the chemicals that compose them will refuse to act to their full power unless they are raised to the normal temperature of 60° or a little over; the careful use of a jug of warm water at this time of year will make a great difference in the number of thrown-outs; but all these under and over-exposed and under and over-developed plates need not be all wasted; take the under-done ones first, they can be intensified by bleaching with mercury, followed by a twenty grains solution of potassium sulphide, which will give them a somewhat brown tone; and apparently they are permanent, as I can detect no change in the slide that I will hand round, although I made it some two or three years ago. But the most satisfactory way of improving a plate that has been only a little under-exposed or developed is to tone it with uranium; as this also slightly intensifies it at the same time, very good browns, reds, and sepia can be obtained with it, a solution of half grain each of uranium nitrate and potassium ferricyanide and fifteen minims acetic acid to the ounce will work well. Place the slide in this and watch it, till it has gone some distance beyond the shade of brown that you require and then wash it in water until all the yellowness has disappeared from the white and it has come down to the desired tone; it must not be washed too long or it will all disappear, as the salt that is formed is ferrocyanide of uranium, which is soluble in water. If you want a chalk red or Bartolozzi tone, continue the toning a little farther and then apply a reducer, such as Howard Farmer's, of potassium ferridcyanide and hypo; or, better still, Haddon's, viz., potassium ferridcyanide five grains and sulphocyanide of ammonium ten grains to the ounce of water, this will dissolve out all the silver and leave only the red uranium image.

To come to over-exposed and developed plates, these may be reduced by the last-named reducer, being very careful to watch it well, as it is very rapid in its action. The plate must then be quickly and well washed, and carefully dried, or otherwise the tears left on the plate will go on reducing till it leaves a clean spot where it rested. Chloride plates, over-toned with gold, can be improved by these means, by dissolving away a portion of the silver and leaving the gold behind untouched.

Chloride Plates.

You will notice that I have treated only of the ordinary bromide plate; the chloride wants a different treatment entirely. Very beautiful tones can be got both by simple development and also by toning with gold, but the great drawback to the use of these plates for reduction in the camera is their slowness. Life seems almost too short when you have to use up the whole of one day in summer to obtain a half-dozen slides; but by contact it is another matter, an exposure of two or three minutes to a good paraffin lamp, with a very weak quinol developer will give you all shades of brown or red, according to the length of exposure and development; the longer the exposure, the warmer the tones. These can afterwards be toned in the combined toning and fixing bath to very rich brown, purple, or deep blue.

You will see by all this that there is a little more difficulty, perhaps, in making a slide than there is in making a print in albumen or gelatino-chloride paper, but I think that the results certainly warrant the extra trouble. I don't think that there is any process in photography that will show the amount of detail that there is in a negative better than a lantern slide, or any other sized transparency. There is one great advantage in making a lantern slide of all your good negatives, and that is, that if at any time you break the original negative it is possible to make another by enlarging from the lantern slide, which will be little, if any, worse than the original.

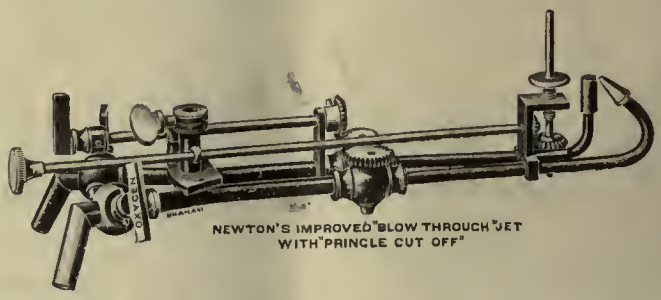
A Question.

This brings me to the end of my paper, and I have only one more thing to say, and that is to ask a question. Why is it, in all photographic competitions, the conditions in the lantern-slide classes imposes that six lantern slides shall be sent in? It seems to me distinctly unfair that one medal to six slides should disqualify prints from the whole of those negatives from being shown in competition where previously medalled pictures are barred. It is infinitely more trouble to make a good lantern slide than it is to make a print by any method that I know of. If six prints are sent in, and six lantern slides from the same negatives, if one of the prints secure an award, it only disqualifies one of the slides; but, if the slides secure the medal, it disqualifies the whole of the prints. This should not be so. Of course one can quite understand the secretaries of exhibitions wish to get as good a show of slides as they can, especially in numbers, which they might not be able to do if they offered a medal for single slides. I think that this is a very good subject for discussion by the forthcoming meeting of Exhibition Judges if it (the meeting) ever comes off.

H. E. Farmer.

AN IMPROVED BLOW-THROUGH JET.

Messrs. Newton & Co., of Fleet-street, have introduced an improved blow-through jet with the Pringle "cut off." The principles and action



of the jet can be readily understood by the lanternist from the above excellent cut.

RECENT LANTERN PATENTS.

PATENT COMPLETED.

A New Magic-lantern Slide.

No. 4668. William Havelock Mason, 8, Harold-terrace, Hermitage-road, Green Lanes.—*January* 14, 1893.

The invention has for its object the production of a new magic-lantern slide, whereby a drawing, writing, or other delineation is made, more or less gradually, to appear upon a screen as though it were being drawn thereon.

In carrying my invention into effect, I take a saturated solution of saltpetre, slightly thickened with gum arabic dissolved in water, or a solution or preparation of other suitable inflammable chemical substance or substances, and with it I write, draw, or print any design, writing, or delineation upon an unglazed paper, or other suitable substance, which is capable of burning away readily at the parts where the solution is applied, but which will remain intact at the other parts thereof.

I mount this prepared paper, or other suitable substance, as a magic-lantern slide, a suitable form consisting of a cardboard "mount," having a square, or other suitably shaped aperture therein, and of somewhat similar character to mounts used for drawings, pictures, &c., on one side of which "mount" I cement the prepared paper or other substance used.

Slides thus constructed are placed in a carrier in a magic lantern, fire is applied to one or more points of the design, and it is then focussed.

The said paper or other substance produces on the screen either darkness or a coloured disc, according to the thickness, texture, and colour of the said paper or other substance. Fire having been applied as aforesaid, the paper or other substance prepared as before described burns away at the parts drawn, written, or printed upon with the solution referred to, but remains intact at the other parts thereof. The result is that the design so written, drawn, or printed as aforesaid is more or less gradually reproduced on the screen in white upon a black or coloured ground, according to the nature of the paper or other substance used.

I would here remark that the lines of the writing, drawing, or other delineation are preferably made as continuous as possible, in order to avoid the necessity for applying fire thereto at any inconveniently large number of places; but, in order that the ground may be retained flat when the inflammable composition forming the design has been consumed, I make a suitable number of spaces in the design so as to leave at intervals unconsumed cross pieces, which connect the various parts of the ground securely together, and thereby prevent any part thereof from falling out of focus. I would also remark that other suitable solutions or preparations of inflammable material may be employed in lieu of the preparation of saltpetre herein referred to.

The claims are:—1. A magic-lantern slide consisting of a sheet of unglazed paper or other suitable material, on which any desired design or matter is written, drawn, or printed by means of a solution or preparation of saltpetre or other readily inflammable material, substantially as herein described and for the purpose stated. 2. A magic-lantern slide in which a design or other matter is drawn, written, or printed on a suitable ground with a solution or preparation which is readily inflammable, substantially as herein described and for the purpose stated.

Before the Bristol and West of England Photographic Association, on February 24, Mr. E. Brightman in the chair, Mr. Gwyer showed a new oil lantern he is patenting, which gave very nearly three times the light of a good oil lantern matched against it. This result is obtained by a new system of concentrating three wicks, using common paraffin, and an ingenious shafting for draught. The lantern worked without any smell.

"Lantern Queries" are unavoidably held over.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*April 7, 1893*

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

Mr. Walter Tyler, of Waterloo-road, has kindly promised to give, early in the ensuing season, a Lantern Entertainment, in aid of the funds of the Photographers' Benevolent Association.

* * * * *

On the occasion of the Leicester Society's Exhibition a fortnight ago, Mr. H. Pickering, the Hon. Secretary, was agreeably surprised at the receipt of a testimonial from his fellow-members in recognition of his services to the Society. It took the form of a handsome lantern by Messrs. Archer & Sons, of Liverpool. By the way, Mr. W. J. Archer informs us that he, too, is "off to Chicago." "Are you going to Chicago?" is a question as frequently asked just now in the photographic world as Messrs. Pears' "Good morning! have you used Pears' soap?" is in the newspaper advertisements.

* * * * *

We learn that nearly 2000 lantern slides were examined and tested recently by Messrs. F. C. Beach, William H. Rau, and Dr. G. Hunter Bartlett, the Committee of the American Lantern Slide Exchange. Over eight hours were spent in the work. Fifty per cent. of the total were sorted out as passable. Many of the others were marked with a letter showing the reason for rejection, and returned to the clubs from which they came. The slides have been arranged in nine sets, and there is also a set of English slides. The slides are already going the rounds of clubs in the Exchange. The defects in most of the slides rejected were from under-exposure and too short development.

* * * * *

This is a lantern story—and a true one. At a popular place of entertainment, not a hundred miles from Sydenham, an elderly gentleman of respectable appearance one day presented himself for admission, when, to his surprise, the money-taker turned to an adjacent officer in blue, and said, with a laugh, "I say, Bill, look here; we know this man, don't we?" "Know him," replied Policeman X, grinning; "rather. Why, he's quite a notorious character!" "What do you mean?" demanded the visitor, in mingled astonishment and annoyance. "Oh, you'll do," said the money-taker; "but we've seen you too often for *that* sort of thing, you know." "I should think so," chimed in the policeman; "why, we've had our eyes on you every night for the last fortnight." The elderly visitor looked amazed. "I've never been in the place in my life before," he gasped, and then the policeman and the money-taker burst into loud laughter, to the utter discomfiture of the other. When they had had their laugh out, they explained that they had seen the elderly gentleman in uniform on a big white sheet—and then a light dawned upon him. It seems that, like Mr. Bumble, he was a "public character," and that he had been (in his picturesque official panoply) photographed, "lantern-slided," and projected on the screen at the nightly Lantern Entertainment. And so all ended happily.

* * * * *

On Tuesday evening, March 28, the Photographic Society of Great Britain indulged in the mild frivolity of a Lantern Evening—just like the smallest and humblest of its adopted children. But it was quite an accident. Mr. Fred Hollyer was prevented by illness from giving his promised demonstration of *Platinotype*, and so at the last moment the bill had to be filled by a scratch collection of slides. And very good slides they were too, chiefly of Yorkshire scenery, and contributed by the Leeds Photographic Society. The chilling solemnity of the Parent Society's meetings might, in the winter months, be very well relaxed in the interests of the younger members by an occasional Lantern Night.

* * * * *

Writing of the keeping properties of oxygen in cylinders, Mr. C. T. Milligan, in the *Exhibitor* (Philadelphia) says: "Our plant of tanks is in constant use, and consequently has not given us much opportunity to test this subject thoroughly, because new gas is pumped into them perhaps once every week; but we remember that, some years back, a gas tank turned up that had been out of our possession for at least two years. It had been sent away with oxygen in it, and had been stored away out of sight, we cannot tell exactly how long; but we remember when the valve was opened, it was evident, from what was blown out of the valve, that some insects had made their nests inside." Insect cultivation in oxygen sounds a bit out of the common. We always thought, and it certainly is taught, that life could not be sustained in an atmosphere of oxygen.

* * * * *

Mr. Milligan has been, he says, experimenting in the direction of doing away with regulators, and, after studying out the subject for some time, tried the experiment of connecting the gas tanks having great pressure, with the lanterns direct. He found there was no difficulty whatever attending the trial, and that, with a single lantern, he could just as readily connect with a cylinder having eighteen hundred pounds pressure as one having twenty or thirty pounds pressure. There is no more skill required in operating one than the other, and no more danger in using one pressure than in using the other. The regulating of the supply of gases is done at the gas tanks the same as it is done with the lower-pressure tanks. The next experiment was with a pair of lanterns and with a dissolver. He took a pair of tanks, each having eighteen hundred pounds pressure, with no regulator, used his ordinary high-pressure dissolver that is attached to the lantern, connected the dissolver with the tanks by ordinary rubber tubing, and was enabled to get perfect dissolving. He found, he states, that it was better dissolving than with the lower pressure, and this result merely corroborated the theory on the subject which led to these experiments.

* * * * *

The results of the foregoing experiments justify Mr. Milligan, he says, in condemning all regulators. He thus meets possible objections to this condemnation: "We imagine that the first answer to our condemnation will be that the regulators make a uniform supply of gas all through the exhibition. Our answer to this is, that the very

fact that the tanks being smaller, and the quantity of gas used at any one time being the same with either form of tank, that the smaller the tank the more uniform the flow will be during an exhibition. Therefore, from a small tank we expect a uniform flow. This is true when the pressure is high. The higher the pressure the more uniform the supply. We advise that regulators be thrown aside."

* * * * *

From a letter published in the Journal this week it will be observed that the Plymouth Convention slides have been lost in the course of their wanderings among the various photographic societies desirous of seeing on the screen, pictures of the places to be visited next July. We hope the missing set will be recovered.

CUTTING LANTERN MASKS.

The size and shape of the mask employed is often a matter of far greater importance than the producers of lantern slides appear to think, as in very many instances an otherwise good picture is spoilt by having too much foreground or sky included, owing to the regular size of mask not suiting the particular subject. Besides this, when working from such sizes of negatives as, say, 8×5, it becomes abso lutely necessary, if the ordinary masks are used, to waste nearly half the subject, with the result, very often, that the composition is altogether ruined.

The manufacturers of lantern requisites have not yet come to fully recognise the difficulties arising from the difference in shape of the lantern plate and most of those in general use for landscape purposes; but, even if they did their utmost in the direction of supplying masks in variety, it would be impossible to meet the requirements of every individual picture or to provide for every contingency that may arise. Many amateur slide-makers are fully awake to the desirability of suiting the shape of the picture to the subject, and cut their own masks, but by far the greater majority are content to rely solely upon whatever may be put into their hands by the manufacturers.

The trouble attending the production of one's own masks is not great if the matter be taken systematically, and the result is then quite equal, with a little care, to the commercial article; but to have to turn to without proper appliances to cut half a dozen masks of different shapes and dimensions is neither an easy nor a satisfactory job. I have seen a whole evening spent in the task of cutting the masks for and mounting three or four slides which would not lend themselves to the ordinary shapes, when the same amount of time and labour devoted to the means for cutting the masks would have rendered the operator practically independent for all time.

For general purposes, especially where only one size of negative is made, three or four standard sizes will generally suffice. For instance suppose the negative be $7\frac{1}{2} \times 5$—a rather awkward size for lantern purposes—three or four fixed openings in addition to the square, measuring two and seven-eighths or two and three-quarter inches, as may be preferred, in the longest side and narrowing by eighths, will cover almost every pictorial requirement; and it will only be very extraordinary subjects, such in fact as will scarcely be worth making into lantern slides, that will necessitate any further departure from the square.

In the last number of the *Record*, Mr. C. Ray Woods described his method of cutting odd-shaped masks by means of a half template graduated for different sizes, and this plan answers admirably where a great variety is required; but, if we decide to adhere to a few fixed shapes, it is, I think, an easier plan to have a set of complete templates cut in zinc. Any zinc worker will cut them accurately from a paper pattern for a few pence a piece, or it will not greatly overtax the skill of a moderately "handy" amateur to do them himself. If he be a fret-sawer the job will be a comparatively easy one, the opening being cut nearly to the previously marked outline with the saw, and carefully finished off with a fine file.

If a fret saw or "piercing saw" be not available, the procedure is rather different. Suppose it is an ordinary "cushion"-shaped aperture we wish to make, the first step is to draw an outline of the dimensions required, but with rectangular instead of round corners, then, taking a common carpenter's three-eighth centre bit, accurately mark the four points at which it has to be worked to clear out the corners, and bore the four holes, which is easily done in the soft zinc. Next lay the zinc on a surface of hard wood or iron, and, with a mallet and carpenter's chisel, cut through from corner to corner of the rectangle between the holes, dividing the metal into four triangular pieces. Finally, with a strong-bladed knife or the corner of a chisel, score partly through the straight lines of the outline, joining the four circles on both sides of the metal until it is thin enough to break off on gently bending to and fro, and finish off with a fine, flat file or a piece of emery cloth wrapped round a flat piece of wood. A dome-shaped template is rather more difficult to cut without the saw, but it may be chipped roughly to shape with the chisel, and finished off with a half-round file, the finish being given with emery cloth.

Such a template will last for a very long time, and, if used with one of the "American" print-trimmers, will cut a mask in every way as perfect as those purchased. The trimmer, however, must be one of the real American make, not the cheap imitations now on sale with revolving cutter the size of a sixpenny piece, and requiring almost a circus ring in which to revolve. The cutter of the real "Robinson" trimmer, too, is pivoted in the same manner as a glazier's diamond, which greatly facilitates its going round corners or curves; in fact, with one of these, a circle, oval, or cushion-shaped mask can be cut in a single stroke without stoppage, which is not the case with the fixed cutter.

Some few years back there was described in the *Scientific American*, I think, a method of making a die or cutter for stamping out masks in a single operation. This, though extremely useful where large numbers of one size are required, is rather too elaborate for the purpose of only occasional use. However, it may be useful to some who probably have not seen it described. A block of hard wood is first carefully worked to the exact size and shape of the opening required. A piece of old clock-spring is then obtained, punched with holes at regular intervals, and, while hot, bent round the wood block, made to fit accurately, and fixed in position by means of screws. The ends of the spring are made to meet as accurately as possible, and the edge sharpened, when a really efficient cutter for light work is produced. I made one at the time the description appeared, and was astonished at its efficiency.

This, however, is of no use except for the one size, but corner cutters or curves n be made on the same principle. A better plan, however, for cushion masks is to substitute a hollow punch such as those used for cutting gun-wads, only smaller, and proceed in precisely the same manner as described for cutting the template. Still simpler, let an opening of the size desired be cut in a sheet of stout cardboard, but with rectangular corners. On a block of hard wood or other suitable surface lay half a dozen or a dozen sheets of the paper from which the masks are to be made, and over these the cardboard shape or guide. Get an assistant to hold this firmly, while with the hollow punch just mentioned placed in each corner of the guide in succession four circles are cut out, forming the corners of the cushion. Then, either using the cardboard still as a guide, or preferably treating each mask separately, with a sharp penknife and straight edge complete the outline by joining the circles, and a series of masks will be obtained that will be difficult to beat if proper care be taken.

This plan is, of course, available for any shape or size, and if the cardboard rectangle be only truly cut it is impossible to get the cushion corners out of square or to introduce any irregularity, and the circles then form an accurate guide for the subsequent application of the straight edge.

The methods I have given are more difficult to describe than in actual use, and, if the subject seems trivial to some of the readers of the *Record*, I dare say there are others who have experienced the difficulty of cutting odd-shaped masks.

W. B. Bolton.

LANTERN MEMS.

There was much to interest photographers at the meeting of the Royal Meteorological Society, on March 15, when Professor Shelford Bidwell, F.R.S., gave a lecture on "Some Meteorological

Problems," and illustrated the same by experiments. As the optical lantern assisted in the demonstrations, some description of the part it played may be a fit subject for the LANTERN RECORD.

* * * * *

As many of the experiments were shown in a fairly lighted room, and the projection of the photographs was quite clear to a large and representative audience, it may be said, with reason, that the optical lantern, as far as lectures and class-room work is concerned, is quite as useful in summer as in winter. In this instance the lantern was not only used for ordinary projection, but for illuminating chemical and other apparatus, and making visible the results of the experiments.

* * * * *

AFTER showing electrification produced by evaporation and by friction of dust, many photographs of lightning flashes were exhibited as well as photographs of electric sparks, and by means of suitable connexions and apparatus the projection of a Leyden discharge was performed, and its resemblance to lightning made manifest. The phosphorescence of the air was clearly shown by means of an electrically connected board, covered with Balmain's luminous paint, and also by the revolution of a vacuum tube.

* * * * *

SOME idea was given of the duration of a lightning flash by means or a rotating colour disc. This was of the usual "Newton disc" order, with successive sections of seven colours, and was made to revolve at a rapid rate, so that only a grey colour was seen on the disc. When the electric spark illuminated this disc the coloured sections were distinctly seen, and it was stated as a result that the duration of the flash must be less than 1·10,000th part of a second for this to be seen.

* * * * *

THE value of photographs of lightning flashes was clearly shown, and many optical effects illustrated by the different pictures, the so-called ribbon lightning being clearly traced to a movement of the camera, and certain dark streaks in the sky of zigzag or branchlike pattern were due to complementary impressions on the plate following a comparatively long exposure when photographing the lightning flash. In some such way as we get a complement by looking at a bright window, and then closing our eyes and looking away we see dark for the light of the glass windows and light for the dark sashes.

* * * * *

MANY other effects, such as the flicker of lightning, the efficiency and non-efficiency of lightning conductors under certain atmospheric conditions, the production of two forms of lightning discharge on Professor Lodge's plan were illustrated by the convenient electrical apparatus, in the capable hands of the lecturer and his assistant, while the optical lantern was again requisitioned in illustrating why thunder clouds are dark and large raindrops fall during a thunder shower.

* * * * *

THE first was shown to be due to the electrification of vapour, for, by means of a spirit lamp and vessel of water, with a bent tube (twice bent at right angles), a jet of steam was projected on the screen, and, at first, looked quite clear, in fact, only just showing by the flicker or waving of the air; but, directly it was electrified by means of a rod charged from the Leyden jar, it assumed a blackness on the screen that was very decided, and each successive contact or withdrawal of the rod produced alternate clear or opaque projections.

* * * * *

THE electrification of water showed that while a jet of water, after rising, fell, as one naturally sees it in a fountain, with a certain amount of spray, when it was electrified the drops coalesced and came down remarkably solid. The projection of this spray was managed by shadow on the screen, the rays from the lantern illuminating that part of the fountain which had been arranged on a table in front of the lantern.

* * * * *

AFTER demonstrating that dust in the air was essential for the condensation of water vapour, and that the colour of the sky was due to refracted rays and not direct rays of light, a pretty and fitting conclusion was made to the lecture by the performance of Captain Abney's experiment illustrating the formation of sunset colours.

* * * * *

FOR those who have not seen this interesting effect I may mention how it is performed. An opaque screen is placed in front of the condenser with a small aperture in it that can be focussed on the screen to resemble the sun. A trough is placed on the stage of lantern having some hyposulphite of soda; on this is poured dilute hydrochloric acid, and, as the solution is stirred, the disc on the screen changes colour from bright yellow to orange, and, finally, to red.

* * * * *

A FEW words respecting the lanterns used. They were quite simple, without any pretensions to appearance, but had arrangements whereby the front could be withdrawn from the stage for the insertion of tubes, troughs, or apparatus. If one had been disposed to criticise, one would have said they were too simple for ordinary projections where the apparatus is placed between the audience and the screen, for until something was improvised to stop it the light streamed out at the back of the lantern into the eyes of a number of gentlemen in that part of the lecture-hall.

* * * * *

THIS shows the value of having a curtain at the back of the lantern, for one can never tell in a hall or room what will be the most convenient place to fix up the apparatus. And again, viewed simply as an optical lantern for projection of photographs, the nearness to the screen and the considerable tilt or angle of the front prevented square pictures being rectangular when projected on the screen. They were considerably broader at the top than bottom. With so much of interest and so many experiments brilliantly performed, one hesitates to say one word that may be considered disparaging, and my only idea in mentioning it is, that if a lantern cannot be elevated so that the beam from it is nearly at right angles to the screen, then a greater distance must be arranged for placing the lantern, that is, to project ordinary photographs, if one desires to get the best results all round.

* * * * *

THIS lecture of Professor Shelford Bidwell's was so full of interest that I would advise all who possibly can to get a copy when it is published, as I hope it will be, in the *Journal of the Royal Meteorological Society*; and should it be possible to arrange a repeat, say at the Society of Arts, a great treat will be in store for the members and friends.

* * * * *

THE field open for the Optical Lantern is a large one, and almost all the sciences can by its aid be taught, and demonstrations made to large or small audiences of so much practical value that would not have been possible before photography was simplified and the introduction of compressed oxygen and hydrogen had made the limelight the simple, clean, and of course powerful light it is, so convenient to hand. Medical and surgical subjects, chemistry, electricity, astronomy, geology, botany, optics, and physics generally can be shown, or phenomena and laws demonstrated, by photographs or actual experiments, and it is only for exact requirements to be known for apparatus to be forthcoming to aid to this end. G. R. BAKER.

THE GENESIS OF THE REGULATOR.

As no one seems to answer a recent correspondent's question *re* the first compressed gas regulators, possibly the following notes on the subject may be of interest.

The first regulator that came under my notice was in 1882–3; it was introduced by Messrs. Pexton & Ash. The construction of this was the ordinary Bourdon gauge tube, the movement caused by the deflection or straightening with the pressure submitted was taken advantage of, and, by attaching to the free end a lever connected to a screw valve, the condensed gas was to be controlled; but, forty years back, both French and German patents were taken out for a reducing valve for condensed gases, such as carbolic, but evidently did not answer, as they were never worked. I think I am right in saying

that the first effectual automatic regulator was produced by Oakley & Beard in 1884, but owing to its bulk never met with much favour. This was followed by Clarkson's bellows-regulator, worked much upon the same principle, having a lever instead of the central differential screw spindle, possibly the outcome of Mr. Hepworth's miniature gas bag and pressure board connected with the lever-key of cylinder direct. I also heard of Mr. Mellor having a gas-regulator which he worked by a column of water about twenty inches, but have never ascertained the exact working.

The next regulator was Beard's (small size) of present-day pattern. This was at once seen to meet every requirement, being extremely portable and the working parts being protected. In manufacturing these instruments it was soon seen that a moving valve upon its seat could not long be kept sound, and hence the life of a regulator which depended upon the soundness of its valve was very short. With the lazy levers in conjunction with the two eccentrics any amount of leverage upon the valve could be obtained, and absence of friction upon the valve seat greatly prolonged the life of the regulator. It was evident that a direct-acting valve (that is, a valve which has only vertical movement) is the best kind for automatic regulating valves for high pressures, or, where lower or very accurate and even pressure is required, the pressure could be stopped down, as it were, from one regulator to another (see patent specification). After the introduction of this form others quickly came into the market, all more or less following upon the same lines.

The first to follow was Messrs. Clarkson & Spurges duplex regulator, an analysis of which soon reveals the bisection of the eccentric arrangement, viz., only one eccentric with a compound lever attached to the bellows, in the high-pressure chamber; this is again stepped down by a secondary valve which is attached direct to bellows-cover.

During this time Henry Brier, of the Scotch and Irish Oxygen Company, was working at this metallic bellows-regulator, and, I should think, might have been on the market long before had it not been for the difficulty of manufacturing the bellows. The principle of the regulating mechanism is the straightening of a bent rod, the valve being pressed against its seat by the end of a broken arm, as it were, the shoulder being the fulcrum, and the elbow, connected with a rod from the movable bellows-cover, the hand pressing the valve — a very ingenious arrangement, and it will be seen, as the straighter the arm gets, the more power is exerted upon the valve, without increasing, to any very great extent, the pressure in the bellows.

Suiter's valve was next put upon the market. No multiplying leverage was employed, the spring of the metal diaphragm acting as the movement for the controlling valve, the valve being attached to the diaphragm direct, exactly similar to the well-known Bickerdike diaphragm regulator for house gas, the diaphragm being metal in place of leather. Since, an improvement upon this has been introduced, and a lever employed; the valve in this shuts upon the gas.

By the above it will be seen that all the valves now in use are vertical-acting, only being pressed upon their seats by the various mechanism employed by the gas-inflating bellows or diaphragms.

I may, in conclusion, remark that the life of a regulator is dependent upon the property the valve has of remaining gas-tight.

R. R. Beard.

HOW TO COLOUR LANTERN SLIDES.

[Scientific American.]

Nothing is more interesting and satisfactory to the amateur photographer than to place upon the screen, by means of a good lantern, the results of the summer's work; and, while it may be questioned whether anything can be more desirable for projection than a really first-class, well-toned lantern slide, yet experience proves that the majority of people who enjoy an evening with the lantern are pleased when a well-colonred slide is shown.

A suitable subject, carefully printed and artistically coloured, when reflected from the screen, strongly resembles a huge water-colour picture, the great difference between such a picture and a water colour being a superabundance of detail, which is inherent in photographic pictures and which is not desirable in a water colour. A photograph can be made which will answer admirably for colouring which would not be satisfactory as an uncoloured picture. Such pictures are taken through a large diaphragm or with full opening. The foreground is made sharp, while the middle distance and distance are softened down by being a little out of focus; however, it is not advisable to try to make negatives expressly for coloured pictures.

The print for colouring should be moderately light and without great contrasts. Inky shadows are to be avoided, and it is well to vignette off the distance to give atmosphere. The sky should be transparent, unless cloud effects are to be shown. While specks and pinholes are very damaging to an otherwise fine lantern slide, they entirely spoil a picture, for colouring. In a picture well broken up, as in a wooda scene, where little sky appears and when there is no placid water, these small defects do little harm; but, in a sky or in a clear lake or pond, they can never be concealed or removed so as to be unnoticed, so that the first requisite for a good coloured lantern slide is a good print of the proper intensity, and with transparent lights. The second requisite is a knowledge of colours and colouring, and the third and last thing needed is an assortment of colours and brushes.

With regard to the slide itself, it might be mentioned in passing that anything which tends to harden the film in developing, fixing, or after-treatment, interferes with the free working of the colours. For instance, alum in the fixing bath, intensifying and reducing solutions all tend to harden the film, and prevent the free absorption of colour.

The first operation in lantern-slide colouring is to soak the plate in cold water until the film will absorb no more; then, while it is still wet, go over the entire surface of the film with a thin wash of warm colour, which may be either yellow or pink, depending upon the subject. This kills the chalky whiteness of the high lights, and gives the entire picture a warm and desirable tone, even though the wash is not sufficiently strong to be detected when the picture is thrown upon the screen.

The colours used for this purpose are transparent aniline colours, prepared for colouring photographs. They are labelled brown, blue, violet, flesh, orange, green, and so on. The ordinary aniline dyes may be used instead of the prepared colours, as they are practically the same. The manipulation of the colours is the same as in water-colour painting. The film is kept wet continually, from the beginning to the end of the operation, but, after the broad washes of the first warm tint and the final sky colour, the water lying on the surface of the film is allowed to dry off leaving the film still swelled and wet, but without the surface water.

The prepared colours can rarely be applied to the slide without being reduced with water. Sometimes the best effects are produced by mixing different colours before applying them, while in other cases the effects are secured by separate washes of different colours, superposed. Each wash of colour sinks into the film, and is not removed by a subsequent wash.

Although an easel, or support something like a retouching frame, may be useful, the writer prefers to hold the slide in the hand, as shown in the engraving. The wet plate is held in a slightly inclined position in front of a lamp provided with a plain opal or ground-glass shade. The write, prefers artificial light for colouring, as the pictures are to be shown generally by artificial light, which is yellow. If the pictures are designed for projection by sunlight, it is undoubtedly better to colour them in daylight.

The first wash is preferably put on while the slide is held in an inverted position, and while it is still flowing the blue is added for the sky —at first very light, near the horizon, increasing in intensity toward the top of the slide. After this wash is set, and superfluous water has evaporated, the water accumulating along the lower edge of the plate is removed with the fingers, and the slide is turned right side up, when the extreme distance, whether it be mountain or foliage, is covered with a light wash of blue, and this wash is brought well down toward the foreground. If the blue appears cold, it can be toned down by a very light wash of yellow or red. Trees in the middle distance can now be gone over with a light wash of orange, or orange with a little of the flesh colour or pink added. When near the foreground, a very light wash of green is applied to the foliage, but the raw green of the colour set cannot be used for this; it must be modified by the addition of orange or of brown. If, when applied, the green appears too cold, it may be toned down by a light wash of brown, of orange, or flesh colour. It is desirable to produce variety in the foliage.

Rocks in the distance are washed with blue, and the colour is subsequently modified by washes of red or brown. Trunks of distant trees and some rocks may be left nearly the original colour of the photograph, but near rocks and tree trunks may be tinted with brown, blue, or warm green, and subsequently modified by washes of green, red, brown, yellow, or orange.

It is useless to trace the smaller branches of trees and shrubs, and it is rarely necessary to deal with single leaves or blossoms; when this must be done, a jeweller's eyeglass is required, and fine, small brushes are used, great care being taken to keep within the outline of the object being coloured. In all this work the artist does well to remember that the colouring is to stand the test of great magnification and strong light.

The plate is apt to dry out in some places while the colouring is going on at other places. As colouring cannot be successfully done on a dry surface, it is important to wet the surface before proceeding. This is done by applying water with a soft camel's-hair brush. After the surface water has disappeared, the colouring may proceed.

It is obviously impossible to mention every modification of colour that may be produced by mixtures and washes. This is something to be acquired by practice. The writer uses very few colours—rarely more than the following: blue, green, brown, orange, flesh, rose, and yellow. The last is a strong colour, which must be applied with caution. Green and blue are also strong colours, which can never be applied without the admixture of a warm colour, or a subsequent wash of the same. Brown, in different strengths, has a large application. It is useful in toning down bright greens, for rocks, tree trunks, earth, &c. A wash of blue over the brown produces a different but useful grey.

The principal points to be observed are: to keep the plate always wet, to use light washes, to modify colour by subsequent washes, and, in working up details, to preserve the outlines.

Should a small area be over-coloured, the colour may generally be partly removed by means of a soft brush charged with clean water, the brush being gently and repeatedly passed over the spot. The brush is frequently washed during the operation. When the broad washes show streaks, or when the entire slide is too highly coloured, or the effects are unsatisfactory, the only remedy is to place the slide in cold water, and allow it to soak, with occasional changes of water, until the colour is partly or entirely removed.

It is well enough to bear in mind that a coloured lantern slide bears all the colour that is to appear on the screen; consequently it must be more highly coloured than a transparency for direct vision. On the screen, however, a picture is better under-coloured than over-coloured. It will often be found that prints which are too light and flat for use as plain slides answer very well when coloured, and pictures which are too dark for use as plain slides may be tinted with blue, and presented as moonlight scenes.

Brushes for this work should be of the best quality, very soft and pliable; and such as are used for working up detail must have a fine point.

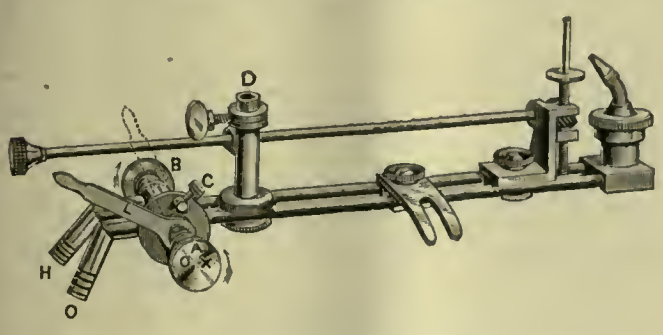
This method applies to portraits and figure pieces.

The coloured slides are generally mounted in the same manner as the plain ones. If, however, the highest perfection is sought, thin plate glass is used for the sensitive plates, and glass of the same kind is used for covers, the cover and coloured picture being cemented together with Canada balsam. Made in this way, the slides are more transparent; but, in view of the extra trouble and expense, the improvement over the uncemented slides is hardly sufficient to warrant the general application of this method.

GEO. M. HOPKINS.

BEARD'S NEW CUT-OFF JET.

MR. R. R. BEARD, of 62 Alscot Road, Bermondsey, S.E., has recently brought out a new jet. The connections for supply are as usual H and O, and the regulating screw-down valves A for oxygen and B for hydrogen. The index arrows show their method of adjusting. The lever L is



attached to the cut-off plug, and the dotted line shows the position when gases are cut off, it being stopped by coming in contact with the by pass adjusting screw C. The jet-holder D is a solid, having the pear-shaped hole for securing rigidly to the pin of ordinary lantern trays. The mixing chamber and nipple are constructed with the greatest care to obtain the best possible light combined with quietness and economy.

THE LANTERN IN JAPAN.

AMONG the pleasantest entertainments of the winter season in Yokohama are the lantern meetings of the Photographic Society of Japan, and in the past many an enjoyable evening has been spent by the members and their friends in Kiel's-buildings, while the work of the year has passed in review through the agency of the magic lantern and its attendant screen. The ubiquitous cameras of the society have penetrated almost everywhere in Japan, from the Emperor's chrysanthemum garden to Uyeno's cherry groves and Ginza's bustling thoroughfare; the daintest bits of land and seascape, charming maid and ancient temple, have been caught in their loveliest aspects by them, to be enshrined for the benefit of the stay-at-homes in collotype, platinotype, bromide, carbon tissue, or beautifully coloured positives. Perhaps the views which recently evoked most applause were the exquisite moonlight scenes which came from Mr. Kajima's collection. They were delicate pieces of art workmanship, and their rare technique was undeniable. Another set which ran them close in beauty and vividness were the yachting plates taken by a Yokohama amateur. Professor Burton exhibited several of his famous views of volcanoes, their exteriors and craters, and some snow scenes. Great hilarity was provoked by the "combinations" and "subject" pictures, many of which were running over with kindliest humour. The quaint idyll of "The Three Old Belles of Tokyo" was a delicious story without words, but it spoke ill of the morality of one that she sat with unconcealed glee with five aces in her hand at a quiet game of poker! The loss of her bedroom clock, at the pilfering hands of a gentleman of the night, was, however, a sufficient punishment for this trifling misdemeanour on the part of a dear, comfortable, old soul. Altogether, the audience were well pleased, and the society are to be congratulated on the successful result of the evening.

PHOTO-MICROGRAPHY.

[Amateur Photographic Society of Madras.]

1. THE representation of microscopic objects was one of the earliest applications of photography, and even as far back as 1802 fugitive photo-micrographic impressions on paper and leather were obtained by Sir Humphrey Davy and Wedgewood. At first great things were expected from the new power thus brought into play, but as results fell short of anticipations the process came to be looked on with a certain amount of disfavour. Now, however, that a juster appreciation of the capabilities of photography prevails, this manner of delineating microscopic objects is much used, and many beautiful photo-micrographs are existent, showing a delicacy and fulness of detail which could not have been obtained by any other process. In a short paper like the present it is only possible to deal with photo-micrography in a very sketchy way.

2. Some slight knowledge of the microscope is necessary before any attempt can be made to use the instrument in conjunction with photography, and of course before any really good work can be done a considerable amount of facility in using the instrument and in the management of light must be attained. However, as very little practice, and a not expensive outfit will enable many interesting photographs to be taken, it is hoped that beginners may not be scared by the imposing outfit recommended in the catalogues of many dealers in scientific instruments.

3. The picture of a microscopic object should show all the details with as perfect distinctness as possible, but where the object to be represented has any appreciable thickness, the whole of the details are only visible through the microscope by successively changing the focus of the instrument to suit the principal planes of the subject. A microscopic illustration is consequently a diagram showing as if they were simultaneously visible, details which can only be seen at different focal distances. These requirements impose a limit to the application of photography, for if we attempt to change the focus of the microscope during exposure a confused negative will be the only result. It is therefore obvious that the flatter an object is the more suitable is it for photographic reproduction under the microscope, and that it is hopeless to try and take in one operation a subject having much relief. The greater the magnification employed, the more limited is the depth of focus, that is, the thinner is the portion of the object clearly visible at one time. Hence, irrespective of the difficulties in the manipulation of high powers, a flat object is the easiest to photograph, where the structure can be properly shown under low magnification. Good photographs can however be obtained under very great amplification with skilled manipulation and suitable lenses, for the reason that high power subjects are very thin, and that one position of focus embraces all the planes necessary for serviceable representation. The most satisfactory field for photo-micrography lies at the extremes of amplification from, say, magnifications of 20 to 70, and from 500 to 1500 diameters. Subjects requiring objectives of a quarter to one-sixth of an

inch focus for their examination will probably be found the most difficult to photograph.

4. Although medium power objects cannot be photographed to advantage in one operation, it is, of course, possible to take a series of negatives of the most important planes and combine the results into one picture. In delicate subjects this is not very easy, but it is worth trying, especially if the operator has facility in drawing. Another method adopted with success consists in painting out on the negative the indistinct portions, and taking an under-exposed print on smooth bromide paper. This positive is used as the basis of a diagram which can be filled in by hand, and which, when worked up in Indian ink and pencil, presents the appearance of an elaborately finished drawing. A treatment of the difficulty, which has been recommended by some authorities, is to take in the first instance a photograph under a low degree of magnification, and afterwards enlarge it by any ordinary photographic copying process. This method has the advantage of shortening the time of exposure, but necessitates the focus of the original negative being extremely sharp.

5. Photography as applied to microscopy is further complicated by the differences in transparency, and the great contrasts in colour which are frequently present in the same object. In ordinary photography, the first difficulty is not met with, as objects are illuminated by reflected light and variations in opacity do not influence the quality of the negative. In the microscope, however, the majority of preparations can only be viewed by transmitted lighted, that is, light which passes through the object, so that the resulting negative is very largely affected by the colour contrasts, and the variations in transparency of the subject to be photographed. The yellow colour of many anatomical specimens so interferes with the transmission of light as to almost preclude the possibility of making a photograph. Again, the thinness with which modern sections are usually cut renders them too actinically transparent to be photographed with low powers, but, at the expense of prolonging the exposure from three to four times, this may be overcome by the interposition of a screen of yellowish-green glass. Where great differences in colour are present in the same preparation, or where non-actinic colours, such as deep brown, prevail, orthochromatic plates offer decided advantages. Many dark-coloured objects, such as insects, may be bleached by prolonged maceration in turpentine, while sections of dark woods may be treated in nitric acid.

6. The only absolutely essential apparatus required for micro-photography are a few good object-glasses, with some type of stage and illuminating arrangement, and some form of camera or its equivalent, whereby the picture formed by the objective may be received on a sensitised plate. A very large number of arrangements have been devised to meet these requirements, but it is impossible in this paper to do more than discuss them in a general manner. It will be convenient to consider photo-micrographic apparatus as divided into four classes as under:—

(*a*). The attachment of a special camera to an ordinary compound microscope.

(*b*). The combination of an ordinary camera with a compound microscope.

(*c*). The substitution of a dark room for the camera and the use either of an ordinary compound microscope or a system consisting of stage, objective, and mirror.

(*d*). A combination camera and microscope forming one piece of apparatus.

7. A very simple method of effecting the first arrangement (*a*) is by attaching a pyramidal light tight box to the microscope, the small end of the box fitting closely to the eye-piece, and the large end being adapted in the usual way to take a focussing screen and a dark slide. The focussing is effected by the adjusting screws of the microscope, which can be used either with the body horizontal or vertical.

8. The second arrangement (*b*) is still easier for all who possess an ordinary photographic camera. It merely consists in the insertion of the eyepiece end of a compound microscope placed with the body horizontal into the lens aperture of the camera. The space between the microscope and the woodwork of the front must be carefully closed to exclude light. When working with lamplight, any black cloth packed well into the space will answer all purposes. The eyepiece of the microscope may or may not be removed; it is simpler not to do so, as its presence permits of a short camera being used, and the focussing screws of the microscope remain within reach of the hand. Most of the well-known microscopists recommend the removal of the eyepiece, as its use involves a loss of light, but in this case some mechanical arrangements must be devised to actuate the focussing screws which will not be in reach. Dr. Woodward, in place of the eyepiece, employs a special combination, which he calls an achromatic concave. Dr. R. Neuhauss has found that the ordinary eyepiece can be used instead of a projection ocular for throwing the picture on the focussing screen. The lenses of the eyepiece are separated a little distance and an additional diaphragm is fitted on. The arrangement is simple, a paper case or tube, 2½ cm. long, is fitted on to the brass tube, the internal diaphragm remains in its original position, while the new one is fitted over the eyepiece by means of a short movable tube. The nearer the objects to be photographed are to the focussing screen, the further must the lenses of the eyepiece be removed from one another.

9. The third arrangement (*c*) may be exemplified by the plan adopted by Mr. Wenham, who dispenses with a camera and uses instead a dark room. This room he closes with a shutter having a circular aperture three inches in diameter; upon the outside of the aperture is placed a reflector of same type, which can be actuated from inside the room. The microscope body is arranged horizontally on a table or bench, so that its axis, if prolonged, would pass through the centre of the hole in the shutter. The object to be photographed is suitably placed on the stage of the microscope and near to the inside of the aperture, the light around the stage being cut off by a black cloth. A vertical stand, grooved to carry a sensitised plate or a white card, completes the arrangement. The enlarged view of the object to be photographed is first projected on to the white card and focussed, the light is then cut off and the sensitised plate is inserted in the grooves which held the card. The plate is then exposed by readmitting the light for the necessary time.

10. The fourth arrangement (*d*) need only be briefly referred to. A stage with mirror and objective is attached to the front of a special camera provided with necessary fittings for adjustment.

11. The next point to be considered is illumination. The sun, the electric, oxyhydrogen, magnesium or zircon light, and the ordinary paraffin or petroleum flame are the usual sources of illumination. Of these the majority of operators prefer sunlight, but in using it with any form of condenser care must be taken to guard against the intense heating effects of the rays, which are liable to injure the object, and even in the case of high-power objectives to uncement the lenses. In the case of subjects requiring long exposure, it will be necessary to supplement the apparatus previously enumerated by a heliostat in order that the solar beam may be reflected in a constant direction; without a heliostat rapidity of impression is absolutely necessary for the most perfect definition. Various devices have been resorted to for overcoming the heating effects of the condensed solar rays, the most common plan being to reflect the light through a cell filled with a solution of sulphate of copper, the blue colour of which filters off the heat rays while allowing the actinic components of the solar beam to pass through. Another plan is to break up the light by means of a large prism of wide dispersion and then intercept the rays of the red end of the spectrum. In this way the defects of chromatic aberration may be avoided, and a more perfect definition obtained. A very ingenious method, proposed by Mr. Reade, for using his hemispherical condenser with a solar condenser, is given *How to Work with the Microscope*, by Dr. Beale. The rays furnishing light and those giving off heat having different degrees of refrangibility, we have here the cone of light rays formed within the cone of heat rays, so that, when these rays cross the axis their respective positions are reversed. The hemispherical lens is so arranged that it is separated from the principal focus of the heat rays by its own focal length, when the principal focus for light will be found at a greater distance than that for heat; the heat rays will thus be rendered parallel, while the light rays will converge to a second focus furnishing an intense light unaccompanied by heat. The same object is effected by Dr. Woodward by placing an achromatic lens at such a distance from the achromatic condenser of the microscope that the solar rays are brought to a focus and begin again to diverge before they reach the lowest glass of the condenser. This method is so successful that enough light can be obtained to give excellent definition on a cardboard screen under a magnification of 5000 diameters.

12. When using sunlight, it will sometimes be found that diatoms and soft tissues, when illuminated with parallel rays, will produce interference lines. A ground-glass screen, preferably greased, interposed between the mirror and the condenser, will remedy this inconvenience. The electric light, by exaggerating the effects of light and shade, is well suited for delicate objects possessed of little contrast. In using this illumination the pencil of light should be first rendered parallel by means of the condenser usually supplied with electric lamps for this purpose, and then condensed, as with solar light. The electric light is said, by some authorities, to be cumbrous, unsteady, expensive, and troublesome, but these remarks would appear to be directed against the arc light, as the incandescent lamp seems free from these objections. The magnesium and oxyhydrogen lights are of special service in photographing soft tissues, and, no interference phenomena presenting, the greased glass

screen can be dispensed with. The light is concentrated on to the lower lens of the achromatic condenser, and the ammonia-sulphate cell should invariably be used. The fumes of magnesia, which give trouble by the deposits on surrounding objects, may be collected on a muslin chimney, made by covering a spiral wire column five feet long, the cloth being folded in similar fashion to the bellows of a camera. The zirconia light is produced by placing in the oxyhydrogen flame a mass, made by strongly heating, in an iron mould, a paste composed of zirconia, mixed with a solution of boracic acid. This illumination is even more brilliantly luminous than limelight. Zirconium is very resistant, and gives a regular, steady flame. It will be found, however, that petroleum light is sufficient for almost all purposes, and any good lamp may be used, but the ordinary microscopic lamp, which can be raised or lowered bodily, will be found most convenient. A very intense illumination may be obtained from paraffin oil by using it in a triple-wick lamp, with a condenser to parallelise the rays. This pencil will, of course, have to be rendered convergent before it enters the optical portion of the microscope. With all lighting, the achromatic condenser must be carefully centered, as otherwise unequal illumination will result. After centering, the condenser must be moved back until the field is uniformly lighted.

13. Certain objects, such as diatoms of close striation, require the use of very oblique light, which can be obtained in the following way, given in Davis's *Practical Microscopy*: "A parallel pencil of solar rays from the heliostat and plane mirror is intercepted by a blue cell and diaphragm, which only allows a circular pencil of half an inch diameter to pass. The light enters parallel to the optic axis of the microscope placed in the usual position for photography, but at a lateral distance to the right or left of three inches. If the light is intercepted by a large achromatic prism of a focal length of about three inches, the desired obliquity can be obtained without difficulty. The best result is obtained when the rays are concentrated to a focus upon the object, and it is indispensable that the stage of the microscope should be as thin as possible. The illumination thus obtained is in general sufficient to produce negatives by the wet process up to 2500 diameters, with three minutes' exposure."

14. The magnified image of the object to be photographed can be focussed by projecting it on to a white screen, or on to a ground or plane-glass plate, or by examining it with the ordinary microscopic eyepiece. The ground glass usually supplied with the camera is too coarse for fine focussing, and should be reground with the finest emery and water, or a focussing screen may be made by coating an ordinary glass plate with the following varnish recommended by Davis:—

Gum mastic	40	grains.
Gum sandarac	160	,,
Ether	4	ounces.
Benzol	1½	,,

This varnish is not easy to apply, as even the heat of the fingers is sufficient to make the coating immediately over them dry with a smooth instead of a matt surface.

If a piece of plate glass be used, the image is viewed by a focussing glass or eyepiece held against the plate glass, the focus of the lens corresponding exactly with the anterior surface of the plate. The simplest, and I believe the best, method of focussing is to use the ordinary low-power eyepiece inserted into a series of apertures in a thin wooden board substituted for the usual ground glass, care being taken that the diaphragm of the eyepiece is in the exact position that will be occupied by the film side of the sensitised plate.

15. In connexion with focussing it is to be noted that, objectives being over-corrected, it frequently happens with low and medium powers that the actinic and visual foci are not coincident. The result of this is that a blurred and indistinct negative may be obtained, although the image viewed by the eye when focussing showed perfect definition. This drawback can be remedied by having the objectives specially corrected for photography, or by withdrawing the object-glass after focussing a certain amount determined by experiment. The number of turns of the fine adjustment screw necessary to get the chemical focus is easily obtained by developing a negative taken at the best visual focus, and then withdrawing the objective till the image appears to the eye as indistinct as it is on the negative. I append the amount of correction required by various objectives, which have been extracted from Beale's and Davis' works.

Beck	1½ inch	Browning	4 inch
,,	⅔ inch	,,	1 inch
,,	⅒ inch	,,	½ inch
Dancer	2 inch	,,	¼ inch nil.
,,	1 inch nil	,,	⅛ inch nil.

In Beck's recent catalogues, however, it is stated that these makers' objectives can be used without alteration, the two foci being so nearly coincident, and, as far as my limited experience goes, I can substantiate the statement.

16. As in ordinary photography, many assert that the wet process gives results superior to the dry, but I much doubt this. If there is any difference it is so slight that only an advocate of the wet plate can detect it. Gelatine plates should not be over-exposed, especially in the case of delicate work, or all the finer details will be lost. No precise directions can be given as to the time of exposure necessary for the production of a good negative. The exposure is largely dependent upon the quality of illumination, but even more so upon the nature of the object. By direct sunlight, with a not too dense subject, under the strongest magnification and sufficient weakening of the light by a filter a few seconds should suffice. Opaque objects illuminated by reflected light require a much longer exposure than transparent subjects with transmitted light, and the difficulties in focussing increase rapidly with the magnifying power. As a guide to exposure I extract from Davis' *Practical Microscopy* the following table relating to Mawson & Swan's "fifteen times" plates:—

Objective.	Subject.	Exposures. With microscope lamp.	Exposures. With a triplexicon or selopticon lamp.
4 inch	Wing of blow-fly	6 seconds.	3 seconds.
2 ,,	Proboscis of do.	60 ,,	10 ,,
1 ,,	Do. do.	70 ,,	20 ,,
½ ,,	Glass crystal	60 ,,	30 ,,
¼ ,,	Section of deal	7 minutes.	2 minutes.
⅛ ,,	Podura scale	10 ,,	2½ ,,
1/15 ,,	Pleurosigma attennatum ...	15 ,,	3 ,,

In recent years instantaneous work has been taken up with a view to photograph moving organisms, and exposures from one-twentieth to one-two-hundredth of a second are reported to have been satisfactorily given with immersion lenses. Formerly infusoria, &c., were rendered stationary by killing them with an electric shock. A flashlight recommended for instantaneous work is produced by the ignition of the following mixture which gives a flash lasting from one-fiftieth to one-thirtieth of a second:—

Magnesium	30	parts (by weight)	in	powder.
Chlorate of potash	60	,,	,,	,,
Sulphide of antimony	10	,,	,,	,,

The combustion of this powder is effected in a metallic tube closed at one end and provided at the other with a glass plate and diaphragm, the aperture of which corresponds accurately with the diameter of the illuminating lens. Within the tube, and on a level with its central point, is a metal plate upon which the powder with a piece of touch paper is placed. The latter is ignited through a slit in the tube closable by a shutter. The tube is further provided with a very long chimney.

17. With long exposures it is very essential that freedom from vibration should be secured, and this is a matter of considerable difficulty. Dr. Woodward used to isolate his apparatus from the floor of the room by placing it on solid concrete pillars built up independently from the ground, but even this was not always satisfactory. However, long exposures can be made, and photographs of phosphorescent bacilli have been taken by their own emitted light with an exposure of thirty-six hours or more.

18. As regards development, the same rules as apply to ordinary photography hold with photo-micrography, but in fine work it is not advisable to push development too far lest the more delicate details should be lost. There is no object in giving recipes for developers, as it will be best to adopt the formula which the operator is in the habit of using for ordinary work. A. D. G. Shelley, Captain, R.E.

THE SIMPLICITY OF LANTERN-SLIDE MAKING.

[Anthony's Bulletin.]

Much has been written on this subject, and from the constantly increasing interest shown in their production and use it would seem as if there was plenty of ground to be covered. In all the publications connected with the photographic art that have been issued, the manipulation

of the lantern slide has been very lightly touched upon. I know a case where most elegant examples were shown, and those who enjoyed seeing them declared that the party who made them had a secret process he would not divulge, hence there was no use asking him. Not being blessed with timidity to such a degree, I questioned the gentleman, and he promptly replied, "There is no secret whatever in the manner in which I make them, as I used the —— lantern-slide plate, a ready-mixed developer I get from ———, and fix them in hypo the same as any other party. The only secret to the entire process is the use of brains." Like all other good things, to obtain the best results, care must be used and operations closely watched. The best mode for a beginner would be to take a good average negative and use no other until he is satisfied he can produce from it as good a slide as it will yield. In the trials will enter different exposures and various strengths of sundry developers. Take one of these developers as recommended by some one in whom you have confidence, and do not change until you are convinced that you have as good a slide as can be produced by the method employed.

The great stumbling-block will be the time of exposure. If over-exposed, you will find that before you secure sufficient density your skies will be greyed over or filled up. If too short a time has been given, it will develop up to a certain point, and before you have sufficient detail it will be too dense in parts and then stop, refusing to go farther, and continued forcing strains the slide. Experience as to the time for each negative (and you rarely have two just alike) can only be gained by practice. Do not attempt to rush them through too quickly, but take your time. Six or eight really handsome slides are better than so many dozen poor ones. A good rule for a transparency developer is: To your normal developer, as used for negatives, add an equal bulk of water, and to every six ounces of this solution add five drops of a saturated solution of bromide of potassium in water. In developing a negative, you make your developer give way to the negative, *i.e.*, weaken or strengthen as required during development; but in making lantern slides, if you use judgment in printing them, you can use the same developer for a large number, having six or nine in the same tray at once undergoing development. The fact that there is more latitude in the exposure of a transparency plate is of great assistance, and often prevents what would be a total loss if a quicker plate were used; but the true exposure is always the best, and, with care and judgment, there is no necessity of losing one plate out of several dozen.

Printing by contact is by far the easier method, and if the plate admits of such I would always so print them. It happens often, however, that larger negatives are to be used, and for this purpose very handy cameras are in market, called "copying, enlarging, and reducing cameras." They are, in fact, so handy for the amateur in many ways, that no well-regulated establishment is complete without one. They are so arranged that the negative is placed in one end, the lens in a centre compartment, and the holder on the rear end. By varying the distance between the negative and lens, the amount of subject shown in the large negative can be varied at will, and I have made three distinct slides from one 5 × 8 negative, by taking different parts at a time. Care must be taken that nothing will be opposite the negative that would be photographed through it. If the camera cannot be so pointed that you have a clear sky for a background, put a screen covered with smooth white tissue paper two feet distant from the negative. This will destroy all lines and shadows. Use a small diaphragm in the lens in order to secure the sharpest results, and you can judge of the time as readily as when printing by contact, only it will probably be minutes, where before it was seconds. These minutes can be employed in looking at those developing or fixing, placing another plate in your extra holder, and selecting the negative for subsequent exposure. In fact, you need never be idle. I have covers for my trays, to enable me to turn on full gaslight and work at other things during developing, fixing, &c.

Exhibiting the pictures on the wall or screen during the winter evenings is the most enjoyable part of photography, and prints on paper, even from the same negative, pale before the lantern slide. If you have not tried it, do so at once. You will never regret it, and you will find there is no mystery in the production of them, but endless enjoyment, both for yourself and friends.

H. S. Nutt.

POMPEII ON THE LANTERN SCREEN.

At the Bath Photographic Society a Lantern Evening was given on Wednesday, the 22nd ult., at the Royal Institution, when Mr. Austin J. King, president, gave an illustrated lecture entitled "Some Memoirs of a buried City" (Pompeii). The chair was occupied by Dr. G. Norman.

The Secretary announced that the lens to be used that evening for the projection of the lecturer's slides was of a new pattern, manufactured and forwarded for the occasion by Swift & Son, Opticians, London.

Mr. King dwelt not only with the existing buildings of Pompeii, of which many photographs were exhibited, but also with the numerous bronze articles of household and domestic use which have been found in the course of the excavations. With the aid of these and of plans of the Roman houses and villas he attempted to show what manner of men and women inhabited Pompeii, and how they lived their lives. The streets, the temples, the theatres, the amphitheatre, the palaces of the rich, the hovels of the poor, the baker's shop, the public bakery, the inn, the wine bar, the baths, were made to tell their story. Some pictures were from photographs by the lecturer, others from drawing of Gill's restoration, and others again were descriptive. The audience was a very appreciative one, and followed the lecturer closely through his account of what had been based upon what there still is. All agreed that not only is Pompeii just the place where good photographers would like to be sent to, but that, without the aid of photography, the great treasure of this marvellous City of the Dead would be lost to nineteen-twentieths of those who now revel in the archæological and ethnological treat which the excavations have provided.

The Chairman very cordially thanked the lecturer. Mr. King, he said, was always doing something for the Society, and this last entertainment had afforded them a better opportunity of studying the subject of the buried city than it had been his (the Chairman's) privilege to witness hitherto.

THE LANTERN IN TASMANIA.

At the last meeting of the Hobart Photographic and Art Association a very large collection of lantern slides was exhibited. Messrs. E. Ash, G. Hull, H. J. Buckland, C. Gruncell, Rev. J. T. Pierccy, Russell Young, F. J. Paterson, W. K. Morris, and N. Oldham contributed slides. The lantern was managed by Messrs. W. K. Morris and N. Oldham. A collection of coloured slides by Miss Hope and Miss Minnie Smith were also exhibited, and proved that these ladies will soon be able to produce coloured slides of an excellent quality. A large quantity of members' work was placed upon the table, including crayon drawings by Miss Hope, photographs by Messrs. Clayton and Hull, oil painting by Miss Minnie Smith, and a new lantern slide making camera by Mr. H. Downing. At the conclusion of the meeting Mr. Russell Young offered a prize for the best painted lantern slide, open to any Association member.

Lantern Queries.

F. R.—The slide sent is far too dense for projection. Try again, and do not force development so much.

L. Morris.—The optics of the lantern are fully dealt with in the editorial article in the Almanac for 1888.

Wm. Strange.—From a circular just received from Messrs. Wilkinson & Co., of Holmeside, Sunderland, we observe that they make a speciality of lantern-slide painting. Put yourself in communication with them.

Lanterno.—Yes, the "Lantern Record" will appear during the summer.

Barium.—The barium is heated to about 1300° Fahr.

C. (Balham).—Thanks. We have read the article in the *Daily Telegraph* on "Magic Lanterns and their Users." It is evidently written by a non-technical journalist, although the information it conveys is, in the main, correct.

Simplex.—The crystallisation on the slide is probably due to imperfect fixation. We have met with such cases as you cite on several occasions.

J.—The heliochromoscope, so far as we are aware, is not yet obtainable commercially in this country. Mr. Ives is, however, we learn, making arrangements to that end.

RECENT LANTERN PATENTS.

PATENT COMPLETED.

Improvement in Limelight Jets.

No. 5541. David William Noakes, 23, Nelson-street, Greenwich, Kent.—*February* 18, 1893.

When the lime jet is used as a radiant, either singly or in conjunction with optical instruments, it is desirable to obtain the utmost intensity of light. Hitherto limelight jets have been constructed with one mixing chamber only, into which hydrogen and oxygen, or oxygenated ether and oxygen, or other suitable gases, are introduced by means of separate conduits. After coming together and mixing as far as possible in this single chamber, they issue from the outlet, and being lit impinge upon a piece of lime, heating it to incandescence. The more intimately the gases can be mixed, the greater the state of incandescence that can be produced. In my invention the gases are more intimately mixed by using two chambers in lieu of one, which to suit existing apparatus are preferably constructed one within the other and conical in section, although for some requirements it might be necessary to separate the chambers or alter their sectional shapes.

MONTHLY SUPPLEMENT

TO THE "BRITISH JOURNAL OF PHOTOGRAPHY."] [*May* 5, 1893

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

"AT the recent Exhibition of the Manchester Amateur Photographic Society," says the Society's organ, the *Photographic Record*, "among the many interesting slides was one—taken as a snap-shot—of a group of four editors of the photographic journals engaged in friendly chat with each other, and evidently quite innocent of the fact that they were being made into 'copy.' They had been attending the Photographic Convention at Edinburgh." That slide should be preserved as a witness of the amicable relations that subsist between photographic pressmen, of which testimony is not altogether unneeded.

* * * * *

BEFORE the Society of Architects, on April 20, Mr. William Allport, F.S.I., read a paper on the *Use of Photography in its Relation to Architecture*, in the course of which he touched upon the uses of lantern slides for projections of architectural subjects:—"As to the use of photography in connexion with lantern slides for demonstrations of architectural subjects, the illustrations we have seen this evening fully show what a powerful agent and adjunct it has proved to be in connexion with photography in the development of architectural art, and in the illustration of such papers as are given from time to time by this Society. It is even adopted by an eminent bishop as the most efficient means of making an impression on his flock. His practice is to prepare clear, terse, short sermons in simple language; photographs of these are then taken, and put on to lantern slides and exhibited through the medium of the lantern to his audience; and he states that he finds this manner of discoursing to be far more telling, impressive, and attractive than when it had been vocally delivered; that the same practical effect equally applies, if not more so, to lectures on architecture, must be admitted by all, especially as when on the same slide examples can be shown side by side, specimens of good and bad design or construction, thereby impressing upon the minds of the students facts and matters of importance in a manner that no other process, with the like facility, can give with accuracy."

* * * * *

SINGLE limes for the lantern, each packed in hermetically sealed tubes, can now be obtained from our local dealers, says the *Photographic Gazette*. This innovation has been introduced at the suggestion of the Committee of the West Surrey Society, and will be best appreciated by those who have experienced the trouble and loss entailed in keeping the larger quantities usually put up by dealers. We concur in the last remark, and regard the hint as one which might with advantage be taken by dealers at large.

* * * * *

THE optical lantern of the Society of Arts was put to considerable use during the Camera Club Conference on April 12 and 13, no fewer than five of the papers being illustrated with slides, some of which being only of diagrammatic interest were shown with as much success in the afternoon as others were in the evening.

* * * * *

IN no class of photograph does the blurring or halation of the image stand out with such disagreeable prominence as in a lantern slide projected on to the screen. During the past winter we saw many otherwise good slides marred by this defect, which may be so easily avoided by backing the negative plate, that we should have thought few photographers taking pictures with a view to making lantern slides from them would neglect it. Now that the subject of halation and its remedies—including the use of multiple-coated films, such as the Sandell plate—is a topic of much discussion, and seems likely to remain so, it is to be hoped that lantern slides showing halation will be subjected to more criticism and objection than has been the case hitherto, and that an improvement in this respect will result.

* * * * *

THE safe packing of a large number of lantern slides for constant circulation among, say, the various photographic societies, is a subject of no little importance, and one that demands more care and consideration than may at first sight seem necessary. The number of negatives in twos and threes which are constantly reaching this office in a pulverulent condition, through bad packing, makes one tremble at the thought of what would happen to a collection of 100 or 150 lantern slides if packed according to the same free-and-easy system, which so many adopt. Mr. R. Child Bayley, of the Photographic Society of Great Britain, who has charge of several ever-circulator sets of slides, contributed by affiliated societies, and who feels the need of a safe system of packing, informs us that he proposes adopting the following method:—The slides are first packed closely together in a strong box lined with strips of rubber, the box having a shut-over lid, the bottom of which is lined with rubber, which, when the box is closed, comes in contact with the tops of the slides. The latter are thus securely held in a casing of rubber. This box is then placed in an outer box, strongly iron-bound, and having a sliding lid secured or opened by means of a single screw. The opinion of those having experience of the transmission of large numbers of lantern slides, on this or any other plan that may have been found satisfactory, would no doubt interest many.

* * * * *

LOOKING in at the lantern-slide entertainment in connexion with the Crystal Palace Exhibition on Saturday evening last, we found a large audience evidently enjoying a miscellaneous collection of slides that was being shown, several slides from frenagraphs (we believe that is the correct term for negatives taken in Messrs. Beck's ingenious Frena camera) securing much applause. By the way, in our notice of the Exhibition on April 14, we omitted mention of the fact that the series of enlargements from frenagraphs which Messrs. Beck had at their stand were made by Mr. F. A. Bridge.

* * * * *

THE lantern in use at the Crystal Palace was a biunial by Messrs. W. Watson & Sons, and at the time of our visit it was working smoothly and evenly in the hands of Mr. Wollaston. It was fitted with a pair of Mr. R. R. Beard's new cut-off jets (which we described at page 53 of the "Lantern Record" for April 7), and the same gentleman's safety dissolver, suggested by Mr. W. Brooks some time

ago, and identical in pattern with that which had been in use with lanterns previously used. Mr. Beard had also provided extra large limes for the jets.

* * * * *

For the information of those of our readers who have never attended a Lantern Exhibition at the Crystal Palace, it should be mentioned that the distance from the lantern to the screen is 110 feet, and that the available size of the screen is about thirty feet square—that is, the dimensions of the proscenium. This large screen was one of the Mason & Payne kind.

* * * * *

The plant for supplying the gases for use in the optical lantern in the theatre at the Crystal Palace was laid down at the time of the first photographic Exhibition, and being, we were informed, such as is commonly adopted at most theatres, and at the same time specially designed for use in lantern shows, it looks as if the Company contemplated making this class of entertainment a permanent feature of the Palace. Mains are laid on to the stage for limelight purposes, as well as up to the lantern gallery, both being available at any moment. The gasholders or tanks are situated in the basement, and are of a capacity of 100 feet each. The hydrogen is drawn from the main; the oxygen-holder is filled from high-pressure cylinders.

* * * * *

Although the apparatus section of the Exhibition was, as we said at the first onset, very small, we were pleased to learn that several of those who did exhibit were rewarded for their enterprise. Mr. J. D. England (who showed negatives on celluloid, lantern transparencies, &c.), the Cresco-fylma Company (whose elegant and simple process of enlarging negatives and transparencies was in course of constant demonstration and attracted much attention), and other exhibitors, assured us they were pleased with the result of the three weeks exhibit. Great interest also seemed to be excited by Messrs. Beck's, Messrs. Theobald's, Messrs. Noakes', Messrs. Platte & Witte's and other exhibits, all of which were connected with the optical lantern, more or less. Indeed, but for the lantern exhibits and cognates, and the lantern-slide entertainments, which always tickle the public taste, it is appalling to think what would have been the fate of the Exhibition as a whole. So, Crystal Palace Exhibition of 1893, *au revoir* or farewell—which?

IRON CARBONYL IN COMPRESSED GAS.

So many readers of the Journal possess a competent knowledge of chemistry that I am not without hope we may obtain from one or other of them assistance in the matter described above. This I have no hesitation in saying is now found the principal practical nuisance and drawback in the use of cylinders for the mixed jet, whilst I am not satisfied that it is altogether free from danger. It is in that hope I wish to direct more special attention to it.

Users of oxygen alone are never confronted with this difficulty; but those who use compressed house gas, as the use of this in cylinders has also extended, have been finding, again and again, that the gas as it issued from the jet was often "impure." In many cases, before the oxygen is turned on, the small flame of gas will smoke greatly, and after a little time the lime or other incandescent body appears where played upon of a deep red colour, so deep sometimes as to be nearly black. The colour in itself does not seem to matter much, and, according to the usual laws of radiation, a *black* line, if one could be made, should give more light than the white; but in a pronounced case of this impurity the light does suffer most woefully. The Editor will personally remember that on a recent occasion, when verbally discussing this matter, another operator told us how, on more than one occasion he had been utterly baffled by the impossibility of "getting a light." I have never found it so bad as this, but serious loss of light has been experienced frequently. In fact, but few readers who use the mixed jet from cylinders will not be able to bear out from experience all the above.

Till lately, so much was all that was known; but in 1891 Mond and Quincke followed up the discovery of nickel carbonyl by that of iron carbonyl, similarly formed by the action of carbonic oxide upon iron. Roscoe and Scudder found that "water gas" compressed in steel cylinders formed the same compound. Finally, Mond and Langer obtained *two* different iron carbonyls in a state of purity, having the formulæ of $Fe(CO)_5$ and $Fe(CO)_7$. They were able in one day to prepare about one grain of viscous liquid carbonyl from 100 grains of finely divided iron. It differs from nickel carbonyl in being much less volatile, distilling at about 102° C. The consequence of this is that in some cylinders not only is the gas "impure," but liquid carbonyl itself is deposited in the shape of an oil, which will run out of the valve if the cylinder is inverted when empty. Instances of this have been observed.

Besides the loss of light caused in this way, I have hinted that the formation of carbonyl *may* not be free from danger. For it is clear that the metal is acted upon and disintegrated; and the question is, to what extent? Unless confined to an infinitesimal degree—which I am by no means sure of—the metal may be in time so thinned or become so spongy as not to be safe under the pressure. This side of the question especially needs careful investigation. But the mere loss of light is bad enough, and the practical question is, Can anything be done to either prevent, or, at least, greatly diminish the evil? Here I hope for help from some who have more chemical knowledge than I can pretend to; still, I add what suggestions occur or have been suggested to myself.

1. A chemical friend, alluding to the recently discovered but now well-known fact, that *perfect dryness* prevented chemical action in gases, suggested that, if a hydrogen cylinder were dried out by heat before pumping, and the gas dried by passage over calcium chloride, in the ordinary laboratory manner, whilst passing to the cylinder, the evil would probably be diminished. It is possible, but I have doubts whether it would be practicable. Only practical pumpers could decide that question.

2. Gas is commonly called carburetted hydrogen. It does not, however, appear that the carbon thus combined with the hydrogen does the mischief. Rather it seems the portion of carbon monoxide present in the gas which is responsible. This looks to me more hopeful, and I do not think it should be impossible so far to *purify* the gas before compression as to separate the carbonic oxides from the truly inflammable gases. If the gas can be *thoroughly* purified from both carbonic monoxide and dioxide, I believe the evil will cease, and it is not even certain that dioxide causes any.

3. If this is not feasible, the question will occur whether some hard *varnish* cannot be found which will resist the gas under pressure, and chemically protect the steel of the cylinder from contact or chemical action. Surely this should be practicable; and, if so, such a varnish or coating could be readily melted over the inside by heat before the valve was screwed in.

4. High temperature greatly facilitates the action; therefore, keeping the cylinder cold under pumping should be carefully attended to.

The above, I am sorry to say, exhaust my stock of suggestions. It has appeared to me that this formation of carbonyl has increased since the improved steel cylinders came in; and it may possibly be that steel (iron already *combined with carbon* in another way) may be more readily acted upon; but there is no doubt that iron itself is attacked. There is also no doubt at all that a given cylinder goes on getting *worse than at first*, and that some are worse than others. It is also, I have reason to believe, fairly certain that *stale* gas pumped (as from a store gasometer some time filled) is worse than fresh. I think the first fact is explained probably by a film of grease, or some other protective varnish, accidentally protecting some cylinders more than others (again pointing to a varnish); and the second fact by the gradual formation in stored gas (of which there is some evidence) of more free carbonic oxide.

Be all this as it may, the only practical palliative I know at present is to use gas (if one have influence or power to get it) fresh pumped to use it new, or fresh, and not keep any; and to use a "necky" cylinder. To keep the gas in cylinder seems to make the latter get worse and worse; better let it go. This objection to "keeping" gas is one of the greatest nuisances of the situation. Altogether, no more pressing problem demands solution at the hands of the compressed gas industry.

Lewis Wright.

DOUBLE PRINTING FOR TRANSPARENCIES OR ENLARGEMENTS.

The simple operations of printing in a sky to a transparency or enlargement, of taking out one portrait from a group, or even of successfully vignetting a single figure, although perfectly easy in theory, are sometimes very troublesome, if not really difficult, in practice, owing to the want of a little system. The following plan, which I have used for some years, while thoroughly efficient for the purpose, entails very little initial trouble and a minimum of skill in its working.

It is simply an elaboration of the rough-and-ready method of vignetting by holding a card with an aperture in it between the lens and enlargement during exposure, the screen in this case being held in a frame provided for the purpose. Even in simple vignetting much of the effect depends upon the proper centering of the picture and the vignetting screen; but when, as in the case of double printing, an irregular outline has to be rather closely followed, the importance of this point is vastly increased, and it is just the difficulty of accurately masking the various parts of the picture by hand work that constitutes the trouble. When, however, a properly centered frame is provided in which to fix the screen, the latter may be placed in any desired position along the axis of the lens, and any degree of sharpness or the reverse of the outline secured without losing centrality.

The precise mechanical details of the screen are unimportant, and will depend in some measure upon existing arrangements. When the enlargement is made upon an easel running on a tramway, the vignetting screen, as I may call it, may consist of an additional framework running upon the same lines, or, if preferred, the arrangement may take the form of an attachment to the enlarging lens itself. Such a one, which answered my purpose very well some few years back, consisted of the discarded mount of an old whole-plate portrait lens, which was attached to the front of the enlarging camera behind the lens, or between the lens and the enlargement. In place of the cap a series of wooden frames was made to fit on to carry masks of different sizes, and the rack and pinion served to give the necessary motion for securing accuracy of adjustment and softness of outline.

The capability of thus altering the position of the screen smoothly and easily, and preferably by mechanical means without losing centrality, is one of the most important features in the arrangement, as it not only greatly helps in the adjustment of the screen as already mentioned, but is absolutely necessary in preparing an accurately outlined screen, upon which, of course, depends the success of the operation. In simple vignetting this is, of course, of comparatively little moment, as all that is necessary is an aperture of oval or irregular shape placed sufficiently out of focus to give a softened edge to the printing. In blocking out a sky, or a figure, or other object, however, the case is different, as the exact outline must be closely followed in cutting the mask, which must be so placed that it just cuts off the requisite portions of the picture without showing too abrupt an edge on one side or too much diffusion on the other. To make such a mask may at first sight appear extremely difficult, but it is really the simplest matter in the world if properly taken in hand.

In some respects the simplest plan of all is that adopted in blocking out the background of a negative for direct printing, namely to cut out the outline for a silver print as carefully as possible with a sharp penknife. If such a screen or mask be placed exactly the same distance from the lens as the latter is from the negative, and accurately centered, it should be in the proper position, and only requires a slight motion to and fro during exposure to give the desired softness of edge. But with this arrangement there still remains the difficulty of getting the mask properly centered, whereas, by following the plan I have to describe, the task is performed automatically.

In making the mask I use the travelling framework itself as the easel on which to make a tracing of the outline. Although not absolutely necessary, it is convenient to adhere to some definite proportion in the relative dimensions of the negative and the mask, if only that it obviates the necessity for any wide range of motion of the screen. The mask may be the same size as the original, it may be smaller, or it may be larger, as may be preferred. I use myself a fixed proportion of two to one, the mask being twice the dimensions of the negative. A piece of thin paper is attached to the travelling frame in such a manner that it can be taken off if desired and restored to exactly its original position; then, regardless entirely of the dimensions of any subsequent enlargement, the temporary easel is placed in position, and accurately focussed for an enlargement to two diameters, and the required outline is then carefully traced with a pencil upon the paper, and cut out with a sharp penknife.

It is obvious, that if the travelling vignetting frame is accurately centered and moves truly in the axis of the lens, the mask so produced will also be correctly centered, and only requires adjusting to the right position between the lens and enlargement to secure the necessary softening of the edge. The exact position should be, with the dimensions in question, just twice the distance from lens to mask as between lens and negative, this rule holding good whatever may be the dimension to which the negative is enlarged. Observe that it is not a fixed position, but will vary with each degree of enlargement, although the dimensions of the mask remain the same; thus, in using a six-inch focus lens, and making an enlargement up to four diameters, the correct position of the screen would be fifteen inches from the lens, while, if the enlargement were to, say, nine diameters, the distance would be only thirteen and one-third inches. However, it is not necessary to resort to such calculation in practice, since the eye will be the best guide, provided the mask has been correctly made.

For some purposes I have used in the travelling framework zinc plates with central apertures to which to attach the cut-out paper mask. A mere bordering of zinc resembling a *passe-partout*, to which the paper may be gummed, is all that is needful, and this should be so arranged that it can be replaced in the wooden frame in exactly the same position. This is easily effected by drilling three holes in the zinc to correspond with a similar number of pins in the frame.

There are, however, cases in which the zinc plate is useless, as for instance, when a central figure or object has to be masked while a background or landscape is being printed on to the margin of the picture. Here there is nothing for it but to stick the figure mask on to the centre of a sheet of glass, which should, of course, be as free from faults as possible, since the image has to pass through it. In preparing such a mask in all probability both portions will be wanted, that is to say, both the figure cut out and the surroundings from which it is cut; or in the case of a landscape, probably both the landscape and sky portions will be required for separate use.

In such instances I proceed as follows in the preparation of the double masks, which require to register not only with the negative, but with one another. For this purpose the wooden framework should be provided with a sunk rebate, accurately cut and finished, into which specially cut squares of glass fit neatly. The glasses should be preferably ground at the edges so as to fall readily into exactly the same position in the rebate. One of the glasses being placed in position, a piece of paper of exactly the same size is laid on it and the outline traced. After cutting the mask, the two portions are laid upon the glass in the rebate in proper position, and the marginal or landscape portion having been gummed is made to adhere. Then the other portion, the figure or sky as the case may be, while still in position is touched with gum on its upper surface and another piece of glass laid carefully down upon it and pressed into contact. If this is properly done, the result will be a fair accurately registering mask, by means of which either portion of the negative may be covered at will.

It is beyond the intention of this article, even if space permitted, to go deeply into the details of the application of this contrivance, but many suggestions will present themselves in connexion with vignetting, double printing, and even with combination printing, from a number of negatives. I have dealt more especially with the application to enlarging, but with a little variation the plan is equally applicable to the production of lantern slides by reduction in the camera, in which case the masks may be applied either inside or out of the instrument. It is, however, scarcely necessary to enter into details here.

W. B. Bolton.

Mr. Alfred H. Saunders, of Mount Pleasant, Brierley Hill, has sent us his price-list of lantern-slide making and colouring. For the former Mr. Saunders employs the wet-plate process. The prices appear to be moderate.

LANTERN MEMS.

Ether and other saturators have for some years past been matters of interest to lanternists, and considerable ingenuity has been displayed in the design of new forms, or development of old ones. Among names associated with work in connexion with the same, one remembers those of Broughton, Hardwich, Ives, and the late Albert Scott.

* * * * *

The latest form of saturator is that combined with a jet—the invention of Mr. Lawson, and members of the Lantern Society had at the last meeting an opportunity of seeing it worked practically by Mr. Hay Taylor with every appearance of success, the light, as most lanternists are aware, when oxygen gas is passed through ether or benzoline, being brilliant, quiet, and steady.

* * * * *

From the remarks made after, it would appear that saturators generally have to live down a questionable reputation, and, on the principle of "Give a dog a bad name," nothing but practical proof over an extended period will cause lanternists and the public to have thorough confidence in the oxy-ether light.

* * * * *

Personally I have always thought the light a useful one, and, under certain conditions, almost indispensable, while in my own hands, and those of my friends it has been quite successful. It has, unhappily, come under notice on more than one occasion that others have not been so successful, as testified by destroyed apparatus, &c.

* * * * *

That it is a light that can be indiscriminately used with some of the forms of saturators on the market will not be admitted by many; but, surrounded with safeguards, it no doubt can not only privately but in public (especially for single lantern) be employed with success. I have used the Broughton-Hardwich ether saturator and compressed oxygen in the field for special purposes of limelight work, and moved the apparatus about during operation, but a similar apparatus in the hands of those for whom it was purchased quite failed.

* * * * *

Then, again, I had occasion to adapt a similar oxy-ether light, with saturator, to a triple lantern for use in South America, and it not only answered perfectly here, but on last hearing from the owner continued to do so; hence the conclusion is that, the more the difficulties are made known and overcome by apparatus being perfected, the more certain *will* the satisfactory working of the light become.

* * * * *

For dissolving with the regular forms of gas dissolvers, such as those known as "universal," the "Star," &c., certain modifications have to be made, so that the light does not pop out; and, as the action of dissolving causes an accumulation of pressure on the supply side, and an exhaust to a certain extent on the other, pumice chambers immediately under the nozzle of the jet are, in my opinion, absolutely necessary.

* * * * *

Although in the case referred to ordinary dissolvers were employed, I should strongly advise that double plug dissolvers be used as a general rule for the oxy-ether light, so as to keep the saturated *gas* quite distinct from the pure oxygen. With old patterns revived and new ones introduced there will be no difficulty in selecting one suitable for the purpose.

* * * * *

Photographers know well the nature of sulphuric ether, but for all that it is not always kept under control, and whether in its stoppered bottle or in the saturator too much care cannot be exercised to ensure that none escapes. As to the quality, there must be no question about that, it must be the best, *and best only*, somewhere about ·770 specific gravity (·750 or ·760 will answer), the filling to take place in the open air, or in an outhouse away from any light or fire. All washers to be periodically tested or changed so as to ensure perfectly tight joints, and each indiarubber tube kept to its own gas (oxygen or saturated).

For England, and wherever both hydrogen and oxygen gases can be obtained compressed, I should always prefer to use the *two* gases; and, as house gas is so much easier for the companies to get and compress in lieu of pure hydrogen, there is no reason why that should not be continued to be used, providing (and this is where the *if* comes in) they have it purified before compressing.

* * * * *

The price charged for compressed house gas should be ample to supply a practically pure gas, and it is not enough for the oxygen compressors to shield themselves behind the excuse that the compressed house gas is only supplied to oblige the customers who use their oxygen (as I once heard stated), for without hydrogen for limelight work (as at present mostly employed) oxygen would be little or no use. Probably, by some arrangement with the large gas companies, a specially *good* quality of gas could be supplied for compression.

* * * * *

A new use has been found for the old lantern favourite of childhood's days—the "chromatrope"—which has been introduced in the now popular serpentine dance. With a dark cloth background the dancers in their ample skirts gyrate in the rays of the limelight, constantly changing in colour with all the prismatic hues and its effectiveness, and then when a number of jets below the stage are sending up clouds of steam to surround the dancers and create a weird effect, the chromatropes from the lantern in the front of the stage, and hidden from sight, are projected on the dancers and revolved.

* * * * *

Patterns for the chromatropes have been selected that lend themselves to effective contrast, among them being a pattern that produces a serpentine twisting of the design, while others are of the stereotyped patterns. In all, I believe, five lanterns are employed at the Canterbury Theatre of Varieties, where this innovation occurs in *Satan Junior*, by Charles Lauri, the clever pantomimist of Drury-lane renown.

G. R. Baker.

THE DISSOLVER.

I.

Strictly speaking, the lantern season was over, for April had come, when the Society's biunial and gas bottles were usually consigned to inactivity until the shortening days of the autumn should release them from their imprisonment in the big cupboard of the old-fashioned room which the Society rented at "The Flat Iron and Sugar Tongs." This year, however, an extra lantern night, to take place in the middle of April, was decided upon. Mr. Samuel Skinner had proposed it, Mr. William Poddleton had seconded it, and the proposition was carried unanimously. So said that unimpeachable witness, the minute book.

But there were several circumstances connected with this extra lantern night which the minute book did not record. For instance, had the worthy Honorary Secretary instead of making the contents of the sacred volume a bald, exact, and colourless *résumé* of the Society's proceedings, imported a thread of explanatory and vivifying narrative into it, it is quite certain that he would have mentioned the interesting fact that this was the first time that Mr. William Poddleton had seconded anything that Mr. Samuel Skinner had proposed at the Society's meetings.

Yes, Skinner and Poddleton had agreed at last! Wonderful! and not merely agreed—but over a lantern matter! That was the astonishing part of it. The Society, so to speak, would have rubbed its eyes with amazement at beholding Skinner and Poddleton in accord over anything, but that they should be of one mind as regards something directly or indirectly associated with the optical lantern was a phenomenon of such an extraordinary nature that the Society gasped and wondered what would happen next. Momentarily recovering their surprise, however, members held up their hands in favour of Skinner and Poddleton's proposition; and, when the Chairman declared it carried, and the members looked curiously at Skinner and Poddleton, who sat glaring at each other with hatred gleaming in their eyes and illuminating their faces, they instantly took in the position of affairs, and chuckled with the enjoyment of anticipation. For lively times were in store at the extra lantern night, as Skinner and Poddleton were, of course, going to have a heated and bitter wrangle over the merits of their respective slides. There was always a great deal of fun to be extracted from the photographic quarrels of Skinner and Poddleton, and, doubtless, there would be no exception to

the rule on the extra lantern night. Nay, since Skinner and Poddleton were the instigators of the extra lantern night, might it not be assumed and hoped that some special attraction in the shape of a row of hitherto unapproached piquancy would be forthcoming? Assuredly. So the Society smacked its lips at the delightful prospect before it.

II.

Mr. Skinner and Mr. Poddleton were not exactly, in their two selves, the Great Mugglesby Amateur Photographic Society, inasmuch as the Society had a total membership of thirty-six, but it is quite fair to say that of that number thirty-four counted for so little by themselves, they would have been incapable of sustaining the existence of the Society, which, but for Skinner and Poddleton, must inevitably have died of inanition. The happy pair bore the same relationship to the Society, as a whole, that oxygen does to nitrogen in atmospheric air—they were simply diluted by the other thirty-four, whereas the thirty-four, without the other two, would have been in just about the same position as nitrogen would be for breathing purposes without oxygen.

Still, the other thirty-four members of the Great Mugglesby Society were not, as you might have imagined from what I have just said, all padding, in a photographic sense. Oh, dear no! there were some really good photographers among them, with a great deal of sound technical, and artistic knowledge, which is more easily conveyed in words than works, although not, perhaps, with so much conviction. They talked and read papers at the meetings, showed results, asked questions, spoilt as many plates and made as many lantern slides as, perhaps, any other four-and-thirty amateur photographers chosen at random; but, after all said and done, they were but a mere pack of minnows round those dominant Tritons, Skinner and Poddleton.

For Skinner and Poddleton were *the* authorities of the Society, and, like most authorities, they did not leave those about them in ignorance of the fact. Skinner was one of the last to be converted from collodion to gelatine; Poddleton was one of the first to adopt the newest dry-plate process. Skinner swore by pyro; Poddleton tried every new developer as it came out, and instantly became its oracle for the benefit of the Society at large. Skinner cherished a deeply rooted sentimental loyalty for albumen paper; Poddleton went into ecstasies over platinotype. Skinner declined to consider the feasibility of any process coming up to collodio-bromide for lantern-slide work; Poddleton averred that *he* could not tell the difference between *good* gelatine slides and those on collodion.

What Skinner recommended Poddleton denounced, and what Poddleton suggested Skinner tried to improve on. They were both endowed with the unfortunate defect of loquacity, so that now and again there were some warm discussions between them. Singular to say, when either of them absented himself from a meeting, flatness and inertness characterised it, and once, when both were away, it really seemed as if the members were incapable of sustaining a discussion, and, although neither Skinner nor Poddleton was liked, it ultimately came to be recognised that, without them, the Society would be shorn of its chief sources of vitality. And, as Skinner and Poddleton knew this just as well as the other members, it raised their self-conceit and mutual dislikes to a glorious extent.

III.

It was not, perhaps, an ill-natured feud; for, as Great Mugglesby is a large town, and as Skinner lived at one end of it and Poddleton at the other, they seldom, if ever, met in private life, and, in point of fact, had nothing whatever in common outside photography; but, photographically speaking, they regarded each other as arrant quacks and asses, a state of feeling possibly largely born of jealousy, and, no doubt, liberally nourished by resentment. It began at the very first meeting of the Society. Skinner showed a negative with transparent spots upon it, for the purpose of eliciting the cause of them. Poddleton incidentally observed that the subject—a rustic scene—was not sharply focussed. Skinner, who had a leaning towards diffusion of focus, retorted that he was not a map-maker. Poddleton opined that it would be to the advantage of photography if "map-making" were a little more prevalent than it was. Skinner said it was a matter of taste. Poddleton said it was very bad taste. Skinner said Poddleton didn't know what he was talking about. Poddleton said, "Sir, to you!" And thus the seed of strife was sown, and the Great Mugglesby Society was assured a career of liveliness which was a capital preventive of somnolence, although, perhaps, no great help to photographic science.

So matters ran on during the three years' existence of the Society, the acute stage of the great Skinner and Poddleton controversy being, of course, reached in the winter months, when the lantern nights were on. They were both great on slides, and were indeed clever workers, but so prejudiced one against the other that, no matter how excellent the one's slides were, the other with insurmountable obstinacy refused to be persuaded of the fact, and continued to find faults where none in reality existed.

"These," the assistant lanternist would say, as he came to them, "are Mr. Poddleton's slides." Then the semicircle of members seated in front of the screen would nudge each other and "ahem!" and Skinner would fold his arms and fix his gaze on the sheet with a remorseful smile and compressed lips.

When the applause on the first slide had subsided—for Poddleton was really a good worker—Mr. Skinner would ask, in a tone of assumed amiability, whether Poddleton had his camera quite straight when he was taking the negative? Now, if there was one thing more than another upon which Poddleton prided himself it was taking his pictures "plumb," all his cameras being most profusely studded with spirit levels, so that he was absolutely independent of that fallacious instrument, the eye.

Mr. Poddleton's retort, which was always allowed a free field by the other members, who never interfered between Skinner and Poddleton except to keep the apple of discord plainly apparent to both of them, would be not altogether untinged by personality.

"Was Mr. Skinner sure he could see straight?"

"Mr. Skinner would confess himself unable to do so after looking at Mr. Poddleton's distorted photographs. Had not Mr. Poddleton rather over-developed the next slide?"

"Mr. Skinner liked a full range of gradation; some people had an inexplicable love of want of contrast."

"The next slide had a bluish tone in the shadows, and a distinct red colouration in the half-tones. How did Mr. Poddleton account for that?"

"Mr. Poddleton would not attempt to account for anything of the existence of which he was unaware. Some people could not distinguish between monochromatic and polychromatic effects. Colour blindness was a deplorable disease in both positive and negative form." And so on.

Mr. Skinner's slides would come on in due course, and then it would be Poddleton's turn.

"Mr. Poddleton would like to know if the clouds in the first slide were in the negative?"

"They were," from Skinner.

"Then perhaps Mr. Skinner would be good enough to explain, for the benefit of the members at large, what peculiar phenomenon in nature was responsible for the clouds being lighted from one side of the picture and the landscape from the other?"

"Mr. Skinner was not responsible for the freaks of nature."

"The next slide was *rather* dense; would Mr. Skinner like a little more gas?"

"Mr. Skinner would like a little *less* gas from Mr. Poddleton."

"What developer did Mr. Skinner use that he should have got that disagreeable brownish-reddish tone?"

"Pyro and carbonate of ammonia."

"Did not Mr. Skinner think he could have got a better result with a mixture of eikonogen, hydroquinone, amidol, metol, and glycin, well restrained, and containing an alkaline carbonate and hydrate?"

"Mr. Skinner had more respect for his collodio-bromide emulsion than to subject it to the noxious influence of such a fearful and wonderful hotch-potch."

From these sparsely culled amenities of the lantern meeting the reader can easily see what a capital fund of amusement the general body of members derived from the rivalry of Skinner and Poddleton. Sometimes they took sides; not, it must be confessed, from any conviction that in so doing they were obeying the dictates of a reasoning instinct, but simply to keep the game alive between the disputants; for, although Skinner and Poddleton were good enough photographers, and had a useful historical and practical knowledge of ancient and modern processes, the other members were in most respects their equals in skill, so that the authority they enjoyed was more fictitious than real. In secret, therefore, as the reader will have guessed, Skinner and Poddleton were laughed at by their fellow-members, notwithstanding the fact that those two gentlemen were the chief instruments in holding the Society together.

IV.

So far, however, the breach between the two opponents had never widened to anything like an extent which would not admit of being bridged over; but, in the nature of things, such a crisis was bound to arise. It arose, and in this way.

There was to be a lantern-slide competition for a challenge cup among

the photographic societies of the county of which Great Mugglesby is the chief town, and naturally the Great Mugglesby Society were among the competitors. It was arranged that the slides to represent the Society should be chosen by the vote of the members upon those shown at a lantern evening to be devoted mainly to the purpose of selecting a representative set. Most of the members sent in collections, and among them were, of course, sets from Mr. Samuel Skinner and Mr. William Poddleton.

The method chosen for ascertaining the opinion of the meeting on the individual slide was the highly simple one of counting audible votes for or against. Thus, when a slide was on, there would be a mingled chorus of "Noes" and "Yeses" from the members, just as they might consider the slide good enough or not to represent the Society. Then the Chairman, if the preponderance of opinion was not sufficiently marked one way or the other, would count the votes and declare the result accordingly.

Mr. Skinner's slides were so good that they were instantly greeted with applauding "Yeses." Poddleton was silent throughout the passage of his rival's slides across the screen; but when the last of them had been shown his voice was heard, in a distant corner of the room, saying, "Mr. Chairman!" A hush fell upon the members, who turned with smiling faces to where Mr. Poddleton was sitting. The fun was about to commence!

"I should like to ask if it is not understood," said Mr. Poddleton, sweetly, "that slides entered for this competition should be from the slidemaker's own negatives."

"Of course," said the Chairman.

"Decidedly," said several members.

"It states so in the rules of the competition," added the Honorary Secretary. The Honorary Secretary was always strong on the rules.

"Then I take it, sir," continued Mr. Poddleton, in honeyed accents, "that Mr. Skinner's slides are ineligible, as they are not made from his own negatives. Mr. Skinner said in this room, only a month ago, that he had no experience of photographing in Norway; so how did he manage to take these pictures there? Has he been there during March, and obtained summer effects?"

"I—I—beg pardon," stammered poor Skinner; "the negatives were lent me by a friend. I forgot to mention it, and—I—didn't know—I—I—I—didn't remember the rule the Chairman refers to. Of course—oh, of course—the slides are ineligible. So, take 'em out, by all means."

So the slides were taken out, much to Mr. Poddleton's delight and the chagrin of Mr. Skinner, who enjoyed nothing so much as favourable comments upon his lantern-slide work. The sharp-eared Poddleton had clearly scored a very good point against his rival, although the feeling of the members was one of regret that he had announced his discovery as to the authenticity of Skinner's negatives in so public a manner. It was evident that there was something more than mere superficial rivalry between the two men that urged Poddleton to take such an extreme course against Skinner, and whatever doubts on the subject may have existed in members' minds were removed later in the evening when Mr. Poddleton's slides were put on; for whether it was resentment or mortification alone, or a combination of both, the members could not tell, but Mr. Skinner, for the first time in the history of the Club, was quite silent while the Poddleton slides were passing through the lantern—yes, quite silent. He looked at them as critically as anybody, but said never a word. Everybody expected an angry outburst of cantankerous criticism upon Mr. Poddleton's slides, or, at least, a fusillade of "Noes" as they were shown, and nobody more so than Mr. Poddleton himself.

When all the slides had been shown, and the meeting was concluding, a further surprise was sprung on the members. Mr. Skinner rose, unnaturally self-possessed and cool.

"The lantern meetings throughout the winter have been so very successful, Mr. Chairman," he remarked, quietly, "that I'm sure we are sorry they are over. As it is possible that members generally may like to have one more lantern night in the semi-winter month of April, I beg to propose that an extra lantern night be held this day month."

"I second that," said Mr. Poddleton.

The surprise of the members at this unexpected partnership of the two old foes was not so acute that it prevented them from acquiescing in the suggestion, and so it was carried. But after the meeting, and for days following, the temporary coalition of Skinner and Poddleton was the theme of speculation and discussion.

V.

Mr. Skinner was a flourishing dentist and a bachelor; Mr. Poddleton was a partner in an extensive grocery business, and also unmarried. As I have said, outside the Society's meetings and outings there was no bond of intimacy between them, and, except on these occasions, they seldom met. During the last few weeks, however, they had stumbled across each other several times, the frequency and circumstances of their meetings arguing that they had both suddenly contracted an absorbing fondness for the drama, for it was at the Great Mugglesby Theatre Royal that these meetings took place.

The Great Mugglesby Theatre was run on the same system as most country playhouses, that is to say, a different entertainment was given every week, provided by travelling companies. For the last few weeks, however, the theatre had been occupied by a company organized by the manager himself, and it was during this "stock season" that Mr. Skinner and Mr. Poddleton, who had hitherto only visited the theatre at distant intervals, began so generously to patronise the local temple of the drama.

Melodrama of the conventional or Adelphi type was the bill of fare, varied in style, although not in nature, from week to week at the Great Mugglesby Theatre, and it was "interpreted by the most powerful company ever got together in the provinces, including the celebrated London actress, Miss Melpomene de Vere." Gifted and beautiful as Miss De Vere possibly was, nobody in London had ever seen or heard of her. There is nothing to be surprised at in this; parallel cases by the hundred abound.

Miss De Vere's histrionic powers do not concern us, although Skinner and Poddleton thought her a great actress; but they, poor fellows, were blinded by her beauty, and, therefore, became quite incompetent to criticise her. She was, undoubtedly, a good-looking and charming young person, and better men than Skinner and Poddleton might have been excused for losing their hearts and heads over her. But this is not a love story, so let me skim through the sentiment quickly. Skinner and Poddleton soon learned, as gallants will, that they were rivals for the favours of the one divinity, and therefore they would have assassinated each other, had they dared.

The extra lantern night arrived in due course. The Society had several visitors, and the room at the "Flat Iron and Sugar-tongs" was well filled. A numerous collection of slides was shown, and altogether the affair—at any rate, in its earlier stages—passed off very well.

Mr. Skinner's slides were much admired, and it seemed that, as if in atonement for his error of judgment in having shown slides from another man's negatives at the last meeting without acknowledging that the originals were not his own, and also, probably, to convince his fellow-members that his own powers of negative-making were not in any way inferior to his friend's, he had, during the past month, made an earnest effort to utilise his undoubted cleverness in photography to its best advantage. The slides he showed were voted perfect in technique and pictorial quality. They were from a series of negatives of the scenery round about Great Mugglesby, which, although the trees were as yet nearly bare of leaves, afforded many opportunities for the production of pretty views, in which lake, river, wood, meadow, and hill could be included with the happiest artistic effects.

As Mr. Skinner's slides were being shown, it dawned upon the members that he had recently taken a new departure in landscape photography—that is, for the first time he had introduced figures in landscape. To be more correct, only one figure appeared throughout his series of slides; it was the person of a delightfully dressed lady, and it is due to Mr. Skinner's artistic instincts to say that she was so placed in each of his views as to fit well into the picture, and assist the composition. In one she was standing by a rustic stile, looking out upon the landscape; in another, walking under a row of trees; in another, looking up at a bird; and so on.

The last of Mr. Skinner's slides was a portrait of the lady herself. It was greeted with great applause, as much for the beauty of the original as for the delicacy of the picture. Then members nudged and whispered each other, and wondered what Mr. Skinner had to do with Miss Melpomene de Vere that he should have had so many opportunities of including her in his pictures. Some admired his boldness in showing them; others condemned it; but all were surprised and jealous at his success.

Mr. Skinner looked across in the semi-darkness to Mr. Poddleton with an expression of countenance that betokened a feeling of triumph; but, if he could have seen the latter gentleman's face, he might have been surprised to find how unmoved and reposeful it was, under what Mr. Skinner evidently looked upon as conclusive proof that *he* (Skinner) was the swain upon whom the fair De Vere had deigned to bestow her choicest smiles. And Mr. Skinner would have seen something more if the gas had been turned up; he would have seen that among those who examined his pictures one gentleman, a visitor, who had been introduced by a friend, a member, did so with rapt interest; and he might have noticed that when the portrait appeared he turned to his friend and asked him who had taken the photographs, and that, on being informed, he asked where Mr. Skinner

lived, and was also told. To say that the real state of the case had dawned on the members at large would, perhaps, be alleging too much; but undoubtedly an inkling of it was abroad, so that, bearing in mind the significant fact that Poddleton had seconded Skinner's suggestion for the extra lantern night, the former's slides were anticipated with much eagerness and curiosity. When they at length appeared, members were not disappointed.

Melpomene de Vere pervaded Poddleton's slides as she pervaded Skinner's, but to a greater degree. Of Skinner's pictures she was but a part, of Poddleton's she was the whole. Poddleton, in fact, had photographed the De Vere at his own private studio in all her characters, and in a variety of attitudes and poses; and amidst all the applause that greeted the pictures it was somehow felt that Poddleton, having been admitted to the privilege of photographing the leading lady of the Great Mugglesby Theatre in character, had beaten the rival for whom she had merely consented to pose in his landscapes. Unable any longer to restrain themselves, members laughingly cheered Poddleton, cheered his slides, and cheered Miss Melpomene de Vere. Some of them asked Poddleton "when it would be," others requested to be favoured with a piece of cake, some inquired when he was going on the boards, and indulged in other pleasantries of a like character, which he took in the best possible part. In the midst of all this hubbub, Skinner contrived to escape from the room. As he left the hotel he encountered the visitor who had been so anxious to know who had taken the landscape photographs in which Miss Melpomene de Vere figured, and who, besides, when Mr. Poddleton's studies of the lady in character appeared, exhibited a similar degree of curiosity as to who *he* (Poddleton) was and where he lived.

The dejected Skinner went home to concoct schemes for outwitting his rival before it was too late; the stranger betook himself to the Great Mugglesby Theatre, and was just in time to witness the last act of the play in which Miss De Vere was appearing.

VI.

Elated with having publicly shown his rival that he had made further progress in the good graces of Melpomene de Vere than Mr. Samuel Skinner, whose outdoor photographs with the lady in them antedated Mr. Poddleton's studies of her in character by some three weeks, and, therefore, were held by Mr. Poddleton and the members of the Society as adducing conclusive proof that Mr. Skinner had lost ground in the contest, Mr. Poddleton, when the lantern meeting was over, hurried off to the Great Mugglesby Theatre, burning to tell the fair De Vere what admiration of her his slides had evoked, and calculating thereby to advance yet another step towards the goal he had in sight, which was the conversion of the lady's name into Poddleton.

When he reached the theatre the performance had concluded. He sent in his card to Miss De Vere, hoping to catch her before she went home. The messenger returned, to say that the lady could not see Mr. Poddleton that evening, and that gentleman had perforce to depart, with the intention, however, of repeating his visit on the following day, which he begged the messenger to intimate to the lady.

Interesting and exciting as the play was in which Miss De Vere had that evening sustained a deeply emotional part, and which bathed the handkerchiefs of the female section of the audience with lachrymatory moisture, it was dwarfed in human interest by the short, but stirring, drama of real life in which she suddenly found herself engaged shortly after the fall of the curtain that same evening; for, when the play was over, the stranger who had been present at the Mugglesby Society's lantern entertainment quickly made his way round to the lady's dressing-room, and demanded and gained admission by the inalienable right of his relationship towards Miss De Vere.

Her sternly sorrowful husband stood before her. The tears that rushed to her eyes were real ones, and her kneeling, supplicating attitude sprang from true, and not simulated, repentance. Six months before, the young couple had quarrelled over a mere trifle, and the man, as men sometimes do, had spoken words of blighting harshness, that had stung the girl into leaving his house and seeking a living by the aid of her undoubted talents on the provincial stage. To do her justice, her triflings with the amatory Skinner and Poddleton had nothing more serious at bottom than the harmless vanity of her sex and profession.

In a quarter of an hour the marital quarrel was at an end, and an hour later husband and wife were comfortably seated in the midnight mail for London, and "Miss Melpomene de Vere" had said "Good bye" to Great Mugglesby, to the footlights, and to the *rôle* of model for amateur photographers for ever.

Mr. Vincent Crummles, the ingenuous theatrical manager of the pages of *Nicholas Nickleby*, wondered, on a memorable occasion, when he saw mention of himself and his doings in a country paper, "Who put such things in print?" and, in a like degree, the same feeling of wonderment survives in many breasts to this day, and remains as a tribute to the energy and smartness of your modern journalist. Two days later the *Great Mugglesby Free Press* came out with a sensationally worked-up article, which Mugglesbyites in general, and the members of the town's Photographic Society in particular, read with feelings of peculiar interest.

"A Magic Lantern Romance" was the heading of the article, and its sub-titles were: "The Runaway Actress and the Amateur Photographers!" "Two Photographic Romeos and one Juliet;" "Mr. Samuel Skinner and Mr. William Poddleton idealise the Goddess of the Theatre Royal in their Photographs;" "The Photographs are shown on the Screen;" "The Lady's Husband is accidentally present, and discovers the Whereabouts of his Long-lost Wife;" "Husband and Wife Meet;" "A Reconciliation;" "The Boards will know the Lady no more;" "Mr. Skinner and Mr. Poddleton have taken a Holiday for the Benefit of their Health."

The article contained a highly embellished account of the events which have been detailed in the foregoing narrative, with several reportorial reflections on the ways and wiles of amateur photographers, and the important part played by the camera in modern *affaires-de-cœur*. Needless to say, it created a great sensation, and drew down upon the Society, and upon its members, no end of banter, which survived for more than the traditional nine days. How the affair got into print remains a mystery to this day, but a clue to it may be found in the circumstance that the treasurer of the theatre was very friendly with one of the staff of the *Free Press*, who had a friend who was a brother of a member of the Society; and that, in all probability, the article was the result of a conference between the three of them.

* * * * *

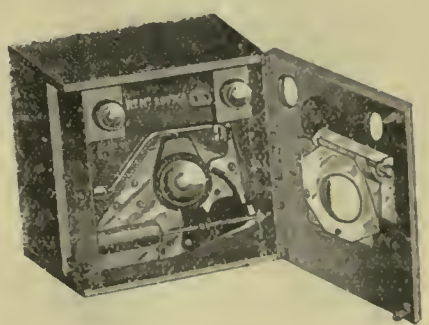
Mr. Skinner decided to look after a branch of his business in a neighbouring town until the affair blew over, and Mr. Poddleton took a spring holiday with the same object. On the next meeting night of the Great Mugglesby Photographic Society nobody turned up, and it was decided, in consequence of these events, to suspend its meetings until the following winter; but, when the winter came, only a handful of members were found to have preserved their allegiance to the Society, and, as Skinner and Poddleton had forsaken it, it was finally dissolved. It will be a long time before anybody starts a new photographic society at Great Mugglesby.

FERRERS OXLEY.

THE "N. & G." HAND CAMERAS.

MESSRS. NEWMAN & GUARDIA, of 71, Farringdon-road, informed us, on a recent visit to their establishment, that the fine weather we have been having lately has made them extremely busy with the hand cameras they have recently introduced. Powerful as the weather is in influencing business, we should be inclined to attribute not a little of the success which the "N. & G." specialities are meeting with to the excellence of the material and workmanship employed, of which we were able to judge from an inspection of all the innumerable parts and cameras in various stages of construction that were shown us the other day.

The No. 1 Standard pattern "N. & G." Hand Camera embodies many of the ingenious ideas of the firm, to which we referred in the course of a



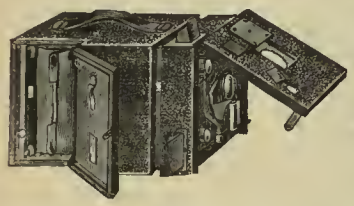
former article. It is fitted with a Wray rapid rectilinear lens and iris diaphragm, and an automatic self-cap in front of the lens. The shutter, which works between the lenses, has an hermetically closed regulating cylinder, effectually preventing all possible entrance of dust, and a pneumatic regulation, giving automatic exposures varying from $\frac{1}{2}$ to $\frac{1}{150}$ of a second.

Both pneumatic and hand releases are provided, and the shutter is noiseless in action. The setting knob is arranged at the top of the camera, and it always indicates the position of the shutter. All the parts are of metal, and the whole working mechanism is fitted on a single plate.

The camera has the well-known detachable changing box for plates or films, two view finders, a central rack and focussing scale from two yards to infinity, celluloid focussing screen and rising front, and is so constructed that every part can be got at for cleaning, the shutter set and released, and all adjustments made from the outside without opening the camera. The camera can be focussed and used on the stand in the ordinary way, and is covered with black morocco. The N. & G. Standard pattern is undoubtedly the perfection of what a working hand camera should be, and from the point of view of the photographer anxious to have an efficient instrument is a veritable luxury. Its movements and minutiæ appeal to one as very elegant.

There are in all six "N. & G." patterns, the one described being No. 1. "Standard" pattern. No. 2 has the addition of a cross front and double extension; No. 3, the addition of a swing back; No. 4 folds and collapses to half the usual length; No. 5 is a stereoscopic camera, and has a rising front, double extension, special shutter, special changing box, level, and can be used either for stereoscopicor single quarter-plate pictures.

No. 6 is a twin-lens camera, and is practically a "Standard," with a smaller camera on the top showing the identical image taken. This has the "N. & G." folding device for accurate focussing, which consists of a cone attachment over the focussing screen, upon which the full-size image is projected, fine focussing being obtained by means of an eyepiece fitted to the cone.



The stereoscopic camera is a particularly handsome instrument, and the twin-lens perhaps the most effective pattern of its class.

Among Messrs. Newman & Guardia's other novelties are the "Eiffel" stand, a very light, slender, but rigid stand for hand cameras, and an adaptation of the familiar changing back for taking twenty-four films in sheaths. This changing back works very smoothly and easily. The Nydia Pocket Camera will shortly be on the market. This is a folding camera, having all necessary movements, which with a dark slide packs up to a thickness of about one and a half inches, and, from the model we saw, is likely to be extremely popular. We were also informed that facilities will be given for adapting the N. & G. "Celeritas" shutter, which Mr. Medland, Captain Hayes, and other well-known workers employ for their photographs of animals in motion, to the Standard hand cameras as required. This shutter works between the lenses at $\frac{1}{100}$ of a second on an inch aperture, an aluminium plate $\frac{1}{250}$ of an inch thick being driven by a very strong spring, the impact on the release being so great that great care and strength of construction are necessary in order to prevent the shutter from smashing itself up.

Messrs. Newman & Guardia's specialities are of a high order of merit, and evince not only much ingenuity in their inception, with every regard to the requirements of the photographer, but that which appeals to all lovers of good apparatus—excellence and finish of construction.

THE "ARCHER" COMBINED HAND OR STAND CAMERA.

Messrs. Archer & Sons, of Lord-street, Liverpool, are placing on the market a "combined" hand or stand camera, which has a double extension to a maximum of twelve inches, leather bellows with side rack and pinion, rising front, and double swing, together with a reversing back and

a double swing back working from the centre. Double dark slides are used. The camera is fitted with a revolving head in the baseboard for tripod, as well as finder and focussing index. A celluloid focussing screen is also fitted to the camera; the lens, shutter, and stand being at the choice of the purchaser. The workmanship throughout is of the highest class.

It will thus be seen that the "Archer" hand or stand camera has all the movements which are demanded in the latest forms of hand camera, which it may be desired on occasion to employ on a stand.

RECENT LANTERN PATENTS.

PATENTS COMPLETED.

Improvements in Apparatus for Printing and Mounting Lantern Slides and Transparencies.

No. 5977. James Robson Rendell, Whinside, Whalley-road, Accrington.—*March* 25, 1893.

The first part of my invention is a frame for printing lantern slides and transparencies. I make two frames of wood or other material. In one of these, which I call the bottom frame, there is an opening, square or otherwise, in the case of lantern slides, three inches square. In the other or top frame an opening is made a little larger than the opening in the bottom frame; in the case of lantern slides three and a quarter inches square. Through this hole a sensitive plate can pass.

These boards or frames are held in contact by springs, in such position that the openings are exactly opposite each other, so that when a negative is placed between the two boards it is kept firmly in position.

At one end of the top board a lever is fixed, by means of which the top board may be raised so as to insert a negative between the two boards in any position that may be required.

On the top side of the top board, a wood or metal back is attached by a special form of hinge. This back fits exactly into the opening of the top board. This back is kept in position by a spring, as usually used in printing frames. These boards are covered with cloth, or other suitable soft material, on all parts which come into contact with the glass plates.

To cut round masks to be used in the printing frame, or for mounting lantern slides or transparencies, I make a pad of wood or metal, flat on the under surface. This pad has a round hole running through its axis at right angles to the under surface. In this hole a rod of circular section, and fitting the hole, is placed. It projects from the pad on the upper surface. A radial arm is attached to this rod by a hinge or a spring. On the radial arm slides another piece of metal, carrying a circular cutter of steel, the plane of the cutters being at right angles to the direction of the radial arm. A scale is engraved on the radial arm, so that the cutter can be placed at any required distance from the centre.

An Improvement in the Production of Names, Titles, and other Inscriptions on Photographic Prints, Transparencies, and Lantern Slides.

No. 20,156. Adam Gray, 142, Mercers'-road, Tufnell Park, London.—*March* 25, 1893.

Heretofore the production of names, titles, numbers, or other inscriptions upon photographic prints has been effected by writing, painting, or printing in reversed characters on the photographic negative itself, which is a difficult operation, requiring special skill, and is frequently unsatisfactory.

The object of my invention is to enable such names or other inscriptions to be produced from ordinary type, so that in printing from the negative the name or other matter in question will appear in clear, sharp, white characters upon the photographic print as a ground without necessitating any retouching of the negative, or of the photographic print, transparency, or lantern slide.

The invention consists in printing from metal or rubber type and with a fatty or transfer ink, such as is used in lithography, the name, title, or other matter upon a gummed or otherwise prepared transfer paper, and in transferring the impression to the photographic negative in the following manner:—

The part of the negative which is to receive the transferred impression must be prepared by rubbing the unvarnished or varnished surface of the film with powdered resin in the same way as for retouching, so as to give the surface a "tooth," to enable it to retain the ink and present a sharp and well-covered impression.

The transfer impression, of which the ink is still moist, is then to be laid face downwards on the prepared surface of the negative, and pressed into close contact therewith by rubbing the back of the transfer paper with a scraper or other instrument by which a uniform rubbing pressure can be applied, so as to cause the impression to be transferred to the negative.

The transfer paper being then stripped off, charcoal, bronze, or other powder is then to be applied to the transferred impression, in order to render the characters opaque, after which the negative should be varnished, whether previously varnished or not.

The operation is the same for lantern slides as for negatives, except that, whereas for ordinary photographic negatives the type used in printing the transfers would be similar to ordinary type, so that, when the impression is transferred to the negative, the letters will be reversed, whilst for lantern slides the type would be reversed as regards direction, so that, when transferred to the lantern slide, they will be presented the right way for reading.

Lantern Query.

Micro.—You seem to have complied with all the necessary conditions required in photo-micrography, and we can only conjecture that the want of sharpness is due to vibration of the floor of the room in which you used the apparatus. It should be employed in a room entirely free from tremor—say, a stone-lined apartment in the basement.

We understand that lantern slides are to be made from the pictures shown at the recent "Sandell" Exhibition, and that Mr. Sandell will be willing to loan the slides to photographic societies.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [June 2, 1893

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

A flashing light for marine purposes, the device of Professor Schevin, has, it is stated, been adopted by the German Admiralty The light is produced by running finely powdered magnesium through a benzoletted air flame. The flashes are said to be visible even by day, and at over six miles' distance. The light is equal to 400,000 candles, and will be specially useful in foggy weather.

* * * * *

We read that "the Parisian Photographers' Benevolent Association is making arrangements to open a kind of photographic theatre. The idea is to photograph the actors at intervals during a performance, and, afterwards, while the photographs are projected on the screen, a reader behind reproduces the dialogue. With good photographs and a clever reader, there is no reason why such an entertainment should not be a success"—or a failure, which?

* * * * *

On September 4, Mr. F. W. Edwards lectures before the South London Photographic Society on *Reminiscences of a few Eminent Men*, with lantern illustrations. A lantern lecture on the fathers of photography, and those who have materially contributed to its technical advancement by their experimental work, should be of great interest to young photographers. There should not be any insuperable difficulties in the way of securing a set of portrait transparencies to illustrate the lecture, which might be made the vehicle of a deal of useful technical and practical knowledge.

* * * * *

As evidence of the useful work which the affiliation Committee of the Photographic Society of Great Britain is doing, it may be mentioned that the sets of slides which the committee places at the disposal of affiliated Societies, have sometimes during the past winter been in request as many as four or five times a week.

* * * * *

The last Lantern Night of the season of the London and Provincial Photographic Association was held on Thursday, May 18, when, in addition to some admirable slides by Mr. C. H. Cooke, a collection by Mr. T. E. Freshwater from negatives taken at the Tower of London was shown. These were of very great interest, many of the principal features of the grim old fortress being represented, such as the Regalia, the Armoury, historical sets of armour, the "Little Ease," and spots associated with Raleigh, Queen Elizabeth, and other celebrated personages. Mr. Freshwater tells us that it is exceedingly difficult to get permission to photograph at the Tower.

* * * * *

It is not easy to tell with certainty in the dark room which is the coated side of most sensitive surfaces, and especially is this the case with lantern plates; with glass plates, celluloid films, and bromide papers the difficulty is only one degree less. To simplify the matter. Mr. W. I. Chadwick has suggested to us that if at the top right-hand corner of the plate, film, or paper a portion of the support was cut away so as to be readily detected by the finger in travelling round the edges, no mistake could be made, as it would then be known that the coated surface was towards one.

* * * * *

The chemical composition of the mantle in the new Auer incandescent lights has lately been discussed. The substance deposited on the cotton web consists of the oxides of metals of the cerium and zirconium groups, which exist in various minerals, for the most part in combination with silicic acid. The oxides are extracted from the minerals, and dissolved in nitric acid. This solution forms the bath in which the cotton web is dipped, and impregnates the latter so thoroughly that, on drying and burning, a finely meshed mantle of the oxides remains.

ORTHOCHROMATISM APPLIED TO PHOTO-MICROGRAPHY.

Before the Société Française de Photographie, on May 5, M. Monpillard read a paper on this subject, in the course of which he said that the design of photo-micrography is, given an object invisible to the naked eye, to obain an enlarged image of it, scrupulously accurate both in form and detail. Nothing is more easy in the case of colourless objects, such as diatoms, sections of bones, &c., the great perfection of modern objectives permitting of the obtainment of great sharpness and detail of image. It is not equally so when the objects are coloured, either naturally or artificially, and it may be said—for experience has proved it to be so—that all colouration degrades the perfection of the photographic image obtained with ordinary gelatine plates, so that, if the object be of a blue or violet colour (the most actinic colours), it stands out badly from the ground, and has its details poorly rendered. On the other hand, if it is yellow, orange, or red, the object is vigorously rendered on the ground, but the details bathed, as it were, in a light that is powerless to affect the sensitive salt, will, if the object be green, be very small, and less so with yellow and red.

In all cases, the employment of orthochromatic plates requires also the use of coloured screens.

Orthochromatic Sensitiveness.

Though commercial orthochromatic plates are sensitive for the green and red, and generally give satisfaction, M. Monpillard says that, for scientific purposes, he prefers ready-orthochromatised plates, which, when used shortly after preparation, have a maximum of sensitiveness to the luminous radiations. The operation of orthochromatisation demands only elementary care. The dark-room lamp should have two thicknesses of deep ruby glass, the flame being reduced to as small a degree as convenient during the bathing of the plates. After the plates are bathed they are passed through three dishes of distilled water, and are finally dried in a drying cupboard containing a vessel in which calcium chloride is placed.

For photo-micrographic purposes, the following colours give the best results:—

1. Erythrosine (for green-yellow; yellow and yellow-orange).
2. Cyanine (for red-orange and red).

M. Monpillard says the following formulæ have given him satisfaction:—

Erythrosine.

(Stock Solution.)

Erythrosine	1 part.
Distilled water	1000 parts.

Sensitising Bath.

Stock solution of erythrosine	4 c.c.
Water	100 „
Ammonia	0·5 „

Cyanine.

(Stock Solution.)

Cyanine	0·2 part.
Alcohol (at 95°)	100 parts.

Only a small quantity of the solution should be prepared, and it should be kept in the dark.

Sensitising Bath.

Stock solution of cyanine	4 c.c.
Water	100 „
Alcohol (at 95°)	5 „
Ammonia	1·5 „

The plates are immersed in either of the foregoing baths for two minutes, and are then washed and dried as directed.

ERYTHROSINE AND CYANINE.

Plates bathed in both erythrosine and cyanine are rendered sensitive to both yellow and red. The first bath consists of

Stock solution of erythrosine	20 c.c.
Distilled water	80 „

After two minutes' immersion the plates are washed in two waters, and are then bathed in the cyanine solution given, washed, and dried.

Plates so treated are, it is pointed out, very much slower, but this is no disadvantage in photo-micrography, and, on the other hand, they do not fog in development, which frequently happens when, to raise their general sensitiveness, the orthochromatising bath is preceded by an alkaline bath.

COLOURED SCREENS.

Coloured screens may be used either in the form of stained collodion, or, preferably, a small glass trough with parallel faces may be filled with either of the following solutions:—

(1) *For Light Yellow Screen.*

Neutral chromate of potash	1 gramme.
Water	100 parts.

(2) *For Deep Yellow Screen.*

Neutral chromate of potash	5 grammes.
Water	100 parts.

(3) *For Orange Screen.*

Bichromate of potash	8 grammes.
Water	100 parts.

(4) *For Red Screen.*

Erythrosine	0·2 gramme.
Water	100 parts.

No. 1 weakens the blues and yellows; No. 2 extinguishes them No. 3 cuts off the blue; No. 4 accentuates the action of the red.

With these coloured screens, and having sensitised the plates for given colours it will be easy to obtain in their true values reproductions of objects coloured or uncoloured. It is necessary, however, that the focus and the exposure should be made in the same monochromatic light, corresponding to a determined spectrum colour; this method of working assures the perfect sharpness of the image, inasmuch as the chemical focus is corrected. For this reason it is desirable to avoid, in exposing on one object, the use of screens of two different colours, except in the case where, on account of the presence of a deep red, it would be useful to prolong the exposure.

The plates, after treatment with erythrosine and cyanine, being sensitive to the red and blue, it is indispensable, to give the image its maximum of effect, to illuminate the object with a yellow or orange light, arresting or moderating the action of the actinic rays, and leaving free to pass the radiations corresponding to the colour of the object, if that is green, yellow, orange, or red. The following table will give an idea of the employment of coloured screens with plates sensitised with cyanine and erythrosine.

OBJECTS IN MONOCHROME.

	Colour.	Sensitiser.	Screen.
Actinic rays.	Blues or violets deep	Erythrosine	Pale Yellow
	Blues or violets pale	Erythrosine	Deep yellow or orange
Chemical rays	Greens, Yellows, Yellow-orange, Orange-red, Red	Erythrosine	Deep yellow or orange
	Greens, Yellows, Yellow-orange, Orange-red, Red, Deep red	Cyanine	Deep yellow or orange
	Deep red	Cyanine	Orange, red

COLOURED OBJECTS.

	Colour.	Sensitiser.	Screen.
Non-actinic colours.	Green and yellow	Erythrosine	Deep yellow
	Green and red, Yellow and red	Erythrosine	Deep yellow or orange, then red
	Green and red, Yellow and red	Erythrosine and cyanine	Deep yellow or orange
Actinic colours in the presence of non-actinic colours.	Blue or violet, with yellow	Erythrosine	Light or deep yellow, or orange, according to the intensity of the blue or the violet
	Blue or violet, with red	Cyanine	Same screens; in case the red is very deep, continue the exposure with a red screen

At first sight it might seem abnormal to attempt to photograph an object of a blue or violet colour with an emulsion sensitised for yellow, but M. Monpillard says nothing is more rational. It will suffice to obtain an image showing vigorously, with the shadows and half-tones well rendered. Now, with an emulsion which is particularly sensitive to the blue and violet, the object in question will appear so luminous that the ground will be slightly lost, and the half tones will not come up well. The interposition of a yellow or orange screen will retard the luminous impression by neutralising the rays emanating from the blue or violet parts of the object; but, the emulsion not being sensitive to the yellow, a general cutting off will result both for the ground as well as for the object, and the image will not have gained. Retaining the same screen and substituting for the ordinary plate a plate sensitised for the yellow, the ground will be forcibly rendered, while the blues and the violets, partly reduced by the coloured screen, will act with less rapidity, and will be rendered on the plate in their proper value. In a word, the plate sensitised for the yellow will reproduce the object as if it were gray and black on a white ground.

Where an object combines both red and yellow colours, it would be possible, at a push, to obtain a true rendering with a plate sensitised for yellow by commencing the exposure with a yellow screen, and continuing for the red with a screen equally red; although, for the reasons already given, the substitution of one screen for the other would endanger the sharpness of the image. It would be better to sensitise for red and yellow, and according to the intensity of the former expose with a deep yellow or orange screen. If blues and violets are found in the presence of yellows, oranges, or reds, it would suffice to use a plate sensitised for the least actinic colour (yellow or red), and, as the plate is, of course, sensitive to the blues and violets, a yellow screen, pale or deep, could be used according as the more actinic parts of the object are more or less coloured.

For development the author recommends hydroquinone with an alkaline carbonate and bromide, and the use of a feeble light in the dark room.

LANTERN MEMS.

The employment of triple lanterns for optical projections will receive a further impetus if Professor Ives' anticipations are realised, and he is able in the course of a year to publish details and instructions for producing his "Chromograms," as he stated he hoped to do when giving his lecture before the Society of Arts in May.

* * * * *

That Professor Ives has not been idle during the past twelve months, and since he first was able to project photographs in natural colours before a London audience, the illustrations the other evening amply showed, and it would be difficult to realise anything more natural, and at the same time beautiful, than the representation of fruit he was able to project on the screen, the colour of the grapes, pears, &c., being perfect.

* * * * *

That the result was not due to the aid of the artist with brush and colours was readily shown, by placing an object in the rays coming from the lantern (between it and the screen), when the shadow of the object on the screen had each of its three images a separate colour corresponding to the colour screen on each of the three lantern fronts. The colours—red, green, and blue violet—when combined very nearly approached to perfect white light.

* * * * *

No doubt details of the optical arrangement will be published in due course, and then one can better judge how far existing apparatus can be used for it; but, as perfect registration formed a special feature of the apparatus, there should be no difficulty in arranging the better class of triple lanterns for this purpose, especially as there are three distinct photographic pictures to produce the one chromo projection on the screen.

* * * * *

These pictures, or rather photographs, Professor Ives calls chromograms, and are taken in a camera having three lenses of the same focus so as to be identical for size, and in each one the light has to pass through a colour screen before forming an image on the sensitive plate. Although to outward appearance an ordinary photograph certain colour rays having been stopped back by the colour screen and others allowed to pass, each photograph is differently effected, and when suitably aided by other colour screens at the time of projection the original colours of the object photographed appears, and that with great brilliancy.

* * * * *

In the demonstrations referred to the Society of Arts electric light lantern was used, and the one-arc light made to illuminate all three pictures. This and the method of registering the three photographs so that they superimposed on the screen seemed most ingenious, it being understood that refraction and reflection from plates of glass both helped to this end. Perhaps an illustration of the arrangement will be published, when the plan will be understood.

* * * * *

With electricity being daily extended as far as area of distribution goes, no doubt in a few years ten persons will have command of current where one has now, and for small projection the incandescent 100 candle power lamps will supersede oil lamps in the optical lantern, while for special work of scientific demonstration the arc electric lamp will replace the limelight; not, however, for ordinary views and photographic projection so much as for the lantern microscope, polariscope, spectrum analyses, and colour experiments.

* * * * *

Now is the time for the invention and introduction of a simple automatic "focus" keeping arc lamp that can be sold at a moderate price—say 5*l.* or thereabouts—and that will give a naked light of 500 to 1000 candle power. It should be fairly portable, and have its adjustment for centering, &c., self-contained, so as to obviate the necessity of an expensive centering table. Several have been invented during the past twenty years, but none of them seem to have stood the test of trial for lanternists' use excepting the Siemens and the Brokie lamps, and these are both somewhat too expensive for general adoption.

The lantern, as a means for advertisement, seems still to find favour, for, while the miniature lanterns can be seen at work daily at some of the underground railway stations and in other "dark places," those overhead in the Strand and Oxford-street attract small knots of people when slides of average interest are being shown, while crowds congregate when something funny is on that appeals directly to the mirthful proclivities of the juveniles. I noticed in the papers, in one instance, neighbours that had been unneighbourly on account of the crowds shook hands in the Law Court, and were friends once more, it being understood that the advertisement of the one was not to be to the detriment of the business of the other.

* * * * *

Limelights have been in general use this Whitsuntide by signallers of the volunteers, who have formed a chain of stations, and have kept up communication, by means of messages flashed by the Moorse code, from the South Coast over the Sussex Downs to Caterham, and thence on one side to Aldershot, and the other to Chatham, showing that, in the case of an invasion and the telegraph being cut, communication could be kept up with our great military centres by night, while in the daytime flags and the heliograph enable messages to be sent as often as desired.

* * * * *

A good joke occurred at the preliminary practice when making oxygen gas to use from bags, as is still done by those who use the same outfit as the Government adopt. The retort, purifier, gas bag, &c., were all ready, and the fire was about to be lit to make the gas when the officer in charge of the signallers was approached by a weather-beaten soldier attached to the headquarters, who, after saluting, said, "Beg pardon, sir, I have had the stretcher put handy." There was an ambulance attached to the corps, and as there had been some considerable fun about the blowing up of the place and the danger of making oxygen gas, and whether the safety valve of the oxygen retort was all right, he had taken it seriously, and thought there must be more danger than facing the enemy in battle. However, all went well, and the gas was made safely, and the old soldier had nothing worse to do than (as he said) "I suppose I can put the stretcher away now, sir?"

* * * * *

In my "Lantern Mems." of last month I put ·770 as the specific gravity of the best sulphuric ether, by a clerical error, instead of ·717. The heavier kind, such as ·750, is very strong-smelling, and ·720 is the densest that can be used for oxy-ether limelight with satisfactory results.

G. R. Baker.

TRANSLUCENCY OF IMAGE IN LANTERN SLIDES.

After the usual technical points on the character of a lantern slide, such as correctness of gradation and clearness of lights, tone, or colour, is considered the one which adds most to the perception of the whole. But colour alone is of no value unless the deposit forming the image is of such a character that its colour is transmitted to the screen, in other words, the deposit must be to a certain extent transparent, or at least translucent. The silver forming the image in fact has to play the same part in a photograph that the pigments do in a painted slide, and no one, I imagine, would be foolish enough to employ opaque colours in painting a picture to be viewed by transmitted light.

It often occurs that a slide, or series of slides, that to the eye appear in every way satisfactory, cause nothing but disappointment when thrown on the screen, the cause being very likely set down as too weak a light, or perhaps to the slides being too dense. In a certain sense the latter may be true, though not altogether so, for if the image be formed of a purely divided and semi-translucent deposit and be in correct gradation, there is scarcely any limit to the general density that is allowable. But when the material forming the picture is coarse and opaque a comparatively thin layer of it suffices to stop the transmission of light, and although to the eye there may be a certain amount of gradation apparent, in the lantern the half tones and high lights are practically equal.

The same remarks apply not only to lantern slides, but quite as forcibly to negatives that are intended for enlargement. For this purpose, as is well known, the best kind of negative is a moderately

thin one rich in detail; but if that detail be composed of an opaque material that stops the light too powerfully, the negative is of no value for enlarging, though it may print well in the printing frame and in strong light. On the other hand, provided the image is translucent, a negative of considerable density—that is, a slow printer—will enlarge well if only a sufficient exposure be given.

The causes of want of translucency are various, and may be due to or found in the plate or film itself, or may arise from the method of development. In the old wet-collodion days the film, although distinctly granular under the microscope, was not sufficiently so to show any structure when enlarged only to the dimensions necessary in lantern practice; besides, the material constituting the sensitive film did not go to form the developed image—the latter being entirely deposited by the developer—although, if of an abnormally coarse nature, the silver in the film might to an extent govern that deposited in development. According to the developer employed, and, almost as a necessary consequence, to the exposure, so would the deposit be dense and opaque, or fine and translucent; in fact, in using the wet collodion process, the translucency or otherwise of the image depends almost wholly upon the exposure and development. If a full exposure be given, and pyro or well-restrained iron development be adopted, there will not be much wrong with the result; but, in case of under-exposure and forced development, the silver will be piled on in too coarse a form, with the consequence that the image is opaque and hard.

With the advent of collodion emulsion, or, indeed, of dry plates with alkaline development, the circumstances were altered, for now the image was formed out of the material contained in the film, that is to say, the silver forming the sensitive surface was itself reduced to form the image instead of merely forming the nucleus upon which metal was deposited from outside sources. Then the film itself began to play an important part in the question of translucency, and from the fact that the particles of silver, in collodion emulsion films especially, attain an extremely fine state of division, these have long enjoyed a high reputation for lantern-slide work.

But, although in such films we start with a finely divided and translucent basis to work upon, it by no means follows that it is impossible to produce opacity of image. On the contrary, nothing is easier, for the slightest under-exposure, giving rise to the necessity of forced development, will inevitable tend to destruction of the transparency of the image. When it is borne in mind that the leaning towards under-exposure is far greater with collodion dry plates than with gelatine, or even wet collodion, the balance of advantage possessed by the former in virtue of their finely divided films is, perhaps, not very conspicuous.

Another element that contributes, in conjunction with development, to the production of translucent (or the reverse) images on collodion films is the organic character of the pyroxyline used, or the means adopted to confer such qualities where they do not exist naturally. The more organic the sample of pyroxyline, as a rule, the greater the tendency to opacity of image, and *vice versâ;* while, of the various means adopted to make density with an "inorganic" sample of cotton, those which tend most to its disintegration or destruction—such as nitric acid and free silver in the emulsion—are the ones which tend to the same result.

But, outside of development proper, it is quite possible to greatly modify the character of the image, and to rob it of any claims to translucency it may originally possess. This is frequently done in intensifying or toning two dissimilar ends, which are frequently attained by similar means. Indeed, most of, if not the whole of, the methods of toning applicable to collodion transparencies are equally available, with little or no modification, for purposes of intensification, Perhaps I should have said that the methods of intensification are equally available for toning; but, if I did so, I should have to include toning methods which are objectionable on the very ground I am discussing their destruction of the transparency of the image. Amongst these I class most, if not all, of the methods based upon the bleaching of the image, and subsequent reduction by a second agent. Whether the bleaching agent be mercuric chloride, cupric chloride, or bromide, the final result appears to be a filling up of the pores of the film, or the interstices between the particles of silver in the original image, with fresh matter that converts transparency into comparative opacity. Bleaching with bichromate of potash and a soluble bromide or chloride is not necessarily followed by the same result, as no new matter is added to the film; the metal is simply reconverted to the haloid state, from which it is again reduced by any suitable developer.

The best and ablest intensifying process—with acid pyro and silver—is also one of the best for toning if properly conducted, but the precautions to be observed are just the same as in successful intensification, namely, to add the silver slowly and in as small quantity as possible. If the silver be added too quickly or too freely, not only will the deposition be rapid, coarse, and opaque, but the colour will also be bad, while by adopting the reverse tactics, although it takes a little longer, the results are in every way satisfactory, and I know no better colour, nor "juicier" (to use the old phrase) image than that produced on collodion by pyro and silver properly used.

Salts of uranium in conjunction with ferricyanide of potassium, have been much recommended of late years for toning bromide prints, and have also been applied in the same manner for lantern slides, both in gelatine and collodion. For the prints I find no objection when the desired tones are given, because any want of transparency of the image is of comparatively little importance; but for slides I consider the plan utterly unsuited. I have seen slides so toned that, to the eye, were as a newly baked brick; but, on the screen, black, heavy, and totally wanting in half-tone and gradation One of the best methods of toning for collodion slides, especially where a little intensification is also desirable, is that with sulphide of ammonia or of potassium—I prefer the former—as it has absolutely no tendency to lessen the transparency of the image. I hesitate rather to recommend it for gelatine owing to the immense amount of washing necessary before and after use.

With gelatine plates we have another difficulty to reckon with, and that is in the coarseness or granularity of some of the plates themselves. At the present day, however, I presume the purveyors of lantern plates take care to avoid this fault, but it is very certain that the plates of to-day are none of them so fine in "grains" as those of twelve or thirteen years ago. I have negatives of that date, that, to quote the old expression, "are more like a stain than a deposit." But with the finest plates it is very easy to spoil them in development by using too strong a developer especially of pyro. Strong pyro in conjunction with a full dose of alkali will "block up" and spoil any film whatever the exposure may be. But pyro is the one developer that gives any power in altering the colour of image; its newer rivals, admirable as they are for cleanness, give only black tones, but these prove generally acceptable, chiefly, I believe, because they are not opaque.

Of toning methods for gelatine plates I know none better than bleaching with bichromate of potash and hydrochloric acid and redevelopment *as a chloride plate.* The same range of colours can be obtained and the same fineness and transparency as with the chloride lantern plates provided the process is carried out carefully upon a good plate to start with.

If more attention were paid to the transparency of the slides shown, there would be fewer bad ones than is the case at present.

W. B. Bolton.

MENDING BROKEN SLIDES.

In a communication to the *Photo Beacon*, Mr. Charles Preston gives the following method of mending a broken slide. He says:—

"It was a picture I was anxious to possess, and could not get another copy. Examination showed that the binding strip adhered firmly to the splinters, and that when the splintered cover was carefully removed bit by bit, the matt simply consisted of four strips of paper pasted on the picture, keeping the pieces firmly in position.

"The picture was laid face up on a piece of thick plate glass, and gently warmed in the kitchen oven, after which a small pool of Canada balsam was poured on the middle, and the picture, still on the glass plate, returned to the oven till something like air bubbles began to rise. It was then removed, and a cover glass, which had been warming in the oven, was laid on the pool, and gently pressed down so as to spread the balsam completely over the picture without enclosing a single air bubble.

"A second piece of glass was then laid over the cover glass, pre-

viously covered with a piece of paper, the whole turned upside down, and the first piece of glass removed and carefully cleaned of a trace of balsam that had found its way through some of the cracks. The slide was then covered with a piece of paper to prevent adhesion, the glass replaced, and the whole set aside to harden, which was thoroughly effected in a few days, after which the superfluous balsam round the edges, and a trace from some of the cracks, was removed by a rag moisted with turpentine.

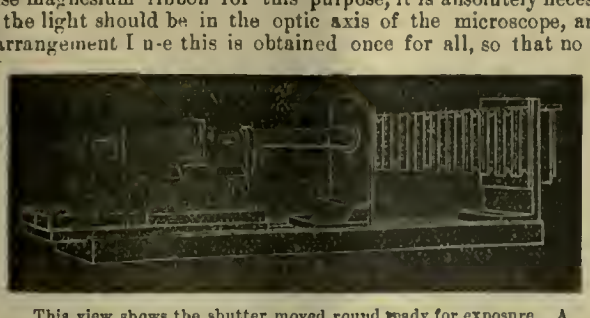
"It was considered advisable, although not absolutely necessary, to place a cover glass on the outside of the picture plate, and the whole was bound in the ordinary way.

"To say that the slide is as good as before it was broken would not be strictly true, but it has been shown among others, and so little is the damage apparent that the spectators did not notice anything peculiar about it."

PHOTOMICROGRAPHY WITH ARTIFICIAL LIGHT.

Photomicrography has been practised by me, more or less, for the last twenty years, and with varying success. My avocations do not permit of my having the advantage of using sunlight, and it is therefore necessary to use artificial light of some kind. For many years I had to be content with the light of a paraffin lamp. This light, even with the assistance of the best condensers, is not satisfactory, as, from the lengthened exposures required, the results are uncertain. With high powers, the long exposure almost renders it impossible to get good results. The light seems to become diffused over the plate, and the resulting negatives are poor and weak. In my case limelight was out of the question from the cumbrous nature of the apparatus. About five years ago I began the use of magnesium ribbon as the illuminant, and I have found it so satisfactory in every way, so simple in the use in the way I use it, and the exposures with it so rapid, that, even with high powers, what required formerly minutes with a paraffin lamp may be got in as many seconds with magnesium. As is well known, magnesium light is peculiarly rich in those rays which most affect the sensitive plate, and is, therefore, one of the best to use for that purpose. The use of magnesium has been so satisfactory to myself that I have thought it would be of use to many others were they made aware of the benefits to be derived from it, and the particular way in which I burn it made known. I find, from the *American Science Review*, that magnesium was tried by the late Colonel Dr. Woodward, but he burnt it in a special lamp. Magnesium lamps are always unsatisfactory. I have tried many of them, but always found the driving arrangement either pushed the ribbon out faster than it could be burned, or too slow, and the light went out. A Mr. Johnson described in the *Popular Science Review*, as long ago as 1864, his method of using it. It is not, however, quite the same as the method I use. I only became aware of Mr. Johnson's paper during the course of last summer.

I have, for a number of years past, made for myself and others a number of photomicrographic apparatus of various forms, but, after a lengthened experience, I have come to the conclusion that the one I am now to describe is the simplest and most satisfactory I have tried. It has no useless parts, and is so easily manipulated that any one, with a very slight experience, may acquire the skill to take very good photomicrographs in a reasonably short time by using magnesium. To use magnesium ribbon for this purpose, it is absolutely necessary that the light should be in the optic axis of the microscope, and in the arrangement I use this is obtained once for all, so that no difficulty is experienced in repeating exposures indefinitely. With this view, it is necessary that the apparatus should be described somewhat minutely to enable it to be understood. The illustrations will show very clearly, with a little explanation, the construction of the apparatus.



This view shows the shutter moved round ready for exposure. A book or any other article of proper height is placed beneath the camera bellows, to keep it straight and prevent any of the field of view being cut off.

The baseboard is 40 inches long by 7 inches broad, and is made of yellow pine 1½ inches thick. I prefer yellow pine, well seasoned, to any other wood, as it is lighter and stiffer than mahogany or any of the hard woods, and, when stained with bichromate of potash and exposed to sunlight, takes a fine dark colour. This length is, perhaps, rather shorter than I would like: four feet over all would be better, and would satisfy all requirements. The baseboard has two strips of pine, half-inch thick and seven-eighths broad, screwed to the upper surface, at the sides, as guides for the rest of the apparatus to slide to and fro within. The end of the camera which carries the dark slide is screwed down to the baseboard by long screws from beneath, thus making it as rigid as possible. I prefer this form to that in which this end of the camera is made movable, as one gets more comfortably at the screen when focussing a very important matter. The front end of the camera is made to move backwards and forwards, and on the front of it is the flange, into which the tube

Side view showing hole in board carrying exposure shutter with lamp in position for arranging object. A small box marked X is placed between the upright board and microscope to catch magnesium oxide.

screws which connects the camera with the microscope. The flange takes a portable symmetrical lens, when the camera may be used for other purposes. The bellows is thirty inches long. The sliding of the camera front, and also the block which carries the microscope, is much facilitated by gluing to each side of their under surfaces lengths of velvet ribbon, as used by Zeiss. The camera only takes quarter-plate size, and the centre of the connecting tube and dark slide are placed about six and a half inches above the surface of the board which carries the microscope.

The microscope I use is one which I made specially for this work. The body consists of a triangular bar of gun metal, eight inches long, measuring one inch on each face, and it is rigidly screwed down on the top of two A's, which again are screwed to the wooden block on which they stand by four screws from beneath, one into the broad flange of each foot. The stage is carried on a saddle, which moves backwards and forwards by a large pinion head on the left-hand side, working into a rack on the under side of the bar. The instrument has in this way great steadiness. The only drawback is that one has to turn the pinion head the wrong way to bring the stage up to the object-glass, but practice overcomes this. The cross arm, which carries the optical part, is made on the Ross model, and is firmly fixed to the triangular bar by a strong screw. The fine adjustment is a very delicate one. The lever is one of the first order. The fulcrum upon which it works is placed about a quarter of an inch from the front end, while that portion of it behind the fulcrum or pin is about one and a half inches. The screw is one of 100 threads to the inch, and in this way one whole turn of the screw is equal to the $\frac{1}{100}$ of an inch. As the button head of the screw is a large one, it is possible with the hand alone to turn it as little as the $\frac{1}{100}$ part, and so move the tube the $\frac{1}{3000}$ of an inch. For low or medium power this is much too fine, and I have another screw of half the pitch, which can be readily substituted for the finer one. The end of the lever raises or depresses the fine adjustment sliding tube by impinging on a small pin screwed into the tube through a slot in the brass of the cross arm, which pin also prevents the tube turning round. The fine adjustment tube has bearings three and a half inches apart. The tube is ground truly round, and highly polished, and after the rings in which it works are turned to size, they are tinned, which seems to make the tube slide more easily and smoothly. The microscope tube is simply pushed on the outside of the fitting on which the fine adjustment tube works, which fitting is turned to size. The microscope tube is one and a quarter inches in diameter, and it has an adapter to take Zeiss eyepieces for adjusting the object, and another one, with a diaphragm, to connect with the camera tube. This adapter has an outside ring, and, as the microscope tube is immovable, no other light-tight connexion is needed.

As the microscope is rigidly fixed to the board, and adjusted once for all to throw the image in the centre of the plate, no after adjustment for collimation is required. The stage is an old one of Andrew Ross's, which was on microscope No. 1773, and which, I understand,

was round the world with the *Challenger*. The photographs do not show a focussing rod, as I had to take it off for another apparatus I was making of the same kind. I use for it a three-sixteenth round iron rod, with a large button on the camera end. This rod turns in bearings made of the screwed ends of brass rings. A linen thread is passed round the rod several times opposite to the fine adjustment button, over which it is placed, and which has a V groove for the purpose, and a half-ounce weight hung on the end, which is more than sufficient to turn it. The upright board beyond the microscope carries the exposure shutter, and is rigidly screwed down to the board which carries the microscope. This upright board is pierced with a hole about one and a half inches in diameter opposite to the centre of the optical combination of the microscope, and it carries behind it an oval-shaped shutter, in the centre of which, at the broad end, is an inch of three-sixteenths brass tube.

The arrangement of this shutter and tube requires some attention. The ordinary microscope lamp is placed behind the upright piece beyond the microscope, and the shutter is held in position by means of a hand vice. (Zeiss) 70 mm. apochromatic object-glass is screwed into the microscope. This glass, although stated by the maker to be of 70 mm. focal length when used in the microscope above described, the tube of which is about eight inches long, requires four and a half inches from the front of the lens to the object. The small brass tube in the shutter may then be placed exactly in the centre of the optical combinations in the microscope by shifting the shutter about till this takes place, the lamplight clearly showing when the shutter and tube is in the right position. A screw nail is then placed through the small end of the shutter as a pin on which it turns, and another small one screwed into the upright on which it turns for the larger end of the shutter to rest on when exposing. One of the photographs will show the shutter turned aside, and the other the shutter in position for exposing.

When about to take a photograph, the board carrying the microscope is slid along to the end of the baseboard and the front of the camera slid back to the other end. A microscope lamp is placed behind the hole in the upright board, and a slide placed on the stage. The operator sits down on the left-hand side of the instrument and by means of the adapter eyepiece he arranges the object to his satisfaction. The connecting adapter is then placed in the tube, the front of the camera brought forward and connexion made. Both the microscope board and front of camera are firmly fixed with the pinching screws shown in the photographs, a correct focus is obtained either by the hand, or fine adjustment button, or by the focussing rod and weight. After the plate is put in the slide, the lamp is withdrawn, the shutter moved round into position ready for the exposure. Suppose we are using a Zeiss AA object-glass of 27 mm. focus, with a length from stage to screen of thirty inches, without an eyepiece, a short piece of magnesium ribbon is pushed through the tube in the shutter, and less than a quarter of an inch of the ribbon is burned after being lit with a match. This is more than enough to give a dense negative; and if a light filter is used—say, a piece of deep orange-coloured glass, to counteract the effects of an eosine-stained slide—one and a half inches of ribbon gives fine dense negatives. When using lower powers, such as three-inch and two-inch objectives (by Wray), I find that I cannot, with from thirty inches to three feet of camera, give sufficiently short exposures when no eyepiece is used. It will be noticed that I have not said anything about a condenser.

When the preparation is of such a character that the objective shows all the necessary detail, I never use a condenser, as I find that with magnesium the light is so powerful that everything one wants can be got without one. When, however, it is necessary to produce shadows on the object to allow the lens to reveal the finer detail of diatoms, a condenser is used. Even then, with a very small oblique aperture in a chromatic condenser of my own construction, I have got beautiful negatives by burning only from eight to ten inches of ribbon with objectives as high as $\frac{1}{12}$ of an inch.

Using, say, a C object-glass by Zeiss, of 50°, I get very fine negatives by burning only from two and a half to three inches of ribbon with a camera length of three feet, using, of course, no eyepiece and no condensers of any kind. The two negatives sent herewith of a section of the lung of a cow ill with the so-called corn-stalk disease and of another ill with pleuro were both done with this lens in this way.

I also send two transparencies of *Navicula spectabilis*, a diatom measuring $\frac{1}{1\frac{1}{2}\frac{1}{0}}$ of an inch in length; one taken with a Zeiss four-mm. apochromatic and projection eyepiece No. 2, and the other with a Zeiss water immersion apochromatic 2·5 mm. and same projection eyepiece. Both of these were photographed without any condenser. The magnesium was simply burned in front of the slide through the small tube. I used less than ten inches of ribbon in each case.

It is not necessary for one to multiply examples to show the immense benefit to photo-micrographers by the use of this light. The rapidity of the process, and the simplicity of the apparatus, are its best recommendations. Those interested in its practical results will see these exemplified in a paper by Professor J. M. Macfarlane, of the University of Philadelphia, formerly of Edinburgh, in the last number of the *Transactions of the Royal Society of Edinburgh*, on the hybridisation of plants. The whole of these photo-micrographs were taken by Professor Macfarlane himself by means of an apparatus I made for him, the same as that above described, and the exposures were made in the same way. Professor Macfarlane had had but a limited previous experience in photography, but with magnesium he had no difficulty in getting the results he wanted with a minimum of time and trouble. I have, perhaps, explained the detail of the apparatus more fully than desirable, but I have been induced to do so to make everything plain.

I never use any but Ilford ordinary plates, and have no difficulty in getting the results I desire with them.

It is not, of course, every one who can afford to set aside a special microscope for this work. Indeed, that is not necessary; but if the microscope is to be used for other purposes, care—the utmost care—must be taken that each time it is used for photo-micrography in the way I have described to have the small exposing tube exactly in the centre of the optic axis, otherwise failure will result.

There is another point to which allusion may be made, viz., photographing objects with polarised light. Of course, the Nicol prisms stop a very large portion of the light, but with magnesium no difficulty will be experienced, as another inch or so of ribbon is only required to give the density required.

I have been induced to publish this method of using magnesium by the fact that some of those who are recognised as good workers in this line still use oil lamps and a number of condensers to intensify the light. Reference may only be made to the report of the meeting of the Royal Microscopical Society in October last, as showing how both time and trouble may be wasted by using an inferior light. No such failure is possible with magnesium. As its manipulation is so simple in the way I have indicated, it would seem to be the light which all photo-micrographers must sooner or later resort to in the future, if the best results are desired with the least amount of trouble and also expense.

PROCELLA.

HOW I MAKE LANTERN SLIDES.

[Photographic Times.]

IN the first place I wish to define my position as it may stand related to what I have to say on the subject of this paper. I wish it understood that I am simply relating *my* methods, making no claim of superiority over others. I am familiar with the *fact* that a given formula for almost any photographic work will not produce uniform results in the hands of different operators. The question *why* is an interesting one, but cannot be discussed at this time, as it would furnish material alone for a lengthy article; it therefore must suffice to simply note the fact as a reason why it is not expected that every one who attempts to try my way will succeed in obtaining the same results. In the *Photographic Times* of December 23, 1892, was published a paper which I read before the Photographic Section of the American Institute, which I illustrated with seventy slides, made in the way I am about to describe, and the unanimous verdict of those who heard the paper and saw the illustrations was, that my position was correct, and the illustrations were superior to the generally accepted slide, inasmuch as they gave artistic effects. I refer to this as presenting sufficient evidence that I work my way successfully, whatever may be the result in the hands of others.

The first thing to be observed in the production of a lantern slide is cleanliness. So many otherwise good slides are ruined by appearing on the screen as if a pepper-box had been partially emptied over either the negative or slide when wet, so the first thing to do is to see that the negative from which a slide is to be made is perfectly clean; if the negative is not clean, and cannot be made so, do not use it. Use only clean negatives. The next most important element in this class of work, as well as in all photographic manipulation requiring development, is the *developer*. For several years I have been using caustic alkalies in most of my experiments. After introducing to the photographic fraternity the carbonates of soda and potash as a substitute for ammonia, I turned my attention to experimenting with caustic alkalies, and published some results in the *International Annual*, for the year 1888. In that article I gave an account of some experiments obtained with lime water. About two years after this publication, my attention was called to the saccherate of lime by Mr. Easterbrook, I think it was, who had a formula for its use printed on a card, one of which he gave me, but which I lost before I had

tried it. I mention this because, if the formula which I have worked out is, in the main, like the one he gave me, he will be entitled to the credit, if any is due. Suffice it to say, that I have used the saccharate of lime mainly for the last two years, both for negatives and positives.

My way of preparing it is to put into one gallon of water one pound of granulated sugar; when this is dissolved, it is used to slack a quantity of quick-lime.

Two or three pounds will be more than will be dissolved. When the water has become saturated, you will have about five pints of the solution, which should show about sixty-two grains to the ounce by the hydrometer.

Allowing eight grains for the sugar, you have remaining fifty-four grains of lime to the ounce, which is about four times the quantity in ordinary lime water; this, however, reduced to less than fifteen grains to the ounce, is much more energetic than plain lime water. This solution is slightly coloured by the heat evolved in its production on the sugar, and should be about the colour of pale sherry.

How to use this solution to prepare a developer will depend upon what effect you wish to produce, whether it be a negative or a positive, or whether the plate to be used is very sensitive or the opposite, and whether the exposure will be instantaneous or time.

For the development of a lantern slide on a very sensitive plate, I use one ounce of the lime solution, and three ounces of water, dissolve in this twenty grains to the ounce of glucose, or, in other words grape sugar, the most convenient form in which it can be found is in any candy shop by the name of rock candy. Maple sugar will answer, or twenty minims of honey, whether natural or artificial. The addition of grape sugar renders the use of a bromide unnecessary, and assists in producing intensity, which is more difficult on a very sensitive plate than on a slow and specially prepared plate. The next thing to add is sulphite of soda-fifteen grains to the ounce. This will cause a little reaction by converting some of the lime into an insoluble sulphite, which will give the solution a milky appearance; it will soon settle, however, and leave the solution clear. You need not wait for this, however, as it exerts no injurious effect on the plate. When the sulphite is dissolved, add four grains of hydroquinone. When this is dissolved, the developer is ready for use.

It can be used repeatedly until all used up. If any is left over, do not return to the bottle containing that which has not been used, but put it into a bottle especially for old developer. By constant use it becomes charged with the bromide released by the decomposition of bromide of silver in the sensitive film, and becomes slower in its action, but will develop just the same if about double the time of exposure is given. A little fresh developer added restores its activity. I have made beautiful negatives with the old after standing all winter in the cellar of my country home.

For landscape, and general out-of-door work, two grains of hydroquinone is all that is necessary, and for a specially prepared plate for lantern slides, one or one and a half grains will be found sufficient.

My comparative experiments with amido are incomplete; the most serious charge I have against amido, as compared with hydroquinone in the form in which I use it, is that it lacks the keeping qualities of the latter. The best results of my experiments, as far as keeping qualities are concerned, are as follows:—

Water	1 ounce.
Rock candy	20 grains.
Sulphite of soda	20 ,,

I would say here that I use the granulated sulphite, and my samples are quite alkaline. To neutralise the alkaline property in twenty grains I use five minims of formic acid, then add two grains of amidol, and it is ready for use, and is a powerful developer. This is the only form of amidol that I have tried where a bromide was not necessary. As soon as the weather will permit I shall give it the final comparative test by instantaneous exposure. This developer will produce beautiful lantern slides. I apprehend, however, if a trial should be made the next day with the developer which had been used the day before, that the hydroquinone would prove victorious. In developing a lantern slide on a very sensitive plate the developer should be constituted so as to produce the necessary density in the least possible time.

In slacking quick-lime the product is, in fact, calcium hydrate. I have tried various quantities of sugar in given quantities of water, and have evaporated these solutions to dryness, forming salts which, being dissolved in water, formed, when treated as above described, the same developer and as effective. In this form it becomes a commercial article, and I am informed that this salt is for sale by a wholesale druggist on Third avenue. In one experiment, in making saccherate of lime, I used rock candy, one pound to one gallon of water, and from the comparative tests so far made, am inclined to give it the preference over cane sugar. It frequently happens that a slide, or a negative when completed, is not as intense as might be desired.

With me it is the exception that I do not strengthen a negative or positive, and may sometimes reduce them; my method of intensifying I published many years since, but on account of the prejudice against the use of mercury, and a misapprehension of the chemical nature of the iodide of mercury, some chemists discouraged its use. It is prepared by dissolving in 10 ounces of water 60 grains of mercury bichloride; in another 10 ounces of water dissolve 180 grains of iodide of potash, or 175 grains of iodide of ammonia, whichever may be most convenient.

When dissolved, pour the iodide solution into the mercury solution. The iodide of mercury will immediately be precipitated in the form of a red powder. This is iodide of mercury, and is soluble in hyposulphite of soda, and by some has been recommended in such solution, but if used in this form will in time destroy the negative treated with it. The iodide of mercury is also soluble in a solution of either the iodide of ammonia or potash, and the formula which I have given contains sufficient iodide to dissolve all of the iodide of mercury formed, and leave a small amount of iodide in excess.

In this form it is ready for use, and will keep indefinitely, and, as only the mercury is taken up in the process of strengthening, the proper equilibrium can be restored at any time by keeping a saturated solution of the mercury salt always on hand. When the mercury becomes depleted, which will be indicated by its working slow and weak, add a small quantity of the solution of mercurial chloride, and the red iodide formed will soon be dissolved by the excess of iodide. If by putting in too much of the mercury more of the iodide of mercury is formed than can be dissolved, add crystals of some iodide sufficient to make the solution clear. A plate should not be put into the solution while any of the iodide of mercury remains undissolved, as it would fill it with pinholes.

The negative to be strengthened should be thoroughly fixed and dried. The action is quite rapid, and care must be taken not to get too much intensity; if, however, you should, the ordinary reducing agents will act as on ordinary negatives. In the process of strengthening a gelatine plate in this solution some iodide of mercury combines with the gelatine and cannot be washed out. You can determine this by washing a plate after strengthening and letting it lay for half an hour in a dish of clean water; in this time the plate will have turned to an orange colour by reflected light. By this it becomes apparent that this must be fixed out; but *this* iodide of mercury is not soluble in an iodide solution of ammonia or potash, but is instantly dissolved in a solution of hypo, and therefore should always be fixed in hypo for at least thirty seconds. As the plate has been dried and is hard, the hypo does not penetrate the film, and can be washed off in a few minutes under the tap. A plate so strengthened is, in my opinion, absolutely permanent. I can show many plates as old as the gelatine process, and some from which several hundred prints have been made, without any signs of change or deterioration. Some of the leading professional photographers of this town, to whom I have given it, have used it for years, and would not be without it. To produce a superlative negative or positive, the force of the developer used must correspond *exactly* to the needs of the exposed plate. My method of making a negative from a time exposure is to expose the plate double the time necessary for a new developer, and commence with my old developer. I have another graduate glass with old developer, containing a small quantity of new developer. What I mean by new is that which has not been used, and another glass containing new developer; thus equipped, I feel my way until I determine just the requirements of the exposure. In this way I am always sure, with a good plate, to secure a negative as near perfect as possible under the circumstances. HENRY J. NEWTON.

COLOURED LANTERN SLIDES.

THE beauty of a coloured lantern slide is, of course, in direct proportion to the care, precision, and taste shown in applying the colour. I have felt so disturbed by the crude, raw, and fantastic work which is exhibited upon screens, says Mr. L. C. Laudy, in the *Photographic Times*, and am so confident that work of a superior quality could be produced by many who are possessed of correct judgment and some natural facility in the use of a brush, that I beg to say a few words in relation to this interesting subject. The slide-makers and lecturers are in need of good colourists, those, too, who can combine the knowledge of technique with the discernments requisite for producing truthful and artistic results. As also I have frequently received letters in reference to this subject, I believe that some simple directions would be very generally useful, and might lead some thoughtful person into the cultivation of this beautiful art, which, to-day, is perhaps less occupied than any other field of employment.

At the outset, have the transparency or slide which you propose to colour of very good quality, as good, in fact, as it can be made, sharp, not too dense, and with perfectly clear high lights. In the second place, procure the proper colours, and insist, in getting them, to receive only such as are warranted and made for this purpose. The artist can employ water or oil colours, but the former are more generally used in this country, and perhaps can usually be more readily obtained. The article needed is the Tube Transparent Water Colours, put up by G. Rowney & Co., of London, and which have printed on their label "For Glass Painting." This direction is very essential, as other moist water colours prepared by this firm are not transparent, and would be utterly worthless in work of this character. Almost any dealer in art material will order them, and will also furnish a list of the colours needed. I have had my attention called to the unpleasant experience of some colourists in not receiving what they order, and meeting with a very objectionable inclination on the part of dealers to supply some substitute. In all such cases insist upon the genuine material, as the results the artist aims to secure cannot be reached without the very best colours and the most flawless slides.

The slide or transparency having passed inspection, and the proper colours having been obtained, flow the plate with any good negative or positive spirit varnish, and then prepare the colours. The colours should be pressed from the tube in small quantities upon a clear glass; the best way, perhaps, is to take out the ground glass from a retouching frame and substitute a clear plate glass, upon the upper part of which, in one or two rows, squeeze out a very small quantity of the colours to be used. In this way waste is avoided. Then place the slide to be coloured, after having it varnished and well dried, on the plain glass, resting upon a strip of wood, in the same position as that assumed by a negative when it is retouched.

Procure good sable-hair brushes provided with fine tapering points, and also one or two flat ones, about one-quarter of an inch broad. Let them be of the best quality. The colourist provides himself with a cup of clear water in which he moistens his brush, and then, dipping it in the moist colour, and avoiding filling his sable with too much pigment, begins the application of the tint. Begin with the sky in a landscape, as the effectiveness of a landscape picture depends greatly upon the perfection, softness, and graded colour of the sky. The treatment of the sky can be varied according to the effects desired, and the artist may be led into the most successful imitations of nature. For ordinary broad daylight effects commence with blue at the top and wipe a line of colour clear across the upper part of the slide and bring it down near the horizon, when a little yellow is brushed across the slide down to the land line. The mingling of the edges of these two coloured zones must be nicely done, and for this purpose stipple the outline of the two sections with the second or third finger of the right hand. This blending along the line of contact can be very successfully accomplished after a little practice. Should the colours seem a little too dry for manipulation, breathe on the slide a few times, and the operator will be surprised to see how attractively he will be able to stipple or blend the two colours together, and let him continue the breathing as often as necessary, as these colours, ground in honey and glycerine, soften naturally to this treatment. He can thus secure a clear and soft sky. For sunset effects use below the yellow a thin streak of red and stipple as before until it is pleasantly blended with the overlying yellow. If, in the application of these sky colours, steeples, towers, mountain summits, houses, or trees have been covered with colour, they can be readily cleared with a clean brush and a little water. After these cleared parts are dry, proceed to the body of the slide and colour the foliage, ground, rocks, and building, as near to nature as possible, avoiding too deep greens, as this colour shows intensely through the lantern projection. For snow and ice scenes use a very slight tint of azure blue. There is in all cases no shading, simply smooth even washes of colour, as the shading is already furnished by the photograph.

In regard to moonlight effects, it must be strongly recommended to omit the painting in the slide of an artificial moon, or, more properly, clearing a spot for this unnecessary luminary. In selecting a slide for moonlight effects, choose one with strong contrasts, deep shadows and bright high lights. Frequently a blue wash over the entire picture, carefully removed with a brush and water from the high lights, produces excellent results of this character, while a few red spots in windows or street lanterns will enforce the expression of a moonlight scene. Sometimes a sombre sky of a grey tint and properly stippled will produce the night effect quite perfectly. In colouring dresses, &c., brilliant colours are generally most effective and pleasing.

When the slide is finished, it will be dry in a few minutes, then flow a spirit varnish over the surface, drain, and set aside to dry. Then put on a mat of fair thickness, cover and bind in the usual manner. This mode is the most simple, practical, and effective. The second method, by the use of oil colours, requires much practice and experience, and is much more tedious and slow, and may be treated in another article.

In conclusion, I may suggest to make the reflector in the retouching frame a sheet of white cardboard instead of the ordinary mirror. Sit near a window in painting, without sunlight, and in every way avoid dust. Too much care cannot be taken in this last regard, as the prettiest and most painstaking efforts may be ruined by the intrusion of grains of dirt and floating hairs.

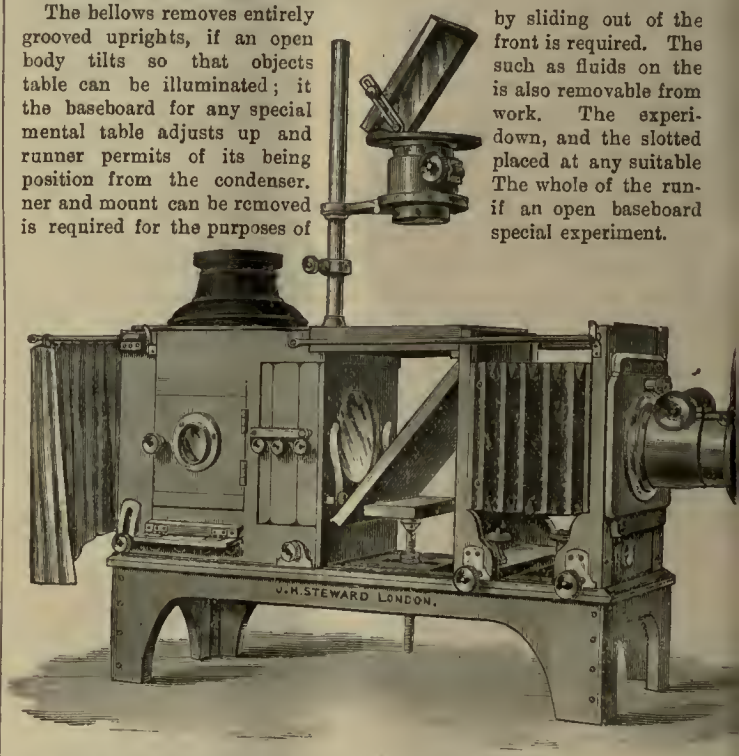
Let the novice practice first upon simple subjects, and by modesty in colouring reach a high ideal. So much rubbishy painting is extant, harsh, wild and sensational colouring, that, while the field is an open one to new aspirants, it is to be hoped that those who may be led to colour lantern slides from these remarks will try to restrain that childish appetite for lurid and glaring effects, and be guided by a chaste and educated taste.

The field of lantern-slide colouring is an excellent and tempting one. It can be made a profitable one. Of course, there are difficulties to be overcome but practice will gradually dissipate them, and, when the art is acquired, it will be found delightful in itself, and lucrative in its results.

STEWARD'S NEW OPTICAL PROJECTION LANTERN.

In this lantern, Mr. J. H. Steward, of 406, Strand, has introduced several points of novelty. The condenser is a triple form, and is made to separate, so that a short or long focus can be obtained at will, and the front lens of the combination can be supported on the ledge of upright as the condenser for the vertical attachment.

The bellows removes entirely by sliding out of the grooved uprights, if an open front is required. The body tilts so that objects such as fluids on the table can be illuminated; it is also removable from the baseboard for any special work. The experimental table adjusts up and down, and the slotted runner permits of its being placed at any suitable position from the condenser. The whole of the runner and mount can be removed if an open baseboard is required for the purposes of special experiment.



The rackwork extends the whole length of the board, and the double pinion permits either upright to be moved to the most suitable position. Clamps are provided so as to fix the upright when using the vertical attachment, or for securing rigidity for the support of the objective. The front rises and falls, and adjusts laterally, so as to give facilities for centering, especially when using an oil lamp. The objective can be used for either ordinary projection or the vertical attachment, or two separate lenses, of different foci, can be employed.

As a useful means of enabling a lecturer to apprise a lanternist when to change a slide, &c., Mr. W. I. Chadwick, of St. Mary's-street, Manchester, supplies a small metal clip affixed to a woodeu support, which, when slightly pressed by the thumb, emits sufficient sound for conveying the necessary signal.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*July 7, 1893*

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

At a special meeting of the Lantern Society, held recently, it was resolved that the subscription for all members should in future be ten shillings a year. Subscriptions are due on October 1, and members joining between now and that date pay no further subscription until October 1, 1894.

* * * * *

Although Lantern matters are necessarily quiet at this time of the year, the preparation of novelties for the coming season must obviously engage attention a little while beforehand, so that we have no doubt manufacturers and the trade generally, notwithstanding the fineness of the weather, are already devoting a portion of their energies as a provision for the future. Messrs. Archer & Sons, of Liverpool, inform us that early in the autumn they will be putting a species of double jet on the market, one lime only being employed as with the ordinary jet.

* * * * *

Messrs. Sharp & Hitchmough intend sending out a lantern which, according to a few details of its construction, will lack nothing on the score of portability. It will close up to eight inches by eight inches by six inches, and will give such an extension as will allow of a fifteen-inch lens being used. Another of its features is to be that it will open out instantly. It is designed to take Lawson's Saturator. The stage will be made adjustable so as to tilt and centralise the carrier, and when in position will fix it permanently by means of a screw.

* * * * *

Mr. Sharp informs us that he worked Lawson's Saturator all last winter with perfect success, this, doubtless, being one of the reasons why the portable lantern above mentioned is to be adapted to take it. When using a lantern, it is Mr. Sharp's practice to have the cylinder suspended on the tripod, which is thus steadied, the arrangement simply consisting of three stays and a ring for the cylinder. This stiffens as well as steadies the tripod.

* * * * *

We have heard it said, and we have sometimes thought, that the man who takes the lantern at a public entertainment is something like the engineering staff of an ocean liner; he does all or most of the hard work, and, being neither seen nor heard, does not come in for his legitimate share of the credit, as the lecturer does. An experience, possibly not small, of public audiences has persuaded us that in nine cases out of ten it is the gentleman with the voice whom it is thought should deserve the applause, while the poor lanternist is left out in the cold. Where the entertainment is a gratuitous one, the concentration of all the glory upon perhaps the less-deserving partner is all the more calculated to test one's powers of philosophic endurance.

In the following instance, however, it pointed the moral of not hiding one's light under a bushel, which was not lost upon the individual most desirous of profiting by it. A friend of ours was solicited by the vicar of a remote country parish, without considerations of payment, to provide an entertainment on a quasi-sacred topic, and the invitation was cheerfully complied with. A good set of slides and an interesting book were provided, and our friend worked the lantern himself while the clergyman gave the book. The entertainment was a most successful one, and at its close a "hearty vote of thanks," as the society reports have it, was passed to the vicar for the exhibition, and graciously acknowledged by him. Our friend who had provided and conducted the entertainment gratuitously was quite ignored, and had the piquant pleasure of beholding the vicar appropriate all the credit and praise for doing next to nothing. "Henceforth," said our friend, "wherever possible, my place is at the screen! I don't see the fun of that kind of self-sacrifice."

* * * * *

Lantern-slide competitions are so popular among amateur photographers, that for their proper and successful conduct some universally recognised rules are much to be desired. The method sometimes employed of simply judging slides by ocular inspection is not so satisfactory as could be wished, and we are glad to notice that the recent meeting of Judges convened by the Affiliation Committee of the Photographic Society of Great Britain recommended that no award shall be made for a slide without its having been projected on the screen. This is as it should be. Also to the point, in this connexion, is another recommendation that no production from the same negative, whether ordinary print, *lantern slide*, or otherwise, can receive more than one award.

* * * * *

The optical lantern was greatly in evidence at the Convention, in spite of the summery surroundings of the gathering. A display was given on the opening night; again on Wednesday; Mr. Cunningham's marine biological slides were to have been shown on that night, and Dr. C. L. Mitchell was also down to read his paper on "Lantern-slide Making." This is no inconsiderable tribute to the popularity of the optical lantern among the photographic bigwigs and others assembled this week at Plymouth.

* * * * *

The admirable paper on "Standard Screw Attachments for Lenses," &c., which was recently read before the Photographic Society of Great Britain by Mr. W. Taylor, of Leicester, gained not a little in lucidity from the use which was made of the optical lantern to show the meeting diagrams illustrating the delicate points of screw manufacturing and economy involved. As an adjunct to the imparting of information on various departments of photography the optical lantern enjoys an increasing degree of favour.

* * * * *

A month or two back we ventured to hazard the opinion that our friends on the other side of the Atlantic were somewhat behind us in the quality of their lantern-slide work, &c. Mr. Milligan, of *The Exhibitor*, quotes our opinion, and at the same time prints a letter to him from the Rev. W. H. Clagett, dated from "Glasgow, Scotland," in which he says: "By the above address you will see that I am in

Scotland. I want to get a number of slides of English subjects, but find it difficult to get *good* coloured slides here, as a rule they do not compare with American slides." This inspires our *confrère* with the *tu quoque* allusion to the "beam in the brother's eye." The "Rev. W. H. Clagett's" difficulty in obtaining here good coloured slides of English subjects is open to explanation on several grounds, among which we are sure our readers would not permit us to include the one that such slides are not to be had.

METOL AS A DEVELOPER FOR TRANSPARENCIES AND NEGATIVES FOR ENLARGEMENT.

Of all the new developers introduced during the past few years none have gone so near displacing pyro as metol—indeed, I fancy it will only be a question of time for it to supplant all the rest. So far as my own experience goes, which, though necessarily short, has extended to several dozens of negatives exposed under almost every variety of circumstances, there is nothing that pyro will do that cannot be done in better style with metol. It seems to be absolutely free from any tendency to stain the shadows of the negatives, and that is a point on which hinges the only fault that can be found with pyro. Even when the acid-alum bath is systematically used, it is impossible with some plates to obtain shadows free from some slight yellowness, but with metol I have never yet seen the slightest symptom of colour.

The rapidity and yet regularity of action of metol is another strong point in its favour, as, even when used with a fairly large proportion of bromide, it brings out the picture with greater rapidity than pyro; when employed without bromide, if there is the slightest over-exposure, it is almost too rapid for proper management, for which reason I prefer to invariably use a small quantity. On first using metol I was inclined to think that pyro offered greater facilities for the treatment of cases of over and under-exposure, but a closer familiarity with its action, and especially with the addition of bromide, has led me to believe that it is in every respect as elastic as the latter. If employed without bromide, there is a strong tendency in forcing for detail an under-exposed plate to produce veil, or even fog, before the detail is obtained; but under the restraining influence of bromide, and by the exercise of a little patience, I think even better results can be got from a short exposure by metol than by pyro. In instances of over-exposure the free use of bromide is, of course, compulsory, owing to the extremely rapid action of the developer, and I prefer to rely mainly on the checking action of bromide rather than to dilution of the developer, although this may sometimes be resorted to with advantage in addition to the bromide.

I have said that I have met with no symptoms of colouration of the shadows of a negative when using metol, but I must make a slight reservation in favour of two of the finest specimens of "green fog" I have seen for years. I do not blame these on to the developer, but solely on to the plates, for the conditions under which they were produced were entirely normal, and I mention the case only to put on record the fact that green fog is producible with metol, and, moreover, in conjunction with sodium carbonate. Plates that show green fog badly with pyro and ammonia are generally free from it when one of the carbonates is substituted for the ammonia, and these have come to be looked upon as almost a panacea for the evil. But my two examples were both obtained with carbonate of soda, and that the plate was to blame is, I think, proved by the fact that in one case while there was no attempt at forcing, the exposure being quite "normal," the result was obtained with the same quantity of solution that produced, both by previous and subsequent development, images perfectly free from green fog.

I may remark that, although the fog was most pronounced by reflected light—so much so, in fact, as to show almost as a negative by reflection—only the very faintest and scarcely perceptible tint of pink was apparent in looking through the plate, which was a most excellent printer, and suffered not the slightest from the fog.

But, perhaps, the greatest advantages in the use of metol will be found in a direction in which the readers of the "Lantern Record" are most especially interested, namely, in the production of lantern slides and of negatives for subsequent enlarging; and this, of course, brings the whole body of hand-camera workers into participation. For lantern slides, not only in the clearness of the lights, but the colour of the image, metol gives a purer and better black than can be obtained by any other developing method with which I am acquainted. Ferrous oxalate, in colour, runs it very closely, but it is entirely out of the running when transparency and gradation are considered. Indeed, two transparencies, developed with metol and ferrous oxalate respectively, present quite as great a difference as a highly enamelled and an entirely matt surface print.

In the last number of the "Record" I made some remarks upon the advantages of translucency of image, both in lantern slides and in negatives intended for enlargement. It is in these two departments where opaque or non-translucent images will make themselves most seriously apparent; but it is obvious that for any style of printing the gradation must be materially affected by the translucency or otherwise of the deposit forming the negative image. The image produced by metol is remarkable for its delicacy of gradation; but whether this is due to the production of a wider scale, or to a larger number of steps in the existing scale due to the translucency of the image, I cannot decide. Certain it is that a good metol-developed negative seems to contain a larger number of gradations between high light and deep shadow, and to be capable of reproducing them, which is of greater importance, than any other sort of negative I have seen. The nearest approach is to be found in some of the earlier pyro-developed gelatine plates, in which a peculiar softness of gradation was produced by the excessively fine state of division of the bromide of silver. But these negatives would be handicapped in a competition with metol by the comparatively yellow colour and the consequent prolongation of time in printing.

It is a most noticeable fact in connexion with metol-developed images that, although apparently thin, they possess great printing value. The perfect freedom from stain, combined with the excellence of gradation, produces this result, which further means great rapidity in printing; and it is not unusual with some of the more rapid printing papers to obtain a fully exposed and vigorous print in two or three minutes, where on albumen paper, and using a pyro-developed negative, possibly twenty minutes or half an hour would be required in the same light.

An image of this character is, of course, admirably suited for enlarging from, because, in addition to the fine gradation it gives, the gain in curtailment of exposure is of especial value, particularly when artificial light is employed. The combination of delicacy, translucency, and at the same time vigour—I say nothing here as to colour—is also of marked value in a lantern slide in obviating the necessity for a very powerful light, for, although a strong dense slide absolutely requires a correspondingly powerful illumination, a *good* thin slide will show well with almost any light.

I need not go any further to show the value of metol for the special purposes indicated, but will conclude with what I have found to be the most convenient formulæ, simply premising that, under the head of convenience, I class as a not unimportant condition that the figures shall be readily divisible and easily remembered, which is scarcely the case with the formulæ issued by the manufacturers of the new developers.

For negative work, the two-solution formula that I gave at page 326 of the Journal will answer well, but it is improved by the addition to solution B of a little bromide, and also, for the sake of ready calculation, by the increase of the quantity of soda from the somewhat indefinite "two ounces" to 1000 grains. The formula will then stand:—

A.

Metol	120 grains	or	6 grains.
Sulphite of soda	1200 „	„	1 drachm.
Water	20 ounces	„	1 ounce.

B.

Carbonate of soda (crystals)	1000 grains	or	50 grains.
Bromide of potassium	20 „	„	1 grain.
Water	20 ounces	„	1 ounce.

For use, take one part each of A and B, and dilute with from one to two parts of water according to circumstances. The more concen-

trated solution gives greater density, and different plates require very different treatment in regard to dilution, as well as in the proportions of the two solutions. The above, however, will be found to answer with most good plates.

For transparencies the proportion of bromide may be doubled with advantage, and, as it is comparatively easy to secure uniformity of exposure, a one-solution developer may be prepared consisting of—

Metol	120 grains	or	6 grains,
Sulphite of soda	1200 „	„	1 drachm,
Bromide of potassium	40 „	„	2 grains,
Carbonate of soda	1000 „	„	50 „
Water	20 „	„	1 ounce,

dissolved in the order named. For use, dilute the part with from one to three parts of water. For line work or where great density is required, two parts of stock solution to that of water. The "one-solution" stock solution may be used for negatives if preferred, the bromide being reduced to twenty grains instead of forty, and the part of solution being diluted with two or three of water.

Personally I prefer ammonia to carbonate of soda; but the undoubted convenience of the latter renders it a general favourite, hence I give above formula. W. B. Bolton.

LANTERN MEMS.

With the thermometer standing between 70 and 90 degrees in the shade on a June day, it requires some great attraction or special enthusiasm and love for work to shut oneself up in a semi-dark room at four o'clock in the afternoon; but, when a number of professors and gentlemen of the press and others interested in science can leave the fresh if somewhat hot air of the London parks, and, ignoring the gaiety of Piccadilly in the height of the London season, turn into the rooms of the Royal Society, it is not difficult to understand something unusual is to be seen or heard.

* * * * *

The fact is, a rehearsal or private view of the lantern portion of the exhibits for the *conversazione* in the evening is to take place, including an exhibition with the lantern stereoscope, and also of photographs of the eclipse of the sun and the instruments used by the members of the expedition, in addition to some photographs of mountain scenery taken at very high altitudes. As the lantern stereoscope was the *pièce de résistance* as far as I was concerned, I will say a few words about that first, for it is one of the ideas that have occupied the minds of men, and who have been striving to realise it for years past.

* * * * *

Descriptions and drawings of the apparatus used have already appeared, and so I do not propose here to give a detailed description of Mr. John Anderton's invention, but express my own opinion of same and impressions of the results obtained by polarising the two halves of a stereoscopic transparency.

* * * * *

This is done by cutting the stereoscopic photograph, and mounting the right and left half separately in carriers, and placing them in the two fronts of a biunial or in the stages of any pair of lanterns, and projecting them on the screen so that they appear as one (or nearly so) to the audience. In front of each nozzle or objective is placed what is known as a bundle of glass, placed at the polarising angle, and the separate plates arranged to prevent blur from refraction.

* * * * *

The effect of the combined projection is not pleasing to the unaided eye, for there is naturally considerable confusion, due to the pictures forming the stereogram being taken from different points of view, and therefore not including the same amount of subject in each half; but, when the polarising is completed by analysing the light, the same as usually has to be done in ordinary lantern or micro-polariscopes, then a marvellous change takes place.

This analyser is quite novel in its application, for it is not attached to the instrument, but is in the form of a binocular, and held up to the eyes. Each of the audience must have one, and the best effect is obtained near about the centre of the room, or rather somewhere near the optical axis of the apparatus. The analyser may be made of two Nicol's prisms, or two tourmaline plates; but in this case preference was given, on account of economy and the difficulty of getting large Iceland spar prism or clear tourmalines, to moderate-size glass bundles set at the proper angle, so that light after polarisation passes in one position and is stopped at right angles. Hence it follows that, if one of the halves of the stereogram is polarised in a vertical plane and the other half in a horizontal, and the binocular analyser arranged to pass vertically, and the other horizontally polarised rays, the observer will only be enabled to see one picture with each eye, and this the corresponding one right or left, as the case may be, the same as he would in the hand stereoscope to get stereoscopic vision.

* * * * *

Although there may appear eight legs on the screen for a quadruped to the unaided sight, the superfluous legs disappear when the binocular analyser is held to the eyes, and the animal stands out with marvellous stereoscopic effect. The illumination of the picture on the screen, considering the amount of stray sunlight coming from the venetian blinds at the window, was by no means bad.

* * * * *

This stereoscopic effect is altogether different to the very fine results sometimes produced from ordinary lantern transparencies by strong contrast of light and shade, and which have such a pleasing effect on an audience, in that the space between foreground and distance is so real and great solidity apparent everywhere objects are portrayed.

* * * * *

The important part played by the screen may be gathered from the fact that a professor, well known for his researches in optics and electricity said that stereoscopic projections had been his constant dream for years past, besides causing him to resort to practical experiments, and after trying polarisation of various kinds he was baffled because the screen he used (linen or surfaced opaque material as ordinarily employed) only returned him the two images as projected, and not the one stereoscopic projection required and now accomplished.

* * * * *

The screen used at the Royal Society looked from the distance as if faced with parchment, but it is stated to be a silver-paper-faced screen. It is, however, certain that something of the nature of a reflector must be used to send back the polarised beam to the eyes of the audience, for, with an ordinary surface absorbing the light, there would be no visible polarisation; but how would a transparent screen do with the audience on the other side?

* * * * *

This opens up a very enjoyable field for experiment and it is to be hoped that the inventor (Mr. John Anderton) will shortly see his way as patentee of the system of putting the adjuncts on the market for adaptation to all existing biunial lanterns so as to reap the benefit of his labours; for there is nothing whatever to prevent, in my humble opinion, any one using polarisers as described or adapting analysers to their use for the purpose of amusing friends, providing in doing so they do not attempt to make money by entertainments or offer the apparatus for sale.

* * * * *

Some wonderful specimens of photographs of glacial scenery were those taken by Mr. Wm. Conway in the Karahoram Mountains, Kashmir, India, those at the great height of 22,500 feet being from the summit of "Pioneer Peak" and others known as the Golden Throne, Maderbrum, and Gusherbrum, with K. 2, being probably the highest group of mountains in the world. So interesting were these that one regretted the time allotted to each lecturer did not permit of their remaining on the screen very long.

The *Daily Graphic*, which one looks for regularly of a morning as one does one's breakfast, is to be congratulated on the information it gives on scientific subjects, for not only did we have at the time it was of interest good illustrations and descriptions of the apparatus to be used during the eclipse of the sun, but since then of the work done by the expedition; and, comparing these with the photographs shown at the Royal Society's *soirée* by the electric lantern and explained by Professor J. Norman Lockyer, F.R.S., one sees how accurate as well as interesting these particulars are.

* * * * *

As lately as the first of July we are shown how the optical lantern and technical education and industries go hand in hand. The "Bee Van," built to be suitable for travelling round the country from village to village, after demonstrations in daylight are given by experts in bee-keeping as to hiving and transferring a swarm of bees, is converted into a lantern van, the end holding a transparent screen, the limelight projecting on the screen the photograph illustrative of bees and hives, &c., and the natural history and value of bees explained, not only for honey but for fertilisation of flowers and fruit.

* * * * *

I should have liked to have referred again to sulphuric ether and "Free Lance's" kind reference to my previous Mems., but must leave it over for next month, or some period before the winter session commences, as just now I am reminded by visions of ether of another kind, from preparations for a life under canvas for three weeks, where, with fresh breezes from the Surrey hills bringing its pure ozone, I trust not to be troubled by any thoughts of comparative smells of sulphuric or any other chemical ether, but get the necessary health and vigour to go into lantern matters practically as the season comes round. I trust that my readers may enjoy their summer or autumn trip, of which one is reminded this week by the meeting of the Photographic Convention at Plymouth. G. R. Baker.

THE INCANDESCENT ELECTRIC LIGHT IN THE LANTERN.

Whilst lanternists in England have been enjoying the latest modern conveniences in the shape of compressed gas, gauges, &c., the worker in the colonies has had to put up with all the old cumbersome system of gas bags, pressure boards, &c., not, too, without accidents in this part of the world, so that insurance companies have put restrictions on the method of using it. Happily the time is not far distant when the larger centres of population—nay, even some small towns which in England would rank as mere villages—will have the means of putting their pictures on the screen with no more trouble than that involved in coupling a switch or two. When a suburban village is lit with electricity, and the church is illumined in the same manner, as is the case within two miles of where I am now writing, it is reasonable enough to look to that source of light to make our lantern shows a very simple matter. Electricity is making its way here, where coal is dear. Messrs. Siemens Bros. have undertaken a contract to illumine Cape Town by electricity derived from water power, and before many years are over every building of importance and many private houses will have it laid on.

The arc light is troublesome and unsteady in the lantern, even when used with every convenience at hand. Within the last few years incandescent lamps have been made specially adapted for lantern use, but one hears very little of them. It is not every one who has a private installation, and electricity as an illuminant has made comparatively little headway in England. Sooner or later it must come, and hence a little experience with the incandescent lamps in question may be of interest.

In company with Mr. Torrance, an electrical engineer well known in Cape Town, I visited the house—at Newlands, on the mountain side—of Mr. Rudd, of British South Africa Company fame. I took my own lantern with me, and some of my most familiar slides. The lamp we were to try was an Edison-Swan "Focus" lamp, to give a light of 200 candle-power with a voltage of 100, such as could be got with fifty storage batteries of two volts each. The globe enclosing the filament is about five inches in diameter; the filament is a flatted spiral of about four turns, the breadth of the filament being about one-sixteenth of an inch, and the whole space covered by the spiral being about one inch by three-quarters—rather a large surface compared with the limelight, but small compared with the oil-light. Looked at edge on the spiral would be about three-quarters of an inch by one-quarter; but as the light given out in that direction is comparatively small, the very first time the current was turned on told us that we were to use it broadside towards the condenser. We suspended the lamp in the lantern in a very primitive fashion, by coiling the conducting wires over a metal rod stretching across the lantern, and steadied it with a wire rod and ring encircling the pointed end of the glass bulb, which was, of course, downward. A few trials up and down, to right and to left, and to and from the condenser, gave us the right position, and there we fixed it. As the glass bulb or globe was then but little more than a quarter of an inch from the surface of the condenser, it was evident (let me italicise this point) *that no lamp of higher power could be used in an ordinary lantern with four-inch condenser unless the greater lighting power was obtained without enlarging the containing bulb.* Mr. Torrance informed me that the batteries would soon want recharging, and that we were only working the lamp at ninety-eight volts, a little below the voltage for which it was made, and therefore at a slight disadvantage.

In describing its practical value under those conditions, I wish to be as explicit as possible, and to leave no uncertainty in the mind of the reader. Let me therefore state what I consider good lighting with the oil lamp. My own lantern, wicks properly trimmed, best oil used, top of chimney carefully adjusted, lantern allowed to warm up, flame high, but not to smoke, working under the best conditions in short, satisfies me with a full size two and seven-eighths inch square, enlarged up to six feet square. My lantern is a little inferior to some, and a little superior to others. I am familiar with most patterns, and mine is a fair average sample. A six-foot *picture*, not circle without carrier, satisfies me when it is working at its best. Others may try eight, nine feet, or more, but I like a well-lighted picture with a clean slide.

Now, first we tried a picture of eight feet, and I considered the lighting equal to what I get with my oil lamp. We reduced the size, however, to a little under seven feet, and liked it so well that we left it at that, and proceeded with an exhibition. I may say, that before the carrier was put in, we got a perfectly illuminated circle, no unevenness, and no bright or dark streaks, in spite of the gridiron-like shape of the incandescent filament. The reader will, however, be surprised to hear of one defect, the great heat thrown out. Of course, I am not one of the uninformed public to expect no heat with the light, but I was certainly surprised. Whether the vacuum was not good, or whether the heat was no greater than might have been expected from a lamp of 200 candle-power, I will not venture to say, but the mahogany casing of the lantern got hotter than it does with the oil lamp, and some pent up fumes of damp and oil escaped into the air. The use of an oil lamp means, however, a great circulation of air in the lantern. With the electric lamp the circulation of air is practically *nil*. Practically *nil*, also, is its heating power on the air of the room, and literally *nil* its power of rendering the air impure. The fumes already mentioned would not have occurred with a new lantern; but the heating of the lantern I particularly mention, as good workmanship in the woodwork must be looked to.

The result of the trial was, so far, satisfactory. Had the dynamo been running we could have done more. As already stated, the lamp was working at a disadvantage. By increasing the intensity of the current beyond 100 volts a more brilliant light can be got, only the lamp will be destroyed sooner. If, however, this is not carried too far, the danger of a lamp giving out in the middle of an exhibition is not great, and is quickly replaced if a spare lamp is at hand, nor is the extra expense involved in the more rapid consumption of the lamp a serious one. By increasing the current to 110 volts the light may be increased fifty per cent., nor is this the only advance that may be made. The greater portion of the light given out by the lamp is given out in two directions; one half of this goes to the condenser, the other half is thrown to the back of the lantern, and much of it might be saved by a reflector.

Concerning reflectors, as usually met with in the optical lantern, they are simply a delusion and a snare. Whilst they do not greatly increase the available light, they are one of the prime factors in producing the bright ribbons of light shown on the screen. They are frequently in the wrong position, and often of the wrong curve. The curve is really a difficult matter to fix on where a large body of flame is concerned. The luminous film in the lamp referred to is not outrageously large, but if the makers can reduce its size, we shall have much to be thankful for. Given a luminous point, the question of curve to the reflector is a simple one; it should be purely spherical, and the point of light should be situated at the centre of curvature. Then every ray from the point will strike the reflector perpendicularly, and be reflected back to the point. If the point is trans-

parent, then through the point on to the condenser, properly reinforcing the rays which the condenser receives direct. And here it is that the incandescent lamp lends itself well to lantern work. All that is necessary is to deposit a film of silver on one half of the bulb. A large portion of the otherwise wasted light will then find its way back through the gridiron-like spiral, and should not cause much, if any, unevenness of illumination on the screen. We shall see. I impressed this matter on Mr. Rudd, and feel perfectly confident that, what with a silvered lamp, and what with slightly increased voltage, a ten-foot picture will be simply a matter of drawing the lantern from the wall and turning a switch. C. Ray Woods,

Photo. Assist., Royal Observatory, C. G. H.

INDURATION OF THE GELATINE FILM—A SUBSTITUTE FOR VARNISHING.

The following formula has been used for two years, and found to give uniformly good results:—

Alum	2 ounces.
Tannic acid	1 drachm.
Water	16 ounces.

The negatives, after fixing and washing, are immersed for three or five minutes in the above solution, rocking the tray to ensure uniformity in action. The colours of the negative become darker, the appearance more brilliant, and the surface of the film glass-like to the touch. The negative is washed for fifteen minutes and dried.

The induration should not be prolonged beyond the time given, lest the adhesion of the film to the glass be destroyed. It is impracticable to intensify an indurated negative.

Treated in this manner, the gelatine film is nearly waterproof, so much so that water may be poured over the plate and wiped off with a cloth without injury. Indurated gelatine is transparent and slightly elastic, resembling parchment in appearance.

The indurating solution may be used repeatedly until the strength is exhausted. The employment of induration with films that it is desirable to strip from their supporting surface is suggested.

W. P. Jenney, Ph.D.

LIGHTHOUSE ILLUMINANTS.

[Science.]

In *Science* for February 6, 1885, a sketch was given of the progress of lighthouse illumination in Great Britain and Ireland, together with a short description of the strongest lights and apparatus utilised up to that time. Since that article appeared the conflict between the advocates of electricity, mineral oil, and gas, respectively, has not decreased, nor has any settlement satisfactory to all parties yet been reached. The matter has on several occasions been brought before the Imperial Parliament, and in February last some further correspondence on the subject was laid before the House of Commons.

A consideration of some of the points lately elicited will be an interesting addition to Mr. Kenward's notes on lighthouse apparatus in *Science* for April 21 last.

The lighthouses of the United Kingdom are under divided control: the English lights are managed by the Trinity House, the Scotch lights by board of commissioners, and the Irish lights by a separate commission—all under the general direction of the Government Board of Trade, and each anxious to maintain lights of the highest efficiency, almost regardless of cost.

The English authorities, from the observations made in 1885, are satisfied of the superiority of electric arc lights where the highest possible power is required, and consider oil lights the cheapest and most easily managed for ordinary purposes. The Scotch commissioners endorse this view of the case; but the Irish board seems to favour the use of illuminating gas.

The chief opposition to the decision of the English Trinity House appears to be instigated by Mr. John R. Wigham, of Dublin, the inventor of the gas system. He claims that he did not get fair play in the trials of 1885, because a rule was adopted restricting the size of the lenses and lanterns within limits that prevented him from obtaining the best results from his gas lights. Since that time he further claims that, by enriching common gas with hydrocarbon, a greater amount of light can be obtained from it than from the richest cannel-coal gas. Actual experiments have shown that cannel-coal gas has an illuminating power of twenty-eight candles, nearly double that of ordinary Newcastle coal gas—sixteen candles. By passing the ordinary gas through the vapour of solid naphthaline, or albocarbon, a perfectly safe and inexpensive material, it is enriched with hydrocarbon to such an extent as to give double the illuminating power of cannel gas. He also suggests, as an improvement in lighthouse illumination, placing lenses so as to form a quadrilateral or trilateral figure, which would permit the use of lenses of much larger illuminating surface and of much longer focal distances than is possible with the six, eight, or even sixteen-sided lenticular apparatus heretofore used, thereby immensely increasing the illuminating power of the lighthouses.

Mr. Wigham has had a lens of long focus made, with a bull's-eye or central portion nineteen inches in diameter, and two concentric rings, one four inches and the other four and a half inches wide, giving a total diameter of thirty-six inches, all in one piece. This is surrounded by a belt of prisms two feet ten inches wide, consisting of ten rings, outside of which is a third portion, consisting of eight rings of totally reflecting prisms, partially surrounding the second portion, so as to complete a lens about ten feet ten inches wide by about eight feet high. In the focus of this lens is placed an "intensity" burner composed of 148 fish-tail jets, grouped to burn the enriched gas, which, when lighted, forms a solid flame of fourteen inches diameter by six inches high. The illuminating power of the burner is calculated to be about 8500 candles, which should give an actual intensity of light through the lenses of about 2,300,000 candles. Experiments made with this apparatus showed splendid results at a distance of six and a half miles. In full moonlight the beam cast a strong shadow, and was very large and dazzlingly bright, reducing a neighbouring first-order fixed light to what seemed by comparison a remote and feeble glimmer.

The case for and against gas as a lighthouse illuminant seems to be as follows:—Its advantages are facility in increasing or decreasing the power of the light to suit the various states of the atmosphere, and also speed and sharpness in eclipsing lights by cutting off the supply of gas, and thus occulting them, while at the same time saving the illuminant; as well as the fact, that where gas is used for illumination it can be utilised at a minute's notice to operate a gas engine in connexion with a mechanical fog alarm, while with any other source of power delay must occur in putting the fog alarm into operation. It is further claimed that the large size of the gas flame, giving an unusual number of extra-focal rays, has a better effect in illuminating a large area of fog, and consequently makes the light more readily visible.

The weak points of gas are the difficulty of manufacturing it at some isolated stations, and also the necessarily large size of the flame, which involves the use of very large lenses, and a long focus, to prevent a wasteful distribution of extra-focal light.

The arrangement of illuminating apparatus proposed by Mr. Wigham for a most powerful light is a battery of four giant lenses, surrounding a central burner, intensified by having similar lenses with additional burners arranged one over the other in three tiers, or "in triform." To accommodate such an apparatus would require a lantern with glazing at least twenty feet in diameter by twenty-four feet high. The lenses alone would cost 8400*l.*, an expenditure which would only be justified by the necessity for an exceptionally powerful light.

Mr. D. A. Stevenson, Engineer to the Northern Lighthouse Board, in a report on electric light as an illuminant, claims that the complaints against the penetration of this light in fogs are not well founded, and that many criticisms of its power are due to prejudice, partly owing to the persistent way in which it is decried as a lighthouse illuminant by certain writers to the press, partly from a misunderstanding of the fact that, being very rich in the most refrangible rays of the spectrum, that is, very white, it suffers a greater percentage of diminution in passing through fog than oil or gas light, which is redder; but, nevertheless, owing to its enormously greater initial power, the electric light is always a better penetrator of fog than the others. He claims that sailors, on their ordinary courses, are never in a position to form an opinion of the subject that is worth anything, because they cannot see different lights in the same conditions of atmosphere. He adduces observations, made by keepers in his service on each other's lights, which go to prove that the electric light is in all cases the more powerful. These are observations from one station burning an oil light to another electrically lighted, and the reverse. Three pairs of such stations are instanced, in every case the electric light being visible in fog that totally obscured the oil lamp. Wm. P. Anderson,

Chief Engineer of Marine Department, Ottawa, Canada.

LANTERN SLIDES IN SUMMER.

[Canadian Photographic Journal.]

Why do I select this subject on which to give a little good advice to my amateur brethren in the April number of the Journal, a time when those who possess lanterns and are interested in lantern work are thinking about laying them aside for the season? Well, it comes about in this way. I have, during a pretty long intercourse amongst lantern-loving and slide-making folk, become the fortunate possessor of a tolerably large collection of slides, gathered from "A' the airts, the wind can blaw,' and including almost every conceivable subject. During the recent gloomy winter that will now soon be away, it occurred to me that I could do something to break its monotony to the villagers amongst which my lot is at present cast, by occasional lantern exhibitions, and the first attempt was so successful that they were repeated weekly, to, on each occasion, as many as could be packed into the largest room of the house; and so thoroughly were the pictures appreciated that many drove, or rather sleighed, again and again distances varying from two to four miles.

Now, with such an audience—perhaps, spectators would be the better word—it is not always the best pictures, either artistically or technically, that are most highly appreciated, although I noticed that even with them glaring errors in composition had a dampening effect; but one thing was particularly noticeable, viz., the enthusiasm evolved by recognisable bits of local scenery, snap-shots at children playing in the village streets, or pictures of the various operations incident to the farm, with which most of them were practically acquainted.

If, as I suppose it may be taken for granted, the average amateur photographer derives as much pleasure from the exhibition of his work as he does from its production, he may increase that pleasure a hundredfold by making a lantern slide from each suitable negative and either, or both, showing them himself or lending them to others who may have opportunities of doing so.

But although the making of lantern slides by camera copying from negatives of any size, or suitable portions of any negative, is a simple affair, I know very well that for various reasons it will be adopted by only a very few, while the mistakenly supposed to be simpler and easier printing by contact would be employed more than it is if the average output of negatives were generally suitable.

Here, then, is the *raison-d'être* of this article! An earnest plea to the amateur photographer who would secure for himself a happy winter by making others happy, to begin now the preparation for that desirable consummation, by seeing in every pretty bit or interesting group a possible slide. Those who confine themselves to sizes not exceeding 5×4, need do little more than see that they focus carefully, as there are few negatives of that size that may not be utilised by contact printing; indeed the same may be said of sizes up to 8×5 as made by probably a large majority of the amateur fraternity, their object apparently being to get as much as possible into the plate. Negatives of the kind illustrated in my January article, that not only bear but need heroic cutting down, are, of course, available, but such wilful waste is not to be commended, and the more nearly negatives from 5×4 upwards approach perfection artistically the more they become unsuitable for slide-making by contact.

The remedy is obvious. Of every suitable subject make two negatives, one from which to print by any of the ordinary methods, occupying the whole of the plate, not with scattered masses of uninteresting, or more frequently actually injurious and distracting material, but only with the principal subject and its necessary adjuncts, never forgetting that in all probability the beauty and effectiveness of the picture will be in proportion to the simplicity of the composition.

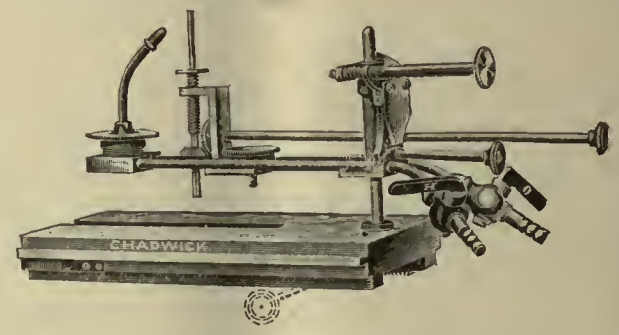
If the photographer is thoroughly satisfied with the composition, all that he has to do in exposing a second plate for lantern-slide purposes is to move back to such a distance that the whole will be included in a pencil-marked opening of about three inches square on the ground glass. But the impecunious amateur, or the careful amateur whatever may be his financial position, will not waste forty inches of plate where fourteen will answer the purpose as well or better, and those of them at least who employ double dark slide or plateholders, will furnish each with a *kit* or carrier for a $4\frac{1}{4} \times 3\frac{1}{4}$ plate on which to make the slide negative. This, at least, is how I managed before I adopted reduction in the camera; and, although, on the whole, better results may be got by that method than by contact printing, I have many contact slides that not even an expert could distinguish from my best made by the camera.

I may add, that to prevent mistakes the dark slides should be numbered on both sides, and the large plates put, say, in the odd, and the small ones in the even numbers. John Clarke.

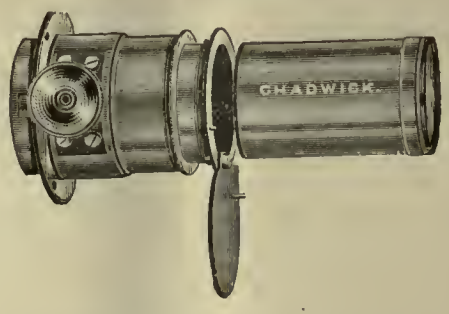
CHADWICK'S LANTERN SPECIALITIES.

Prominent among those whose theoretical and practical knowledge of projection photography has helped to elevate the optical lantern to its present height of favour is Mr. W. I. Chadwick, of Manchester, with whose name, as our older readers are aware, many valuable writings on

lantern matters that have appeared in The British Journal of Photography during the last twenty years are identified. Some fifteen years ago these writings were in a measure concentrated in book form: the *Magic Lantern Manual*, a little work in which Chadwick gave what was then a highly useful fund of practical information, and most of which, notwithstanding the mild revolution which compressed gas, gelatine plates, and other recent advances have effected in applied lantern work, remains of enduring value to this day.



Mr. Chadwick's skill as a lanternist in ordinary slide projection, as well as in the somewhat more involved and difficult branch of scientific projection embracing photo-micrography, optical and scientific phenomena generally, is often called into requisition and appreciated in the North of England, and, it need hardly be said, stands him in good stead in the

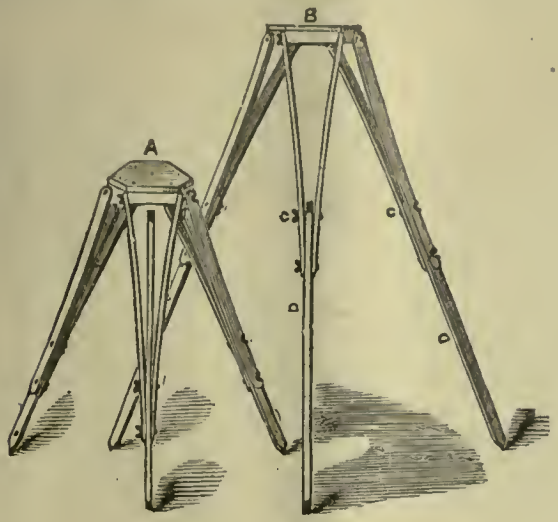


conduct of his business, besides being freely placed at the disposal of those who ask for it. In the field of lantern work which Mr. Chadwick has commercially occupied for the last few years, this well-cultivated, practical knowledge has accompanied him, and its influence can be plainly traced in his numerous lantern specialities, a few of which it is our present purpose briefly to notice.

The type of lantern which Mr. Chadwick favours has the initial merit of simplicity, and dispenses "elaborately polished brass slide stages with spring plate," "brass studs and milled heads," "telescopic draw tubes," the objection to the latter being that rigidity is frequently imperilled.

The "No. 2" optical lantern is an evolution from the "Perfect" form introduced a few seasons ago, and may be briefly described as follows:—(The illustration shows the lantern with Leach's lantern microscope and polariscope attachment, to which we shall advert; the lantern, however, is that ordinarily used.)

It has a metal body, with doors on each side and a flat top, convenient for warming slides or apparatus. The slide stage is open at both sides and top. The objective holder is an upright (which by preference should rest upon the top of cabinet or on a table), attached to which is a long



guide sliding in grooves in the polished wood base. It may be extended to suit the longest foci objectives, and is perfectly rigid at its greatest extension. The space between the condenser or slide-carrier and objective may be left open, as shown in the illustration, for projecting scientific apparatus and experiments, the application of the vertical attachment, and for use with the lantern microscope and polariscope. Light in the room, by reflection from the lenses, is cut off or closed in by an opaque velvet curtain, which is provided with suitable "drawings" to slide on two brass rails hinged (or socketed) to the body of the lantern and projecting forward. When not in use, these rails may be turned back to lie flat with the body of the lantern.

The lantern takes either limelight or any standard oil lamp, the three-wick Refulgent lamp or Stock's patent four-wick lamp being equally well applied.

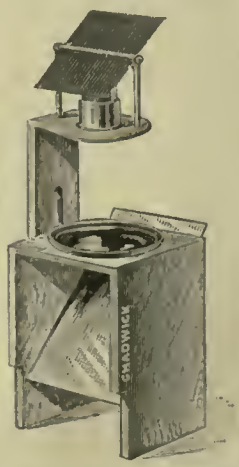
Having examined the lantern as sent out, and being favoured with a projection demonstration when in use, we can confirm what is claimed for it on the score of simplicity and efficiency.

The Chadwick Jet has several mechanical adjustments which are a great convenience to lantern workers, and its advantages can be appreciated from the following short description of how it is used in actual operation. The top milled head permits of the adjustment of the jet sideways; the one projecting beyond the tap rotates and raises the lime; the milled head beneath it elevates and lowers the jet, and the milled head shown by the dotted portion below the stage is attached to a pinion head extending through the lantern body, and racks the jet in and out.

We may here pause to quote Chadwick as an uncompromising opponent of mixing chambers, which he contends do not prevent hissing or roaring, which he attributes to defectively constructed nozzles.

The lantern is fitted with the now well-known triple condenser. The objectives are supplied with foci varying from four to twelve inches. Each combination is in a separate tube, which is made to slide in the rack front, and can be changed from one to the other instantly without unscrewing the front. The focal length of each objective is engraved on the mount.

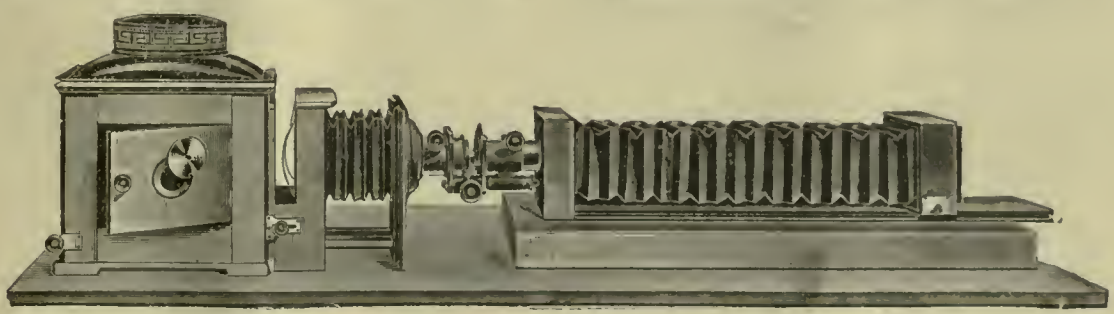
The lantern packs in a box or cabinet of pine, varnished black, with door on side, and the necessary fittings for extra objectives, carrier, and lime case. When the lantern is in use, it can be placed on the top of the cabinet, and the door pushed into two grooves, to form a convenient shelf for slides and apparatus. The whole can also be mounted on a tripod stand. In the next illustration we show a tripod stand supplied for the purpose. More often than not, this useful and one would think necessary adjunct finds no place in the lanternist's outfit, a makeshift arrangement of boxes and tables being frequently made to do duty for it. This tripod has the power of adjustment to work at various heights, either at standing height or at five to nine feet high when the exhibitor wishes to show over the heads of the audience. At A the stand can be adjusted to a height of from four to five feet, and at B it will stand nearly double that height. In order to alter the stand from single to double height, the screws at C are taken out, and the last joint of each leg, D, is turned down, and the screws, C, replaced. Each leg is pointed at both ends.



From an inspection of the front of the No. 2 lantern as shown in the first illustration it will be apparent that a vertical attachment, for showing on the screen objects in a horizontal position, such as fluid surfaces, cohesion figures, camphor motions, magnetic and other experiments, can be easily applied to it. The one supplied by Mr. Chadwick is made in walnut with mirror and five inch plano-convex condenser, six inch water-condenser, glass disc, and adjustable slide for carrying the objective.

The photo-micrograph camera, as here shown, extends to thirty-six inches on a sliding baseboard, and has fine rack-and-pinion adjustment, dark slide, and two focussing screens, one plain and the other ground.

The lantern microscope, which is shown attached to the lantern in the first illustration, is that known as Leach's. It is fitted with rack-and-pinion movements to both sub-stage and objective-holder, and fine screw focussing adjustment; all the necessary fittings for entirely rotating the polarising and analysing prisms of the polariscope, compound wheel of diaphragms,



concave sub-stage field lens, two sub-stage condensers, Barlow-lens amplifier, three objective adapters, the whole being fitted in a polished mahogany cabinet, with water trough.

In Chadwick's Slide Catalogue are given particulars of a large collection of slides for sale or hire, many of them being made from his own negatives. These include British scenery, foreign scenery, popular science, humorous stories, and the customary religious subjects, which find so much favour with clergymen and others who make use of the optical lantern for imparting Biblical and sacred knowledge to their flocks. The Lantern Catalogue is prefaced by a few words of practical advice to lantern aspirants, the worth of which is in the inverse proportion to its brevity. One piece of advice we should like to see more frequently borne in mind by lantern-makers and lantern-users. It is

this: "If the reader decides to purchase an oil-light lantern, let it be so constructed that limelight can be supplied at some future time without alteration." All the oil lanterns catalogued by Chadwick are so constructed, and the list further includes particulars of lantern accessories generally, selected with the judgment we should expect in such a case, and entirely unencumbered with many of those useless and obsolete appurtenances to lantern work which are contained in so many catalogues. Yet a third catalogue of scientific apparatus for optical projection is devoted to polariscope accessories and illustrated descriptions of the apparatus and objects required in scientifically instructive and entertaining experiments. Finally, another pamphlet gives a tersely written and clear little guide to lantern-microscopy and photo-micrography.

The lantern specialities of Mr. Chadwick are conceived with a leading desire to combine simplicity with efficiency, and those undertaking projection work would in his hands be sure of safe and practised guidance. For amateurs this is a recommendation of special value.

THE OFFICIAL PHOTOGRAPHER AT THE WORLD'S FAIR.

[Chicago Tribune.]

Mr. C. D. Arnold, the official picture-maker of the Exposition, posed yesterday as a bigger man than Director-General Davis, the National Commission, and the Board of Control. He defied the authority of all these, and a permit which the Director-General had issued to a publisher to take photographs on the grounds he coolly placed in his pocket and refused to return it to its rightful possessor. The fact that it was signed by the Director-General made no difference to Mr. Arnold, and the bearer of the permit was arrested, and, in order to prevent the confiscation of his private property, hurriedly left the grounds.

Mr. Arnold and Harlow D. Higinbotham, son of President Higinbotham, are jointly the possessors of the photograph concession for the grounds, and a concession out of which the Exposition Company expects to reap at least $250,000. Of the net proceeds of the concession Mr. Higinbotham and Mr. Arnold are to receive 10 per cent. each, besides a salary of $2000 each per annum.

Mr. Albert Brodie Stone was the owner of Director-General Davis's permit. Mr. Stone is the editor of a souvenir volume of the dedication exercises last October. The volume was authorised by the Ceremonies Committee, the Board of Control, and the Ways and Means Committee of the local directory. Mr. Stone, it is understood, is to pay five per cent. of the receipts from the sales of this volume to the Exposition Company. In order to enhance the value of the work, Mr. Stone desired to secure some views of the buildings with which to embellish it. In accordance with the action of the National Commission and the Board of Control, he asked Director-General Davis for a permit to take the pictures. This permit was granted June 2, and yesterday Mr. Stone, accompanied by Mr. C. S. Pinter and two photographers, visited Jackson Park. Mr. Pinter and the photographers were sent to the pier at the south-eastern portion of the grounds, and were taking photographs of the peristyle and other structures when one of Captain Bonfield's detectives approached Mr. Pinter, and asked him if he had permission to take photographs. Mr. Pinter said he had, and produced the order from the Director-General.

"I guess that won't go," said the detective, after examining the document. "You will have to go before Mr. Arnold, and get a permit from him."

"I am not violating any rules," replied Mr. Pinter, "and I will not go before Mr. Arnold. If you wish to take me before President Higinbotham, Director-General Davis, or any other official, I will accompany you, but Mr. Arnold is not an officer of the Exposition."

"I guess there are guards enough here to take you before Mr. Arnold," was the response of the detective, and thereupon he called two Columbian guards. All the violence necessary was the laying on of hands, and then Mr. Pinter was marched by the detective to Mr. Arnold's office, where, somewhat in the character of a magistrate, he passed upon the case. In relating the circumstances here, Mr. Pinter said, yesterday afternoon: "Mr. Arnold asked me what right I had to take photographs without a permit from him. I told him I had a permit from Director-General Davis. He asked to see it, and, drawing it from my pocket, I handed it to him. Mr. Arnold read it, and then, saying, 'That's no good,' put it in his pocket. I demanded the return of the permit, but he refused to give it. I explained that it was private property, to which he had no more right than he would have to my watch. He said that was all right, and kept the paper.

"I was next walked to Captain Bonfield's office. The captain was out, and I explained the situation to his sergeant and asked him what right his men had to arrest me and haul me about the grounds without any warrant of authority. I further asked him what he wanted to do with me. He said 'Nothing,' and told me to go. Thereupon Mr. Arnold asked for the plates, and an officer was sent back to the pier for the two cameras and the photographers who had been left there under guard. When the instruments were brought to the photograph building, Mr. Arnold told me that if I would destroy the plates I could go. I told him I would do nothing of the kind, that they were private property. He reached for me, but I warned him to be careful, and then he withdrew and we left with our cameras."

Director-General Davis, when informed of the action of photographer Arnold, declined to make any further statement than that his orders would have to be obeyed. Mr. Stone, Mr. Pinter, and members of the National Commission's Committee, which investigated the photographic concession, called upon the Colonel, and will to-day present their case to the Council of Administration.

This photographic concession, which permits Mr. Arnold and Mr. Higinbotham to charge illustrated newspapers $2 a day for the use of a Kodak, and so much for pictures of larger size, has caused a great deal of annoyance, and yesterday's arrest will be used as a test case to discover whether Mr. Arnold or the Director-General is the greater in Jackson Park.

The concession for the exclusive right to take pictures in the park was not granted until a few months ago. By the approval of the Executive Committee, April 5, 1893, Harlow D. Higinbotham was let into the benefits of the concession by the following resolution:—

"*Resolved*, That the Ways and Means Committee does hereby recommend that Harlow D. Higinbotham be appointed Official Photographer jointly with C. D. Arnold at the same compensation, viz., a salary of $2000 per year and ten per cent. net of the receipts of the Bureau of Photography after deducting all costs, charges, and expenses, the powers and duties of Mr. Arnold and Mr. Higinbotham to be equal and co-ordinate, and to be defined by a written contract fixing the details of their rights, powers, and duties, the execution of which shall nullify this resolution."

"I understand," said Mr. Stone, yesterday afternoon, "that Herbert Booth King, a photographer of New York, offered $250,000 for the concession, and also to bear all expenses. This offer was made several months before the concession was granted to the present owners."

Official Photographer Arnold, before whom Mr. Pinter was taken, came forward, cool and smiling, to explain the circumstances.

"In the first place, I think Mr. Stone is a fool," he said. "One of the detectives found his man down near the Casino with a camera, and, as he had no permit from me, they simply gathered him in, that's all. If I understand anything about the facts, I am the only man who is authorised to issue permits to photographers on these grounds."

"But how about the written permit of the Director-General?"

"He showed it to me and I put it in my pocket, and I've got it yet. I took the plates from the camera and exposed them to the light, so that, if any views have been taken, they are spoiled now. Stone was around here, talking about getting out a writ of replevin for the plates, but I'm not at all alarmed. Now he is beginning to talk about compelling me to give up the Director-General's order."

"Did not the Board of Control pass a mandatory order upon you to allow representatives of illustrated papers and periodicals to make photographs of the grounds and buildings?"

"I don't know anything about a Board of Control, and never saw its order. Somebody told me something of the kind was printed in the papers, but I never paid any attention to it."

"Did not the permit of the Director-General expressly state that Stone was to make views solely for the purpose of illustrating his souvenir volume?"

"I believe it did refer to him as a publisher or something of that kind, but I didn't pay much attention to it. I know what belongs to me and I mean to have it at all hazards."

"Was Mr. Pinter put out of the grounds?"

"No, he stayed here watching his instrument for several hours, and finally took it away with him."

It is extremely probable that inside of two weeks Mr. Arnold will no longer occupy the proud and exalted position he now holds. One of the men high in Exposition affairs said last night: "Mr. Arnold's concession and its management have been so detrimental to the Fair and its interests that we have been discussing the advisibility of paying him a bonus and letting him go. We recognise the necessity of making other photographic arrangements, and to-day's occurrence will, in my opinion, only precipitate the inevitable."

Lantern Queries.

Mat.—There is nothing novel in the idea of a combined mask and binder. Several such are obtainable commercially.

F. Penton.—Consult the advertising pages of the Lantern Record, where you will find the announcements of several who colour lantern slides.

C. Snelling.—Try the effect of reducing the slide with Farmer's solution (hypo and ferridcyanide of potassium). You must be careful, however, that the reduction does not proceed too far.

E. Bagster.—Mr. Baker, in his "Lantern Mems" last month described how the effect at the music hall referred to is produced. It is also employed at several theatres in Paris where the "serpentine" dance is given.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*August* 4, 1893

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

Apropos of stereoscopic effect on the screen and means suggested for obtaining it, it is interesting to note that the late Mr. Thomas Sutton suggested the projection side by side upon a large screen (by means of a pair of lanterns) of the two views composing the complete stereoscopic slide, and then getting them merged into one by the aid of a pair of prismatic spectacles, which were to be used by each person present. The effect, when tried, did not come up to expectations.

* * * *

Another plan proposed by a French experimentalist, as follows, may also be recalled. With a pair of dissolving lanterns, both images were simultaneously thrown on the same disc. This produced confusion in several parts, but a cap with a red glass was placed upon the objective of one of the lanterns, another cap with a green glass being attached to the other. The spectator now examined the confused picture on the screen through a pair of spectacles, one eye protected with the red, and the other with the green glass, the result being that the eye protected by the green glass saw only the image projected from the green lantern, the red covered eye doing the same for *its* colour. The combined image composed of the two colours—each complementary to the other—formed a true stereoscopic picture, not a very brilliant one, but otherwise perfect.

* * * *

In exchanges, says an American contemporary, we frequently find suggestions in regard to lantern-slide mats, and it is scarcely a wonder. The "regulation price" is altogether too much. Moreover, the sizes do not seem to be just what they ought to be, and the "gilt lines" which recommend them so highly are anything but desirable on account of the bronze which sifts off between the slides and the cover glass. Mr. Humphrey, in the *Photo-American*, makes a suggestion which appears to be good. He marks the size of the opening wanted on a piece of thin wood (cigar box fills the bill) and with the papers clamped between this and another piece saws out the mats with his bracket saw. A paper that is white on one side and black on the other for mats, together with white binders, assists considerably in the manipulation of the lantern.

* * * *

In a treatise on optics, published at the comparatively recent date of 1835, the optical principles of the lantern are discussed and dismissed in the following paragraph: "The magic lantern: The construction of this instrument is precisely similar to that of the solar miscroscope, except that the object is illuminated by a lamp placed behind it in a box instead of sunlight. The objects are generally grotesque figures of men, devils, &c., and are thrown upon a white wall or sheet."

* * * * *

We understand that Messrs. Newton & Co., of 3, Fleet-street, are supplying lantern slides from the negatives taken by Mr. W. Saville-Kent to illustrate his lately published book, *The Great Barrier Reef of Australia*. From the collotype reproductions it is evident that the negatives, of corals and coral reefs, pearl and pearl shells Bêche-de-Mer, and the marine fauna of the Barrier Region, are of great beauty, and should make equally beautiful slides of interest to others besides biologists, &c.

* * * * *

A new system of lighthouse signals has been tried experimentally, the idea being that, with a system of shutters to cause flashing lights, a number may be designated as far off as the light can be distinctly observed, and by reference to a "port book," the light-houses being all numbered and recorded, the master of any vessel approaching the coast at night could ascertain for certain what locality he was in. Some consider that this would be a more unmistakable system for the recognition of lights than the present style of so many flashes per minute or differences of colour, height, &c.

* * * * *

The *South Australian Photographic Journal* has the following remarks in reference to the dilatoriness of certain societies in contributing lantern slides to a projected set for transmission to this country:—"The Intercolonial Slide Exchange is not progressing as rapidly as we anticipated when the invitation to contribute to the collection was given in these pages. The Photographic Societies of New Zealand and Tasmania are slow in responding—we are at a loss to understand why they do not do so—but, having been asked to fix a date on which the slides may be forwarded to London, it becomes necessary to obtain definite replies from each Association. The South Australian Society is collecting lantern slides with a view to sending a set, first to the Australian Societies, and then forwarding them on to England; but they are quite willing to fall in with our idea, and to subscribe the required number of slides, together with a full description therewith. Surely no hesitation is needed for other Societies to follow their example; all must be aware that united action is required to make the collection worthy of the Land of the Golden Fleece."

* * * * *

As an outcome of the Edinburgh Convention, held last year, a large crop of lantern slides resulted, Newhaven fishwives figuring on the screen at the lantern nights of several London Photographic Societies with a frequency that very nearly begot a feeling of monotony. From all accounts, though the number of hand cameras at Plymouth was large, it does not appear that a great deal of photographic work was done. Nevertheless, the peculiarly festive nature of the gathering gave opportunities for the hand camera's facility in securing amusing groupings and situations, which, if shown on the screen, would doubtless be productive of great mirth. The ease with which, in these matters, the bounds of good taste can be passed should, however, give the slidemaker, anxious to raise a laugh at the expense of somebody else, a little caution in the choice of his screen subject

During the exhibition of the Photographic Society of great Britain, the lantern exhibitions form such an exceedingly popular item with the general public that it is to be hoped those Societies and individuals who have been appealed to for loan sets for display will not fail to supply them. The summer has, on the whole, been an excellent one for outdoor photography, so that, no doubt, any number of good negatives have been obtained suitable for reproduction for projection purposes. We may just hint that, possibly a little variety in the choice of subjects would be welcome, most sets having an undue preponderance of landscape and architectural views.

* * * * *

Of the new developers, glycin seems to us to have special recommendations for lantern-slide development, its clearness, evenness of action, and richness of tone marking it out as eminently suitable for this kind of picture. Experiment would, doubtless, point out a ready way of accelerating its rapidity of working without impairing its good qualities.

MAKING TRANSPARENCIES AND ENLARGEMENTS WITHOUT A CONDENSER.

Many amateurs are deterred from attempting enlarging or the production of lantern slides in the camera by the want of proper apparatus and the supposed necessity for a condenser of considerable dimensions and great cost; but in reality very satisfactory results can be obtained with the simplest and least costly of appliances, if intelligently applied.

Of course, the possessor of a lantern is in many cases in a position to make enlargements at any rate from quarter-plate negatives by artificial light, but the vast majority of optical lanterns for projection purposes have condensers too small even for this, and there is, therefore, no other alternative than to use daylight, which, in turn, involves the fitting up of a special enlarging room or camera at some cost and inconvenience.

By far the greater number of amateurs, too, are so placed that the hours of daylight are not available for the purpose except at rare intervals, while the evenings are, if only the means of utilising them were available.

Many plans have been put forward from time to time for securing evenness of illumination without a condenser by the employment of a number of different lights placed behind a translucent screen, in order to blend and diffuse them; but, apart from the great heat given off, and the difficulty of securing uniformity in the lights themselves, the results have never been eminently satisfactory. A single light of great intensity employed in a similar manner with a diffuser presents the difficulty, that it is next to impossible to subdue the extra brilliancy of the centre of the illuminated screen without placing it at such a distance from the source of light that most of its power is lost or wasted. Cutting off the direct rays of the illuminant by means of an opaque, or semi-opaque, disc has been tried to obviate the last-named difficulty, but this has been in connexion with a parabolic reflector, which is in itself an expensive piece of apparatus and difficult to obtain.

The necessity for such a reflector is, however, imaginary, for very satisfactory illumination can be obtained with no more elaborate an appliance than a billiard lamp shade, if it be properly used. I do not mean that the best results can be got with such a reflector, I mention it simply as the type, but by constructing one on the same lines with a definite object in view the illumination is all that can be desired for practical purposes.

The points to be considered are, first of all, the light to be used; then the material, shape, and dimensions of the reflector, the position of the light, and the size and position of the opaque discs and of the translucent screen. As regards the light, nothing seems better or more convenient than magnesium ribbon, on account of its actinic value, the comparative absence of heat, and the compactness of the apparatus required for its ignition. Its price nowadays, too, is so low that it is practically as cheap as gas or paraffin, especially when its convenience is taken into account.

The reflector may conveniently be of tin, and could be made of suitable dimensions by any worker in sheet metal for a shilling or two; but, if the amateur prefers to manufacture it himself, he can easily do so out of stout cardboard or paper pasted in successive thicknesses until a sufficiently stout shell has been formed. The precise details of procedure I will describe presently.

The shape, however, is the most important point, for on this, taken in connexion with the position of the light, disc, and screen, will depend the character of the illumination obtained. If a rough diagram be made upon paper, showing the section of a conical reflector, with the light and disc in position, it will be found, by tracing the direction of the rays, both direct and reflected, that there is one position for the translucent screen, which is the best for that particular set of conditions. It is not necessary to adhere to any particular shape or dimensions; but it must be understood that, whatever they may be, there is only one proper position for the screen. I will attempt to explain this as briefly as possible.

It will be found, on tracing the direction of the rays proceeding from the illuminant, that a portion of them fall directly on the screen, a portion strike the reflector, and are thence thrown on to the screen, while still another portion are arrested by the opaque disc, or fall on portions of the reflector where they are practically lost. If the screen be placed too close to the light, a shadow of the opaque disc will be formed in the centre, and probably it will show two distinct zones of lighting—the direct, at the edge of the screen; and the reflected, midway between that and the centre spot. As the screen is moved further away, however, the central shadow grows gradually less, until a point is reached at which it disappears, the reflected rays gradually overlapping the opaque disc until they meet in the centre. At the same time, the bright zone of direct illumination grows larger; but this we have nothing to do with, as it is only the reflected rays that can be relied upon for equality of illumination.

It will be seen, then, that, according to the position of the light and screen and the angle at which the sides of the cone meet, we can calculate, by means of a diagram, precisely the size and all other details for any purpose, but space will not permit of my entering very fully into that part of the question. Generally speaking, though, it will be found that, the relative position of light and disc being the same, the sides of the cone must meet at a more obtuse angle in proportion to the size of the available disc required; and, further, as a matter of necessity, the shallower or more obtuse the reflector the larger it must be.

I will give two instances. Suppose the light to be placed 3 inches from the point at which the apex of the cone would be if it were complete, and a 3-inch disc be placed 2 inches in front of it, a reflector whose sides meet at an angle of 90° would have to have the screen placed 9½ inches from the apex or 6½ inches from the light, perhaps practically a little more. The total diameter of the front of the reflector would then be about 19 inches, and the available circle of equal illumination 9 inches, or enough for a half-plate negative. If a larger circle of illumination be required, the angle may be increased to 120°, when, keeping the light and disc in the same relative positions, the screen would have to be 14 inches from the back of the reflector, which would entail a total diameter of about 4 feet, with a circle of illumination of 15 inches, or nearly sufficient to cover a 12 × 10 plate.

Such a large reflector is, of course, out of the question, but it is not necessary that it should be so constructed. Even supposing the screen to represent a circle of 4 feet diameter, only 15 inches of that is of any practical use, and if the reflector be limited to the latter dimensions, and placed at the proper distance from the translucent screen, every purpose will be served. But the space between the reflector and the screen should in this case be covered in with blackened material, to prevent irregular reflection from the work bench and surrounding objects, and while this task is being performed it is worth while doing it properly, so as to reap every little advantage that is to be gained. If a rough cylinder of cardboard or tin be placed between the reflector proper and the screen, of sufficient length to bring the latter into proper position, it will arrest and throw on to the screen much of the light that would otherwise be lost, and thus increase its working value.

I have spoken of making the measurements from the apex of the cone, but in practice the back of the reflector will always be

cut off as in an ordinary lamp shade. A certain portion immediately surrounding the apex is always useless space, the light it reflects falling behind the opaque disc, and this part may therefore be cut away to permit of the insertion of the lamp and ventilating tubes should such be deemed necessary. These may, in fact, be so placed as not to interfere with any portion of the useful reflecting surface. The "lamp" I use consists of two brass tubes arranged in a somewhat similar manner to those of an oxyhydrogen jet, the one carrying a cotton wick soaked in spirit, the other a strand of magnesium ribbon driven from the back between a pair of rubber-tube covered rollers, in the same way as the useful little magnesium lamp introduced by Mr. F. W. Hart some years ago.

The inside of the reflector should be painted dead white, whatever material it may be composed of, as the illumination is far more even than is the case from polished tin. The screen may be of ground glass for small sizes, or tissue paper or tracing linen for larger; but the latter is rather too transparent in a single thickness.

Those who wish to make their own reflector may be glad of a plan for cutting the cardboard or other material to the proper shape to form a cone of the right dimensions. First plot out on paper, to scale, the section of the reflector and find the position of the screen. Measure the distance from the apex to the margin of the screen—that is to say, the side of the reflector, and strike a circle with that distance as radius. Next measure the diameter of the screen, and, having calculated the *circumference* of that circle, measure it off on the circumference of the larger one, and cut away the section representing the remainder. If the two edges be brought together and carefully joined, the desired cone will be obtained. Before joining up, however, a circle should be cut from the centre to join the back opening. It then only requires strengthening by the addition of successive layers of paper or card.

It is not to be supposed that a reflector, such as I have attempted to describe, gives absolutely uniform illumination, or even as near an approach to it, as a well-worked parabolic reflector; but in actual use, if it be put together with due regard to the points I have indicated, it is difficult within the limits of permissible error—or latitude—to find any serious fault with the results obtained photographically. Theoretically, of course, the illumination is a little stronger in the centre of the screen, but in practice the difference is inappreciable.

W. B. Bolton.

LANTERN MEMS.

I had hoped this month to have given some particulars of the optica lanterns on exhibition at the Chicago "World's Fair," for a friend who has just returned has been good enough to place his note-book at my disposal; but, unfortunately, there is nothing in this respect to chronicle, for the Optical Section of the Great Britain Exhibits is in such an out-of-the-way place, and so poorly representative when found, that there is little to see or to repay one for such a long journey.

* * * * *

As the traveller is a member of a well-known optical firm, and during his hurried visit for pleasure really *tried* for three days to discover all that was noteworthy in optical and meteorological exhibits, there must be a screw loose somewhere for so barren a result, and it will be of interest if some other visitors to the "greatest Exposition the world has ever known" can enlighten lanternists who are not so fortunate as to be able to visit the United States this year, what *they* have seen that shows novelty or advancement in the optical lantern or optics generally.

* * * * *

No doubt the heavy duty of forty per cent. or so has had the effect of stopping many English (and Continental) makers from exhibiting; for the time occupied in getting out and home, even if a lengthened attendance was not contemplated, is enough to contend with, without being debarred from doing business with sales of duplicate exhibits on account of the prohibitory duty.

Unless there has been a decided alteration of ideas lately, the fashion with American lanternists does not give the English style of optical lantern and dissolving-view apparatus much chance in the States, for different models altogether are adopted for the "Stereopticon," as they call it; and as in many other instruments, notably surveying instruments, microscopes, &c., it takes a long time to get popular ideas modified so as to accept new, and what are supposed to be improved patterns, in place of those that have become familiar. In fact, nothing short of a "boom" produced by some special success of illustrated lectures will do it, as far as the lantern is concerned.

* * * * *

With the perfecting of the stereoscopic lantern invented by Mr. Anderton, or, should I say, its development, so that there is no reasonable limit of size of picture producible, and that a very large audience can witness in ease and comfort the pictures so marvellously rendered solid by means of polarisation, a new era may be created, and English models made more acceptable to our American cousins.

* * * * *

I am indebted to the inventor for some extra information respecting the lantern stereoscope he has courteously sent me, in which he says he is now making arrangements for supplying the parts necessary for converting ordinary biunials into stereoscopic lanterns by the addition of polarisers, silver-faced screens, and the analysing eyeglasses.

* * * * *

Regarding screens, Mr. Anderton reports he has tried many transparent materials, and has discovered only one that does not depolarise the light; and this possesses three serious drawbacks, it being expensive, unportable, and lacking in brilliancy. This being so, he has decided only to have silver-faced screens made.

* * * * *

The making of the eyeglasses, or analysers, that each one of the audience has, to view the pictures on the screen and get stereoscopic effect, has given an immense amount of trouble. In fact, giving his own words, "I have made thousands of experiment and trials, and although they are now of simple construction, I rather fancy that an ordinary amateur would find it extremely difficult to make them. Very much depends upon the analyser, and I have spent countless hours in trying to produce them at a low price, and in this I have succeeded."

* * * * *

As the makers, Messrs. Field & Co., have always co-operated with the optical trade in placing on the market any of their specialities, lanternists who think of trying this addition to dissolving apparatus will do well to get their optician to supply Messrs. Field with the necessary sizes and information, that there may be no chance of failure, for Mr. Anderton justly says, "with low price, there will be little inducement for amateurs to make them for themselves, and less chance of the lantern stereoscope getting a bad name." Personally, I know the value of a good "send-off" with all new inventions, and the effect of reports of practical trials by experts on the popular mind.

* * * * *

During this month or next, lanternists should make up their minds what alterations they intend to make in their apparatus, so that they may be ready in good time for the lantern season. If the body or brass work requires renovating, it is better for it to be done before the lantern-makers get busy, and, if all goes well, they should be by October.

* * * * *

New designs in limelight jets and electric light lamps are on the *tapis*, and they will be matured sufficiently for full particulars to be published next month. It will therefore be well for those that contemplate radical changes in apparatus to hold their hand for a short space, for something worth waiting for will be announced by a well-known firm of lantern-makers.

* * * * *

Our friend "Free Lance" referred to my remarks on sulphuric ether as to specific gravity and smell. My authority as to the denser kinds being strong-smelling was the well-known firm of Messrs. Alfred White & Sons, and by their list I see they have Æther. Sulph. Methyl. ·750 ·730 ·735, washed redistilled, and what they recommend

for the Oxy-ether Limelight ·720, or Anæsthetic ·717. These latter are specially marked on the list they gave me for the purpose of lantern operators. Messrs. White will be pleased to show "Free Lance" their various samples, and explain how they get the light kinds of methylated ether practically free from smell.

* * * * *

As photographic holiday-makers are availing themselves of all opportunities to get pictures, no doubt the coming lantern season will be enriched by a large addition to the lantern sets. I saw several enthusiastic amateurs busy with hand or stand cameras at Bisley Camp, taking the groups of the Headquarter Staff from Aldershot, the Queen's Prize-winner, Miss Leale the lady shootist, and also pretty bits of scenery on the canal close by. No doubt photographs in which life is depicted are always appreciated, and the improvement in sensitive plates and apparatus make this possible and easy.

G. R. Baker.

SOME NOTES ON AMERICAN AND ENGLISH LANTERN PRACTICE.

[Photographic Society of Philadelphia.]

In a recent issue if the "Lantern Record," a monthly supplement of The British Journal of Photography, devoted to the interests of the optical lantern, the editor, in referring to the visit of a London dealer to the United States, and his probable intention of keeping an eye on lantern matters here, with a view of picking up any unconsidered trifles in the way of novelties for next season, added, "That is, if there *are* any lantern novelties to be met with in America." The writer went on to say that, from what he "can gather by a study of the literature of the subject, our friends across the water are somewhat behind us" with regard to the lantern and its accessories, both in quantity and quality.

I have been struck by another English opinion of American lantern matters, which is implied in the selection of an illustration for Mr. Lewis Wright's admirable work on *Optical Projection*. This is a cut of a lantern which Mr. Wright would have his readers believe is an American type of lantern, but which, so far as my knowledge goes, is about as far from being a fair illustration of lanterns used in this country as could well be imagined. It is of a clumsy, antiquated pattern, cloth curtains taking the place of back and sides, and is such a box as one might have expected to find in use thirty years ago—if then.

My purpose in calling attention to these matters is not so much to defend American lanterns as it is to bring to your notice one or two points in American and English lantern practice, and to account, in part, perhaps, for adverse opinions such as have been quoted. There is no question but that we are far behind our English friends in the matter of lantern literature; so far behind, in fact, that I am led to wonder whether the writer in The British Journal of Photography did not form his judgment from the absence of a lantern literature rather than from an actual reading of it! Not only do the English lantern men enjoy the advantages of an excellent monthly journal devoted exclusively to this subject, and also ably conducted lantern supplements to two of the best of the photographic periodicals, but the journals *all* devote more or less space to lantern matters.

On the other hand, here in the United States, with the exception of a little quarterly, issued with more or less regularity in Philadelphia, we have no lantern journal, and the American photographic papers give their readers far less lantern news than its importance and its close association with photographic work would seem to deserve. I cannot think that this is because there is any less interest in the optical lantern in America than in England, or that, in this country, we fail in any respect to recognise the great importance of the lantern as an aid in educational and scientific progress.

It would be impossible, I imagine, to get at any statistics which would enable us to make a comparison of the number of lanternists —to borrow a modern word—as of the number of lanterns in use in this country and England, but it cannot be that we are very much behind in these respects. The only explanation will be found, I fancy, in the fact of the "magnificent distances" over which our population is distributed, and the difficulty of frequent comparison of notes on details of practice; and in the further fact that, in America, a far larger proportion than in England of those who use the lantern are busy men, who take it up as a recreation or in connexion with other lines of work, and who have not the time to indulge in the refinements of detail which, to judge from the literature of the subject, are so dear to the hearts of English lantern men. (I do not wish to imply, however, that one can become truly expert in these matters without attention to detail.)

To leave the question of the literature of the lantern, my observation of American lanterns leads me to believe, as already indicated, that our type of lantern is very unlike that selected by Mr. Wright for illustration. His book is so valuable, and, with its companion volume on *Light*, has been of such great help, that I cannot but hope that this blemish will be removed in any future editions which may be issued. It is but fair to say that the author had particular reference to lanterns for scientific projections, but even in that case the type shown is no more American than it is English, French, or German.

Without attempting to say what *is* the American type of lantern, if such a thing exists, I have been struck in "the study of the literature of the subject"—in this case the catalogues of the makers —by the fact that American lanterns tend more and more to portability, and that, except in rare cases, where the lantern does not have to be moved, we are fast drifting away from the massive structures of mahogany, and walnut, and brass, so popular among our friends on the other side. When dissolving views and "effects" were novelties, the general public, knowing less of the methods employed than they do to-day, looked with a certain amount of awe and wonder upon the lantern and its operator, a feeling which was systematically encouraged. Details of working were, for a time, profound secrets, and there was therefore some reason for the ponderous and showy apparatus. To-day, so far as the showing of views is concerned, the ideal to be reached by the lantern operator, according to my view, is to have everything work so smoothly and perfectly that the audience will not know, so to speak, that there is a lantern in the room. How far from reaching this ideal most operators are, it is needless for me to point out.

For scientific projections the heavy type of lantern is unsuitable, so that in the adoption of more portable forms I think we are ahead. A glance through the catalogues of five or six representative makers here and in England will show what I mean.

In the production of oxygen by cheaper and better processes, and in the adoption of the drawn steel cylinders and their accompanying appliances, it must be admitted that we are compelled to take second place. But there is a curious fact in this connexion which is very striking. Prior to the introduction of pressures of 1800 pounds, gas tanks in which the gas was compressed at from 200 to 300 pounds were in much more general use in America than in England. Here, for the past decade at least, gas bags and blow-through jets have been almost unknown, while in England they were and are frequently met with, particularly among professional operators. These gentlemen prefer the clumsy and troublesome bags because of the slightly greater expense of compressed gases, while in the United States the vastly greater convenience and safety of cylinders is regarded as overweighing every other consideration. Furthermore, those who depend on the use of bags on the score of expense seem to take no account of the element of time, as if that was of no value, nor of the uncertainties and danger attending the process of making oxygen. They tell us "there is no danger with bags, in experienced hands;" but this very qualification, "in experienced hands," upsets their argument. If we had to devote the same time which they do to the preparation of the gas, and were obliged to build barricades around our cylinders as a safeguard against possible interference and a disastrous explosion; if we had to test the contents of each tank before the opening of an exhibition, and suffer the other inconveniences which the advocates of bags submit to, then and only then would the difference in cost be worth considering, even though we are "not all millionaires."

It is also to be noticed that, while in England the so-called "safety jets" are listed in every catalogue and are recommended to beginners by all the text-books, here in America they are almost unknown. Few, if any, dealers keep them, and I remember some years ago when I used such a jet here at the Society it was examined by the members quite as a curious relic of the past.

While it does not do for any one to stop work, and rest on past laurels, American lantern men have no reason to be ashamed of their record in this connexion. Our English friends have given full recognition to work of Mr. Marcy, of Philadelphia, whose oil lamp, introduced twenty-five years ago or more, is the type upon which nearly all oil lanterns have since been based, and who by this invention probably did more than any other one person to popularise the magic lantern. And we also know what has been done in the field of optical projection by our own member, Frederic E. Ives, not only in connexion with the ether saturator and his folding lantern, but in one of the details of his greater invention—Composite Heliochromy.

The purpose of this very hasty and crude communication has simply been to emphasise the fact that, while we gladly recognise our indebtedness to England in matters of lantern practice, we also in America have contributed our share; and, if visitors from abroad this summer fail to find any novelties in minor apparatus, they will at least see a marked improvement in the style and form of the lanterns themselves. But, after all, the matter of size and form is one of taste, and I have but expressed my own preference, and that of most American lantern men, as I believe, for the lighter and more compact forms. If Englishmen like the formidable specimens of the work of the cabinet-maker and the metal-worker, well, to quote Abraham Lincoln, "that's the sort of thing they like."

EDMUND STIRLING.

RURAL TECHNICAL EDUCATION AND THE LANTERN.

IN the last issue of the "LANTERN RECORD" Mr. Baker makes reference to the use of the lantern in connexion with the tour of the Herefordshire Bee Van, supported by a grant from the County Council. As I have had the arrangement and making out of this matter, and as I think that outdoor technical instruction with the aid of the lantern on summer evenings is a new departure, a few details may be of interest to readers.

The general plan adopted is to send a properly equipped travelling van from village to village giving lectures and practical instruction in bee-keeping at each place.

In the afternoon the expert gives a demonstration in the garden of some local bee-keeper, illustrating the method of subduing and handling the little insects.

About 7.30 in the evening a practical talk is given, illustrated with examples of modern bee-keeping appliances. Then, as the shades of evening fall (about 9 o'clock, as the work is done only in the summer months), a transparent screen is let down in the open end of the van, and a short lecture on the natural history of the bee and some important points in practical management is given.

The van, built to order early in 1892, is a one-horse one, about 11 feet long and 6 feet wide, thoroughly ventilated at the top, and fitted with sleeping bunks. In the front is a central door. The back ends lets down, like the tail-board of a wagon, to form a lecturing platform. The end of the van is, therefore, perfectly open, and in the open end a muslin screen is let down from an ordinary blind-roller. The lath at the bottom of the screen catches under two deals on the floor, and three tapes on each side strain it tight. The lantern is placed in the open doorway, about 10 feet 6 inches from the screen, and a picture a little over 5 feet is shown. A 40-feet cylinder of gas is used with Beard's regulator. A Turnbull's spirit jet is used with great success, hardly a hitch having occurred in the two seasons' use, although the instructor had never seen a lantern at work before starting. With this jet the spirit reservoir is inside the lantern, a good deal depends upon the careful opening out of the wick, which by the way is not even charred. The jet is charged from a quarter pint measure of spirit, which lasts for the lecture of about 40 minutes (25 to 30 slides shown), and any residue is always thrown away. About 2 feet of oxygen is used for each lecture. The lantern lecture, which is always given as near the centre of the village as possible, always draws good and attentive audiences, considerably larger this year than in the first season when the work was less known.

The slides shown are all my own photographs from nature (I have been making up the set for some years), such as queen, drone, and worker bees on one and on separate slides, every stage of the development of the bee from the egg to perfect insect, queen cells, photo-micrographs of different parts of the bee, some special photographs of fruit blooms to illustrate the use of the bee in fertilising them, various operations in bee-keeping and illustrations of various appliances.

In the course of some years' experience in lecturing on the subject, I have found the need of impressing certain first principles by pictorial means, and have therefore devised pictorial mottoes for the purpose, such as "Never kill the bees," "Give room to get honey," "Don't let your bees starve," "Bees bring fruit," &c.

Perhaps the method of producing these mottoes may be of interest. A suitable photograph is suited for a background, and a rather lightly printed bromide enlargement (12 × 10 or 15 × 12) made from it; this is fastened to a board. The letters forming the motto are formed in rustic fashion of twigs of wood (larch twigs chiefly), cut and bent to shape, and fastened in their proper places on the enlargement by means of needle points. A negative is then made of the whole composition, and the lantern slides printed from this. I have used this same method with success for the frontispiece of a book.

The van method of technical instruction has been, to my mind, a decided success. In my experience there is a freedom in these open-air meetings, where all are free to attend or depart at their pleasure, which is very delightful, and, with the aid of the pictures, the instructor is able to keep "in touch" with his audience, even although the subject is rather beyond the usual scope of their knowledge.

I am sure that there are other subjects (horticulture, &c.) which could be most efficiently taught by the same methods, and I am glad to say that the lead of the Herefordshire Bee-keepers' Association has this year been followed by the Berkshire Association, who have had a bee van built in Hereford, and are now engaged on a similar lecture tour with the lantern.

The lecturer travelling with the van requires a lad as assistant (his son in our case), who changes the slides while he talks at the front. They find a Rippingill paraffin stove most efficient for cooking their meals.

The season's work concludes this week, and sixty-five of these village lectures will have been given since the commencement.

ALFRED WATKINS.

OPAQUE LANTERN SCREENS.

"LIMELIGHT" writes, in the *Photographic Record*, the organ of the Manchester Amateur Society, "It is often urged against the ordinary sheet screen that it does an injustice to the pictures that are thrown upon it. The stretching of the material on all sides tends to open the cloth, and to a considerable extent filters the image away, destroying its brilliancy." There is a great amount of truth in this. The ideal screen should retain the whole of the scene on its surface, for every ray of light that finds its way to the back reduces the strength of the picture, and detracts from the general effect. It is quite evident that nothing short of a thoroughly opaque surface will give the best results. The importance of this, to some lanternists a trifling imperfection, is such that a few well-known lecturers, such as Mr. Paul Lange, refuse to show their slides unless they can be accommodated with something better than bleached cloth, and will take the trouble of providing their own screen rather than put up with the old time-honoured sheet. Photographers must move on with the times, and our Society is behind. The opaque sheet has its difficulties, I admit, but they are not insurmountable. The roller screen is inconvenient for stowing away because of its length, but it offers the advantage of being quickly erected and taken down. As for its tendency to irregular stretching at the margin, that is but the fault of bad construction. There is an opening for new ideas on this subject, and I would suggest that our members be invited to contribute their notions upon the best form of screen suited to the purposes of the Society. The subject might be introduced at one of the monthly meetings for discussion, or suggestions might be sent to the Council, written on paper, with rough diagrams. Certainly something should be done before the next lantern season comes round."

COLOUR PHOTOGRAPHY.

AN INTERVIEW WITH MR. FREDERIC IVES.

PHOTOGRAPHY in colours is a dream that has inflamed many besides the mere amateur and the enthusiast (says the *Pall Mall Gazette*.) Like several other delusions that will never die, it has been reported a *fait accompli* over and over again; yet the world still waits for coloured photographs, and waits in vain, if what it expects are correctly tinted reproductions, taken direct from nature. There are no such things, and, in all probability, there never will be.

The best that has ever been done in this respect, and it is very wonderful, is the so-called "composite heliochromy" of Mr. Frederic Ives, which was exhibited last year by special request at the Royal Institution and at the Royal Society and the Society of Arts. In this process three pictures are taken simultaneously on one plate, through coloured screens of special construction, by means of which each image is made to represent one of the three fundamental colour sensations produced on the eye in accordance with the vision theory of Young and Helmholtz. These three images are superimposed one on another by a triple optical lantern, or in an instrument of highly ingenious construction called the "heliochromoscope," of Mr. Ives's own invention, by means of which the original object is shown not only in apparent relief, as in the familiar stereoscope, but also in the exact colours and shades of nature.

No one who has seen Mr. Ives's picture could fail to be impressed with the beauty, the brilliance, and the absolute faithfulness to nature of these reproductions, which are based upon scientific principles of a very high order; but, speaking vulgarly, they are not coloured photographs.

The three actual images on each plate are black and white as usual, with a difference merely as regards the distribution of light and shade in each; it is only when they are combined, and when the proper conditions are restored, that the illusory effects of colour are given.

Recently there have been wild reports of colour photography emanating from France. The Messrs. Lumière, working on a process known as Lippmann's, with dry plates of their own manufacture, are said to have eclipsed this roundabout method entirely, and, by a new system, to have succeeded in reproducing exactly in one picture all the delicate tints of nature. M. Léon Vidal, who is recognised as an authority on the subject in France, writes —

"The great characteristic of these projected pictures is the faithful representation of landscapes. The effect is extraordinary, on account of the admirable reproduction of the colours of nature. The blue of the sky, the greens in their various tints and gradations, with all the most delicate greys and whites—all is here depicted with unrivalled exactitude."

Similarly glorified accounts have appeared in other papers, English as well as French, and a representative of the *Pall Mall Gazette* called upon Mr. Ives one morning in order to find out how much had really been done in this direction. Mr. Ives, it should be explained, is a Philadelphian, and was recently on a visit to England. He had engaged to exhibit specimens of his work at the Royal Institution on the occasion of Professor Thorpe's lecture.

When the business was explained to him, Mr. Ives smiled his faintest. He is a tall and somewhat delicate-looking man, with eyes that show the lines of patient study, a thin, black beard, and the hand of a born experimenter.

"I have read M. Vidal's remarks," he said, "and several others besides, notably those of Dr. Vogel, by whom I have had the honour of being personally vilified."

"Why so?"—"Well, because I am inoffensive, perhaps, and not a member of a close corporation like the French savants."

"Is that an adequate reason? Well, what do you think of this Lippmann-Lumière process?"—"A scientific friend of mine who has been to Paris to see it says that the results are pure humbug. I have studied the process myself, and I am inclined to think that M. Vidal has either seen a miracle, or is stating what is not. The colours got by it are due to interference of light by thin films on plates backed with mercury. They are what we call iridescent simply, and are such as you can often see on the surface of stagnant pools. Even if they possessed no other drawbacks, the fact that white light in these photographs comes out a deep brown would be sufficient to condemn them; but it happens, besides, that the colours in the rest of the photograph are merely a matter of the length of exposure, so that, although perhaps once in the course of ten tries a tree may come out green, it is just as likely to be pink or blue or anything else in the remaining nine. The colours are an accidental effect, and vary according to the light in which they are looked at."

"How does M. Lippmann print his photographs?"—"They are not printed at all. By inclining the plate at a suitable angle to the light you can get a coloured effect; that is all. And the colour varies with the angle. Those beautiful greys and whites that M. Vidal spoke of were nothing more than the ordinary reflection of the sky off a glossy surface.

"What led you to the idea of heliochromy?"—"It is not new. Mr. Collen, the Queen's painting master, suggested the idea of photographing three images to represent the three primary colours twenty-eight years ago, and various methods of carrying it out have been tried abroad, by Cros & Du Hauron in France, and Dr. Vogel in Germany. But they did not hit the true idea. It has taken me eight years to perfect my three-colour screens in such a way as to make each image, when taken, a true representation of one of the fundamental colour sensations, so that, when the three were once more blended in a common image through similar screens, the actual colours of nature would be returned to the eye."

"And have you succeeded in this?"—"Look at these specimens."

Here Mr. Ives brought down his heliochromoscope, a small square box with an eyepiece, somewhat resembling a camera. After turning it towards the light, he slipped in front of it what appeared to be an ordinary photographic negative, with three pictures on it, arranged in trefoil. This however, he asserted, was not a negative, but a simple positive, taken on glass instead of paper. The images were not coloured, but merely differed from one another in regard to the arrangement of light and shade. On putting one's eye to the eyepiece, there appeared in full relief an absolutely perfect representation of a dish of fruit; glossy red apples, mottled yellow bananas, and a luscious bunch of green grapes, covered with a tempting bloom, that made one's mouth water more than all the efforts of Dutch *genre* painters could ever do. Several similar objects followed; then came photographs of coloured pictures of oil paintings of Swiss scenery in all the living colours of nature. "How is it," one exclaimed, in breathless amazement, "that the world knows nothing of this?"—"Perhaps because I am not quite ready to supply cameras to the world. I have only just succeeded in perfecting my own. However, they are very welcome to know all about the process, and how it is done. I have no secrets from them."

"Can you print your photographs in colours?"—"I can, but it is a difficult and expensive process. Besides, the results are not nearly so beautiful as I can get with a little relief, and I have preferred to devote the greater part of my attention to reproducing them in this way. The Washington Museum possesses a set of lantern slides in colours, which I gave them. These were made by printing on gelatine and cementing the three images in layers in a particular way; the colour was not touched by hand."

"Can any one take coloured photographs by your process, or does the apparatus need special adjustment?"—"None whatever. You take photographs in the ordinary manner, develop in the ordinary manner, and print in the ordinary manner, except that for purposes of heliochromy you print on to glass instead of paper. Here is my camera attachment. The light which comes from the object is split up automatically by an arrangement of transparent mirror, so that part goes to a circle covered by a red screen, part to one covered by a green screen, and part to another covered by a blue screen."

"But white light is made up of more than three colours, is it not?"—"With three colours you can reproduce perfectly the *sensation* of white."

Here Mr. Ives projected on to a sheet from a lantern a red disc; to this he added a green disc, and then a blue disc, and, lo! the effect was a white disc.

"My photographic screens," he said, "are based upon Maxwell's diagram of the curves of colour sensation. The most remarkable fact shown by this diagram is that the rays which represent a fundamental colour sensation are not the ones which most powerfully excite that sensation. The *red* sensation is excited by all the spectrum rays from red to green, but most powerfully by the orange. Thus, in order to get the effect of the red sensation on my negative, I must use not a simple red glass, but one which will admit (in definite proportions) the red, orange, yellow, and yellow-green spectrum rays. Similarly, to get the effect of the *green* sensation, I must admit on to my negative the joint action of the orange, yellow, yellow-green, and green-blue spectrum rays, but only in proportion to their power to excite that sensation. So with the *blue-violet* sensation. Allowance is, of course, made for the difference in sensitiveness of the eye and the photographic plate. No one has attempted to do this before, and that is where my work differs so widely from that of the French people, who have proceeded on these lines. They have simply been content to use the ordinary red, green, and blue-violet screens to produce the effect."

"In concentrating the three images back again into one image, do you use the same coloured screens?"—"No, that is rather strange. For this purpose the pure colours must be used, which represent the fundamental sensations."

"The heliochromoscope is arranged like the reverse of your camera, I suppose?"—"Practically it is. I use a pure-coloured screen to each image, and the three images are superimposed at one focus by means of an arrangement of mirrors. The three rays, so to speak, are interfered with by the lights and shades on the photographic plate, through which the light passes, and the composite effect of these interferences is to produce the original colours of the object photographed. You will see, if no plate intervenes, the rays passing through the three coloured screens of the heliochromoscope produce a white disc merely."

"Does your camera reproduce every colour and shade in nature?"—"Certainly. That is more than the Lippmann process can claim. Or less, perhaps I should say; for the Lippmann process is certain to photograph in colours, whether the object is coloured or not. My camera does not do that. Here is a photograph of an ordinary photograph pasted on to bands of bright colours; you see the photograph remains in brown monochrome while the bands are bright. One photographic worthy has described my process as 'looking at ordinary photographs through coloured glass.' I can't think why people should wish to detract from it. It is a perfectly honest scientific process, and I have not forced it on them. Since Captain Abney and other of the leading scientists have taken it up, however, this pettiness has ceased."

"Is colour photography your principal work?"—"No; it has been little more than one of my favourite hobbies. I am best known in

America as the inventor of the first successful system of half-tone block engraving."

"Why do you call your process of colour photography by such a long name?"—"Because, popularly speaking, it is not colour photography at all, and I do not wish to mislead. Colour photography, in the sense of reproducing directly the colours of nature in a camera, I believe to be an impossibility, and certainly no such picture has ever been produced. Besides Lippmann's results, I have seen hand-painted affairs masquerading as colour photographs, and in Paris I went to see some marvellous results which I had read about in three columns of fulsome print, and found they were nothing but lithochrome reproductions from collotype plates, touched up by hand. I would not go a yard aside to see a 'coloured photograph' now."

"When do you expect to be ready to supply heliochromoscopes and chromograms?"—"Can't say. I have promised my friend Mr. Swan the first. I have had a great many requests. A dealer in Oriental rugs in America when he saw my pictures offered me a hundred dollars for a heliochromoscope and a set of photographs of the rugs that he used to carry about with him to show their colours and patterns. There are many uses that could be found for the instrument, quite as many, at all events, as there ever could be for the phonograph, which does the same service for sound as this for sight, and does it far less perfectly."

HOW TO TAKE STEREOSCOPIC NEGATIVES.

Mr. F. Dunsterville says: My camera is a half-plate one of the usual pattern, with double swing back (vertical swing only is necessary), rising and falling front, bellows extending to thirteen inches. It has a centre partition of very thin leather, with folds one-quarter inch wide, kept flat by a bit of thin elastic. There are six double dark slides.

For lenses, I have a pair of Ross's portable symmetricals for interiors and architectural views in confined spaces, and a pair of Wray's six-inch rapid symmetrical lenses for general work and quick exposures.

On the rising front of the camera I have permanently fixed a Thornton & Pickard's stereoscopic shutter, with centres of holes three inches apart. The lens flanges are screwed on to the front of the shutter, and both pairs of lenses fit the same flanges. Focussing is done by pulling the cord and opening the shutter half way. Exposures from, say, a quarter of a second to sixty seconds, are easily given by using the "time" movement of the shutter; very quick exposures are given by the "instantaneous" arrangement; and those over one minute are given by putting the caps on the lenses, opening the shutter as for focussing, and then removing and replacing the lens caps as nearly together as you can manage it. I find absolutely no vibration whatever in either the "time" or "instantaneous" movements, freedom from which I have found in no other shutter (and they are many) that I have tried.

For plates, I use Wratten & Wainwright's "ordinary" and Thomas's "extra rapid, thickly coated," both $6\frac{1}{2} \times 4\frac{3}{4}$. For the usual *outdoor* photography of buildings and scenery there is, in my opinion, no plate in the market that comes within reach of Wratten's "ordinary." In the Christmas holidays of 1890 I exposed some six dozen of them, 12×10, travelling some 4000 miles, and there was not a spot or blemish on one of them. They are dearer certainly, but they are worth every pie of the cost.

When it comes to taking a stereoscopic negative, you will find that the focussing screen, after making allowances for the rabbet plus centre partition shows two spaces for pictures each $4\frac{1}{2} \times 3\frac{1}{16}$. Now, if you intend to confine yourself to making paper prints, you should mark out on the ground glass two spaces $2\frac{3}{8} \times 3$, inside which the pictures should be composed. For transparencies by reduction in the camera to the size of the masks usually sold (aperture $2\frac{3}{8}$ inches square), you should rule lines on the focussing screen with a space $3\frac{1}{16}$ inches between them; if you are going to use masks $3 \times 2\frac{3}{8}$, you can then rule lines $3\frac{1}{2}$ inches apart, and the spaces then enclosed, $3\frac{1}{2} \times 3\frac{1}{16}$ will reduce to $3 \times 2\frac{3}{8}$ exactly.

It will be noticed that the lenses are permanently fixed with their centres three inches apart. This is a good average distance for ninety-nine out of every hundred subjects one comes across in this country, and up to the present I have had no occasion to regret having fixed upon it. For taking stereoscopic portraits, the lenses should not be more than two and a half or two and five-eighths inches apart, and, if you wish to photograph very distant mountains, the distance between the lenses may be *increased* to the greatest extent possible in the camera.

With the shutter fixed as mine, it is, of course, impossible to vary the distance; but, for those who wish to have the power of alteration, I can recommend the use of a very ingenious front sold by Mr. Gotz, 19, Buckingham-street, Strand, the London agent for Suter's lenses.

Having decided upon the subject, and placed the camera at a suitable distance, ascertain whether the baseboard is perfectly level. To do this it is absolutely necessary to use a proper spirit-level, either let permanently into the baseboard or carried loose in your pocket. A very good one, made of brass, about four inches long by five-eighths of an inch diameter, packed in a nice little wooden case, can be got for about a shilling.

The next thing is to get the picture very accurately focussed, and I strongly recommend the use of a strong magnifying-glass for the purpose. In my opinion, *all* stereoscopic pictures should be of the very sharpest focus possible; no blurring, out-of-focus, or fuzzy-type views are good when looked at in a powerful stereoscope. Having settled this to your satisfaction, pull the cord of the shutter so that it is set for "time" exposures, put in the proper stops and cap the lenses; put the dark slide in the camera, draw the shutter, take off the lens caps, and squeeze the pneumatic ball for the length of time; let go, replace the caps, push in the shutter of the dark slide, take out of the camera, and put the slide back in its case. If you have no shutter, you must take the caps off and put them on again at as nearly as possible at the same moment, for it is, of course, necessary that the two halves of the plate should both have the same exposure.

The proper exposure is generally the rock upon which our novices get wrecked, and, to help them, I may say that my standard exposure for almost any building which contains a range of tones from the brightest white to the deepest black, and which takes up about two-thirds the length of the plate, using a lens with stop No. 128 (f-45), and Wratten's "ordinary" plate, bright sunshine, between 8 a.m. and 4 p.m., is *six* seconds. This may sound somewhat crude to the expert, but may be the means of saving many a plate to the novice. I should give the same exposure to a building like the Taj—a pure white tomb framed in dark foliage—or to a red-brick building surrounded by trees—the development, with all due deference to Messrs. Hurter & Driffield, gives one the power of producing excessive contrast or flatness, and also of avoiding those extremes.

To develop stereoscopic negatives, of course, you follow the same procedure as in ordinary negatives. I advise you to use the developers recommended by the manufacturers of the plates, only reducing the pyro to one or one and a quarter grains to the ounce of developer, and beginning with half the alkali, adding the rest as requisite. If you intend to devote yourself to the production of transparencies only, keep your negatives rather thinner than necessary for brilliant silver prints. When you have developed, fixed, and washed your negatives, dry them very carefully in a place free from dust (I have a sort of muslin mosquito curtain on a frame which surrounds the drying frame, and effectually keeps out all dust); and, if you varnish your negatives, filter the varnish as if you were going to use it for lantern slides.

Having produced the stereoscopic negatives, you are in a position to make therefrom the finished pictures to be viewed in the stereoscope; these can either be on paper or on glass. I strongly advise you to keep to transparencies on glass; but, as paper prints are very much cheaper, I give directions for turning them out with little trouble. Cut your sensitised paper into strips, say $6\frac{1}{2} \times 3\frac{1}{4}$. In placing the paper on the negative in the printing frame, see that the bottom edge of the paper (which may be cut straight) touches the same spot in each half of the negative, which spot should be in the nearest foreground of what will be the finished print. Print for the necessary time, and do not aim at getting a brilliant picture, or it will look very snowy in the stereoscope; the prints should be full of detail, with very few spots of white in the picture, and, compared with ordinary silver prints, look somewhat flat. Tone, fix, wash, and dry as usual, then flatten them by passing a wooden or ivory paper-knife with one straight sharp edge over the *backs* of the prints, and cut them out as follows.

Firstly, I may say, that, when mounted, the centres of the two pictures should not be more than two and three quarter inches apart, and therefore, allowing an interval of one-eighth of an inch, each half can be only two and five-eighths inches wide. This restriction, however, does not apply to the height of each picture, which may be of any convenient height possible on the mount, but should not, as a rule, exceed three inches.

My meaning is that, allowing an interval of one-eighth of an inch between the two pictures, the distance between their centres should not exceed two and three-quarter inches, and therefore each picture cannot be more than two and five-eighths of an inch wide; the height may, however, be the full height of the card (three and a quarter inches), but is better kept down to three inches as a maximum, allowing a margin of one-eighth of an inch top and bottom.

COPYING PHOTOGRAPHS BY ARTIFICIAL LIGHT.

[Manchester Amateur Photographic Society.]

The title is rather misleading, as I intend to give you a brief account of the way in which I copy not only photographs, but also maps, engravings, lithographs, woodcuts, and book prints.

Apparatus.—With regard to the apparatus, if you have occasion to take a great number of copies, it would be advisable to have special apparatus such as the copying apparatus sent out by Middlemiss, which I can recommend; but, if you only intend to make copies now and again, then the arrangements I intend to explain this evening will do equally well.

I shall not inflict upon you a long account of the many experiments I tried before I settled down to my present arrangements, but shall try to confine my remarks to why I have adopted the different parts I now use.

The apparatus consists of three parts, arranged on any flat surface that may be at hand, such as a table, bench, or long board. First, the camera, with its lens, dark slide, and stand; second, the holder on which the object to be copied is placed; and, third, the source of illumination.

Any rigid, light-tight camera will do, providing it has bellows long enough to allow of the extension required when copying same size, viz., twice the focal length of the lens used, or a longer extension if an enlarged copy is required. I say a rigid camera, for swing back, rising front, and complicated movements are not necessary for copying purposes, as I shall show presently. The size of the camera must be in accordance with the size of the copy you desire. In my case (as I required the copies to make into lantern slides for lecture purposes), I used a quarter-plate camera, but even for them a larger size can be used by using a carrier. I also use a single dark slide, because I find it handy, but a double slide may be employed for this purpose.

The lens should be rectilinear, if you desire accurate copies. I use a rapid rectilinear or a wide angle, but prefer the longer-focus lens wherever I can use it, and employ the largest stop that will give me the definition I require.

I mentioned, as the first part of the apparatus, a camera with its lens, dark slide, and *stand*. This stand is a case of the survival of the fittest, at least of the best of the ones I have tried. It consists of a board on which to place the camera, having a hole in the centre to allow the screw out of the ordinary triangle to be passed through, and the camera is thus fastened. The board is supported at each end upon a block of wood.

In copying, it is essential that the centre of the lens should be opposite the centre of the object being copied; therefore before we can say what height the wood blocks to support the camera should be, we must try to decide what will be the vertical distance from top of the table to centre of the largest object we think of copying when the object is placed vertically on the holder, and then place such blocks under the camera in order to raise the centre of the lens to the same distance from the table. I say the largest object we think of copying, because we can place a smaller object higher up on the holder, when we cannot place a larger sheet lower down.

Secondly, as to the holder or stand on which the object is placed. If we desire to have our copies anything like accurate, it is necessary to have the object to be copied and the plate on which it is being copied in parallel planes and with their centres opposite, and the lens placed on a straight line drawn from the centre of one to the centre of the other, and at right angles to both. Assuming our table top to be horizontal and our camera back vertical, we require to place our object vertical. To accomplish this, I use an ordinary box having its side at right angles to its base.

If the print, engraving, &c., is in a bound book, I simply place it with the page on which is the object to be copied against the side of the box, and allow the opposite page to lie horizontally on the table. The vertical page is fastened against the side of the box by passing one or more pieces of narrow tape over the page, then around the box, and tie up the ends. If the object is mounted on cardboard, fasten it with drawing pins to a small drawing board, which is placed against the side of the box. In the case of a thin, limp object, such as an unmounted photograph, place it on the drawing board (laid flat) and cover it with a sheet of plate glass before raising it vertically against the side of the box.

Thirdly, the source of illumination. After repeated trials I prefer gaslight to any other form of artificial illumination. If I was in the country where I could not get gas, I should use paraffin lamps. I prefer gas to daylight, because I get a more constant light and one which I can move about to adjust for equal illumination. I use two ordinary burners on stands connected with a gas bracket by indiarubber tubing, and get fairly equal illumination by placing one on each side of the lens, at about the same level as the lens.

Having described the apparatus I use, I will conclude with a few words as to the actual working.

I use ordinary slow plates, and employ the developer recommended by the maker of the plates; it is used normal strength without any modifications, altering the length of exposure by trial till I get satisfactory results. In the case of highly coloured lithographs, in which true colour values are to be secured, I have used isochromatic plates and a yellow screen with very good results, but for all ordinary work ordinary plates and the yellow light of the gas are quite sufficient.

In using the apparatus, I first fasten the object to the holder and then test with a try square to see if the holder is at right angles with the top of the table and the edge of the table. Then I place the gas jets one on each side of the object, at a distance equal to about twice the length of the object, and opposite the ends of the object.

In screwing the camera to the stand, see that the back of the camera is at right angles with the side of the stand and the top of the table; adjust your lens opposite the centre of the ground glass, then slide the stand up to the holder, and see that the centre of the object is opposite the lens. Draw back the camera and adjust the distance, focussing so as to get the copy the size you require.

In exposing, try to give the shortest exposure that will develop out, as a short exposure gives a vigorous negative, such as in a landscape we should term soot and whitewash, but that is just what we require in a copy. A long exposure tends to a negative with great detail, but this also brings up the grain of the paper on which our object is printed, a feature we wish to avoid.

F. W. Parrott.

THE LANTERN IN SCIENTIFIC STAGE EFFECTS.

Some new scientific stage effects were introduced into a recent performance of Wagner's *Die Walküre*, at the Grand Opera House, Paris. The scene where the sons of Wotan, mounted on steeds and brandishing their lances, are seen in the clouds, is described as very realistic. The foreground is wild and rocky, and the clouds are seen to scud across the sky. This effect is produced by projecting the image of a cloudy sky by an electric lantern on a curtain of translucent blue cloth. The continuous movement of the clouds for half an hour is produced by painting them on the edge of the disc of glass twelve inches in diameter, and rotating the edge past the lens of the lantern. Three lanterns are employed to blend the clouds. The wild cavalcade of Wotan's heroes is produced by a line of mechanical horses, full-sized, and carrying real performers. They are supported on a scaffolding, and drawn by means of a cable across the scene at a suitable elevation. The mounted men are strongly illuminated by the electric light, and thus rendered visible through the translucent curtain representing the heavens. The scene terminates by a conflagration, in which great flames run along the rocks, while thick fumes, reddened by Bengal fire, spread through the atmosphere. The flames are due to fulminating cotton placed in advance on the rocks, and lit by the machinists. Lycopodium powder is also blown through holes in the stage. Weird cloud effects are produced by steam.

Lantern Queries.

Silex.—No; two similar lantern slides will not do "for making stereoscopic transparencies." The subjects must be dissimilar, that is, taken from different points of view.

L. E. F.—Messrs. Newton & Co., Fleet-street, we believe, supply chlorate oxygen.

P. Wood.—You refer to a Salter's balance. Enquire of a firm of scale-makers, or of Messrs. Avery, Digbeth, Birmingham.

Doubtful.—No; most, if not all, the commercial lantern slides are made by the wet-collodion process.

Novice.—Yes; there will be a lantern-slide competition in connexion with the Exhibition of the Photographic Society of Great Britain, and at most of the other exhibitions, particulars of which are given week by week in The British Journal of Photography.

C. Paul.—Rectangular condensers are ordinary articles of commerce. You would have no difficulty in procuring one from a dealer.

Secretaries of Societies will oblige by sending us their Lantern Night Fixtures for the ensuing autumn and winter.

We have received the *Annuaire de la Photographie* for 1893, edited by M. Abel Bugnet (Paris: Société d'Editions Scientifiques, 4, Rue Antoine-Dubois). It is in the main a directory of French and foreign Photographic Societies, industries, journals, &c. The information as to English Photographic Societies is singularly meagre; it enumerates only about sixty, whereas there are about four times that number.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*September* 1, 1893.

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

The optical lantern is often used in the teaching of Pitman's shorthand, the characteristic outlines of which are more easily impressed upon pupils on a large scale than when drawn by hand on the board to a necessarily restricted size. By the employment of projected positives, made from carefully prepared originals, greater accuracy of outline is also obtained—no small advantage.

* * * * *

Judging by the experiences of last season, and deducing therefrom a forecast for that about to open, single lanterns are likely to have an enhanced degree of popularity in the near future. As we stated two months ago, several new forms, all aiming towards the acme of portability and simplicity, will shortly be introduced. The ease of manipulation of the single instrument, especially in comparatively inexperienced hands, is not the least feature in its favour.

* * * * *

A well-known authority on the optical lantern says: "It has been stated that lamps with four or five wicks give more illumination than those with two or three wicks, but this is not correct so far as lantern illumination is concerned. Of course four or five wicks will produce a *larger* flame, but in lantern illumination it is intensity, not volume, that is required; the intensity, too, must be in the right place, which is the optical centre and the focus of the condenser, and is limited to a small area, and any illumination out of this area is considerably worse than useless."

* * * * *

Mention of oil lanterns reminds us of the following story, illustrating the combination of ignorance and carelessness so often found in the beginner. A gentleman purchased an oil lantern of a celebrated lantern-maker, and in a day or two returned in a state of wrath at his inability to obtain a light with the lantern. He said that he had placed the lantern in position before the screen, inserted the carrier, applied a lighted match to the wick, and failed to obtain any light whatever. After much talk he was asked, in the last resort, whether he had filled the reservoir with oil? On discovering that oil was necessary in order to obtain illumination, he was both surprised and disgusted. He evidently fancied that the lantern carried a supply of gases, which gave light by means of a wick!

* * * * *

Messrs. Mawson & Swan, in their useful little pamphlet on *How to Make Transparencies, Lantern Slides, &c.*, have the following practical remarks on the qualities of lantern slides for different illuminants, which makers of slides would do well to bear in mind:—"The first requisite is perfect clearness of the lights and freedom from fog; a slight veil that would pass absolutely unnoticed in a negative would utterly mar an otherwise good lantern slide. Full detail and gradation must also be secured, without over-density or hardness; indeed, the deepest shadows of the picture should be penetrable by the light. With regard to the degree of density necessary, this will depend upon the kind of light to be employed in the lantern. oxyhydrogen requiring greater strength than oil, and also upon the size of the enlarged picture. A transparency, suitable for an oil lantern, would, upon the same-sized sheet, be rendered very weak and flat by the greater penetrating power of the limelight, but would improve as the enlargement became greater. Conversely a transparency, specially made for the limelight, might, on a ten-foot or twelve-foot disc, be too heavy for an oil lantern, though it would show well on a much smaller sheet. This it is well to know, as i enables the amateur to have private exhibitions at home, on a small scale, with slides that are, perhaps, specially made for public exhibition."

* * * * *

Daylight is a cheap illuminant whenever it can be obtained, which, during the lantern season, is not so frequent as it might be. For contact slides the Paget Company's print-out lantern plates should be popular, as they are manipulated in practically the same way as the now favourite gelatine papers. Mr. W. J. Belton, who has been demonstrating the Paget plates before numerous societies, informs us that the idea of a print-out lantern plate has been received with a marked degree of favour by slide-makers.

* * * * *

Many a lantern slide of good quality suffers no slight deterioration, when cast on the screen, from some defect in the cover glass. Good quality glass should always be used for the purpose, and pieces with bubbles, prominent scratches, ineradicable dirt marks, and other faults, rejected. The glass should, of course, be carefully cleaned and polished before being bound up with the slide. Another point to note is to select glasses of uniform thickness, any great variation in this respect sometimes being responsible for the slide refusing to fit in the carrier.

* * * * *

The exhibition season will soon be in full swing. At most of those to be held during the autumn and winter, lantern-slide competitions will be included. Particulars of the principal exhibitions are given week by week in The British Journal of Photography.

* * * * *

In the popular serpentine dances, wherein comely young ladies twirl voluminous folds of diaphanous drapery into elegant shapes under variously coloured limelights, little, if any, credit has been publicly given to the individual quite as much entitled to it as the dancer—we allude to the limelight man. Recently, however, due recognition was made of his services, the lady taking a call in company with the limelight man. This is as it should be.

* * * * *

A *New York Herald* telegram reports that four members of the Lyceum Company—Mr. G. Biggs, gas superintendent, Mr. James Alexander, Mr. G. Powell, and Mr. William Templeton, calcium-lightmen—who arrived on Saturday at New York, have been detained

at Ellis Island on the ground that they are labourers, and come under the contract law. The men admit they came to America under contract, but at the same time claim that they are artists, and are indignant at the treatment to which they are subjected.

SOME POSSIBLE CAUSES OF LANTERN EXPLOSIONS.

In the recently published proceedings of the Photographic Club for 1892 will be found a discussion on the gas explosion in the club-room last November. The observations of the expert lanternists who took part in the discussion are full of matter of practical interest to users of compressed gases, and we therefore make no apology for reproducing in brief the essence of what was then said. The information, we hasten to say, should be regarded as of assistance in a preventive character, rather than as affording the slightest necessity for alarm.

It will be remembered, from a paper on the subject which was read by the Hon. Secretary of the Club shortly after the occurrence, that that gentleman, in turning on the gas from a twenty-foot cylinder of oxygen, was disagreeably surprised by an explosion, attended by flame, while the gauge attached to the cylinder burst, and parts of the regulator were blown off. We had an opportunity of inspecting the fragments, among which was a gauge dial that had lodged in the ceiling of the club-room, while at the time of the explosion we were present and heard the report, which was a loud one, and caused no little commotion among others who were also present.

The Photographic Club, at one of its meetings, discussed the subject, and several explanations of the occurrence were given. Mr. A. M. Levy directed attention to one or two points. There was a rupture in the pipe of the gauge, the cause of which had to be explained, and there were also fragments which had apparently been ignited. In the neck of the bottle was a screw pin, which had been melted off. The heat in the valve must have been at least 1800° Centigrade. There was a connexion between the regulator and the bottle, lined with copper tube, which appeared to have been in a semi-fluid state. In the regulator the heat appeared to have been small, as the bellows were not damaged except by rupture. The brass tube which contained the whole thing showed signs of heat on one side, the lacquer being burned and the solder removed where the flame went up. Mr. Murray (of Brin's Oxygen Company) had said that his Company used water as a lubricant in compression. Oxygen by itself was incapable of explosion, but, in the presence of a small quantity of an organic body, such as grease or oil, it was explosive. Egress of gas took place at a very great speed, and sufficiently so to heat the sides of the tube. Oil would set fire to metal, especially to the more easily ignited metals such as copper. For the last three years the makers had used water, not oil, as a lubricant, but some greasy matter was probably there, and the leather was saturated with it. With gas in the bottle at a very high pressure, one could imagine the effect of a considerable amount of heat. No wonder the gauge gave way.

Mr. K. S. Murray agreed with Mr. Levy that a small trace of oil would be sufficient to cause the explosion. Such accidents invariably occurred when gauges were used. With regulators there was not the euddden impact of air when the oxygen was turned direct into the pipes leading to the burner. To obviate these accidents, he (Mr. Murray) suggested doing away with gauges. Oil undoubtedly did get in gauges, and consequently danger arose, but how the oil got in it was impossible to say. When gauges were tested with water, there was practical immunity from danger. As regards the valves, for which his company were responsible, no oil was used, only water. He recommended beeswax as a safe lubricant. It was absolutely impossible that there was more gas in the bottle than there should have been.

In reference to the latter point, Mr. G. R. Baker mentioned having just previously tested a bottle, the gauge in which registered 125 atmospheres, when the glass went, and the gauge then registered 150.

Mr. T. E. Freshwater was opposed to gauges. He would not advise anybody to use them, but would recommend trusting to the people who supplied the oxygen. Gauges were dangerous to use, and were not at all necessary. If one wanted to know how much gas was left, it was easy to weigh the bottle. If the caps of the regulator were bored with holes in them, there would not be the chance, when anything went, of an explosion, as the gas would escape.

Mr. R. R. Beard said that he supplied the fittings in question, and therefore knew something about them. With regard to the gauge, it must have been tested with oil. He had only heard of one accident occurring where there was no gauge used. With a regulator on the cylinder there was perfect safety.

As the lantern season is approaching, the experiences of the above able lanternists as to the danger of oil in proximity to compressed gas in cylinders, as well as the *pros* and *cons* involved in the use of gauges, may be of service to many less familiar with lantern manipulations. And with this idea we feel that we may be pardoned for having drawn upon the interesting proceedings of the Photographic Club for the above abstract of those gentlemen's views.

A COMBINATION LANTERN FOR THE DARK ROOM.

Ten or a dozen years ago, when many amateurs made their own plates, lanterns of the "combination" type I am about to describe were far more frequently met with than at present, since they served a variety of purposes for which they are not now required, illumination, in conjunction with compactness and portability, being chiefly sought after. But though the necessity no longer exists for warming emulsion and plates before coating, or creating a warm current of air in the drying box, there are still circumstances, especially in connexion with the making of lantern slides, in which a combination of lantern and stove will be found useful in the dark room, and in winter-time such an arrangement is particularly valuable in keeping the dark room and its contents at an equable temperature.

There are several lanterns on the market that, either intentionally or by accident, fulfil the dual conditions, but they are mostly of the more expensive and elaborate description, while the modern tendency is in the direction of simplicity and economy. The apparatus I am about to explain partakes, to the fullest extent, of these qualities, is as efficient as the most expensive and elaborate, and has the further advantage that it may be constructed for a shilling or so by any one with the most elementary acquaintance with the use of tools.

The only principle involved is the utilisation of the top of the lantern as a hot plate, and in its simplest form I used it for many years for the rapid drying of collodion plates and for heating negatives previous to varnishing. It consisted of a tall, rectangular box, something like a curtailed "grandfather's" clock case, in the front of which a sheet of non-actinic glass slid in rather deep grooves, so as to prevent egress of white light. The top was open, but at each corner a nail or screw projected about half an inch or more above the general level, and on these rested a sheet of stout tin plate, bent into the form of an inverted dish, and fitting loosely over the outside of the box, the sides being deep enough to hang about an inch below the top of the woodwork, so as to permit the heated air to escape, but not any light. This was effective enough for its particular purpose, and its only fault was that, unless made considerably higher than was otherwise necessary, the heated air in the upper portion was liable to crack the glass.

For drying collodion lantern plates after coating, for heating the slides before varnishing, as well as warming the room, a much better arrangement can be constructed at no more cost. In most households there will be found to accumulate, with unpleasant rapidity, a variety of canisters of one sort and another that have contained mustard, cocoa, canned fruits, and the like, and these come in very conveniently for this and similar purposes. With two such empty tins, properly selected as to size, a most perfect "light trap" may be constructed, which, at the same time, forms a useful and efficient warming apparatus for the purposes named.

The body of the lantern may be of any form. I shall have a few words to say about that presently, but just now I shall deal only with the top or roof, which in this instance must be closed in with wood, instead of being left open, as before described. Select two canisters, one of the short and "squat" form, the other tall and narrow; or a can of the requisite diameter may be cut down in

length to suit the dimensions of the narrower one. In the wooden top of the lantern case cut a circular aperture a little smaller than the diameter of the smaller canister, and carefully finish it off with a half-round rasp or file or with coarse glass paper, until the tin will slide tightly into it. It is not absolutely necessary that it should fit perfectly light-tight, though it is better so.

Round the circumference of the tin, at a distance of about half an inch from the bottom, punch a series of holes, to allow the heated air to escape from the lantern, and then push it into the circular aperture, open end first, until one half projects on each side of the woodwork. The portion projecting inside acts as a chimney, and prevents the heated air accumulating in the upper portion of the wooden box, which would otherwise be charred. Now take the second and wider canister, and punch a similar series of holes round its circumference, but at the lid end and just clear of the lid itself, and cut an aperture in the latter to fit loosely over the other canister. When the second one is placed in position over the first, a perfect system of ventilation is provided, without the least escape of light.

The above is the simplest and easiest mode of construction, but a more elegant one is to make the light trap complete in itself by fixing the two canisters together instead of having them disconnected. In one arrangement I have I was fortunate enough in finding a couple of canisters that just suited one another, the outer one being one of the patent "air-tight" cans, with flanged top, in which "Lyle's golden syrup" is put up, and the other an "Embden groat" tin, the latter fitting nicely into the flange of the former. But where matters do not happen so fortunately, it is easy to run a little solder round the junction of the two canisters, or to get a tinman to do it for a penny or twopence, and the thing is perfect. In any case the lid of the larger tin should be removable in order that the inside may be accessible in case of its getting choked with soot. The outer dimensions of this "trap" are three and three-quarter inches diameter by four inches high, rather too small for a lantern slide, but capable of sending out a good deal of heat. A three-pound tomato can is just the size required, namely, four and three-quarter inches in diameter.

The dimensions of the case will, of course, depend upon the lamp or light employed, but should be so arranged that the portion of the canister projecting inwards comes sufficiently near the flame (or chimney, if such be used) to lead off the heated air. A small paraffin lamp is advantageous, on account of its chimney, which, however, must not reach into the canister or it will soon crack; and, if sufficient ventilation be provided, *i.e.*, if the apertures made for the egress of the hot air are sufficiently large or numerous to let it escape quickly, the inside of the lantern will keep perfectly cool, and there will not be the least danger from the paraffin heating. That is more than I can say for some of the best (or more expensive) commercial lanterns.

I have spoken of the casing as being of wood on three sides, but all four sides may be glazed if so desired. I have one in which four uprights of one inch square wood are fixed on to base, consisting of two pieces of wood, separated by about half an inch, to form a ventilating trap, the top being formed of a single piece. Grooves are provided in two sides of each of the uprights to receive the glass, one square of which is made removable in order to get to the inside. This forms a lantern suitable for the centre of a room, and a simple wire handle permits it to be hung up if desired, when it shows its light in all directions. If for hanging on a wall, one side may be solid.

There may be amongst the readers of THE LANTERN RECORD those who are not sufficiently *au fait* in wood-working to put together a simple box; if so, let them procure a sheet of stout millboard, and make a framework of that, making the joints by glueing strips of paper over them. The tin canisters can be attached in precisely the same manner as in the wooden box, and the bottom may be made detachable, in order to get at the lamp inside.

Such a lantern has proved most useful to me in making, drying, exposing, and varnishing collodion emulsion slides, and, if left burning with an ordinary benzoline lamp in the dark room in winter, it will keep the temperature several degrees above freezing point, and prevent a great deal of trouble and annoyance, at a cost of not more than a penny for twenty-four hours. W. B. BOLTON.

LANTERN MEMS.

To say that the optical lantern is a popular instrument is only to repeat a truism, but to realise how much it has developed in the last twenty years one has only to refer back to the photographic almanacs and year-books and the various trade catalogues.

* * * * *

I HAVE before me as I write THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACS from 1885 to 1893, and the improvements in pattern of those illustrated in the advertisements is very marked, while the augmentation of the number of makers and sellers of magic lanterns and dissolving-view apparatus speaks much for the popularity of the instrument and its great uses for scientific and commercial purposes.

* * * * *

IT is to be hoped that each and all who have embarked in this branch of the optician's business find it answer, but personally I cannot help thinking it is a little overdone, for, although a certain amount of change is rendered necessary by advanced ideas and modern requirements, the life of the ordinary type of optical lantern continues fairly long, and, not being like articles that wear out, is, with a few exceptions, purchased to do duty for many years.

* * * * *

THE few exceptions are, fortunately, the optician's friends, and encourage him to make the improvements, so that, should his new design of apparatus not be a commissioned order, there will be a reasonable chance of disposing of the apparatus when completed. If it were only like the cycling mania—a new machine every year, or every second year, at least—one would have no anxiety about the great increase in the army of lantern-suppliers.

* * * * *

IF an apparatus is not to be soon changed for another, and is to do good service while in the hands of the purchaser, care should be taken that attention has been given in fitting up as well as in construction to those points of detail that make a lantern practical and convenient.

* * * * *

NEW departures are constantly being made in the lighting arrangements of lanterns, and, the limelight being always a convenient source of illumination, a great deal of ingenuity has been displayed at various times in the construction of jets, notably for the adjustment and fixing of the jet in position from the outside of the lantern, and regulation of the gases by means of screw-down valves and cut-offs.

* * * * *

THERE is shortly to be placed on the market a jet that not only fulfils the lanternist's requirements in this way, but studies the audience as well, for it will effectually prevent the light streaming out of the back of lantern. This jet, which will be named the "Anti-glare" mechanical adjusting jet, is the subject of a patent, and will be ready during September. Mr. Barton is the inventor.

* * * * *

LANTERNISTS will find some excellent information in the "Light" portion of *Sound, Light, and Heat*, by William Lees, M.A., in Collins's "Advanced Science Series," and many of the phenomena clearly explained there are capable of being demonstrated by means of the optical lantern. I came across a copy of this work quite accidentally, and was quite interested and pleased with it.

* * * * *

ALTHOUGH the magic lantern is dismissed in one paragraph, and dissolving views and the solar microscope have each the same small space devoted to them, there is an excellent chapter on the Interference of Light and Diffraction, and two chapters on Polarisation of Light, so clearly expressed that students should find these generally little understood subjects much more easy to grasp.

As a question has been raised as to the invention of dissolving views, and the date they were first used, the following may be of interest. It is copied from "Optics," in *Chambers's Information for the People*, the preface to which is dated November 1, 1848, and, after describing the magic lantern, adds: "Lately the mode of representing scenes has been further improved by using two lanterns placed at equal distances. In this case, while the view in one is being withdrawn, the view in another is coming on, and the eye is charmed with seeing, for example, a scene in winter dissolve and assume the appearance of a similar scene in summer."

* * * * *

From the writer saying "lately," one would think that in 1848 it was considered a novelty, and this date would agree with the generally accredited date of the invention of Mr. Childe's in 1846, although earlier phantasmagoria effects were undoubtedly produced not only by Childe but also by Phillipstall. From the particulars published Childe, it seems had the assistance of his pupil and partner, Mr. Hill, in producing the effect of dissolving.

* * * * *

There is no doubt that dissolving is a very agreeable effect if not over-indulged in, and, as in modern biunial and triple lanterns the operator has the alternative of rolling up one view and revealing the next, or can show photographic or other transparencies panoramically, there is no reason for letting the entertainment get monotonous by continuously showing slides either way. G. R. Baker.

PRINT-OUT LANTERN SLIDES.

The practice of making lantern slides from negatives has become so popular since the advent of the commercial lantern plate, that it may need some little excuse for drawing attention to other and perhaps more charming methods of producing them. At the same time, also, the habit of using the ready-made article has become so ingrained into both amateur and professional, that one is almost afraid to put forward a process which involves the trouble of the preparation of the sensitive material for oneself. For such as will take this effort, however, there are several methods of making lantern slides by printing-out methods which have much to commend them. In addition to a very fine grain, which may be better described as an absence of texture—a point of the very first importance in a good slide—there is the additional advantage of the possibility of a considerable range of colour—warm red, purple, and blackish-blue, to warm blacks. As these variations in colour are produced by means of the ordinary gold toning baths—borax, acetate, or carbonate—and are therefore under a reasonable amount of control, the process is free from the disagreeable uncertainties which nearly always attend an effort to secure variations in colour of deposit by restrained development and a corresponding increase in the exposure.

On the other hand must be placed a disadvantage on the score of sensitiveness, or rather, I should say, on the score of lack of sensitiveness, for, as far as my experience goes at the moment, I have been quite unable to secure sufficient sensitiveness to light to make print-out plates workable in the camera, even when only a faint original image is looked for, and subsequent development with gallic acid relied upon.

But, as far as this is concerned, I do not know that any very great disadvantage occurs, for I think it is pretty certain that the majority of lantern slides are made by contact. Professed slide-makers use the camera method almost entirely, but, by the rest, the bulk of the work is done by contact, and it is a small point whether the routine be to print right out, or, on the other hand, to give, as with the commercial bromide lantern plate, a brief exposure, and subsequently develop.

As a matter of fact, there are certain advantages in a printing out over a pure development process which cannot rightly be overlooked. In printing-out processes, the exact progress of the image can be closely watched, local exposure or retardation may be effected, and the precise result aimed at—subject only to an allowance for decrease of density in the fixing bath—can be secured. Combination printing, whether it be the addition of figures to a landscape, or simply the addition of a sky, can be effected with greater ease and more certainty; whilst, when it comes to such *tours de force* as adding the reflected image of the sky to a sheet of water, so as the more truly to simulate the effects of nature, it is infinitely more easy—I might almost say more possible—to do this by a printing-out method where the effects can be judged, because they can be seen and valued by the eye, than to be obliged to guess or estimate both the position and the exposure required, as obtains in a pure development process.

It may also be a moot point whether the warmer tones obtained by very restrained development do not alter in character with time or the action of light. At least, I have heard the statement made that such may be the case.

With this apology for the process made, I propose to give a brief description of a simple method of making sensitive lantern plates to print out, and I shall add to it an easy method of making a registering frame for holding the slide whilst printing, so that an examination of the progress can be readily effected from time to time. And I shall close the article by a few well-tried methods of toning the images, so as to secure pleasing and well-coloured slides free from the double colours not infrequently met with ingelatino-chloro-citrate papers.

To begin with, a room which can be set apart—it may be only temporarily—for the purpose of coating and drying the plates is necessary. I do not advise, or at any rate insist upon as necessary, a drying box, although such a piece of apparatus is useful though cumbersome. Any of my readers who desire to go in for such an *article de luxe* will find plenty of drawings and detailed descriptions in past issues of The British Journal Photographic Almanac. As, however, our plates will not be more sensitive to light than a reasonable blocking out of the windows with yellow paper will suffice for, I shall recommend the use of an ordinary room, protected by having the blinds well and carefully drawn. Then, supposing our plates to have been prepared over night, they will be dry enough, and ready for storing away in the morning.

The next necessary piece of apparatus is a square glass, or slate, of the dimensions of, say, twenty by sixteen inches. This must be carefully levelled up upon a table, so that, when the glass plates are coated with emulsion and placed upon it, they (the plates) will set with the gelatine emulsion quite evenly distributed over them. The best and simplest way to effect this levelling is to make three little wedges of wood, measuring, say, three inches long by one inch wide and one inch high, but tapering down to one end. These wedges are to be placed, two of them under one long side of the large square of glass, one at each end, and the remaining one under the opposite long side of the glass square, but in the middle. To adjust the square slab, first level it is necessary to use a carpenter's spirit level for the purpose—the glass plate between the two wedges which are on one side, and then, with the spirit level placed at right angles to its first position, adjust the third wedge until the air-bell of the level shows that in that direction also the plate is flat. I need hardly say that it is not absolutely necessary to have a setting slab so large as twenty by sixteen inches. An old twelve by ten negative, or waste plate, or even a ten by eight, will answer the purpose. The only advantage of a larger plate is that, if the weather or temperature of the room be warm, say, over sixty degrees Fahr., the work will proceed more slowly with a small setting slab.

Two or three jugs, a graduated measure, a chemical thermometer, and a pair of scales capable of accurately weighing to half a grain, will enable us to make a start with the emulsion-making.

Of course, with an emulsion of this kind a very considerable amount of light may be used without disadvantage of any kind. Probably, as I may surmise the making of the plates to be an evening occupation, the use of gas or other artificial light (except electric arc lamp) will be most convenient, but if daylight be used it must be filtered through a yellow paper, and, in fact, be of the same character as would be suitable for changing sensitised prints in.

Before commencing to prepare our emulsion, it will be advisable to clean the glass plates, and have them all quite ready for coating. This may seem a small matter, but, in point of fact, it is not. The cleaned glass may well wait for the emulsion, but it is quite inexpedient that the emulsion should have to wait for the glass to be prepared. The best way to clean the glass is to place it upon a flat piece of board, and to rub it with the following compound:—common whiting, water to moisten, methylated spirit, liquor ammonia.

The whiting must be made into a thick paste with clean cold water, to which is added sufficient liquor ammonia (or carbonate ammonia) to make it smell fairly strongly. A little methylated spirit is added to make the cleaning paste dry more readily upon the glass. In cold weather more spirit will be useful, in warm weather less. The function of the liquor ammonia is to counteract the grease which is always found in considerable quantities upon new glass. If old lantern-slide glasses are to be used, they must be cleaned up quite free from gelatine, in some hydrochloric acid and water, sufficient acid being used to cause the last traces of adhering gelatine to be thoroughly removed. If new glass be used, it may as well be purchased in pieces either $6\frac{1}{2} \times 3\frac{1}{4}$, or six and a half inches square, unless, indeed, the use

of a glazier's diamond for cutting the plates afterwards be a bogey sufficiently formidable to counsel the use of pieces the actual size required. What I really mean in this connexion is that it is little, if any more difficult to acquire skill in the coating of plates with gelatine emulsion of a size of six and a half inches square, than it is to coat the smaller dimensions of $3\frac{1}{4} \times 3\frac{1}{4}$. A steady hand, and a regular flow of the liquid emulsion—always in one direction—and the thing is done. But of that more anon.

Having then rubbed off all the grease and dirt from our plates with the whiting compound, they must be thoroughly rinsed under a stream of running water to get rid of the whiting. If the water flows and drains easily from the plate, it is a sign that it is clean and free from grease, and fit for coating with emulsion. If the plates are greasy, it will be found more difficult to make the emulsion flow over the plate.

The plates must now be set up to drain and dry. When dry, they may be dusted with a broad camel's-hair brush, and packed away in clean white paper wrappings. S. Hennent Fry.

(To be continued.)

THE CAPABILITIES OF PHOTOGRAPHY NOT UNLIMITED FOR ILLUSTRATING ALL CLASSES OF OBJECTS.

The comparatively recent departure from old methods in various fields of scientific research (says M. O. G. Mason in *Science*) has called into action agencies for solving problems of initial progress and results not known or utilised by earlier workers. Discoveries within the last few years have so advanced the lines of study, and an active scientific press has scattered so broadcast the knowledge of progress made that, although the field is boundless, he who reads has little excuse for reworking ground from which all reachable fruit has been gathered. In eagerness for the new, a desire to find some hidden shorter paths into the mysteries of nature, do we not often fail to recognise obstacles, or to sufficiently consider the best means for their removal? With pen and pencil our predecessors sought to leave a record of their work. What they thought and what they saw have been handed down to us through the best means at their command. For the physician, the botanist, mineralogist, and the geographer, the artist sketched, elaborated, and finished illustrations having a more or less amount of truth, often obscured by some personality, which rendered them valueless or even misleading. In no class of objects have such defects been more conspicuous than that requiring the use of the microscope. Therefore, he who had used with dissatisfaction the hands of the draughtsman was eager to utilise the means offered by photography. He had seen the results obtained in other fields, and, without knowing the difficulties in the way, believed it easy to obtain all desired brilliancy, detail, and amplification. It may be asked, Why have not these expectations been more fully realised? When we pause to consider that colour is a most important feature in photographic work, and that a majority of objects studied under the microscope reflect or transmit the least actinic rays of light, red, orange, green, and yellow, we may well understand why we do not secure brilliancy. Again, when the microscopist studies his subject for detail, he mentally eliminates all those parts which do not belong to the special point under observation. A crystal, cell, or fibre which over or underlies his object, or forms a full or partial background in the field of the objective, is left out in the mental summing up of his study. The laws of chemistry and optics do not permit such selection and elimination from the photographic image. A slight tremor conveyed to the microscope by a passing vehicle in the street, a step about the room or house, may be annoying to the observer, but does not prevent securing results by longer application. But when we consider the necessity of absolute immobility of the instrument, often for a considerable length of time, in order to impress upon even the most sensitive plate the image of many-coloured objects, we can well understand one of the greatest causes of failure to secure detail; and this obstacle of motion becomes far greater as the amplification increases. It is plain that motion is multiplied equally with the diameter of the object; or, in other words, if we magnify an object one thousand diameters, a motion of that object to the extent of one-thousandth of an inch becomes in the amplified image a motion of one inch, which very readily shows why good results cannot be obtained under such conditions.

When observing with the microscope, it is possible and quite feasible to focus the instrument above and below the general plane of the object, in order to study any projecting points which may be within or without the general plane. This feature is not possible with the photographic process, save in so far as diaphragming the lens and modifying the light may effect the result. *Over*-estimation of the possibilities of photography and *under*-estimation of the careful preparation of objects have occasioned much unnecessary labour and great disappointment by failure to produce results which should be sought through different channels. When the investigator contemplates the employment of photography for illustrating his work, let him consult his photographer before preparing his objects. No one human being has yet encompassed *all* that is known. When the anatomist takes to his photographer a *thick* section of muscular or ossified tissue, and asks to have the individual striæ and cells isolated and delineated with distinct outlines and minute detail, he will fail to realise his expectation. When the mineralogist or geologist prepares his sections of crystallisation or deposits, he must not calculate that *all* his various planes will be perfectly shown in one photograph, even if the specimen *be* translucent. Colour, mass, and position are important factors in all photographic work. With orthochromatic plates many objects heretofore impossible of proper illustration may be quite successfully treated; but, with objects of this class, another factor, that of time of exposure, offers a barrier of limitation. The mobility of life, animal and vegetable, is a most important element, which cannot be ignored in exposures of hours, or even minutes, and seconds. A vegetable fibre, when placed in concentrated light, may make one or more entire revolutions during the time of exposure necessary to properly impress its image upon an orthochromatic plate; and especially is this the case when a high-power objective is used. Thin sections devoid of the less actinic colours, red, orange, yellow, and green in their darker tints, or admixtures, may be easily treated. Circulating fluids or objects changing size or position are susceptible of instantaneous exposures only. When such objectionable features as motion and non-actinic colour are present, the problem becomes far more complicated, and, if the photographer fails in its clear and complete solution, his patron sometimes looks upon such failure as a proof of incompetency or a lack of proper effort. Like her sister handmaids in the advance and illustration of scientific thought, photography stands ready to do her proper work. She has done much, and, it is believed, will do more, to enlarge the field of human knowledge and gather the harvest; but we should not ask her to accomplish the impossible.

ON THE USE OF ISOCHROMATIC PLATES IN PHOTO-MICROGRAPHY.

[Journal of the Quekett Microscopical Club.]

Some months ago a letter appeared in the *English Mechanic* from Mr. Lewis Wright, lamenting the smallness of the available supply of fluorite for the production of apochromatic objectives for the microscope, and further mentioning the difficulty of getting it, as a formidable obstacle to future optical improvement.

With regard to the truth of the charges made in that letter as to the firm of Zeiss having obtained nearly all the fluorite procurable I have nothing to do; but, having been engaged for some time past in experimenting with ordinary achromatic lenses as applied to photography, the conclusion I came to was that, given certain conditions, the total failure of fluorite might not be so disastrous as it seemed.

My reasons for arriving at this conclusion were that, when using lenses in which the visual and actinic foci were widely divergent when used on ordinary plates, the image came out in sharp focus when isochromatic plates were substituted, thus raising the possessor of an ordinary achromatic objective to the level, photographically, of the owner of the more expensive apochromatic.

Considering the number of microscopists who now register their results by photographing them, I thought this discovery of mine was so simple a one that I hesitated to announce it as something new, but further inquiries convinced me that it was not so known, and I believe the fact is placed in writing here for the first time.

Of course, I am aware that the advantage of using isochromatic plates has been several times mentioned lately, but, being always mixed up with the use of a coloured screen or other light-filter in conjunction with it, the impression conveyed is that the sharpness of the resultant image depended upon such screen or light-filter. To take one single instance. At the last meeting of this Club, Mr. Lees Curties exhibited a bottle to hold solutions for giving approximately monochromatic light—such as, for instance, copper chromic solution—and in the discussion which followed Mr. Houghton Gill said that, with this solution and isochromatic plates, he had obtained as good, or almost as good, results with a cheap achromatic as he had been able to do with an apochromatic objective, used without the absorption fluid.

Now, I cannot help feeling that there is some confusion here between cause and effect, and it is to the isochromatic plates, and not

to the solution, that is due the fact that the image in the negative came out in the same plane as the one placed on the screen, even when ordinary achromatic lenses were used. I agree with all that Mr. Gill stated with regard to the results obtainable with ordinary lenses, but the evidence of the effect of the solution to me is not conclusive, unless it can be also shown that the results were different when the isochromatic plates were used only without any ray-filter. I do not wish for a moment to deny that any monochromatic light will make a great difference in focus when ordinary photographic plates are used, but it is isochromatic plates we are here dealing with, and I wish to prove that, when these are used, no light-filter whatever is required to produce sharpness of focus; and for this purpose I beg to exhibit prints and negatives taken first on isochromatic and then on ordinary plates, to show the difference of result. The lenses used were all by one maker—Swift & Son—and I believe that the Jena glass is used, but no fluor spar; but I do not wish to imply from this that other makers' objectives will not give the same results.

Prints Nos. 1 and 1*a* show the proboscis of blowfly, taken with an inch objective at 300 diameters, first on an isochromatic plate, and then on an Ilford ordinary, and you will see that while the first is sharp in focus, the second is all fluff. I may say in justice to this lens that there is but little divergence of focus when used photographically up to fifty diameters on any sort of plate, but that does not vitiate my argument that whatever difference may exist is corrected by the use of an isochromatic plate only. It is not for me to say how this is brought about, but content myself with announcing it as a fact, and leave it to those with more special knowledge to explain why.

Prints Nos. 2 and 2*a* show the Podura scale, taken at about 1100 diameters, with a one-sixth inch, and shows the same difference of result when taken on the two sorts of plates.

Nos. 3 and 3*a* are prints of *Coscinodiscus asteromphalus*, taken at 1750 diameters with a cheap one-twelfth inch oil immersion, and here the difference in focus is simply that between a positive and a negative image of the same diatom when taken first on an isochromatic, and secondly on an ordinary plate, the former being the image produced on the screen of the camera.

All these were taken without any screen whatever, but I have other prints here, taken of histological subjects with the same lenses in which the yellow screen has been used, not, however, to produce a sharper focus, but to render certain colours in the objects more or less actinic. Here a screen certainly is necessary, but, as I have often found when leaving it out accidentally, it makes no difference in the focus whatever.

I can quite bear out Mr. Gill's experience that, on suitable subjects, almost, if not quite, as good results can be obtained with ordinary objectives as with the more expensive apochromatics, and I may add to this that I have found it a great convenience to be able to include more of the object by not using the eyepiece; but this, with me, only applies to the lower powers, as I find that, when using a wide-angled one-sixth inch or one-twelfth inch this way, the curvature of the field more than neutralises the increased image taken in.

In conclusion, I may say that I bring this subject before you in no controversial spirit, but only to elicit the truth, whatever it may be.

T. F. Smith, F.R.M.S.

ENLARGING BY DAYLIGHT.

Enlarging is one of the most fascinating and interesting branches of photography, says Mr. H. C. R. Harley in the *Journal of the Photographic Society of India*. It is, moreover, by no means difficult work. This does not, however, mean that from every negative one possesses a good enlargement can be made; but many negatives which are thin, from perhaps over-exposure or other causes, yet sharp and full of detail, will give excellent enlargements on bromide paper, although they may be of no use for printing on albumenised paper.

The introduction of bromide paper for enlarging has, within the last few years, opened up a comparatively new field of enterprise for the amateur photographer; this is due in a great measure to the simplicity of the process, and the permanent character of the results obtained by it.

Of the two methods of enlarging—viz., by daylight and by artificial light—the former only is here treated of, as being easily worked and presenting but few difficulties, and the process here given is the one which has been successfully followed by the compiler of this article, who gained his knowledge by consulting several periodicals, annuals, and works on photography. The principle upon which enlargements are made is briefly as follows:—

Rays of light are transmitted through a negative, an image of which is projected for a certain length of time on a sheet of sensitised paper by means of a lens placed in the path of the rays and then developed, fixed, washed, &c.

The first essential in making an enlargement is to secure a room to work in, which, if possible, should face the north, and have a window or opening on that side; the next thing is a table, which should be about eight feet in length, and a little wider than the largest picture which may be required. This table should be of such a height that the centre of the negative, when placed in position in the window, and the axis of the lens of the camera on the table, are in line. The table should have at its end furthest from the window an easel attached, to which is fixed the sensitive paper on which the enlargement is to be made.

The table used by me is in two pieces, and the focussing is first performed by sliding in, or pulling out, the front part of the table, and finally by the milled headed screw of the lens. But should the table be in one piece, it should have at its end furthest from the window, and for a length of two feet or so, a slot cut in its middle, to enable the easel to traverse backwards or forwards; to the easel a clamping screw should be attached, so that when the required adjustment has been made, it may be clamped tight and kept in that position; as a further precaution, two strips of wood should be fixed at either side of the table, which will prevent any movement of the easel.

The focussing should be first done on a sheet of white paper fixed to the easel, a sheet of bromide paper being afterwards substituted for it. As the negative to be enlarged should be well and equally lighted, it is necessary to have for this purpose a reflector on the outside large enough to illuminate the negative thoroughly, and which can be of white cardboard or a mirror glass fixed at an angle of 45°, and controlled from the inside by a string. As no light but that which passes through the negative should enter the dark room, it is necessary to close the whole of the window effectually, except a portion which should contain a frame. This frame should have on the outer side a groove for a ground glass 12 × 10 inches in size, and on the inner side, leaving a space of 4 or 5 inches from the ground glass, an arrangement for carriers to fit from the largest to the smallest size negatives to be used.

The negative to be enlarged should be well defined, and full of detail, with sharp definition, and with a slight tendency to thinness; fix this in the carrier in the window with the film side towards the lens and upside down. Then take your camera (I use the one with which the negative was taken), and taking out the focussing glass, push it up as near as possible to the negative, the lens pointing to the easel, and shut out carefully all light at the junction of the camera back and window; and having decided on the size of the enlargement, fix your lens and easel in position in accordance with the following formula, viz., multiply focus of lens by one more than the number of times of enlargement required. This will give the distance from lens to enlargement; then divide the product by the number of times the negative is to be enlarged; this will give the distance from lens to negative. For instance, suppose you are working with a lens of 12-inch focus and wish to enlarge your negative four times: then $12 \times 5 = 60$, or 60 inches is the distance of lens from enlargement or easel, and $60 \div 4 = 15$, that is, 15 inches is the distance from the lens to negative. Now focus sharply and accurately the image thrown first on a sheet of white paper pinned to the easel, and see that it is evenly and well illuminated; then cap your lens, insert the necessary stop, substitute a sheet of bromide paper for the white, uncap and expose.

To ascertain the correct exposure, expose and develop a small strip of bromide paper on that part of the picture containing the greatest contrasts; do this a few times till correct exposure has been attained, and regulate subsequent exposures from that negative by the result.

Should it be desired to vignette an enlargement, cut a suitable aperture in cardboard and allow the rays to pass through it, moving the card to and fro between the easel and lens during the exposure.

Alpha paper may also be used for enlarging, and yields prints of very pleasing tones, either with or without toning, to develop which, the instructions sent out with the paper, if followed, will give excellent results.

Several developing formulæ are given, all of which are well and highly recommended.

The paper after exposure and before development should be soaked in water till quite limp; the water is then thrown off, and the developer

poured over it. Should the exposure have been correct, the picture will appear in a minute or so, and gradually gain density and detail. After the image is well out, pour off the developer into a separate vessel for use again, and, without washing, flood the print with the clearing solution; let it soak for, say, a minute, then throw it away and repeat the dose a couple of times. The picture should now be well washed and fixed in the usual way. The object of the clearing solution is to prevent the precipitation of the iron in the oxalate of potash and iron developer on the film of the paper, and this can only be done by keeping the paper acid whilst washing out the developer.

Should the picture have been over-exposed, it will flash up quickly under the action of the developer, which should in that case be instantly poured off, and more bromide added to it and the development continued. The image on a correctly exposed print should appear gradually, and should never stop appearing; and, provided that details keep on appearing, they cannot come up too gradually, provided they follow each other steadily.

SCRAPS FROM MY NOTE-BOOK.

They do not appreciate art as applied to photography in the far Hebrides. I had an amusing experience recently when attempting to obtain a view of three Skye cottage-women. They were dressed in the curious fashion of the "Isle of Mists," their dresses being sufficiently short to show several inches of bare brown calves. With red handkerchiefs over their heads and tied under their chins, they were walking along a leafy, old-world lane, with their creels on their backs, chattering in their guttural Gaelic tongue like so many magpies.

As I was not carrying a hand camera, I had to crave permission to "make a picture of them." Only one of the three understood English, and she interpreted my request to her companions. They at once shook their heads and refused point blank. Pressed through the interpreter for a reason for their refusal, they said that they could not think of standing for their photographs unless they had their Sabbath frocks on! Some hours afterwards I saw them returning with their creels full of peat. Hastily getting my camera ready, I took a flying shot at them as they hurried by, swearing loudly in their Gaelic at my presumption. The result of the incident, as shown on the negative, is not without humour.

An amusing incident occurred whilst I was travelling through the Highlands with a camera a few weeks ago. Near Oban is the ancient Castle of Dunstaffnage—a somewhat picturesque old ruin, standing on the shores of Loch Etive, and dating back to before the Christian era. After duly "taking" the Castle, I, in company with a fellow-photographer, who had journeyed there on the same errand, glanced at the interior of the ruin, but finding there was nothing to see save bare, ivy-grown walls, we prepared to depart.

Outside the Castle, however, we were met by a burly Highlander, who promptly demanded, in the broadest of Scotch, threepence each for viewing the ruin. My companion, whilst grumbling that "the old Castle wasn't worth threepence altogether!" was about to comply with the demand, but I checked him, and remonstrated with the Scotchman. I remarked that I had visited Dunstaffnage on several previous occasions, and had never before had to pay toll, and that, moreover, as the local guide-books described the ruin as free, I did not intend to be imposed upon. "You won't pay the saxpence, then?" he queried, in the broadest of Scotch. "Certainly not!" I answered. He glanced at my camera and tripod for a moment, and gathering himself up for a crushing reply, he blurted out, "Then ye won't use yer old kemerra on my ground to-day, so there!" "Thanks, my friend," I rejoined, as I moved away; "I've got a picture of the Castle in my pocket already. Good morning!"

If amateur photography continues to spread and grow at its present rate, it will soon be necessary for every hotel proprietor, who wishes to keep abreast of the times, to set aside an apartment for his photographic guests. One of the pleasure-boats to Norway did this last year, and the idea was immensely popular. Why shouldn't "mine host" do likewise?

Photographers on tour are frequently puzzled to know how to safely carry exposed plates when luggage has to be limited in bulk or weight. Of course the tin or cardboard boxes usually recommended for this purpose are quite out of the question where much work is intended to be done. The plan I adopt is to use the thin cardboard masks sold by Wheller & Co. and other makers. When my plates are exposed, I replace them in the box from which I originally took them in their unexposed state, placing a mask between each plate. In this way very little space is occupied, and the plates carry safely and securely. It is an exceedingly simple plan I know, but it is really surprising what a large number of camera-carrying acquaintances to whom I have mentioned it had never heard of the plan before. A hundred masks can be bought for a shilling.

A Tourist.

EXPLOSIVE GAS IN HOT-WATER APPARATUS.

In the hot-water apparatus used in heating houses, says Mr. A. H. MacKay, in *Science*, it is well known that gas or "air" accumulates from time to time. This is let off from the radiators where it may collect by turning the "air" tap provided; otherwise the accumulation under ordinary circumstances would interfere with the circulation of water through the pipes. Being curious as to the nature of this gas, on a certain occasion I smelled it when escaping from the tap, and detected a peculiar odour of what I took to be a hydrocarbon compound. Collecting some of the gas, I cautiously applied a light to it, which produced an explosion.

The furnace was a small, upright one, with the water heated between its double walls, large enough to warm in winter time a house of seven or eight ordinary rooms. Anthracite coal was used.

With a larger upright furnace, having tubes for the smoke and heated gases to pass through in its upper part, in addition to the water-filled sides of the first, the amount of gas collecting in the highest radiator in the house was more abundant, especially when anthracite was used instead of bituminous coal, for which the furnace was also adapted. As a matter of fact, several litres of gas were produced each week in two neighbouring houses supplied with this latter style of furnace, during the period of observation—a few weeks during last winter.

A considerable quantity of the gas was collected for demonstration before a popular meeting of the Institute of Science. Jars of various sizes were filled with the gas, which was burned under various conditions. 1st, The peculiar odour of the gas was tested. 2nd, It burned in the jars when inverted, and otherwise very much like pure hydrogen, giving forth very little light, but much heat. 3rd, The products of combustion showed no trace of carbonic dioxide which could be detected by the lime-water test, which was sensitive enough to detect its presence in the room from the respiration of those present. From this it was inferred that neither carbon monoxide nor a hydrocarbon could be present in any considerable quantity. 4th, Pure nitrogen dioxide injected into the gas gave no ruddy discolouration. Hence, there was no oxygen in the gas. 5th, When mixed with air it would explode like air and hydrogen. 6th, It was not convenient at the time to apply any other tests, or any very accurate ones. The impression was formed that the gas must be nearly pure hydrogen.

If it was nearly pure hydrogen, it must have come from the decomposition of the water, which would apparently imply a corresponding oxidation of the iron piping, or of the heated iron in contact with the water within the furnace. The greater abundance of the gas when anthracite was used suggested that the origin of the gas was the rapid oxidation of the water tubing within the furnace when the heat was particularly intense. If so, every litre of hydrogen produced would mean the conversion of over one and a half grains of metallic iron into "rust."

Again, if a lighted match should be applied to the tap when this gas (pure) is being allowed to escape, the jet would catch fire and "roar" with a hot, bluish flame, of dimensions as terrific as the bore of the tap would allow. As by the "boiling over" of the furnace, the small tank and upper coils under some conditions of water pressure may be emptied and filled with air; what would the consequences be were the mixed gases allowed to escape at night with a lamp held in the hand carelessly near such a jet?

The discussion of these demonstrations revealed the fact that no one present ever knew or heard that the gas escaping from radiators might be explosive—not even the builders, plumbers, and founders.

Query 1. Is the formation of explosive gas within the hot-water apparatus of our houses rare, peculiar to certain furnaces, or is it common?

Query 2. Has an accurate analysis of such gas been made; and, if so, what are its constituents?

THE STATE OF THE LANTERN TRADE.

To one a long time in the business, says the *Exhibitor* (Philadelphia), the study of the peculiarities of each season is instructive and entertaining; from the merchant's point of view it is perplexing. One season is noted for the number of gas lanterns sold, while in the next the oil lantern will be in greater demand; one season will bring a great call for plain views, and in the following the coloured will be in the majority. The distinguishing feature of the season just closing has been the unprecedented demand for lanterns and views for society work. As the use of the instrument in this work is not for pecuniary profit, and the members of the societies cannot spend the time to manage a gas instrument, it followed that the demand was for the oil lantern. The cheapness of this form as compared with the other was also a strong influence in its favour. The marked improvements that have appeared within a few years in the quality of the oil lantern, especially in the important part of a powerful light, have aided this result. Another marked feature of this season has been the small demand for plain views as compared with previous seasons. Has

this been caused by amateur makers? Some dealers think so. To a certain extent, no doubt, it is a factor in the result, but we are inclined to think that its influence is over estimated. We are more disposed to suspect that the increase in the number of professional makers has affected the trade in the channels where it was wont to travel, and the system of hiring slides that has grown so in favour must certainly have cut off many sales, but not so many as on first thought would be supposed, for our experience is that the great mass of the customers that hire would not have had anything to do with the lantern if they could not have hired the views. This class of customers is of special benefit to the manufacturer of the lantern. We have a strong notion that the professional lecturers have not been so numerous this season as for several seasons past. The crop, no doubt, will be heavy in the season 1893 and 1894. The Columbian Exposition will be the incentive to spur them on. The cheap mechanical slides have been in less demand than usual; they seem to be gradually falling out of favour. Views of short stories that are illustrative of intemperance, history, poetry, and pathos are in growing demand. Illustrated song service is taking a foothold here, and will doubtless in a few seasons be as favourite a form of entertainment as it is now in England. There it has had marked success, and the makers of views have furnished many sets to meet the growing demand.

The makers of coloured slides are growing in number, and doubtless their work will improve in quality. We feel justified in saying this from various samples that have come under our notice; they have a wide field before them in this direction. We fail to notice the true artist in any of the work that has been turned out this last season by those that are new to the business, and while on this subject we would suggest that the unprecedented demand for views this season has not tended to improve the quality furnished by any—it was rather otherwise.

The advent of colourists opens up a new possibility to the dealer, and on him largely will depend the success of this spread of the business. It will be necessary for him to resist that continual pressure that tends to lower prices below a healthy profit both for himself and the artist, and in doing this he will be in a position to continually demand a higher grade of work, thus establishing the business on a more solid and independent basis. If the standard is kept high and the pay good, a better class of artists will be gradually attracted to the business. On the quality of the foundation depends the value of the superstructure; if the designs furnished are poor, then, no matter how expert the photographer, or skilful the artist, the result will be a low-grade lantern slide; so the dealer must realise that a fair profit is needed to enable him to procure suitable designs. The outlay in this direction will be heavy and continuous; but, if wisely and consistently pushed on the lines indicated, he will soon be in a position to furnish those subjects for which he finds good demand. What do you think of the lantern becoming a fad? When society takes it up it may. It tends that way now. Invitations to relatives and friends ensure a select audience, and they are treated to a graphic and interesting talk illustrated by the lantern. This talk is necessarily of an informal character, and at times becomes a general conversation, which, by reason of the interest and curiosity aroused in the hearers, leads to more and varied information being obtained than is possible from a set lecture. No one idea has been more forcibly impressed upon our minds than that the lantern has become a necessity—not a need to any one class of the community, but a want felt more or less by all.

A LANTERN-SLIDE EMULSION.

If old plates are to be used, says an American contemporary, the film can be removed by soaking the slides in a solution of concentrated lye and water. Let them remain in it no longer than is necessary. After the emulsion has been thoroughly removed, it is well to give them an extra soaking in a dilute bath of nitric acid and water. Wash them thoroughly, and place them in a rack to dry. If new plates are used, the nitric bath alone will do.

The emulsion is made as follows, and is about one quarter the rapidity of Carbutt B plates:—

Potassic bromide	56 grains.
Heinrich's gelatine	80 ,,
Water	3 ounces.

Heat in a water bath to 130 degrees, and, when all is dissolved, add slowly, with constant stirring, sixty grains of silver nitrate, previously dissolved in one ounce of water; put aside to set. When thoroughly set, shred by pressing through what is called coarse railroad canvas; wash in four or five changes of water; drain, remelt, filter through fine flannel, and coat plates, allowing one drachm of the emulsion to each plate.

We feel that the use of the following developer will produce the best results with the least liability of stain; in fact, it is reduced to a minimum. It is our experience that all developers are much improved by being made of hot water:—

Hydroquinone	10 grains.
Sulphite of soda	60 ,,
Carbonate of potash	40 ,,
Bromide of potash	1 grain.
Hot water	2 ounces.

The fixing bath is of more importance than is generally supposed, for it is an easy matter to stain a slide by fixing it in a dirty or not properly mixed hypo bath. We have used hypo, 1 pound; acid sulphite of soda, 3 ounces; and water, 2 quarts, with satisfactory results. It fixes quickly, leaves the high lights in good condition, and never stains.

Correspondence.

CONSUMPTION OF OXYGEN, ETC.

To the EDITOR.

SIR,—Would you please tell me about how much oxygen a single lantern, with blow-through jet, would burn in, say, two hours? I have an old oil lantern which I am adapting to take a jet, and do not quite know the best capacity cylinder to get. Also, what is an easy way of ascertaining the quantity of oxygen that may be left in a cylinder?—I am, yours, &c., J. PERKINS.

Kilburn, August 24, 1893.

[About six cubic feet of oxygen would be consumed in two hours. Taking that average as a basis, and knowing how long the oxygen had been turned on, you could always roughly estimate the quantity left. A more accurate way is to attach a pressure gauge to the cylinder, turn on the gas, when the index will point to the number of atmospheres of gas contained in the cylinder. Suppose the latter be a ten-foot, divide the indicated number by ten, and the result will be the number of feet contained in the cylinder.—ED.]

THE LANTERN-SLIDE TRADE AND AMATEUR SLIDES.

To the EDITOR.

SIR,—I have noted for some considerable time what has been said or written anent the harm done to the professional's trade by the amateur photographer, and, in my humble opinion, in many cases this is true. Much of it, no doubt, is caused, not by any desire on the part of amateurs to compete in taking the bread out of the professional photographer's mouth, but by the puffed-up self-conceit of the amateur. In the lantern-slide trade this has been felt of late, and the cause is not far to seek. The amateur trots about getting his views, &c., and making his slides from this and that, and, I suppose, naturally wants to get them projected upon the screen on every possible occasion at the lantern evenings of his club, and it is here where his thoughtless selfishness betrays itself, for at 90 per cent. of such exhibitions the whole of the slides projected are amateur work. Does this show a thoughtful or kindly feeling for the trade worker in this line who has to earn his bread by such work? No doubt, in most cases, it is want of thought, and I think it would be well for establishing a kindly fellowship between the two classes if presidents and secretaries of the clubs and societies brought this matter, in a friendly way, before their members; for, if only 20 per cent. of trade slides were used at such entertainments, it would be showing a sympathy for those whose living they are thoughtlessly taking away, and would certainly do some good in return for much harm that has been done during the past few years.—I am, yours, &c., DELINIAVIT.

Lantern Queries.

JET.—Barton's jet is, we believe, to be introduced by Mr. J. H. Steward, Strand, W.C.

J. RICE.—We have in preparation an article dealing with a method of enriching the illuminating power of oil for the lantern.

B. C. WAIN.—"Air-brush" pictures are produced by some operators in the following manner: A positive is projected by means of a lantern on to a sheet of paper, and the principal outlines faintly traced in pencil. The picture is then worked in by means of the pneumatic spray of Indian ink.

LANTERNOS.—It is not necessary to use coloured cover-glasses for the purpose. Coloured glasses for colouring the light may be obtained of lantern dealers.

MR. F. E. IVES informs us that he is engaged in making several improvements in the heliochromoscope, of which the photographic public may shortly have an opportunity of judging.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [October 6, 1893.

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

It is surprising that so few lantern-slide makers are to be found who include stereoscopic photography among their photographic work. The halves of binocular negatives on either 6½ by 4¼, 6½ by 4¾, or 6¾ by 3¼ plates, can easily be utilised for making lantern slides by contact, so that negatives for lantern and stereoscopic transparencies may be taken at one and the same time.

* * * * *

One of the exhibits at the Exhibition of the Photographic Society of Great Britain is a revolving stereoscope, containing a number of choice stereoscopic transparencies, by that accomplished worker, Mr. F. Beasley. We ourselves spent a very agreeable ten minutes in examining these charming examples of one of the most delightful departments of photographic work, and considered the slight backache that was the penalty as having been more than compensated for. Not many visitors to the Exhibition, however, appear either to notice this stereoscope, or know what it is.

* * * * *

Out of six applications for patents in connexion with photography during the third week in September, three were for improvements relating to lantern apparatus, &c.

* * * * *

In the last number of The Lantern Record we answered a correspondent who wrote us asking for an easy way to ascertain "the quantity of oxygen that may be left in a cylinder," by recommending him the obvious plan of attaching the gauge to the cylinder turning on the gas, and noting the number of atmospheres indicated in the cylinder. "Suppose," we, said "the latter be a ten-feet, divide the indicated number of atmospheres by ten." The first "ten" was given in mistake for *twelve*. The rule is, in such cases, for a 6-feet cylinder to divide by 20, for a 10-feet by 12, for a 12-feet by 10, for a 15-feet by 8, for a 20-feet by 6, for a 40-feet by 3. By an accident these particulars were omitted from our reply.

* * * * *

Messrs. Sharp & Hitchmough, of Dale-street, Liverpool, will shortly place a twelve-feet, seamless lantern-screen on the market. There has hitherto been a difficulty, they inform us, of obtaining seamless screens of that size, but this has been overcome.

* * * * *

Apropos of test slides for ascertaining the correct positions of lantern and sheet, Mr. A. P. Wire writes to the *English Mechanic*:—"To show a picture correctly on the screen it is necessary that the plane of the sheet should be at right angles to the optical axis of the lantern lenses. This position is not readily obtained unless one has a correct method of testing. The following simple plan will be found to answer admirably, and I send it for the benefit of your readers. In the first place, for the comfort of working, the lantern is better if placed at such a height that the operator can stand on the floor to exhibit. In this position the lantern must be tilted up in front to throw the picture above the audience, and the screen must be placed slanting, the top leaning forward if the picture is to be shown with every part in focus. To find the exact place of the sheet, use a test slide. To make it, take a piece of clear glass three and a quarter inches square, and rule on it with China ink vertical and horizontal lines about one-eighth of an inch apart. This may be done by using a ruling pen and China ink rubbed up with gum water. If the ink runs on the glass, warm the glass to thoroughly dry it. When done, mount it as a lantern slide with a circular mask. If, now, this slide be put in the lantern and projected on the screen, the eye will at once tell by the appearance of the lines whether the sheet be placed correctly or not. If all the lines are straight and clear even to the edge of disc, the sheet is right. If the lines appear curved or blurred at any part, the sheet requires adjusting, i.e., always supposing the lenses capable of projecting the picture without distortion."

* * * * *

Messrs. Archer & Sons, of Lord-street, Liverpool, inform us that they are bringing out a new lecturer's reading lamp to burn benzoline, and which will have the advantage of perfect safety. During his visit to Chicago, Mr. W. J. Archer was busy with his "Combined" hand or stand camera, and was lucky enough to secure a negative of the Exhibition by night half an hour after the electric lights were lit, showing the electric fountains playing and the buildings and water illuminated. Slides of this negative will be sold by Messrs. Wilson, of Aberdeen, Mr. Archer's other negatives being reproduced by his firm.

* * * * *

On Thursday, October 12, there will be a special lantern display at the Photographic Society's Exhibition Gallery, 5a, Pall Mall, for members of affiliated Societies at eight o'clock. Members of those Societies can obtain tickets of admission from their Secretaries.

* * * * *

We learn that, of the vessels using the Suez Canal during 1892 nearly 91 per cent. pursued their journey uninterruptedly at night by using the electric light, the percentage in the three preceding years being 88·21, 83·56, and 71·74 respectively. The Suez Canal authorities have now made it obligatory that, after October 1 next, vessels passing through the Canal by night shall employ an apparatus for dividing the light of the projector into two divergent rays. Approaching vessels may by this means travel right up to each other without their respective helmsmen being blinded by the light. One of the agents of the Company has invented the "diverging apparatus" which is to be used.

* * * * *

Talking of the Photographic Society's exhibits, it may be remembered that last year we drew attention to the paucity of exhibits connected with the lantern. This year all that has been changed, very nearly half the apparatus exhibits having a direct connexion with the optical lantern. Apparently excellent slides are shown by Messrs. James Dore, E. Dockree, G. Hankins, J. H. Gear, T. H. Morton, A. Brooke

R. & J. Beck, C. L. Mitchell, Newton & Co., A. Watkins, Henry Little, J. D. England, and T. E. Freshwater. We have not seen them on the screen, so that detailed criticism of them would be worthless. Two exhibits of photo-vitro enamels are shown by Mr. G. Pendry and Mons. A. Guye. The former are of a warm tone, and the latter of a more subdued tint. Both sets are charming examples of a much-neglected branch of photography that would probably well pay for more cultivation among professionals.

THE LANTERN STEREOSCOPE.

In The Lantern Record for October 7, 1892, we were enabled, by the courtesy of Mr. John Anderton, to supply our readers with details of the system he employs for obtaining stereoscopic effect on the lantern screen, and to that account we now refer those of them, and they are doubtless numerous, who are interested in the subject. The following reference to it, however, though scarcely so complete as the former one, is sufficiently clear to let the lanternist get an idea of how the effect is produced. The description is Mr. Anderton's:—

"In adapting the stereoscope to the optical lantern, the problem to be solved is, to place upon the screen a pair of ordinary stereoscopic pictures in such a manner that, whilst the right eye can only see the right-hand picture, and the left eye the left-hand picture, yet the two are combined, and conveyed to the brain as one.

"In the invention this problem is solved in an exceedingly simple manner. The pictures on the screen are in full perspective, the various objects forming them standing out as if possessed of three dimensions, and appearing in their correct relative planes. A pair of ordinary stereoscopic transparencies are superposed on the screen as nearly as possible; the pictures not being identical, a perfect registration cannot be obtained. The light from each picture is polarised, one vertically, the other horizontally, and the combined picture is viewed through an analyser similar to a small opera-glass. This analyser is so constructed that, whilst the right eye can only see the image portrayed in horizontally polarised light, the left eye can only see that in vertically polarised light. An important part of the invention is the screen. It is a well-known fact that polarised light is apt to be broken up on reflection. The screen employed is faced with dull or matt silver, a long series of experiments having proved this to be the best material."

To this descriptive outline, which is in the nature of a "popular" one, it is only necessary to add that the super-position of the stereoscopic picture is effected by halving the transparency, and projecting the halves by means of an ordinary biunial lantern. The polarisers are placed before each objective.

The lantern stereoscope is being demonstrated each Monday, Wednesday, and Saturday evening during the lantern entertainments at the Photographic Society's Exhibition, 5A, Pall Mall, and on Friday evening last we, in company with others, were present at a special demonstration held to give representatives of the press an opportunity of witnessing the effects producible.

We may at once say that for our own part we consider stereoscopic projection as worked out by Mr. Anderton, and shown on Friday night, as perfectly successful. Indeed, our expectations never went within measurable distance of what we then realised.

The two pictures, when super-posed, show a duplication of outline, due, of course, to the fact that absolute registration of the two dissimilar halves cannot be got. When looked at through the analyser, however, the blur disappears, the image coalesces in the brain just as when a binocular slide is examined in the stereoscope, and the screen picture becomes at once well defined and truly stereoscopic, objects standing out in apparent relief and solidity with all the charm of reality.

It should be said that, while all the pictures shown yielded stereoscopic effect when viewed through the analyser, some were less successful than others. Interiors, flowers, land-capes, animals were shown, perhaps the most realistic being the picture of a tiger in a cage, the paws of the animal reaching, as it were, out of the picture, the bars of the cage separating from the animal beyond them, and the whole effect being remarkably good.

It is claimed that any subject taken with a binocular camera would be suitable for stereoscopic projection, but we are disposed to think that successful effects, not only to a popular audience but to those not unfamiliar with stereoscopic photography, would be best obtainable by suiting the treatment of the subject to the conditions of the case. Thus, it appeared to us that the most successful pictures shown were those which had been taken with short-focus lenses separated rather above the distance which strict theory demands, so as to obtain some little exaggeration of relief. This, however, is only a reflection in passing.

On the whole, Mr. Anderton is to be congratulated upon the undoubted success of his adaptation of certain optical principles to stereoscopic projection. The Lantern Stereoscope should be widely popular.

LANTERN MEMS.

"The Lantern as a Reformer." This, or a kindred title, has served lately as a text for some of the lay papers and magazines, while a leading article in a daily has enlarged on the subject of the paper read before the Chicago Convention by the Rev. Mr. Patten as if the services of the optical lantern in connexion with Church and mission work were an innovation.

* * * * *

It is well known that in chapels and mission-halls during Lent and Advent, and especially for Good Friday and Christmas Day, illustrated services are regularly held, and thoroughly well attended and appreciated, and I know of at least one Church-of-England place of worship (not perhaps consecrated) where musical services, illustrated with dissolving views with limelight, form a positive item in the year's work.

* * * * *

It has been reserved for the American Churches, according to these authorities, to have sermons "habitually preached" with "photographic" or other illustrations, and the result of same is the reclaiming of a "great number of sinners." Be this as it may, if it is permissible for a blackboard, with chalk drawings, illustrative of Biblical subjects, to be used in an English church on Sunday afternoon at children's services, I feel sure much more success would be achieved by the projection from a good lantern of photographic representations on a screen, especially during the winter time.

* * * * *

The old objection to children having to be in the dark no longer answers, for, with the powerful lights now available, the radiated light from the screen is sufficient for the audience to be well seen by the teachers or those in charge, and overcome a certain amount of afternoon daylight if the screen was shaded by hoods or by the windows near it having the blinds drawn over them.

* * * * *

Blackboard illustrations, even if executed by an artist, would fall short of enlargements from photographic productions of works of art, and naturally a very limited number could be done by the hand, whereas lantern slides at so low a price as one shilling each would enable the teacher to have as many as were necessary to illustrate the particular lesson of the day or moral truth he wished to bring forcibly home to the young minds.

* * * * *

Are saturators superseding hydrogen for the limelight? This is a question often asked now, and it is difficult to answer; for, although ether saturators have become more popular, there are still a fair proportion of lanternists whose memory serves them, and who cannot help thinking of the troubles that occurred in connexion with this light a few years since.

* * * * *

A complete *résumé* of the work done in connexion with ether and benzoline saturators would be a valuable addition to the literature of the lantern world, and I feel sure that personal experiences of your various readers, whether difficulties were overcome or not, would

help to elucidate the mystery and give greater confidence in the use of the oxy-ether limelight.

* * * * *

I FEEL sorry that the compressors of house gas have not yet found out a way to purify the gas before compression so that it will last a reasonable time, and they will certainly have to look to their laurels, if an alteration is not soon made, for pure hydrogen gas will be a necessity, or else an alternative will have to be found.

* * * * *

WHERE electricity is on supply, a lanternist will shortly be able to have an electric arc lamp that will fit in any ordinary lantern without alteration, and give an illumination about double that of the most powerful limelight, and as easily controlled, without any clock-work or difficult adjustment—in fact, capable of being worked by a novice.

* * * * *

THE advantage of a cheap and small electric lamp for optical projection cannot be over-estimated, for with the polariscope, microscope, and other apparatus, where loss of light necessarily occurs, the extra candle power is of paramount importance, as also for demonstrations in daylight or partially darkened rooms.

* * * * *

MR. ANDERTON, whose clever invention of the "Stereoscopic Biunial Lantern," and the projection of apparently natural solid objects, will, I feel sure, be one of the first to appreciate the advent of the new electric lamp invented by Mr. Davenport, of the Society of Arts, for by its means he will be able to increase the usefulness of the "Stereoscopic Lantern," and be able to show ordinary-size projections with increased brilliancy, besides having at command the power to give representations on a large scale suitable for very large buildings.

* * * * *

LANTERNISTS on the look-out for novelty this season must not pass over the mechanical working figures of the "wrestlers" type. This slide and its companions in the series will afford a lot of amusement, for the metallic figures when projected on the screen have a wonderful amount of movement and lifelike effect; and, as a result of the application of the principle of leverage, a development has been made much in advance of anything hitherto done that has been sold commercially.

G. R. BAKER.

THE SEARCH LIGHT.

AN arithmetical error in THE LANTERN RECORD of last month has provided one of your contemporaries with material for "easy" copy. It points out that the way to ascertain the quantity of oxygen that may be left in a cylinder is *not* to divide the number of atmospheres indicated on the gauge by the capacity of the cylinder. Nobody said it was. The substitution of one figure for another in the directions given by you might have lent some colour to the supposition that a misleading rule was recommended, but a careful perusal of what was said, combined with a little reflection would, to anybody of the least intelligence have established the probability that a slip of the pen had been made.

* * * * *

FOR, in dealing in figures, especially those of this subject, it is delightfully easy to stumble. You assumed the case of a 10 ft. cylinder, and told Mr. Perkins to divide the number of atmospheres by 10; whereas twelve is the divisor. Now, the rule may be expressed as follows:—Divide the number of atmospheres to which the contents of the cylinder were originally compressed, presumably 120, by the capacity of the cylinder, say 10, and let the result be the divisor of the number of atmospheres indicated, the answer (in this case 5 ft.) would be the quantity of oxygen in a 10 ft. cylinder at 60 atmospheres. The rule is so simple that it is readily committed to memory, and of course it works out that, where a 6 ft. cylinder is in question, the number of atmospheres indicated is to to be divided by 20; with a 10 ft. by 12; a 12 ft. by 10; a 20 ft. by 6 and a 40 ft. by 3. Absurdly clear as it all is, however, I can quite understand that it is easy for the photographic journalist, whose head has to be tolerably well stocked with the figures of formulæ, &c., to write down and "pass" the sign "0" for "2" on occasions, especially when it is remembered that press work often has to be got through under circumstances best calculated to render the attainment of accuracy the exception rather than the rule.

* * * * *

BUT your contemporary, of course, is severely indifferent to such trifling considerations, and ought, therefore, to be able to point the finger of pride at well-written, carefully digested articles on the optical lantern, flawless in orthography and grammar, and always correct in their facts and figures. Unfortunately for what should be the eternal fitness of things, some wicked spirit frequently gets an opportunity of exercising his malign spells in his pages, the result being that this self-styled paragon of journalistic accuracy, this complacent monopolist of technical infallibility turns out to be, after all, just as many other men are, a brass idol with feet of clay, in fact, quite an ordinary common or garden ink-slinger, like me or you, Mr. Editor. It seems almost incredible to read that your critic, after inflicting a long and hoary disquisition on compressed gases upon his readers—there is no evidence that he has any of the latter, though—wound up by denying that the contents of a cylinder could be ascertained by any other plan than that of rule of three! So much for Buckingham (and Hastings)! "Gas" is the one thing of all others with which the organ of that mystical body, the National Society of Laternists, is peculiarly able to fill its pages; but it had best leave its estimation to others. The moral of all this is (and I commend it to the careful consideration of your contemporary), that people who live in glass houses should not throw stones. It is an old saw, but it is as true now as ever it was.

* * * * *

To judge by one or two remarks elicited by the foregoing subject, some people appear to imagine that the filling of a gas bottle beyond the extent of its normal capacity is either an impossibility or that it never occurs. For the credit of the gas compressors and others, I am certain such a thing does not often happen, but it is neither impossible nor unknown. It is not so very long ago that, in the rooms of a well-known Photographic Society where an entertainment was to be given, a twelve-feet bottle of oxygen was found to contain seventeen feet.

* * * * *

THE Central Photographic Club has, it seems, started at last. As I gather that the social element is to form a leading item in the Club's programme, I trust that during the winter an attempt will be made to organize a good lantern entertainment at least once a month. When I speak of a "lantern entertainment" I don't mean a mere "exhibition of slides," such as every tinpot little Society in the kingdom indulges in, but lectures on attractive and popular subjects, delivered by men of ability, and illustrated by sets of slides of the quality of those produced by such masters as George E. Thompson, Paul Lange, W. Lamond Howie, Cembrano, Wellington, Sinclair, and others. A little vocal and instrumental music could be interspersed, and if the thing were well done the Central lantern nights would become extremely popular among men engaged all day in town, who could drop in and smoke their pipes, listen to the lecture, and look at the pictures without, as is generally the case at Photographic Societies, having to sit through a preliminary purgatory of "minute-reading," "objects of interest," "questions from the box," and other cruelties to animals. Look to it, good Central Clubbers!

* * * * *

I HAVE given the Central Photographic Club a bit of advice; I will now give it a bit of my mind. When the Club was first projected by two or three good friends of mine, it was no part of the scheme that to the three meeting nights of the important mid-London photographic Societies—the Photographic Society of Great Britain (Tuesdays), the Photographic Club (Wednesdays), the London and Provincial (Thursdays)—a fourth meeting night (Friday) should be added; but this is what the Central Club propose doing. On Friday

nights, I believe, papers will be read, discussions held, apparatus exhibited, pictures shown, questions asked—by whom, think you? Why, the very men who, on the previous night, or two or three nights, have been doing exactly the same sort of thing elsewhere. The Central Photographic Club is almost entirely composed of members of other Societies, and will have to look to them to support its meetings. Do you think they are in a fever of anxiety to acquire fresh opportunities for talkee—talkee? Not a bit of it. Do you think country members coming to town will be eager to listen to a discussion on demitol, hangitol, tiddyfolol, or any other ol? Nary! Do you think the Central Photographic Club will be able, after the tingling enthusiasm of youth has worn off, to sustain interest in technical discussions week by week when so many established societies, with the pick of the photographic talent of the country, can scarcely do so?

* * * * *

The more prominence that is given to the "social element" the greater will be the chances of the Club's success; but, if so far as the evening is concerned it is to be conducted on "Society" lines, so much the worse for it. The fact that it *is* a "Club" and not a "Society" decides the principles on which it should be run. If there is one thing more than another which in my experience (and it is not a slight one) frightens most members of the trade and professional photographers away from "Society" meetings, it is discussions on photographic subjects. Here, if I rightly understand matters, it is desired to attract them. The more open, informal, and, within certain limits, the less "photographic" the Club, the better it will succeed in this object. As regards the meeting night, I think it is too late in the week for most London men; and, as it does not matter for the country members, it would have been wiser to have fixed it earlier. But personally, in this instance, except for social purposes, I regard meeting nights as needless, especially as the usual club privileges are to be available.

* * * * *

What has become of the Charitable Lantern Entertainment Society that was started last winter? Its object was a most humane one, and the Society deserved to live. A night's innocent pleasure to the inmates of a hospital or a workhouse, such as the lantern is capable of affording, is worth any amount of medicine or sympathy.

* * * * *

Are we in for a lantern "boom?" It would appear so if one may go by the vast amount of attention given to lantern work by manufacturers, dealers, amateurs, societies, religious bodies, entertainers, &c. Nothing is so certain as winter and short, dark nights; and herein, to my mind, lies an unfailing element in the assured perpetuity of lantern work. With stereoscopic effects on the screen rendered practicable, a new field is opened up which promises well for the future of this branch of photography. I congratulate Mr. Anderton on the results achieved, which are truly remarkable.

Radiant.

COLLODIO-CHLORIDE LANTERN SLIDES BY TRANSFER.

Although, during the past few years, the taste for black or neutral tones in lantern slides has considerably grown, there are still very many photographers who lean towards the warmer shades more closely associated with collodion; but, with gelatine plates, these are far more difficult to secure than was formerly the case, and even with collodion emulsion, either from the introduction of new development methods or other causes, the rich brown and purple tones of former days are seldom seen.

Such tones are, however, very easily obtained by contact printing on collodio-chloride, and, as so large a proportion of the slides now produced are from quarter-plates, that process seems almost universally applicable, but for a certain difficulty in securing perfect homogeneity of film when the emulsion is applied to glass. This arises from the fact that the emulsion must necessarily contain a very considerable proportion of soluble or crystalline as well as of hygroscopic matter, which, owing to the non-absorptive character of the support, and to the extreme thinness of the collodion film, is apt—or, indeed, almost certain—to cause irregular markings when dried.

The evil may be, to a certain extent, mitigated, but not altogether removed, by the use of a porous substratum of gelatine or albumen, into which the soluble matters are partially absorbed; but the very fact of this absorption introduces other difficulties which go far to counterbalance any advantage gained. Thus, a substratum—more especially one of gelatine—confined between the collodion film and the glass, is very liable to become stained by the spontaneous decomposition of the free silver contained in the emulsion; indeed, this result may be calculated on with the greatest certainty if the plates are kept for any length of time after coating, and it is liable to occur even after toning and fixing, although not at first apparent.

The difficulty may, however, be entirely obviated by adopting a method which, though it may appear at first sight a little "round about," is, perhaps, in the long run, rather easier to work. I refer to the method of transfer from paper to glass. The emulsion is coated upon paper, the printing, toning, and fixing being carried out on the paper support, and, when finished, the image is then transferred to glass. To many readers the process may sound a very formidable one, but none except those who have actually tried it can fully comprehend how extremely easy, as well as certain, the transfer process is when properly conducted. The paper support acts as a perfect absorbent of the soluble matter contained in the emulsion, which consequently gives a far more uniform and satisfactory film, and any stain not actually in the collodion itself disappears when the paper is removed. The convenience, too, of paper in permitting the free examination of the print during progress adds very materially in securing uniformity and quality of result.

As a matter of course, the paper requires some little preliminary preparation, but this is of the simplest kind, and consists merely in coating it with a layer of soluble gelatine. This serves the double purpose of isolating the emulsion from the paper and ensuring its easy removal afterwards. By filling up the pores of the paper a much smoother layer of emulsion is secured, and this is readily and quickly separable from the original support by simple immersion in warm water. The preparation of this gelatine transfer paper presents not the slightest difficulty, nor does it require any elaborate appliances. All that is necessary is to prepare a clear solution of gelatine of one of the softer kinds, strength about twenty grains to the ounce—Nelson's "Photographic" or their "No. 1 Flake" answer perfectly—on which or into which the paper is either floated or immersed, and then hung up to dry. The quality of the paper itself is of very little importance provided it is tolerably even in texture; a fairly good sample of "printing" paper, such as The Journal is printed upon, will satisfy all requirements. So long as the gelatine is not allowed to run in streaks, or to lie in irregular patches, perfect uniformity in thickness is immaterial, as this coating is entirely dissolved and removed in the process of transfer.

Such a paper was at one time, and, for all I know, may still be, an article of commerce, and was used by the late Mr. W. B. Woodbury for stripping and transferring collodion emulsion negative films when travelling. His method consisted in applying the moistened gelatine paper to the collodion surface after fixing and washing, and when dry the whole was peeled off the glass, and the latter recoated with emulsion. In this manner a few plates of glass sufficed for a tour of some duration, and the negatives were afterwards retransferred to glass on the return home.

For our present purpose the emulsion is coated directly on to the paper, and the manipulations carried out in precisely the same manner as for the production of paper prints, with the exception that the printing should be carried to a much greater depth in order to secure the vigour needful in the transparency. That being done and the print carefully washed, it is "squeegeed" with its collodion side in contact with a prepared glass and allowed to dry perfectly. The glass is prepared with a substratum of gelatine and chrome alum, ten grains of the former and a quarter of a grain of the latter to an ounce of water. A number of plates can be prepared at once by simply pouring the warm gelatine on to the surface and drawing off the surplus, then rearing them up to dry in a place free from dust. When dry the substratum becomes insoluble, and the plates may be stored away until wanted for use, the prepared side being, of course, carefully marked.

When the time arrives, the transfer glasses are immersed in water for a few minutes to swell the substratum, and the collodio-chloride print brought into contact by means of the squeegee in the usual manner, and the whole allowed to dry, which will firmly attach the collodion image to the glass. This is then again immersed for a few minutes in cold water and then in hot, when the paper will peel easily from the picture, and a short rinse to remove the soluble gelatine will complete the process.

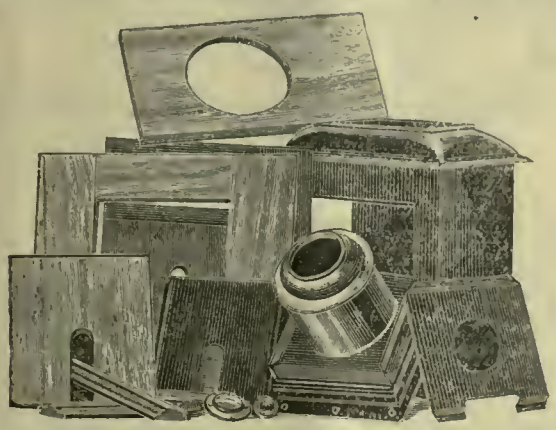
The character of the image obtained in this manner cannot be surpassed by any process, the tones obtainable being precisely similar to those produced upon gelatine or albumen paper of the finest quality while the trouble involved looks far more in the description than it is in the reality.

W. B. Bolton.

RECENT NOVELTIES IN LANTERN APPARATUS.

The "Star" Lantern.

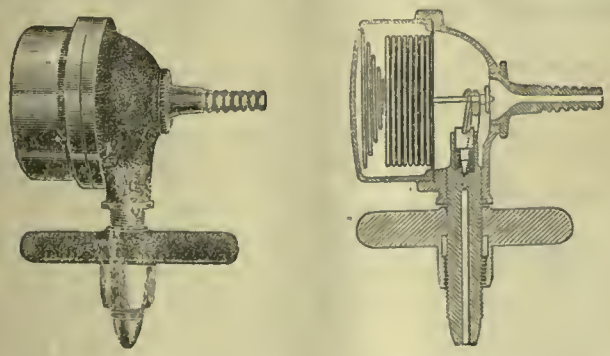
The Sun Camera Company, Limited, Leeds, of which Messrs. Londale Bros., of that town, are wholesale agents, make a speciality of the "Star" lantern, which is designed for the use of amateurs in more ways than one. In a word, all the parts necessary for the lantern itself (minus condenser, objective, lamp or jet, &c.) are supplied, so that an amateur



of average attainment in the handling of tools can occupy himself in fitting it together. The parts supplied are the metal lining, dome, stage, telescopic brass draw tube, knob, and screws for the completion of the instrument, as well as all the necessary woodwork, the sides and door being clamped and keyed, and the front and door turned for sight-hole and condenser, as well as the door mouldings. Two qualities of sets are supplied at moderate prices, and altogether the Star should be popular among amateur lanternists of a mechanical turn of mind.

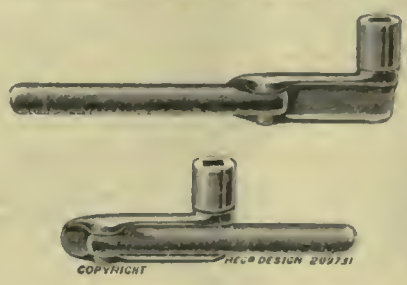
The Scotch and Irish Oxygen Co., Polmadie, Glasgow, N.B.

The metallic-bellows regulator of the Scotch and Irish Oxygen Company (Brier's patent), although not strictly a novelty, inasmuch as it has been before the lantern public for a considerable time, deserves notice in

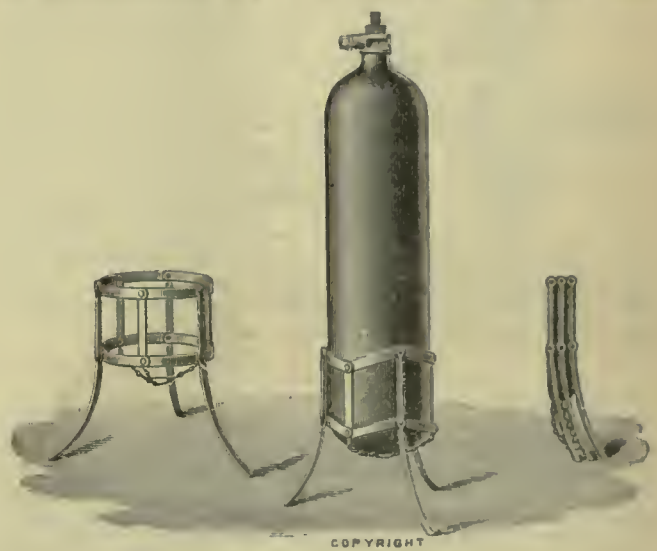


view of several improvements which have enabled the Company to reduce its price. The Company inform us that, so far as can be learned, this is the only regulator having a record of freedom from accidents. It is certainly in the favour of the regulator that none of its parts are of perishable material, the bellows being, as its name implies, of metal instead of rubber, durability and freedom from sudden collapse being not the least of the advantages thereby obtained. The cut in section shows the inside of the regulator, which is a beautifully made and finished instrument that should last a lifetime.

The Company are now the sole makers of the folding lever key, patented by Mr. K. S. Murray, and which we illustrated and described in The Lantern Record for March 3 last. This key shows which way the valve should be turned for opening, offers great leverage, and folds back within itself (as shown here) for closing, thus becoming less powerful, and preventing overstraining of the valve spindle. We can speak from practical trial of the convenience and utility of this form of key.

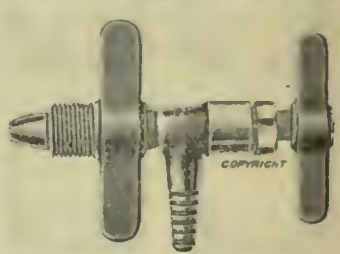


A convenient adjunct to lantern work is the folding cylinder stand which is illustrated below, closed and in use. It is very light and portable, and should be found specially useful for those who desire to hold cylinders in an upright position. It is made with steel legs, bronze connecting links, is very rigid, and may be quickly folded



up into a small space. In use, the weight of the cylinder upon the chains tightens the circles of links, and causes the stand to grip it firmly. By unbuttoning one link of each ring, which is provided with an oval hole, fitting on to an oval-headed stud, the stand may be folded up.

The Company's fine adjustment valve for regulating the flow of gases from high-pressure cylinders has lately been modified, and is considerably lighter than hitherto.



It is made with a stuffing box and screwed gland, so that, should a leak at any time appear at the spindle, it can at once be prevented by screwing down the gland or hexagon nut. This arrangement also enables a damaged spindle to be removed without necessitating the renewal of the whole valve. The productions of the Scotch and Irish Oxygen Company are of the highest type of efficiency, being well and carefully made and calculated to prove exceedingly serviceable to manipulators of compressed gases in connexion with the optical lantern.

Beard's Fine Adjustment Regulator and Pressure Gauge.

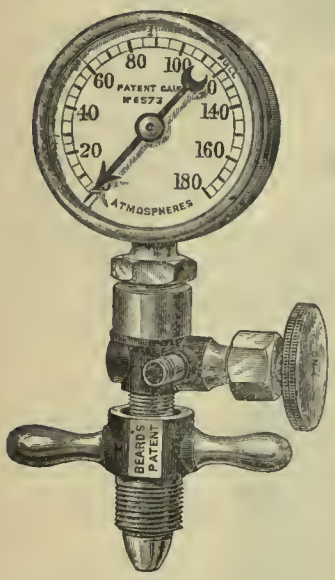
R. R. Beard, 62, Alscot-road, Bermondsey.

Beard's fine adjustment regulator is constructed upon the principle of the screw-down hydraulic valve; its use was proposed many years back,

but was very poorly adapted, an automatic governor then being the only recognised apparatus for the purpose.

Owing, however, to the cheap supply of oxygen, and consequently the great demand for cheap regulators, a large number of faulty instruments have been placed upon the market, which has only tended to bring discredit upon the use of regulators as a whole, many users preferring and resorting to regulating the gas by a long lever off the main valve of cylinder. This requires skill and practice to get good results.

With the fine adjustment valve as an anxiliary valve it places the gas entirely under control, and has the advantage, that when adjusted to get the best result at the burner, there is no need to upset it, for, should the light be required to be turned out, it can be done by the main valve, and in relighting one has no fear of blowing off the tubes, &c., which so often happens when one has only the main valve to work from. Of course, the valve is only useful with a single lantern, &c., or where a given supply of gas is required. It cannot be used for dissolving and triple lanterns.

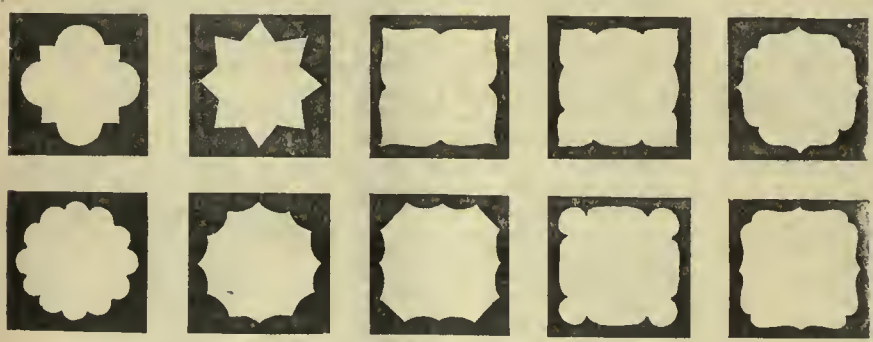


Mr. Beard has also constructed the valve so that a pressure gauge can be used to show the quantity of gas in the cylinder while using from it. This is a great advantage, as it gives the operator the comfort of knowing that his light is not going out in the middle of the lecture, to the confusion of both audience and lecturer.

The pressure gauge is constructed upon a patent principle, and has a check which allows only a small quantity of gas to pass into the tube of the gauge, so that, if it were possible for the tube to burst, it could not be followed by the loss of the whole of the gas in the cylinder, as hitherto.

William Tylar, High-street, Aston, Birmingham.

Mr. Tylar evolves novelties in the way of lantern and general photographic *minutiæ* with an ingenuity that can only be the outcome of a busy brain. Here below are ten illustrations representing the shapes of various fancily cut masks for lantern slides. These shapes, when selected with judgment, should impart pleasing variety to projected



pictures. For binding up and naming slides the pliable gummed binders, strips of thin paper ready gummed, and an index and spot label combined which Mr. Tylar supplies, are also very handy.

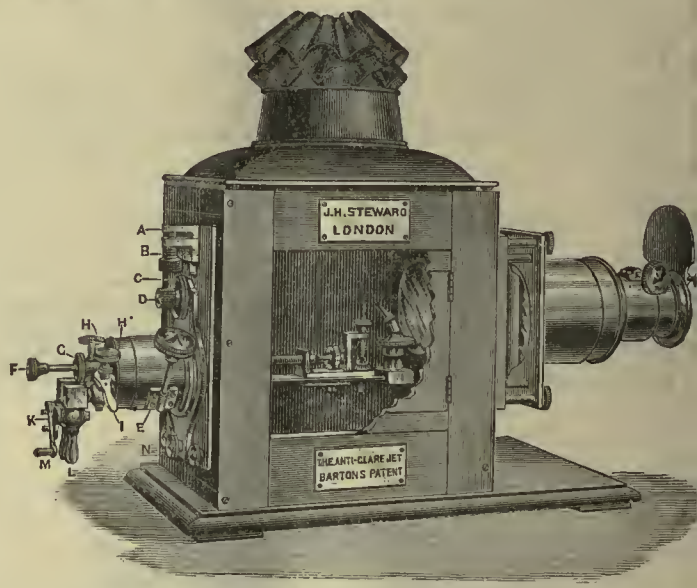
The wholesale agency of the Hill-Norris dry-collodion plate is now in the hands of Mr. Tylar, who forwards us a sample dozen of the lantern plates, which we shall take an early opportunity of trying.

A stand for oxygen cylinders, which folds flat by the side of the cylinder when not in use, and is perfectly rigid when set up, is also one of Mr. Tylar's novelties.

Barton's Patent Jet.

J. H. Steward, 416, Strand, W.C.

As announced last month, Mr. J. H. Steward has introduced Barton's "Anti-Glare Jet," one of the chief advantages of which is that no light can stream in to the eyes of the audience at the back of the lantern



All adjustments are made from the lantern outside in a simple manner, so as to prevent confusion. The working of the Jet may be understood by referring to the cut, in which B is the vertical adjustment, obtained by means of the screw working against the stop A. The side adjustment is controlled by the milled head C, and clamped by the nut D. The screw-down valves H, H, permit of the easy adjustment of the light; M is the cut off for checking the light down; E, the lime turning-rod working through G, which is screwed at the end into the lime support, and so moves the lime to and from the nipple. A spring click to the lime turner, F, is provided, so as to tell how much the lime has been turned. The Jet is fitted to one of Mr. J. H. Steward's lanterns, but can be adapted with little if any alteration to existing lanterns.

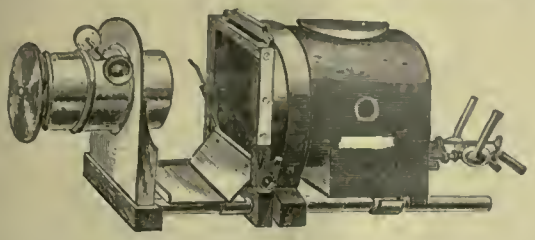
The Supplementary List of Optical Lantern Slides, issued by Mr. Alfred Underhill, of 32, Clarendon-road, West Croydon, Surrey, contains particulars of several series devoted to the Chicago Exhibition and Chicago City, day and moonlight effects at well-known spots of interest, effect slides of the Holy Land, a "Becket" series, bamboo screen effect series, &c. In the latter the first picture remains on the disc, and the subsequent views are exhibited in the blank centre of the bamboo screen. Mr. Underhill undertakes original drawings and designs for all purposes, but especially for reproduction as lantern slides.

Matthews's New Portable Optical Lantern.

Holmes & Watson, Danbury-street, Essex-road, N.

This Lantern is designed to combine efficiency with portability and extreme facility of manipulation. To attain these advantages telescopic tubes furnish a base, upon which run blocks to carry the condenser and objective, as well as the carrier stage and the jet stage; on these tubes perfect adjustment to suit the focal length of the objective, and the necessary distance of illuminant from the condenser, are readily obtained. The rear block is shaped as a crutch or cradle, in which the condenser is firmly held by a brass band furnished with slot and tightening screw, so that, in case of fracture, a condenser of somewhat larger or smaller diameter could be substituted. The front block carries a rigid brass standard, to which the objective is secured by means of a screwed flange. The carrier stage is of novel design, and, being provided with a rising platform, permits the use of various sizes of

slides at one uniform level, without the inconvenience of loose slips as usually supplied; the carrier is also attached to the stage by an entirely new method, bevelled-edge plates superseding springs, and forming a rigid and central attachment. Springs are, however, supplied in case of



need, and these are fixed to the stage and removed from it with great facility. The jet is designed for use with this lantern, and is furnished with all necessary movements for centering, and obtaining the proper distance from the condenser, a convenient lamp of Russian iron covering the light. The box in which the lantern is packed is provided with a rising lid, and forms a stand, with ready means of raising the picture to the desired position on the screen. Mr. Matthews has submitted the lantern to us for our inspection. It should be very popular.

THE LANTERN AND STEREOSCOPE AS AIDS TO EDUCATION.

[Abstract of World's Congress Paper by Professor C. F. Himes.]

After having obtained illustrative photographs, a pertinent question is how best to utilise them? what, if any, instrumental aids are there?

In this connexion, the magic lantern perhaps most promptly suggests itself. The lantern, it is true, has fallen somewhat into disrepute recently. This is also due to abuse of it and want of proper discrimination and thoughtfulness in its use. The improvements and modifications of recent years imparted to it such peculiar possibilities for illustration in the hands of the expert scientific teachers, that a tendency was created to suddenly expand its applications. Instead of calling upon it to do only that which could not be done so well without it, wonderful ingenuity was expended to bring within range of lantern illustration phenomena that are far more impressive to a class of students in their direct presentation. The popular lecturer, too, soon found it an excellent name to conjure with, and, by aid of modern photography, has created such a demand for pictures without much lecture, that he now finds his highest success in fixing them upon the screen with the rapidity of a mitrailleuse from his double or treble-decker lantern, leaving the impression upon his auditors similar to that of a view obtained from an express train. This species of lantern craze has tended to avert thoughtful persons from its use, and obscure to some extent its real merit.

The facility with which photography furnishes slides for the lantern constitutes, even with the educational lecturer, the temptation to overload a lecture with such illustrations, just as there is the temptation, on the part of the young lecturer, to overload a lecture with sensational experiments, that are apt to carry his audience beyond his control. The lantern in the hands of the teacher should be the servant, completely under control, never dictating to or directing the lecturer. Each slide should be as carefully selected for its pertinency and illustrative value, not simply facts, photographic excellence or its beauty, but as the experiment on the lecture table, or as a word in the discourse. They should be rigidly limited in numbers proportioned to the subject. To accomplish this, as I have before intimated, it is almost absolutely necessary that the lecturer should be the photographer. He should be able to cull his illustrations from a wider range than the catalogues of dealers. These, in the nature of the case, are often wanting in freshness. As an example, the slides of scientific apparatus are, for most part, reproductions from leading text-books, often of old models, even where they originate in scientific laboratories. As the lecturer draws from the freshest fields of current literature for his subject-matter, so he should have access to the most recent periodicals of all kinds, even to the advertisements, which often emphasise a point best for his illustrations, as well as perhaps to some little out-of-the-way discovered historic treatise. Apart from the expense involved in having single slides specially prepared by a photographer, no one can understand as fully as the teacher—in many cases—what is wanted, and no one will take the same pains to make the slide all it can be made, for much can be done, even in photography, in emphasising desired features. Besides, time might be a most important element in the case. In an emergency, a negative and slide from it might be made in less time than would be required to take the subject to and explain the wish to a photographer.

But there is a wide field for photography almost untouched, not restricted in its contributions to the lantern. Photographs of actual apparatus, not necessarily of detached pieces, but in groups illustrative of some phenomenon or some application, or, to go still further, arranged on the lecture-table, supporting each other in the progressive course of a lecture, are available to the teacher-photographer. These would afford permanent notes, full notes for the student, which might be supplied as blue prints to such as desired them. These photographs of line apparatus would not necessarily take the place of diagrammatic illustrations, or even text-book illustrations, but would supplement them, and make them real, and they might also have a peculiar value for lantern slides for future reference.

So, too, in the laboratory, apparatus of investigation, *in actual use* by the student, if photographed, would give a record often of general value, as well as of particular interest. Thus, supplementary to the evanescent pictures on the screen, often abnormal at best in many of their features, there might be formed permanent, accurate, highly valuable, as well as unique and peculiarly interesting collections for the student, the instructor, and the institution, and in many cases of general educational value.

But the educational methods of the day are more personal in their tendency. Even students in school do not receive their most effective instruction in crowds. The laboratory, the seminary, are supplementing the lecture each day more fully. The magic lantern thus recedes somewhat in importance. Even people are not as exclusively entertained in crowds. The photographs in the hands for close personal inspection, as long as may be desired, are much more satisfactory than even the best pictures upon the screen. In this connexion a second instrumental aid can be mentioned that far surpasses the magic lantern in all respects. It is a little instrument; it has been neglected, overlooked, displaced by popular fads, but which to-day seems to be experiencing a revival, not only of interest, but of intelligent interest, that will give it a permanent place on the library table and, it is to be hoped, in the schoolroom. I allude to the *stereoscope*. It was introduced into the scientific world just as successful photography was given it by Daguerre. Without photography it would have been little more than an exceedingly interesting piece of apparatus, illustrative of a theory of vision, and with limited educational applications. With photography of to-day it possesses an ever-widening field of usefulness for investigation as well as for education. It maps in space what the camera only gives in projection on a plane surface. It seemed at first limited in range to objects comparatively near until accidentally the pictures of Rutherford and De la Rue of the moon showed that even that body may be made to demonstrate its rotundity through its photographs in the stereoscope. On the other hand, it lays hold of the most minute object, and stereo photo-micrography is almost an untouched field of photography, in spite of the interesting specimens of micro-stereography produced, which demonstrate its usefulness.

It will readily be understood how much higher value the photographs of what I have called line apparatus—of lecture-table apparatus—will acquire if stereoscopic. What might appear a confused mass in any ordinary photograph of the lecture-table, in the stereoscope resolves itself into a wealth of interesting details, all in their proper relations to each other in space.

Without the stereoscope much care might be required in disposing the apparatus so that in many places the picture might not present patches of black or white pasted on a background without intelligible interpretation; with the stereoscope it can be felt that the representation will present itself as it appears to the eyes.

Recently Professor Stine, of the Armour Institute of this city, outlined to me an exceedingly ingenious method for mapping the magnetic field in space by means of stereoscopic photography, as effective in its way as the mapping of a section of it by the many methods in which iron filings are employed. When we consider that not only form is thus reproduced completely, but many other features, notably lustre, the little instrument acquires a new educational value. Thus the valuable unique mineral specimen meets its complete reproduction.

It may be asked, Why has so valuable an educational adjunct been overlooked so long?

In the first place, because, as a popular fad, the great public grew

weary of it. In the second place, because, as an instrument, it was, and has remained, crude and wanting in adjustments necessary to adapt it to personal comfort. At first there was no adjustment to focal length of eyes. Holmes's instrument remedied that. But the gravest defect which, in my own experience with many individuals, has caused its rejection is the want of an adjustment for varying distance between the eyes of different individuals, and for the varying distances of similar points in commercial stereography or varying width of pictures. Often when persons have been unable to see satisfactorily one stereograph, they could enjoy another, simply because the width was less. There are multitudes of simple mechanical movements that will accomplish this adjustment.

Professor Le Contre Stevens a few years ago put in the hands of a prominent photographic firm of world-wide reputation the design for an excellent and cheap one, and it was largely advertised; but, because there was not an immediate and large demand, they ceased to make it, and I was even unable to procure a specimen for exhibition at a lecture upon the subject before a prominent scientific body. The magnificent stereoscopic views of this exhibition, in spite of the revival of interest in the stereoscope, which will create a large demand, will be closed hooks to many, and scarcely satisfactory to others who might derive great enjoyment from them. The man or the firm that will bring upon the market a first-class stereoscope, with these almost necessary adjustments, at a reasonably advanced price, will prove a benefactor to these persons as well as to educators. To be sure, we are not dependent on the instrument; a very little exercise and patience will enable any one to combine, so to speak, the pictures of the ordinary stereograph without instrumental aid, and power to do this is a valuable acquisition which should be encouraged; but many will not take the time and trouble to acquire the power who would enjoy all that the stereoscope affords.

There is another point to which I would allude in this connexion, namely, the frauds practised in recent years, more especially with the revival of interest in the stereoscope. Twenty years ago, during a visit to Europe, I had less difficulty in getting stereographs of desired subjects than photographs of other sizes. In a recent visit, but few were to be had, and those for most part from old negatives. But in several reputable and large establishments where, perhaps, the call had recently been more frequent, I found the larger percentage of stereographs to be formed of duplicates from the same negative, a fact plainly evident without the stereoscope, and admitted by the dealer when his attention was called to it.

The time I have given to the stereoscope I justify to myself by the feeling that there is nothing that will so expand the applications of photography in personal instruction as the intelligent use of the stereoscope as an educational appliance.

LANTERN NIGHTS AT THE PHOTOGRAPHIC EXHIBITION.

The following are the nights set apart for optical lantern displays at the Exhibition Gallery of the Photographic Society of Great Britain, 5A, Pall Mall, East, S.W. On those evenings the Exhibition is open at seven o'clock.

Monday, October 9, *Variety in Hand Camera Work*, by Mr. W. D. Welford. Wednesday, 11, *A Visit to the Zoo*, by Mr. H. Sandland. Saturday, 14, Slides by Mr. J. Carpenter. Monday, 16, *A Photographic Trip to Spain*, by Mr. F. P. Cembrano, jun. Wednesday, 18, Slides by Members of the Birmingham Photographic Society. Saturday, 21, Slides by Messrs. West & Son. Monday, 23, Slides by Mr. J. B. B. Wellington and Mr. Birt Acres. Wednesday, 25, Slides by Mr. Richard Keene. Saturday, 28, Slides by Members of the Newcastle-on-Tyne and Northern Counties Photographic Association. Monday, 30, Slides by Mr. J. Dore.

Wednesday, November 1, *Pictures taken at the Photographic Conventions* by members thereof. Saturday, 4, Slides by Members of the Photographic Club. Monday, 6, Slides by Members of the London and Provincial Photographic Association. Wednesday, 8, Slides by Members of the Manchester Photographic Society. Friday, 10, *Special Lantern Night in Aid of the Photographers Benevolent' Association.* Saturday, 11, To be announced later. Monday, 13, Slides by Members of the Amateur Photographers' Field Club. Wednesday, 15, To be announced later.

The lantern is, as usual, in the competent hands of Mr. R. R. Beard. An improvement on previous entertainments is the provision of seats for the audience. A word of praise should also be given for the abolition of the ragged old lantern stand which formerly took up a needlessly great deal of room, and the substitution therefor of a new, smaller, and extremely artistic stand.

SUBMARINE PHOTOGRAPHY BY ARTIFICIAL LIGHT.

Mr. J. Humphrey writes to *Science*:—"Several of the difficulties experienced in endeavours to ascertain the natural relations of objects existing at considerable depths under water have been overcome by M. Louis Boutan in a remarkably ingenious manner, and the contrivances he adopted are described in a recent communication to the Paris Academy of Sciences:

"He prefers to use a small camera in which several plates can be exposed consecutively, and encloses this in a rectangular, water-tight metal box, into the sides of which plates of glass are inserted to serve as windows. The camera can be so disposed that the lens may face all the windows in turn, if desired, and exposures are regulated from outside the metal case. To avoid any ill effects that might be caused by differences in the internal and external pressure when the apparatus is sunk in deep water, a kind of balloon filled with air is connected with it. As the pressure increases, in descending, the balloon is compressed, extra air is thus forced into the box, and the pressure on its walls equalised. A stout foot to support the apparatus and weights to sink it complete it for practical purposes.

"In water near the shore, not greatly exceeding one metre in depth, the apparatus can be conveniently fixed, without the operator needing to enter the water, and, by direct sunlight, good negatives can be obtained in ten minutes. When the water is deeper, the operator must descend in diving costume to fix the case securely on its stand before commencing the actual work of photography. In calm, bright weather photographs can then be obtained by direct sunlight in from thirty to fifty minutes. Coloured glasses, preferably blue, must be interposed between the objective and the water, in order to obtain sharp images.

"By the use of artificial light to illuminate the surroundings, however, matters are still more simplified. To this end, M. Boutan has contrived a special magnesium lamp. A cask of two hundred litres capacity is filled with oxygen gas, and on its upper end is fixed a spirit lamp, which is covered by a bell glass. A vessel containing magnesium in powder is connected with this lamp in such a manner that the metal can be projected across the flame by the action of a rubber ball which serves as bellows. The oxygen gas, of course, is intended to assist combustion, and the lamp, having been lighted and covered by its protecting globe, the cask simply requires weighting to sink it.

"Good instantaneous negatives have thus been obtained by M. Boutan during a violent storm, when no daylight could penetrate the depths. They are lacking as regards background, but this he attributes to imperfections in the apparatus, particularly the objective. He also found it necessary to place before the lens a diaphragm of very small aperture to secure a sufficient degree of sharpness. If a formula were calculated for an objective, the front of which might be exposed to sea water, he thinks these drawbacks might be remedied.

"As it is, he has proved that photographs can be taken in a brief time under water, in calm weather, by direct sunlight, at depths up to six or seven metres; whilst, by the use of his special lamp, they can be taken, instantaneously, at any depth that can be conveniently reached by a diver, and the state of the weather is of no importance."

THE LANTERN SOCIETY.

Objects of the Society.

To acquire suitable apparatus for the purpose of giving exhibitions of general and scientific interest to both members and their friends.

To obtain the services of specialists in every branch of Art or Science suited to optical demonstration.

To impart instruction in the use of the Optical Lantern, and the apparatus connected therewith.

To form a large and comprehensive loan collection of Lantern Transparencies illustrative of Art, Science, and kindred subjects; such loan collection to be placed at the disposal of every member upon conditions to be laid down by the Council.

To provide a means of inter-communication between the members of the Society, whereby each member may be made acquainted with the private collections of his fellow-members, and may be able to negotiate a mutual loan if so desired.

(*A list of the slides belonging to the Loan Collection, and also of slides in the possession of members who are willing to lend them, is circulated at the commencement of each Session.*)

Meetings for 1893.

The Meetings of the Society are held at 20, Hanover-square, W., at 8 p.m., on the second and fourth Mondays in each month, from October to April inclusive.

October 9. The set of slides going to America will be shown.

October 23. Exhibitions of lantern slides for members and their friends.

November 13. Annual Meeting. The slides received from America will be shown.

November 27. Mr. S. Herbert Fry. Lecture, with demonstration on making lantern slides.

December 11. Mr. G. J. Symons, F.R.S., Hon. Secretary Royal Metcorological Society, on *The Lantern as a help to Meteorology.*

*** Several articles are unavoidably held over.

MONTHLY SUPPLEMENT

To the "British Journal of Photography."] [*November* 3, 1893.

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

We understand that the lantern nights of the Photographic Society of Great Britain have been very successful, the audiences being larger than hitherto. The quality of the slides shown has been, on the whole, high. Doubtless Mr. Anderton's system of stereoscopic projection has been instrumental in making the Pall Mall Lantern Nights popular, but independently of this there is ample cause for gratification at the continued interest taken by the general as well as the photographic public in lantern matters.

* * * * *

It is said that a novel attraction in next year's proposed International Exhibition at Antwerp will be an aerial castle, formed of two balloons connected together by means of three cylindrical compartments, and made captive by four stout cables. It is to be lighted at night by thousands of electric lamps, the current to be supplied from the generating plant illuminating the Exhibition and grounds. Passengers will be conveyed by small balloons to the castle, which is to be capable of accommodating 150 people.

* * * * *

We read that a single electric lamp of 5000 candle power now illuminates the Bartholdi statue of Liberty in New York Harbour. The lamp is situated in the torch held aloft by the figure, and most of the light is reflected horizontally by mirrors, some of it, however, being directed upward through white, red, and yellow glasses to give the effect of a flame. In addition to this, the diadem on the brows of the figure is lit by fifty incandescent lamps of fifty candle power each, and of the national colours, red, white, and blue, thus resembling rubies, diamonds, and sapphires.

* * * * *

The Rev. Mr. Patten, who read a paper on *The Camera and the Pulpit* before the Chicago Congress of Photographers, referred with approval to the employment of the optical lantern in Church services, and since then several newspapers have commented upon the idea as if it were new or novel in suggestion. It is neither the one nor the other. Many years ago the late Rev. T. F. Hardwich, a name of the highest renown in photographic history, when he left King's College to devote his time to religious ministrations among the Durham miners, was wont to use the optical lantern as a means of illustrating his discourses, and as a ready way of appealing to the hearts of his hearers.

* * * * *

"With a series of good negatives secured in the bright summer weather," says Mr. W. Hume in his admirable "Cantilever" monograph, "the pleasures of the field work are revived on winter evenings, as the pictures take larger form through the agency of a good enlarging apparatus, available at any hour, when the ordinary work of the day is over. For it is a remarkable fact that the development of the latent image is watched by the experienced photographer with an interest as keen as that of one who sees it for the first time. This interest is increased rather than diminished in the production of enlargements, as the worker sees before him the first faint outlines begin to appear; his pleasure increases as the positive image acquires strength, half-tone, and vigour; and his satisfaction is complete when the picture is finished, mounted, and hung up."

* * * * *

Messrs. Newton & Co., of Fleet-street, have recently issued a new supplementary catalogue of sets of slides, which include *The Tower of London, Switzerland and the Alps, Spain, Italy, Venice, India, Animal Studies at the Zoo, National Gallery Pictures, Corals and Fishes* from the *Great Barrier Reef of Australia* (recently reviewed in The British Journal of Photography), and other attractive subjects, scientific and general.

* * * * *

The London agents of the lantern stereoscope (Anderton's patent) are Messrs. Harvey & Park, of 56, Charing Cross-road, W.C. This answers several inquiries.

* * * * *

In a communication to *Nature*, Mr. W. Churchill describes the following novel form of image-projection:—"I was on the top of a small mountain in the Dövrefjeld, near Hjerkin, in the late afternoon of August 23, the sun being 10–15° above the horizon, when I saw a remarkable phenomenon. On the opposite side to the sun was a bright disc, perhaps 5° in diameter, shown on some drifting clouds. The shadow of my head appeared in the centre of the disc, that of my body below, while outside the disc the shadow of my legs was faintly visible. The phenomenon continued on and off—that is to say, when the clouds were favourable—for nearly a quarter of an hour. The landlord of the hotel said he had never seen anything of the sort."

* * * * *

We have received from Mr. T. T. Wing, lantern-slide maker and colourist, of Chatteris, Cambs, specimens of his productions in lantern slides, both plain and coloured. The former are of great softness, clearness, and brilliancy; the latter are effective.

* * * * *

A number of processes for the manufacture of pure oxygen from air have appeared recently, all following in a general way the suggestions of the well-known "Brin" process. Herr G. Kassner, in the *Chemiker Zeitung*, claims a superiority for a salt of calcium, the calcium plumbate, Ca_3PhO_4, his process being briefly as follows:—The plumbate, in spongy, porous pieces, is exposed to the action of moist furnace gases which have previously been well washed. Carbonic acid is absorbed by the calcium salt with decomposition, forming calcium carbonate and free peroxide of lead. This decomposition is unaccompanied by a change of form. The resulting mass is transferred to a strong retort heated to redness. Oxygen is disengaged, and the evolution facilitated by a stream of superheated steam. Finally, carbonic acid is given off, and in the last stages this is pure. In the intermediate stage the gases are passed over calcium plumbate, and the carbonic acid there absorbed, leaving the oxygen pure. An-

other similar process has been patented by Peitz, calling for the use of pure carbonic acid.

* * * * *

Le Chatelier proposes a direct method of heating to drive off the oxygen and a reabsorption of the oxygen from the air, but Kassner, who has already experimented with the direct method, considers the higher temperature, the larger expenditure for fuel necessary, and the consequent greater wear upon the retorts, serious obstacles, successfully overcome only by his later indirect method.

* * * * *

Mr. L. Chapman, London, has patented a process depending upon the alternate oxidation and reduction of a mixture of manganese dioxide ("or a similar substance") with caustic soda by means of air and steam respectively. Finely divided manganese dioxide and caustic soda, in the proportions necessary to the formation of the manganate, are mixed with a weight of sodium sulphate equal to the weight of caustic soda taken. Air is passed through small pipes leading nearly to the bottom of the vessel, thus assuring mixture and oxidation by the uprising current. When the oxidation is complete the air is shut off, and the air in the upper parts and in the supply and exit pipes removed by means of steam. Dry steam is then passed. Nitrogen is obtained, with a slight modification, by collecting the gas which escapes during the oxidation and again passing it through the mixture.

AN EASY COLLODION PROCESS.

As there seems to be a tendency in the direction of a revival of collodion and the silver bath, some of the newer readers of the Record may be glad of a simple process which, while it gives all the good qualities for transparency work that are derivable from collodion, is free from many of the difficulties that surround the ordinary "wet" method. It is equally available for the production of negatives for process work, and indeed for all the purposes to which wet collodion continues to be applied, giving in many instances better results than would be obtained by the latter, except under the most favourable conditions and after the acquirement of a considerable degree of skill.

The method I have to describe is a dry one, having collodion and the silver bath as a basis as distinguished from collodion emulsion, with which at the present time, owing to the difficulty in obtaining suitable pyroxyline, many beginners experience a good deal of trouble. This is not the case with the bath process, as any of the bromo-iodised collodions still on the market answer as well as when used wet, or, if preferred for certain purposes, suitable plain collodion can be specially bromised by the operator himself.

The preservative I have to recommend as being at once the easiest to work, and giving the most satisfactory results as regards colour and general good qualities, is the old honey preservative, which may be preferably slightly acidified with acetic acid. This was commonly written down a slow process even in the old collodion days, which I could never understand, as in my hands, nearly thirty years ago, it proved quick enough to take pictures in a fraction of a second, and to render moving figures with a fair degree of sharpness. At any rate, for such purposes as lantern slides, it will not be found much, if any, slower than an average wet plate, while the chances are that the results will be superior. It has the advantage over the wet plate that the film will keep at least for some days if kept from damp, for which the honey has a rather powerful attraction, and consequently it is well adapted to the requirements of the amateur, who can, in a single evening, and at one trouble and mess, prepare a stock of films for subsequent exposure.

The process of preparing and coating the glass is precisely similar to that followed in the wet-collodion process, and it will save unnecessary repetition if I refer readers to Mr. W. E. Debenham's description of the methods of cleaning and coating the plates reported in the Journal of October 20 last. Any of the commercial bromo-iodised collodions may be used, and the formula given in Mr. Debenham's article referred to may be taken as the basis, though, for dry-plate purposes, if a special collodion is being made, it will be as well to salt it a little more heavily, and to slightly increase the proportion of bromide to that of iodide. For instance, six grains of iodide of cadmium and one (or one and a half) grain of bromide of ammonium (or an equivalent of the cadmium salt) will work satisfactorily. It is, above all, important that the collodion should be well "ripened" before use, that is to say, that its salts shall have partly decomposed and given it a somewhat deep yellow colour. If this change has not taken place, the same result may be allowed, as in Mr. Debenham's formula, by the addition of a small quantity of iodine.

If sensitiveness is a matter of importance, the collodion may be salted with bromides alone, to the entire exclusion of iodide, though in inexperienced hands the process will then be slightly more difficult to work to the best advantage, and a much stronger silver bath will be required. The bromised collodion may contain in each ounce five grains of cadmium and three grains of ammonium salt, and the silver bath should not be weaker than fifty grains to the ounce, thirty grains sufficing with bromo-iodised collodion.

The glass is cleaned and coated in the manner described by Mr. Debenham a fortnight ago, but it is well to allow the collodion to "set" for a longer period, or to become drier than when it is intended for a wet plate; it must on no account, however, be allowed to get wholly dry, or anything approaching that state. The immersion in the sensitising bath must also be more prolonged, especially in the case of simply bromised collodion, which, even with the stronger bath, requires a much longer time to fully sensitise than the bromo-iodide. The best test is to watch the density of the layer of silver salts, and, when that appears sufficiently "creamy" or opaque, the process may be taken to be complete. In preparing a number of plates, as only one can be in the bath at once, it is important to curtail the period of sensitising as much as possible, and, in order to economise time, it will be found useful to remove the plates from the bath at the end of one-half or three-fourths the total period that experience shows is required to complete the sensitising, and then to rear them up to drain for some minutes in a place sheltered from dust and light. During the period of draining the surplus solution remaining on and in the collodion film will go on acting, and so finish the process, not yet complete, at the same time less silver will be wasted in the subsequent washing.

After the plate has been well drained, it is placed in a dish of perfectly clean water, which should be preferably rain water previously boiled and filtered, although this is not absolutely needful. After it has remained in this for a minute or two, it should be passed through three or four changes of ordinary water, remaining in each a few minutes, and, after a final rinse under the tap or from a jug, it is ready for the preservative. If the plates are to be kept for any length of time, it will be safer to ensure the complete removal of all traces of nitrate of silver by very thorough washing, or else by the use of a weak solution of salt; but, where keeping qualities extending over two or three weeks will suffice, this is not of such extreme importance.

The preservative, the function of which is to soak into the pores of the collodion film, and prevent its drying up into an impervious skin, consists of a teaspoonful of good honey, and two or three drops of acetic acid, dissolved in an ounce of water, and carefully filtered. This is poured on to the film three or four times from a measure glass, so as to get as even a coating as possible, or the plate may be immersed in the solution in a dish; it is then reared up on end on clean blotting-paper, in order that the surplus may be evenly drained away, and, when all the films have become surface-dry, they are to be transferred to a suitable drying box or cupboard. It is important, during drying, that no sudden change in the atmospheric conditions occurs, such as a great and rapid change of temperature, or a strong current of air, otherwise drying marks will occur. If the films are permitted to become quite surface-dry, they may be rapidly dried over a hot plate, if care be taken that there is no check in the process. When dry, the film will have a bright polished surface of great hardness.

These plates are very useful for contact printing, but much more care must be taken with them than with gelatine, on account of the comparative tenderness of the film. The exposures will vary from ten to thirty seconds or more to a good gas flame, and any of the ordinary dry-plate developers can be used, but pyro and carbonate of ammonia give the best tones.

W. B. Bolton.

THE SEARCH LIGHT.

Does the presence of tobacco smoke in a room where the optical lantern is being worked interfere with the clearness and brilliancy of the projected image? I have never myself been able to detect any degradation of result where, say, thirty or forty photographers have been puffing away at what an acquaintance of mine once termed the "*calomel* of peace," but I have heard it suggested that the smoke does make some appreciable difference. I am just as fond of smoking as I am of optical lantern shows, so I hope no ukase against the use of the soothing weed on these enjoyable occasions will ever go forth. By the way, my enemies ridicule my favourite brand of the weed, and endeavour to destroy my affection for it by foisting their own particular fancies in the way of tobacco upon me; but so far I have preserved my allegiance, and defied the arts of these would-be poisoners. In view of the near approach of the Christmas gift season, perhaps some of my readers would like to know what tobacco I *do* smoke; so I—— Dear, dear! where am I wandering to?

* * * * *

Aided by some good fellows, I have lately perpetrated the harmless but seductive raffle upon one or two festive photographic assemblies on behalf of the Photographers' Benevolent Association, the result being the addition to its funds of a small, but useful, sum of money. I am induced to refer to this matter here, at the risk of being called names, for two reasons. In the first place, I want to thank all those gentlemen who parted so freely with their sixpences and shillings to me; and in the next place to remind them and others that, on Friday, November 10, there will be, at the Exhibition Gallery of the Photographic Society of Great Britain, 5A, Pall Mall East, a special lantern display in aid of the Photographers' Benevolent Association. Mr. Mackie, the chairman of the Benevolent Council, and Mr. Snowden Ward, hon. secretary, both of whom work hard and spend much time in the good cause, tell me that the Association is in need of funds, which, translated into other language, means that it is doing good work among the necessitous. I therefore hope the Special Lantern Night will be well supported. I trust to be present myself, and, if I can persuade my urbane friend, Mr. Child Bayley, to let me apply the magnet to the contents of everybody's purses there, I will engage to provide a work of art to be raffled for, which will generate so much covetousness in the room that the Photographers' Benevolent Association will wake up the next morning to find itself rich. All joking apart, however, the distress among photographers, assistants, and others is just now so keen, that the Benevolent will have to cope with a large and steady drain upon its resources during this winter. So, once more I cry, Give, give, give!

* * * * *

I looked in at the Central Photographic Club the other night, and found an exhibition of lantern slides in progress, by Messrs. Acres and Wellington, in connexion with a talk on the carbon process, and very good slides they were too. I am glad to find, from certain parental observations that I occasionally make as to the progress of the Club, that the powers that be take my last month's criticisms in the best part, and appear laudably anxious to give the Club a character other than that of merely another society for the conversational cultivation of photography, as it might, should, or ought to be, but isn't. Now, the next thing I should like to hear is, that the Photographic Convention of the United Kingdom and the Photographers' Benevolent Association will make the rooms of the Central Club their headquarters. I see that, by invitation of Mr. Thomas Fall (its President) the National Association of Professional Photographers are to meet at the Central and indulge in the "cup that cheers but not inebriates," and discuss matters of interest to the profession. A very good idea, and likely to benefit them and the Central Club as well.

* * * * *

I read in the pages of the *Journal of the Photographic Society of India* that, at the recent meeting of the Amateur Photographic Society of Madras, Dr. Van Geyzel, one of the members, showed a very ingenious device by which he turns his camera into a stereoscope. Such are all the details vouchsafed. Given a pair of lenses, there are, of course, no great difficulties in the way of putting the camera to such a use, but I am sorry that so few particulars of how Dr. Van Geyzel went about it were given. Although it is commonly said that there is not much left in photography for the inventor to turn his attention to, Dr. Van Geyzel's idea suggests to me that after all the common fancy is incorrect. For instance, there is clearly scope for the production of a camera which shall be either a microscope, telescope, lantern, hand bag, knife box, writing desk, money box, as occasion demands, and I hope that, in the interests of amateur photographers, who naturally want the best value for money, such an article will shortly be forthcoming. You see, my brethren, the manufacturers of cameras and photographic apparatus generally are just now making so much money out of that too confiding and trustful Crœsus, the modern amateur, that it behoves us all to use every possible means to prevent such rapacity, and thus to invent one piece of apparatus to do duty for twenty.

* * * * *

The question whether as good results for lantern projection can be obtained on commercial gelatine plates as on wet collodion is one of the vexed variety which apparently is doomed to be always with us. Speaking from a considerable experience of lantern entertainments as a spectator, I do not hesitate to say that, in transparency, clearness, brilliancy, and agreeableness of tone, I have seen results on gelatine which it would be impossible to separate from the finest results on collodion, even in a competition. To my thinking, the process, and not the man, is responsible for any advantage which collodion may seem at times to possess. Gelatine plates, with all their apparent simplicity, require great study and education to get the best results from them.

* * * * *

Chatting the other night with an old platemaker, and one of great experience in most processes, wet and dry, he stated it as his deliberate opinion that dry gelatine could be made to equal wet collodion in the quality of its results, and, when met by the contention that the few great makers of commercial lantern slides still employ the wet process, cogently pointed out that in all probability it did not pay these firms to change, inasmuch as their *employés* were thoroughly well used to wet collodion, whereas they, as yet, had not had the opportunity of becoming acquainted with gelatine. "There's something in that," as the old lady said on a peculiar occasion.

* * * * *

Talking about photographic societies, and those that foregather at them, I will let you into a pretty little secret, my dear reader. There is in existence in London a Secret, Black and Midnight Association, of persons of the highest eminence in photography, who hold in their few hands all the leading strings of photographic progress and enterprise, and who shape the policy of the photographic world at large with a despotic remorselessness only equal to that of the terrible Third Section. Admission to this charmed circle is a thousand times more difficult than to that eerie but Tooley-street-Tailorish body, the Linked Ring, or even to the jovial Solar Club. It is essentially a Lantern Society because it only meets by artificial light. When I hear mention of the Photographic Society of Great Britain, the Camera Club, the London and Provincial, the Photographic Club, the Central, and others of that ilk, I smile at their individual and collective unimportance. For this is *the* Photographic Society. To call it by its initials, it is known as the "A. M. S." Now, reader, what do these three initials stand for? No prizes and no blanks, and please prepay all replies.

RADIANT.

CARRIERS.

With the growth in popularity of the lantern, and the enormous increase in the facilities for slide-making due to photography, the old form of lantern slide mounted in a cumbrous wooden—I had almost said timber—frame has become nearly a thing of the past. Evolution has been at work in this detail of the lantern as well as in others, and the ingenuity of inventors has put upon the market a host of contrivances for facilitating (or otherwise) the change from slide to slide. Into the distinctive features of some of these carriers I propose to inquire; but, before doing so, it would be best to recapitulate a few of the more important *desiderata* which the lantern-slide carrier should possess, and in doing so it is best to state at the outset that the kind of display under consideration is more that required by a photographic or lantern society, or scientific or popular lecture illustrated by photographic slides, than the more or less infantile diversion obtained from what are styled "effects."

A writer, some week or two ago, in another periodical which devotes its attention to photography, after stating that the chief function of lantern slides was to illustrate, and not to decorate, and that they should take the place of diagrams rather than pictures, went on to say that one of the most important rules that lanternists should observe was "that the view on the screen should never be seen to move." Why, I must confess, I entirely fail to see. Assuming that a lantern slide is a *picture*, some of the hyper-sensitive artists, some of those individuals who cannot look at a photograph if there be a camera in the same room—it is so technical, you know—might have some possible complaint to make that the sliding of the picture destroys the illusion; in other words, that the function of a slide is to not-slide. It would be in keeping with other of their contentions. In reply to these gentry, it might be pointed out that even pictures can be taken down off a wall, that there is no case on record where an artist failed to appreciate a picture because it was removable, and that they would hardly decry all works of art with the exception of frescoes? But that a diagram or an illustration should never be seen to move—what can it matter? I have attended lectures where the Professor has had hanging, one upon the other, on the walls a series of "diagrams" or "illustrations" which he took down one after another to illustrate the various points in his lecture. Did he violate a most important rule? We may safely disregard a *dictum* of this sort in considering the most desirable features of a carrier, which are as follows:—

1. The absolute impossibility of sticking and jamming.
2. The prevention of one slide from overlapping another.
3. The absence of either a blank white disc or complete darkness while changing.
4. The possibility of the operator seeing the slide in the carrier before it passes into position in the lantern.

As regards the first two of these conditions, by "absolute impossibility" I mean, at least, as much certainty against accident of any kind, say, as the axle of a railway carriage possesses. There are carriers in existence, marvels of ingenuity, capital methods of changing slides in private, or where a non-critical and indulgent audience would pass over a hitch occurring perhaps once in the course of a display. They act beautifully 99 times in 100, or 999 times in 1000, but the 100th or 1000th time something happens—a slide is too big or too small, a catch or a spring has been wearing, and the carrier "won't work." I have known an excellent carrier in other respects jammed by so slight an accident as the binding paper of the slide becoming unstuck. For a public exhibition such a hitch should be impossible; the slides should follow one another in even and unbroken succession.

The alternation of a blank white disc with a slide is very trying to many persons' eyes, apart from which many of the best slides pictorially are not absolutely bare glass in the highest lights, or these portions bear so very small a proportion to the rest of the picture that, following immediately upon the exhibition of a white screen illuminated with the full glare of the lantern, they look gloomy and dull, and half their beauty is lost. This would seem to favour complete obscurity while changing; but to this there are equal, if not stronger, objections. To sit for an hour, and look at something which every minute or so alternates between a brightly lit picture and Egyptian darkness, is a strain upon the strongest eyesight, provocative of headache, and would put the best audience in anything but a good temper. The middle course between these two extremes consists either in the employment of a translucent screen to cut off part of the light while changing, such as has been constructed with celluloid, opal, &c., or in permitting the audience to see one picture pass off the screen and be succeeded by another, no such dreadful a process now that all the mystery which surrounded dissolving has been sent to the "limbo near the moon."

With reference to the fourth requisite—that the operator should see the slide in the carrier before it is passed into the lantern—this most important point is generally overlooked. It is perhaps hardly an essential of the *carrier*, since, with most carriers, it could be arranged by means of a distinct adjunct, such as a shaded candle with a piece of ground glass or opal in front about the size of a slide. This could be stood by the side of the tube of the lantern, with its back to the screen, the illuminated glass coming immediately in front of the slide awaiting exhibition. The best of operators are but mortals, and fallible; and, when set down at the lantern, with a pile of unspotted and variably spotted slides such as most "scratch" society and other sets generally are (regular lecturers' sets always excluded), can hardly help occasionally getting one in sideways or upside down. It is frequently necessary, when exhibiting such slides, to look through them at the screen to form an idea from the subject of the right way to put them into the carrier; and the screen, covered as it is with the details of another picture, is not at all a good surface to look at for the purpose. Such a little device as I recommend would entirely obviate all this, and would act as a certain preventive with all but the most careless operators of that unfortunate *contretemps* of a slide upside down or lying on its side. As at present managed, the first intimation the operator gets of his mishap is from the audience or from the screen itself.

Such, then, are the chief points which a lantern-slide carrier should possess, and there are several in the market which meet Nos. 2 and 3 absolutely, and No. 1 very nearly; No. 4, as I have already pointed out, can be met, in the case of most carriers, by the addition of a trifling and inexpensive "extra."

The simplest form of carrier consists of a slab of wood—which should, by the way, be well seasoned to stand the unequal heating that it is certain to get—$9\frac{3}{4}$ inches long, by about 5 inches high, by $\frac{5}{8}$ inch thick, down which runs a groove slightly deeper and wider than a slide when bound with its cover glass, and in the centre of which is an opening a trifle over 3 inches square. Into one end of the groove a slide is placed, and pushed on by the next until the edge of slide No. 2 is flush with the edge of the carrier itself, when the first, supposing both are $3\frac{1}{4}$ inches long, must be in the centre of the opening. The next is then put in and pushed home as before. Various modifications of this carrier have from time to time been introduced; the first, chronologically, was probably the extension of the groove at one side into a series of steps, so as to take and centre various sizes of slides. It might be considered advantageous to have the exit end of the carrier of some length, to avoid the necessity of taking a slide out every time one is put in at the other end, but this lengthening is likely to lead the operator to forget and let the slide drop out and fall. A drawback to this carrier is that if the groove is cut to take the thickest slides likely to be met with, it will have to be of such a size as, when very thin slides are being shown, to allow of their overlapping, a most disastrous result. Moreover, carriers of this pattern are often met with on the market which have no definite top or bottom, the groove being equally deep. Hence there is danger either that the groove will be too tight to admit a slide a little over the regulation size, or so deep as to allow one which was a little too small to fall forward or backward. This is easily got over by having the bottom groove of such a depth that the centre of a slide $3\frac{1}{4}$ inches high comes in the centre of the opening; the top groove can be any depth in reason greater than this; slides varying one-eighth of an inch or more can then be passed through without a hitch. One side of the channels carrying the slide, instead of being fixed, can consist of strips of wood or other material actuated by springs, which press them gently into contact with the slide, and prevent too thin ones from overlapping. Such a form of carrier, with the top groove deeper than the bottom, and with the wood cut away on the side at which the slides are inserted, so that the operator can see them *in situ* before they are thrown on the screen, meets every requirement a carrier should possess, while in point of view of reliability and freedom from mechanical details, with their proverbial disposition to go wrong just at the most awkward moment, it offers great advantages over many more complex forms.

By a simple process of evolution from this carrier a form greatly in vogue at the present day was reached; that in which the sliding portion is a frame holding two slides, which are inserted from the top, this frame, by being pushed backwards and forwards, brings one or other slide into position, the other being then outside the lantern, ready to be taken out of its carrier and another substituted. This has now been elaborated by the addition of a spring underneath the slide, which, when the frame is withdrawn from the lantern, causes the slide to project up above the top of the frame, and so facilitates its removal. Whether it is desirable, especially when the pictures are following one another in fairly rapid succession—as is bound to be sometimes the case—that they should see-saw or pass away, one in one direction and the next in the opposite, is doubtful. I must confess that it is unpleasant to me. Otherwise this form of carrier is very efficient.

A great elaboration of this carrier is to be found in another form. Here the motion of the frame bearing the two slides is caused by the partial revolution of a handle. This handle, however, before moving the frame, actuates two levers, which, in their turn, close two vulcanite shutters in front of the condensers; then the frame carrying the slides passes across, and immediately the second slide is in position the shutters open. Allied to this carrier in the method of changing—at least, as far as the audience can observe, although it is accomplished in a different way—is one in which the slides are inserted in a groove, as in the first-described form. In this carrier, however, there is a second similar groove, in which slides a shutter, on which is fixed a projecting stud. The shutter, which is a long one, is pushed

steadily in. It first obscures the slide which is in the lantern. The stud then catches the second slide, and carries it in with it, pushing the other out, until the motion of the shutter is arrested by a stop, which indicates that the second slide is in position, when the shutter is withdrawn. Both these carriers give a momentary darkness while the slides are changed.

Still another form of the sliding frame-carrier is one in which the changing is effected by a lever on the top of the lens tube. On moving this lever through an arc, the first effect is to partially obscure the screen by interposing a celluloid or other translucent disc between the lens and screen. Further motion of the lever causes the frame carrying the slides to pass along and bring the second slide into position, when the disc is withdrawn, and the new picture appears on the screen.

Two other remarkably ingenious carriers are both due to the same inventor. In one, the slides are put upon a metal runner, upon which is a spring catch, which holds the slide in position, and this runner is then pushed right home, when, by an arrangement of levers, into contact with which the slide is brought when it is pushed as far in as it will go, it is accurately centered. The other alluded to is, probably, the nearest approach to dissolving that will ever be obtaind with a single lantern. The methods of its working cannot be explained without diagrams, but its effect upon the screen is as follows: As soon as one slide has been sufficiently displayed, the other is pushed in behind it, being, while in that position, of course somewhat out of focus, until the two entirely over-lap; as soon as this is the case, the bar which has carried the second slide into position is withdrawn, drawing with it the first slide; a spring then brings the new picture into focus with a slight click. A very decided advantage possessed by this carrier is, that the slides are put in and taken out from the same side of the lantern, a *desideratum* when the operator is working without assistance.

All the foregoing carry the slides horizontally into and out of the lantern. This, of course, is much the commoner way, most lanterns being constructed in such a manner that any other method is not applicable to them. For the slides to pass through vertically, the lantern has to be specially constructed; there are, however, several clever devices for effecting this, but in nearly every case they are put upon the market as part and parcel of the lantern itself, not as an adjunct or extra. One of the latest of these possesses a distinct feature of novelty. The slide is inserted from above, and, when shown, does not exactly slide or drop, but, in a kind of combination of the two methods of motion, passes into a tray for the purpose, lying vertically under the lens tube of the lantern.

Another novel form of carrier, and the last space will permit me to mention, consists of a light metal frame, in each end of which, by means of springs, a slide is held. The frame is pivoted on its centre at a point exactly above the centre of the slide when in position. A lever first partially obscures the slide in the lantern by inserting a slip of celluloid, then swings the frame carrying the slides round on its pivot through a semicircle. This brings the new slide into position, while that already shown is at the top of the lantern ready to be changed, the lever finally raising the disc and displaying the fresh picture.

With the number of carriers at present in the market, one could go on for some time indicating their distinctive features, but to no very great advantage. Those above described have been selected more as being typical than as possessing any very marked superiority over any to which allusion has not been made. It only remains for me to reiterate, in conclusion, what I have endeavoured to indicate as my opinion throughout, that the simpler the carrier the more efficient it will be. The first requirement should be the avoidance of the unexpected, and any consideration as to the ideal method of replacing one picture on the screen by another should be relegated to the second, or, rather, the fourth place. For, to parody an old saying, a lanternist's three golden rules should be:—First. No hitch. Second. No hitch. Third. No hitch.

JAMES LEWIS.

LANTERN MEMS.

THAT the lantern season has fairly started one has evidence of on all sides. Men passing to and fro in the principal thoroughfares with gas cylinders on their shoulders, and at the railway stations one sees smaller vessels being carried in the hand by luggage straps; and as a balance in the other hand the well-known lantern box. Lectures are announced in the papers and on the walls and hoardings, in which the optical lantern is used for illustration, and we have recently had at the East End (Charington's Hall) Sir Robert Ball and Professor Fleming lecturing respectively on astronomy and electricity to an audience of something like 5000 persons.

* * * * *

THE use of the optical lantern as an instructor for colossal assemblies has put a new power into the hands of scientific men, religious bodies, and entertainers, and besides it has recently again proved of great value in controlling the united action of a large audience. I refer to the memorial meeting of the Salvationists at the Agricultural Hall, where messages were given to the congregation by means of projections on the screen, the words standing out in huge white letters, capable of being seen by every one present, while the words of hymns, &c., enabled all those who were so disposed to join in the singing.

* * * * *

WITH smoked glass and a pointer, any formula or other explanation, diagram, &c., it is desired to project, can be rapidly and conveyed by the lecturer to the audience, while photographic illustrations assist the explanation of ideas or facts. The National Sunday League are good friends to the Rational Sunday advocates and the working classes, and to their success I can personally testify, for not only do they make it possible for the masses to view the wonderful works of nature and of man during the summer and get needful fresh air by their excursions to the New Forest, Salisbury, and Stonehenge, and all accessible seaside places, but during the winter foster the love of science, art, and music at the various suitable halls in and around London.

* * * * *

As an illustration, may be given the programme for Sunday, October 30, at The Horns, Kennington, when Mr. Eric Bruce gave a lecture on "The Human Eye, and its Wondrous Illusions," illustrating Persistence of Vision by the aerial graphoscope, which the photographic fraternity will remember having seen at one of the photographic societies' Exhibitions. The similarity between the photographic camera and the eye has often been made; and, in fact, is the usual simile, but it is certainly gratifying to a lecturer to know that a large audience (filling a good-size hall to completion) sat interested for one hour listening to a technical discourse, and following the illustrations with pleasure. For the musical part an excellent programme was provided in an overture, intermezzo, and march by a capital orchestral band, while soli and anthems formed the vocal items. That the result is so successful speaks well for the future of lantern entertainments, and opens up a large field of work. Without wishing to be hypercritical when an audience is so appreciative, we can always review a result afterwards, and there are many points that suggest themselves in an exhibition of this kind that deserve consideration and permit of improvement. It is admitted that a lecturer is handicapped the moment he essays the dual task of lecturer and operator as well, and consequently those who have *not* to do this work can more easily see little points of improvement. A candid critic is never liked, and, if the artist were to listen to all his "friends" who came to the private view of his Academy picture, the chances are it would never be "hung."

* * * * *

As an unbiassed unit in the audience, I give my impressions, and, as they no doubt apply to scores of similar entertainments, I trust that they will be accepted in the same spirit as given. The result of an experiment is measured by the effect left on the mind of the audience. If an illusion is to be shown, there is no value in exposing the method of producing it—certainly not before it is an accomplished demonstration. In the case I have before me an aerial image is to be projected. The lantern is placed between the screen and the audience (with the back, by the bye, partially open, letting some light out, and the lath which is to revolve and form the disc on which the projection is to be made is in turn placed in front of a black velvet (or other suitable material) screen, to prevent the image of the slide to be shown going beyond the rotating lathe or destroying the illusion.

* * * * *

WHAT can we think but that a miscalculation has been made in the distance of the black screen or the angle of the lantern when we find

not only the aerial projection but a portion of a fixed one on the wall or part of the stage above the black screen that should have shielded it? I say in reply the simple word, *rehearsal*. As a well-wisher of the lantern, there is, no doubt, absolute necessity for the special experiments of the lecture to be rehearsed in the building in which it is to be given, if perfection is to be achieved, and at any inconvenience this should, if possible, be done. Then, again, in changing the slide of an illusion, the audience should not see the change.

* * * * *

I THINK the Royal Society make a point of having rehearsals; at any rate, in some instances the press view serves this end, and enables the lecturer to have the advantage of a "preliminary canter" and demonstration, before the critical eyes of *savants* have a chance of finding out the weak spots.

* * * * *

WITH persistence of vision on my mind, I must allude once again to stereoscopic projection, for I remember, when I first had the privilege of a private inspection of Mr. Bruce's aerial graphoscope, of suggesting that it might serve as a means of getting a stereoscopic view; and, to prove it, I had a stereoscopic slide sent to Mr. Bruce with the two halves mounted separately, but no practical result came of it.

* * * * *

IT was only the other day, in looking up some other scientific matters, I came across the following, which I cannot help thinking will be of interest just now:—"A. Stroh (without knowing H. Grubb had described the essentials of the apparatus in 1879) has recently (*vide Encyclopædia Britannica*, 1887) invented a new form of stereoscope based on the well-known effects of persistence of vision. Two stereoscopic pictures are simultaneously projected by two lanterns on a screen so as to overlap, and discs, having suitable slits, are rotated in front of the eyes of the observer in such a way that only one picture is thrown on the screen at a time, and also that the view of the picture is seen with the right and left eye alternately."

* * * * *

THIS plan must have occasioned a considerable loss of light, similar to what one gets with the Wheel of Life, but it is interesting in comparison with the accomplished stereoscopic lantern projections as demonstrated this year by Mr. Anderton. G. R. BAKER.

PRINT-OUT LANTERN SLIDES.*

II.

WE have now arrived at the stage at which the emulsion may be prepared, and, as there is no "cooking," or long-continued heating of the sensitive preparation, as obtains in the case with gelatino-bromide emulsions, no heating apparatus is absolutely necessary. It is convenient, however, to have a gas stove, or a paraffin one, and an ordinary saucepan; but, if more convenient, the emulsion may be concocted at the kitchen range at night.

Weigh up accurately the following chemicals:—

Potassium citrate	80 grains.
Sodium chloride	80 ,,
Gelatine (Nelson's No. 1)	240 ,,

Measure ten ounces of distilled (or well-boiled) water, and place in a pint bottle. A clean pyrogallic acid or hydroquinone bottle serves the purpose admirably, and has the additional advantages of being of a non-actinic (yellow) colour, and of not breaking when placed in hot water. Add the gelatine, and, after allowing it to soak for ten minutes, place the bottle and contents in a saucepan of warm water, shaking at intervals to dissolve the gelatine. Whilst the dissolution is proceeding, the citrate and chloride may be added to the contents, and all well shaken up together until the whole is in a froth. Now place the bottle back into the saucepan (water at a temperature of about 150° Fahr.) and allow the froth to settle down. In the mean time have ready weighed upon a clean piece of paper 300 grains of nitrate of silver. This should be purchased of a dealer who has a clean fresh stock of photographic chemicals, as upon the quality of the nitrate of silver almost everything depends.

When the gelatinous solution is reasonably free from froth, and at a temperature of 120° Fahr., the silver may be added, all in one lot, and promptly the solution must be shaken up in the most energetic manner until the whole is once more in a state of froth. A fine creamy emulsion should be the result of this combination, and there should be no perceptible grain or coarseness of texture when the gelatinous solution is examined upon a piece of clean glass. I will go so far as to say that, if these simple directions have been carried out to the letter, and the instructions as to temperature observed, there will be a fine emulsion, but, if, as the lawyers say, the alternative obtain, then the temperature of the emulsion must be raised to about 140° for a few minutes, or until it is fine enough. This is an important point, for one of the leading characteristics of a print-out lantern slide should be the stainlike character of the image.

Of course this emulsification must have taken place in a suitable light—say, lamp or gaslight—but not in daylight, unless the bottle in which the solutions are is of stoneware or opaque.

The sensitiveness of the emulsion will depend, *cæteris paribus*, upon the temperature of mixing, but it is not possible, as with bromide or iodide emulsions, to resort to a prolonged emulsification, for the reason that a slight degradation of the purity of the whites quickly ensues.

So soon as the emulsion, therefore, is seen to be fine enough, the solution must be cooled by artificial means. Place the bottle in a pan of cold water, which will quickly reduce the temperature to the setting point. It is best, so soon as the temperature is reduced, to pour the emulsion into a jam jar or other open-topped, clean, stoneware vessel—into anything, in fact, from which it can be readily and, without waste, removed for washing.

Our chloro-citrate emulsion now requires washing to bring it to perfection. Some makers do not wash their print-out emulsions, but this, I venture to think, is a mistake. And here I shall give a wrinkle which I do not find in the text-books, viz., that, after the thorough elimination of the products of the double decomposition by washing, the emulsion receives great vigour and improved printing qualities by the addition of a little free silver and citric acid.

But, to proceed. The *thoroughly* set emulsion must now be squeegeed through canvas (about sixteen shreds to the inch) into a mixture of equal parts of methylated spirit and water. The shreds must be well stirred about and carefully separated, so as to be brought well into contact with the liquid. It is best to squeegee the emulsion through the canvas whilst underneath the surface of the liquor, as, by that means, the after-separation of the particles or shreds of emulsion is more readily brought about. After five minutes' stirring, drain off the water, and put the shreds of emulsion into another lot of spirit and water for a second five minutes. Now drain off the liquor again by making a bag or funnel of the canvas over the top of a jug, and remove as much of the moisture as possible. This may be much facilitated by placing the canvas upon some clean blotting-paper, and allowing it to soak up as much moisture as possible.

Let me here warn the beginner not to smear a print-out emulsion too much over his clothes or hands. It stains in an emphatic and decided way, and is difficult to remove unless promptly attacked by a solution of cyanide of potassium and iodine.

It may possibly be asked why use the mixture of spirit and water for washing. It is not absolutely necessary, but the citrate of silver being slightly soluble in water, I think, and certainly in practice I find it so, that the use of the spirit lessens waste in water. Moreover, when made in small quantities, and experimentally, the washing process is always a bugbear, and generally the result of inexperience is that the emulsion gets "sloppy." This is easily prevented by the use of a proportion of alcohol—the gelatine is kept firm—and, more important still, the resulting bulk of emulsion does not become too large, and the gelatine lose its setting powers.

The emulsion now washed is ready for the final stage of preparation, and the following must be weighed or measured out, exactly, of course:—

Gelatine (Coignet)	100 grains.
Alcohol	1 ounce.
Distilled water	a sufficiency.
Chrome alum sol. (5 grains per ounce)	30 minims.

Once again heat the washed emulsion to a temperature not exceeding 105° Fahr., and add to it the Coignet gelatine, which should previously have been soaked in cold water, or dissolution will be very slow at so low a temperature as 105° Fahr. This latter must not on any account be exceeded if bright slides *are to be counted upon*.

So soon as the extra gelatine is dissolved add, with plenty of shaking, the alcohol, and, continuing to agitate the emulsion, add the chrome alum solution and sufficient distilled water to make up to a

* Continued from page 93.

total bulk of fifteen ounces. There is no particular reason that I know of why the emulsion should not now be completed and used, but I always prefer to allow it to set, and to remain for twenty-four hours before use. A not unimportant reason for this course is that the emulsion gains considerably in density-yielding powers, and, therefore, in covering powers, and, therefore, is more economical if it be permitted to rest at this stage. The point, however, which I wish to accentuate is that, as I hinted earlier in this article, the additions of silver nitrate and citric acid having been made, the emulsion must be used, as it will not keep in bulk, whereas, before this addition has been made, the emulsion will keep as long as the gelatine remains good, which it will do for a very long time if a few grains of thymic acid be added to the alcohol already scheduled.

When about to use the emulsion, or, rather, just before using, it must be warmed to a temperature of 105° (and not more), and one ounce of the following solution added, and the whole briskly shaken into a froth :—

Nitrate of silver	100 grains.
Citric acid	100 ,,
Distilled water	10 ounces.

So soon as the froth has settled down, the emulsion may be filtered through a piece of clean swan's-down calico to remove air bells and general dirt, and is then ready for coating the plate for the preparation, of which I gave sufficient instructions in the concluding paragraphs of my previous article (The Lantern Record, page 92).

We have now arrived at the interesting period of our platemaking, viz., the actual coating of the plates. I fancy that more amateur platemakers—for I will include under that generic name all those who do not actually make money out of the sale of plates—and perhaps professional platemakers too—have failed over the actual coating of the plates and the subsequent drying of them than in the preparation of the emulsion itself. This is perhaps not difficult to realise, but rather difficult to overcome. The actual technicalties of coating the plates are not difficult to acquire. It is the environment of the plates between coating and the final stage of drying which is all-important.

The four points to bear in mind are:—

1. Set the plates quickly.
2. Dry in plenty of air.
3. Avoid dust.
4. Do not alter the rate of desiccation.

Let me review these briefly.

First. Set the plates quickly. This is a point cardinal. If the plates are sluggish in setting, the silver will settle to the bottom and will be difficult to get at through the gelatine. Frilling may also be expected.

Second. Dry in plenty of air. The best way for a small quantity is to dry in an ordinary room, with the windows blocked or made light-safe. If the coated and set plates be fixed up against the wall in such a way that the gelatine side is slightly downwards, no dust can fall upon the film, and the moisture therein contained rapidly falls away and the plate dries well. I cannot at the moment, and writing without the necessary books of reference beside me, remember who it was who, in the early days of gelatine dry plates, recommended the following plan of drying negatives: Two headed nails must be placed horizontally in the wall about half an inch apart, and driven in until the heads are about half an inch outstanding. A corner of the plate is placed between these two nails, and the glass is allowed to rest against the heads of the nails, whilst the point, or corner of the glass, presses against the wall. The plate will now be just in the position which I have described as a desirable one for drying, and, for reasonable numbers, no more satisfactory method can I suggest.

Third. Avoid dust. I am aware that this is simpler to advise than to carry out, but for small quantities the best way to avoid dust is to leave it alone. If dirt is matter in the wrong place, my suggestion is that it should be left undisturbed just before coating. If cleaning and dusting must be done—and it comes to that sometimes—let it be arranged so long ahead of plate-coating as to give the particles ample time to settle down again.

Fourth. Do not alter the rate of drying. In other words, when once set up to dry, leave the plates and the room alone until the desiccation is complete. Most of the drying marks which occur round the edges of plates arise from a sudden hastening (or the reverse) of the rate of drying.

With these four maxims, or axioms, before us, we can now proceed to coat the glass plates we have prepared with the emulsion we have made. With the plates in a pile upon the left hand, and the bottle of emulsion standing in a saucepan of hot water on the right, take a plate by the corner, between the thumb and first and second finger of the left hand, and hold it in as nearly horizontal a position as possible. Now pour on to the right-hand back corner of the plate a pool of emulsion sufficient to half cover the surface. Tilt the plate, ever so little, in the direction that the emulsion is desired to flow in, until the whole plate be covered, when the surplus emulsion can be poured back into a special (and separate) vessel ready to receive it. It is conventional to flow the emulsion round from the right-hand back corner of the plate, from east to west, or in the opposite direction to that taken by the hands of a clock, but this is perfectly immaterial. If the glass be clean, the emulsion of the right temperature, viscosity, and containing sufficient alcohol, it will flow easily and regularly in any direction the plate be tilted. This is always supposing that the person manipulating the things has a steady and true hand, and a supple wrist.

So soon as the emulsion is evenly spread all over the glass, and the surplus returned to its bottle, the plate is to be placed, without further tilting or disturbing the surface and regularity of the emulsion, upon the glass setting slab already described.

It is impossible to accurately suggest how much a little of the sensitive material should be left upon the plate. One or two plates with varying amounts will be the best guide to experience, but this may be noted, that a gelatine citro-chloride emulsion is rather colourless compared with a bromide one. Much less colour or light-obstructing quality will suffice, therefore, to give ample density, which is the point to be secured.

The plate, so soon as set, which can be ascertained by touching an edge of the emulsion, can then be reared up to dry in the manner described, and, when dry, should be packed and protected both from light and atmospheric action. In my concluding article I shall deal with the printing and toning of the slides.

S. Herbert Fry.

(*To be concluded.*)

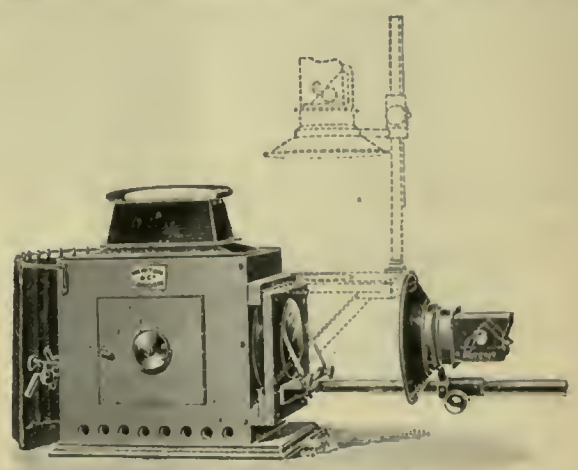
RECENT NOVELTIES IN LANTERN APPARATUS.

Newton's "Demonstrator's" Optical Lantern.

This lantern has been designed for scientific lecturers. A large prism is so arranged that, without being removed from its mount, it can be placed in either of the two bearings, so as to work as a reflecting or an erecting prism.

The space between the condenser and the front lens is left clear for projecting apparatus, &c.

The stage for holding slides, alum trough, &c., being keyholed to the



front plate, can be removed or replaced in an instant with one hand, all screws being dispensed with.

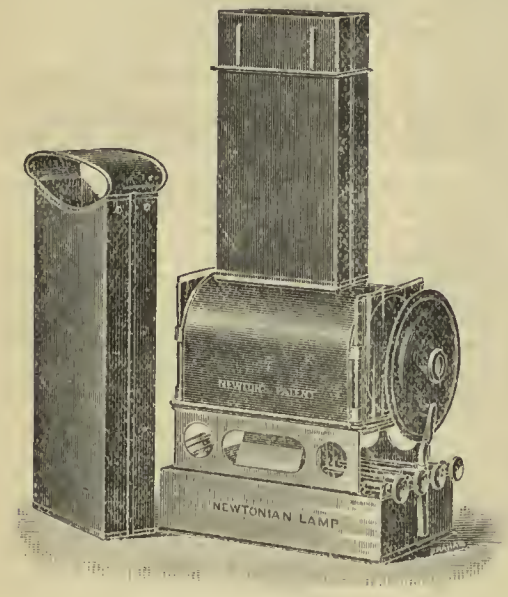
The rack bar, with front lens and prism, can also be similarly removed or replaced with equal ease, leaving the condenser entirely open.

When projecting thermometers, capillary tubes, gold-leaf electroscopes, &c., with an ordinary lantern, the effect is spoilt by the inversion of the image on the screen, and the cost of an erecting prism often prevents its employment. In this lantern the same prism may be employed to erect these objects, that is used as a reflector for vertical projection.

The Demonstrator's lantern should be useful to those for whom it is intended. It is evidently both effective and simple to manipulate.

The Newtonian Oil Lamp.

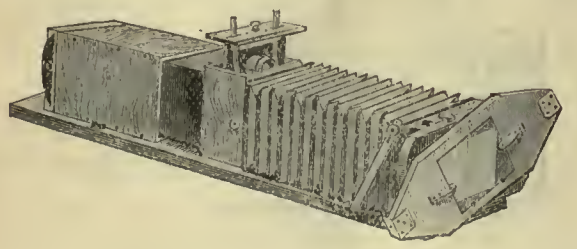
This is a four-wick lamp, for which Messrs. Newton claim great brilliancy and penetrating power. The reflector of each lamp is permanently adjusted to its most effective distance, and the chimney is also



placed to the exact height found by experiment to give the best results. The difficulty of making the flames draw up readily, owing to the sharp draught, is entirely obviated by the peculiar construction of the chimney. If the lamp is lit and burnt for two minutes, using only the lower part of the chimney (see figure), the upper portion may he then fitted into its place on the top, and the flames will at once be entirely under control.

The "N. & G." Lantern-slide Reducino Camera.

Messrs. Newman & Guardia, of 92, Shaftesbury-avenue, W.C., are introducing a new lantern-slide reducing camera, of which we here give an illustration. Speaking of the superiority of reduction slides over those made by contact, they have the following eminently sound remarks:—"The superiority of slides made by reduction in the camera over those produced by printing in contact is admitted on all sides. Quite apart from the constant risk of injuring the negative, ever present in the latter method, it is quite impossible to secure absolute contact all over two plates of glass, and the sharpness of a 'contact' is always inferior to that of an optically produced slide. Besides, when printing by contact, objects are often rendered far too large for the screen, and the more pictorial shape of the usual photographic view is invariably lost in the circle or square of the contact printed slide. Neither is it possible to correct distortion of lines in a printed slide."



As will be seen by the cut, the "N. & G." reducing camera consists of a baseboard, at one nd of which is the apparatus for holding and adjusting the negative; the dark side and focussing screen at the other; and the shutter and lens board in the centre. The shutter board draws right out, so that the lens, &c., may be seen without disturbing the adjustment of the apparatus. It carries a *rigid lens mount*, so that, by means of adapters, any lens can be fitted; also a shutter working close to the diaphragm. One diaphragm, *f*-8, is permanently fixed in the lens; the working diaphragm, *f*-16, is so arranged that it can easily be shifted in and out of position. The shutter and the diaphragm can be actuated, and their position seen, from the outside of the camera.

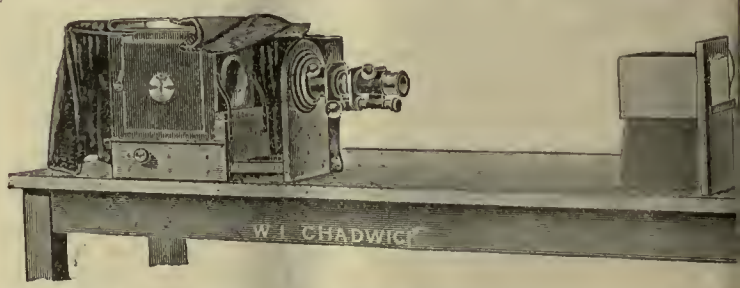
The negative holder is formed of three frames—one hinged to the baseboard, and admitting of being inclined backwards or forwards, and two which can be entirely detached from, and easily fixed on, the camera. Of these two frames, one carries the masks determining the shape of the picture, the other holds the negative to be reproduced. These frames allow the picture to be shifted in every direction, so that the whole or any part of a negative may be reproduced, and errors as to parallellsm of lines, &c., on the negative may be corrected. The dark slides used are single ones of special construction. They will take any lantern-slide plate.

The "N. & G." Lantern-slide Reducing Camera is constructed on simple principles likely to be successful in actual practice. As is the case with all the productions of Messrs. Newman & Guardia, it has been well thought out. That it is well and strongly made goes without saying.

MR. W. I. CHADWICK ON PHOTO-MICROGRAPHY SIMPLIFIED.

Before the members of the Photographic Society of Great Britain on Tuesday evening, October 24, Mr. W. I. Chadwick gave a brief discourse on photo-micrography, submitting for inspection a large number of bromide enlargements from negatives of microscopic objects, chiefly of a popular kind, and explaining the apparatus he employed, which was on view. He said there was no branch of photography which was deserving of more consideration than this, and, when one got on the right track,

there was nothing that was more fascinating. A lot had been said on the subject which he did not agree with, and which was not calculated to instruct or encourage beginners. Taking high-class subjects with high powers did not popularise photo-micrography; what was wanted were popular subjects which could be done with a quarter-inch objective as the



highest power. Referring to his examples, Mr. Chadwick said that not any of them had been done with higher powers than a quarter-inch, while the most expensive lens he used only cost 1*l*. Speaking upon the subject of colour-correct plates, he said, that in their use he failed to discover any difference between them and ordinary plates. Coming to the apparatus employed, he compared a photo-micrographic system to an ordinary optical lantern system, the movements of the various parts of the two systems corresponding in their relations to each other. He had two photo-micrographic cameras on view, the one consisting of the usual arrangement of the ordinary table microscope and camera, the mirror being employed to facilitate the adjustment of the image on the ground glass, while the operator is working from the objective end of the system.

In the second system employed a camera is dispensed with, the dark room itself acting as it were as the camera, an ordinary projection lantern being employed for the illuminant, a front stage supporting the microscope attachment. In the focus of the objective is a small box holding a ground glass upon which the object is focussed and arranged. Mr. Chadwick uses a simple mirror to reflect the image while partly giving his attention to the adjustment of the microscope.

Mr. Chadwick said he found that most people wanted to do popular work such as he was showing, and this was done by the method above outlined, using one-half, three-quarters, and inch powers. He mostly used an oil lamp. His exposures ranged from one to four minutes.

MONTHLY SUPPLEMENT

TO THE "BRITISH JOURNAL OF PHOTOGRAPHY."] [*December* 1, 1893.

THE LANTERN RECORD.

CONTENTS.

LANTERN NOTES AND NEWS.

AN evening contemporary says: "A new idea in the way of a magic-lantern show has been brought out at No. 230 Tottenham Court-road, where for sixpence the weary shopper can go in and sit down, while before his or her astonished view rotate in endless panoramic form views of all the wonders of the world, stopping one half-minute each. The machinery is run by an ingenious combination of heavy-weight clockwork and electricity."

* * * * *

BY the way, with what tenacity does the ordinary newspaper man still cling to the term "magic" lantern. Apparently he is ignorant of the circumstance that the lantern has scope and potentialities outside the limited field of the toyshop and its youthful supporters. With many brethren of the pen it is also the fashion to refer to the uses of the "magic" lantern as being confined to Sunday-school entertainments and similar quasi-religious festivities. Probably within recent years no optical instrument has done more service in the cause of science than this so-called "magic" lantern.

* * * * *

SPEAKING of the uses of the lantern for religious purposes, there is no doubt that, to the fact that it is so largely employed by the clergy of all denominations, the lantern trade owes a great deal of its success and expansiveness. Not long ago, when in the establishment of Mr. Walter Tyler, of Waterloo-road, we were surprised at the large number of orders emanating from clergymen, &c., a number of which most of our purely photographic readers can have little conception. In this respect science is clearly the handmaid of religion.

* * * * *

FOLLOWING an interesting discussion and demonstration on the carbon process by Mr. Birt Acres and Mr. Skelton (of Messrs. Elliott & Son) before the London and Provincial Photographic Association on Thursday, November 23, the first-named gentleman brought his lantern into requisition, and showed, among others, a series of carbon lantern slides of clouds, land and seascapes, animals, &c., which revealed the singular beauties and charms of the process to perfection. Looking at its comparative ease and the delightful results yielded by the carbon process, it is surprising that so few amateurs undertake it. Such demonstrations and exhibitions as those given by Mr. Acres should go far to lifting it into popularity.

* * * * *

THE lantern used by Mr. Acres was one of the open-front portable variety. A few months back we suggested that during the present season single lanterns would enjoy great favour, and the prediction has been verified. Moreover, several new forms, aiming at great portability, have been introduced. It looks as if for single lanterns the old-fashioned kind, with bulky bodies, heavy front attachments, and large brass objective-holders, are to be superseded by more compact devices. Certainly on the score of portability there was frequently great room for improvement.

* * * * *

THE very able and interesting paper on *Photography in Coal Mines* which Mr. Herbert W. Hughes, an authority on coal mining, delivered before the Photographic Society of Great Britain on the 14th ult., was illustrated by a number of lantern slides made by himself, Mr. Burrow, and Mr. T. Sopwith, all experts in this difficult and out-of-the-way branch of photography. Mr. Burrow's slides represented views in metal mines; Mr. Hughes's and Mr. Sopwith's were taken in coal mines. They showed various phases of mine life—miners at work, &c.—and, according to the testimony of experts in mining engineering, who joined in the discussion that followed the reading of the paper, the slides shown were of great educational value in conveying to mining students an accurate idea of things as they exist underground.

* * * * *

MR. F. W. HINDLEY returned from his annual vacation in Ireland with a large number of negatives, from which he has made slides illustrative of many phases of Irish life, character, and scenery on the west coast.

* * * * *

ON the 15th ult. members of the Photographic Club had a treat. Captain Abney showed a collection of his slides depicting views in the Upper Alps. The slides were of singular beauty, their delicacy of detail, softness, and pearly-grey tones in the lights, with transparent shadows, apparently admirably suiting the subjects. Perhaps the most remarkable feature about them was their evenness and uniformity, although, as Captain Abney said, they were made on three or four different kinds of lantern plates. For developer he used amidol well restrained. A great many of them were snap-shots, but only in one or two instances could these be distinguished from those which had had time exposures. Captain Abney, in acknowledging a vote of thanks, referred to his slides as "the work of an amateur," at which there arose smiles on the countenances of the Photographic clubbers there assembled.

* * * * *

IN another part of THE LANTERN RECORD we print the first annual report of the charitable Lantern Entertainment Society. In a quiet, unostentatious way much good work of a humane nature has been done during the past twelve months, for which the secretaries deserve every one's thanks. We trust our readers will support the Society in its efforts to alleviate the pain and *ennui* of many poor sufferers in hospitals &c.

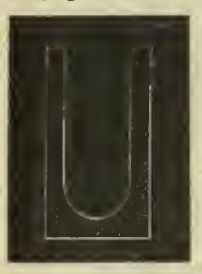
HOW GAS CYLINDERS ARE MADE.

MOST lanternists know that the modern cylinders for compressed gas are made of steel, solid drawn, but few perhaps know the process of production, and, as I recently had an opportunity of seeing some made at the Projectile Company's Works, a description of same may be of interest.

Blocks of rolled steel of the right proportionate diameter and thickness for the cylinder required are heated in a furnace to the

necessary heat, and then treated in hydraulic presses to pressure from a series of punches, each gradually elongating the material with a

hollow inside until the right length is reached, and then the top is closed to make the neck for the valve to be inserted in the metal walls, bulging inwards, as shown in sketch. The number of drawing operations vary with the size of the cylinder, from five to fifteen. To see the men take these pieces of hot metal in the long pincers and lift them into the furnaces or presses, one cannot but help admiring their dexterity.



The metal, between the cold drawing operations and when the cylinder is finally complete, is pickled and slowly heated, allowed to slowly cool, and so becomes annealed.

After the cylinder is drawn the exterior is trued and the superfluous square edge of base (in the large ones) turned off in a lathe.

To test the strength of the cylinders hydraulic pressure is used, and, although it has hitherto been (under some companies' tests) two tons to the square inch, it is considered that one and a half ton's pressure would be more satisfactory.

In Germany there are Government testing places in Brohl and Cologne, where cylinders to be used for high-pressure gas have to be sent to be certified, and where they are tested for pressure, annealing, and general safety, and a record of dates given with the certificate. Any one using an uncertified cylinder is liable to a penalty, and they must be periodically retested and reannealed. A great number of cylinders are used in Germany for the carbonic acid gas so largely employed in the manufacture of lager beer; but I believe the pressure to which they are filled is much less than oxygen and hydrogen gases in England, viz., 50 atmospheres instead of 120 atmospheres.

The works of the Projectile Company cover a large extent of ground to the south of the South-Western and Brighton Railways, between Battersea Park-road and Wandsworth-road, and every convenience seems at hand for the proper manufacture of cylinders, shell, and projectiles, that require varying thickness of tensile strength. The facilities for annealing are such that 500 can be annealed in a day, but two days should be allowed for reannealing. This is, of course, independent of any work connected with valving, filling, repainting, &c., which is done elsewhere. The many processes through which the steel has to go from the time it is a block or disc until it is a finished cylinder prevents a batch of new cylinders being turned out in less than nine or ten days, and, to allow for unforeseen stoppage, in some of the shops the average is taken at fourteen. The machines employed are of great strength, one of the most powerful of which has an hydraulic force of 500 tons to the square inch. The furnaces are supplied with air blast, and in the testing and proving shops the utmost accuracy is shown in ganging, &c., each item, whether it be shot, shell, or cylinder. I am indebted to the courteous Secretary of the Company (Mr. Hatton) for most of my information, and the opportunity of witnessing the process of manufacture.

G. R. Baker.

SILVER INTENSIFICATION FOR COLLODION TRANSPARENCIES.

Somewhat contradictory opinions have been expressed as to the ease or otherwise of intensification in the case of the new Hill Norris collodion lantern plates, but the truth probably is that these, like all other plates, vary more or less in different batches. Those who have had any considerable experience with ordinary collodion emulsion films will know that, whereas some plates will give, with the greatest readiness, literally any amount of density to complete opacity, others, though apparently prepared in precisely the same manner, fail altogether in giving anything more than a mere ghostly image.

This is especially the case with the more rapid kinds of emulsion, and, though the precise reasons for the difference cannot always be ascertained with any degree of certainty, it is usual to attribute the effect either to unsuitable pyroxyline or else to unskilfully washed emulsion. Where the fault originates with the pyroxyline the difficulty experienced may vary very greatly in degree, but where improper washing is the cause it almost invariably amounts to an absolute impossibility to secure any depth of deposit by any ordinary means of either development or intensification. There is, however, one method by means of which any image, no matter how thin, can be intensified, though, of course, it does not follow that the final effect is in all cases perfect. Where, however, a fairly respectable image exists as a basis upon which to work, the means exist of securing both vigour and tone.

With the great majority of modern dry-plate workers, silver intensification is either an utterly unknown or a lost art, and yet it is probably the most perfect in its action, and pleasing in its result, of any of the known methods. With gelatine plates it has fallen into disuse owing to the difficulty, or, rather, the care necessary, in sufficiently freeing the film from the last traces of hypo before resorting to intensification, and perhaps also to some imaginary idea that the action of the free silver renders the gelatine itself liable to subsequent change of colour. The necessity for care in washing does certainly exist, but that the liability to subsequent change is purely imaginary, due precaution, of course, having been taken, is proved by negatives I have in my own possession that were intensified with pyro and silver thirteen or fourteen years ago, and which, whatever their imperfections may be, have undergone not the slightest change.

With collodion plates, however, neither of these two difficulties exists, for, even if hypo be employed in fixing, it is got rid of with such comparative ease as compared with gelatine that a very few minutes' washing suffices to bring the plate into a fit state for intensification. The absence of any permanent action of the free silver upon the collodion film itself is sufficiently testified by the existence of collodion negatives considerably over thirty years old.

When the collodion film is in perfect condition, it is perfectly easy to obtain even more than the requisite vigour by alkaline development alone, that is to say, in one operation; and most photographers, no doubt, will agree with a speaker at the last meeting of the London and Provincial Association, in preferring to dispense with intensification. So far as negative work is concerned that may be all right, but personally, for transparencies, I cling to the old-fashioned style of finishing off with silver; not so much for the sake of intensification as for the sparkle and crispness it gives to the picture, and also for the rich tones that can be produced in this manner.

We are accustomed to speak of the tones obtained upon collodion emulsion plates with alkaline pyro as being the ideal of perfection, and so perhaps they may be when the emulsion is in perfect condition—so far, at least, as mere colour may be conceived. But there is an indescribable something in the look of a silver-finished image that distinguishes it clearly from one developed right out with alkali. Of course it is to be understood that the developed image must be of good colour, to start with, for the process of piling on silver will certainly not disguise a disagreeable tone, and, moreover, it must be performed in a proper manner.

First, with regard to those images which exhibit a total indifference to intensification. Such are frequently perfect in gradation and clearness, and, in fact, in every respect except vigour, and refuse to take any further deposit of silver except in the form of fog. In such cases there is nothing for it but to proceed by a somewhat round-about way, and convert the image into bromide of silver and redevelop it; in fact, to proceed upon much the same lines as in the old method of intensification with chloride of copper, only substituting bromide for chloride.

The plates, after careful washing on removal from the fixing bath, may be flooded with a solution containing equal parts of sulphate of copper and bromide of potassium, the exact strength being quite immaterial so long as it is strong enough to bleach or convert the image in a reasonable time, say, not more than a minute or two. In this solution the picture is converted into bromide of silver, and presents the appearance of a delicate positive by transmitted light, and an equally beautiful negative by reflection. At this stage it is to be very thoroughly washed before proceeding to the next operation.

Another solution, which I prefer for some reasons, consists of bichromate of potash and bromide of potassium, of each twenty grains to the ounce of water, rendered slightly acid by means of almost any acid, but preferably sulphuric or hydrochloric. This solution converts the image into pure bromide of silver, whereas the orher forms also a sub-bromide of copper, which is objectionable, because silver nitrate alone, without any reducing agent, will darken it, and so may interfere with the tone desired.

After bleaching and well washing, the film may be flooded with a solution containing a few drops of a twenty-grain solution of nitrate of silver in half an ounce of water, and exposed freely to light, and is then ready for intensification.

Where the image is of such a character as not to require this treatment it is ready for toning, as I prefer to call it in this case, as soon as development is complete, and this should be arrested shortly before full density is obtained. After well washing it is advisable to flood the plate with a very weak acid solution in order to ensure the total removal of the last traces of alkali, or, which answers the same purpose, to pour over it once or twice the acid pyro solution before adding the silver, or, if it be preferred—and this plan has the advantage of allowing a better judgment of the density and colour of the image to be formed—the plate may be fixed before intensification, in which case the washing must be very carefully carried out, or, if the least trace of hypo remain, the film will be irrevocably stained.

The intensifying solutions consist of pyrogallic acid restrained with either citric or acetic acid in one solution, and nitrate of silver with a little nitric acid in the other. A grain and a half of pyro to the ounce of water, with two grains of citric acid, or ten minims of glacial acetic acid, will form a suitable reducing solution; and the second consists of three grains of nitrate of silver and ten minims of nitric acid to each ounce.

Enough of the pyro solution is taken to well cover the plate, and, after pouring it on to the film two or three times to unite well with the water on the surface, a few drops of the silver solution are dropped into it.

The exact quantity must be regulated by the tone required and the ease with which the particular films take density, bearing in mind that the smaller the quantity of silver the warmer will be the tone, the finer the deposit but the slower the action. If too much silver is added at once, the deposit will be coarse and disagreeable in colour, and most likely too much density will be given. Acetic acid gives warmer tones than citric. The nitric acid prevents the intensifying solution from becoming thick and muddy.

Extremely rich tones and a fine translucent deposit are obtained by the addition of a minute trace of various organic matters to the pyro solution, such as sugar, albumen, or gelatine; but, for all practical purposes, I prefer to rely on plain acid pyro and silver.

When the film is in proper condition, the requisite effect is obtained very quickly, almost in a few seconds. It is only in the case of a defective emulsion that any difficulty will be experienced in getting either density or colour.

W. B. Bolton.

OIL LANTERNS—TRANSLUCENT SCREENS.

Oil Lanterns.

The introduction of compressed gases at prices which place them well within the reach of most amateurs has caused the old-fashioned oil lantern to retire very much into the background; and it is no uncommon thing now to hear of drawing-room displays to small audiences, say twenty or thirty all told, in which the oxy-hydrogen lantern has been employed, with very probably quite a small disc. It is obvious that the slides, which, by reason of their intensity, were quite suited to such an illumination upon such a scale, would be too thick and heavy in the shadows for a disc twelve or more feet in diameter, although, of course, the superior illuminating power of the mixed jet would, to some extent, counteract this. The ambition, otherwise very laudable, to have the maximum brilliancy of illumination over the biggest possible disc, seems, in gatherings of such small numbers, and in the circumscribed area of the modern villa or flat, a little out of place. It may be safely asserted that a result much more satisfactory might be obtained at a tithe of the cost, both in labour and money, by employing our old, discarded friend, the lamp. I say nothing of the relative amount of skill required to manage properly the jet and the oil lamp because I hold that the latter needs quite as much knowledge and attention as the former, although the want of common sense in its manipulation might not have such disastrous results as it might in the former case in spite of the assumed safety of drawn steel cylinders. It seems worthy of consideration whether the requirements of the generality of such exhibitions as those to which I have alluded would not be better met by the use of a lamp burning petroleum and a four-foot disc than they now are by the limelight with a disc of three or four times that area.

The mistake, as I have already mentioned, consists in trying to have the biggest possible disc, and it brings with it more inconveniences than the obvious one of needing powerful light. Screens of any size are very inconvenient, and take a good deal of putting up and taking down, &c. I do not mean for a moment to limit the use of the petroleum lamp to so small a disc as four feet. I have seen excellent results obtained with it of three times that area; but, with an audience of, say, twenty in a small room, a four-foot disc should be ample. Such a size does away with the screen nuisance at once, since good white card of this size can be obtained, and makes the finest possible screen; or, if preferred, very brilliant results can be obtained by using a translucent screen as mentioned below.

In the management of such an instrument as one of the many three or four-wick lamps on the market, there are many points to be considered if the best possible result be wished for. On the score of economy alone, the three-wick instrument is preferable to that which contains a larger number. The consumption of oil is not in strict proportion to the light emitted, and is greater in a four than in a three-wick lamp for the same amount of illumination. Another important matter is the selection of a suitable oil. There is a good deal of petroleum in the market which, while perfectly safe and suitable for lamps in which, by reason of the construction, or material of the reservoir, the latter does not get hot, it would not be advisable to employ in an optical lantern; for the latter, however well designed, can hardly fail to cause the temperature of the oil in the receptacle to rise, on account of the enclosed space in which the various parts are necessarily crowded together, and the metal of which the bodies of oil lanterns are almost invariably composed. Such oils should be carefully eschewed, both on account of their danger, and, if that is not sufficient reason, on account of the unpleasant smell they are certain to give off when the light is burning. The "best crystal" oil which is generally sold at a slight advance in price over the inferior qualities, should be purchased at a shop where sufficient reliance can be placed in the shopkeeper that he really does keep two qualities, and does not draw both brands out of the same barrel. The addition of camphor to the petroleum is said to whiten the light, but I have never been able to detect any difference visually; it certainly tends to cause smoke and smell, and there should be no difficulty in obtaining a white enough disc without it. I have even heard it suggested that "albo-carbon" should be dissolved in the oil—how, was not stated. In the ordinary petroleum it is hardly, if at all, soluble; certainly not enough to cause any perceptible difference in the colour of the light, was taken up by cold crystal oil, although the "albo-carbon" was crushed into a fine powder, and left in contact with the solvent for some weeks with frequent shaking.

The brilliancy of the light as well as the absence of smell depends far more upon the careful trimming and adjustment of the wicks. It will be found much easier to trim the edges smoothly when they have once been burnt for a short time, they can then be cut without difficulty with a pair of scissors so as to give a perfectly even flame. Care should also be exercised to see that all three wicks are doing an equal share of the work of illumination, and that none are turned up so high as to smoke, but that each is so adjusted that the slightest possible rise would cause smoking to commence. They should be turned up fully at first, watched for a few minutes, and lowered as the lantern warms and they begin to smoke, bearing in mind that a lamp partially turned down is sure to smell and to smell horribly. Smell is also avoided to a great extent by the use of a funnel for filling the reservoir and seeing that the slightest trace of oil does not contaminate the outside of that vessel. With this object, at the close of a display the oil should be poured out, the wicks taken out, squeezed in paper, and when nearly dry wrapped up and put away. The metal parts of the lamp can then be washed in water containing a little washing soda, dried and replaced. If a little trouble and attention are given to these points, it is surprising how odourless any petroleum lamp can become, and what a brilliant light can be got from it. It is a good plan to test the burning of the lamp both outside of as well as in the lantern, the proper height for the metal chimney of the lantern can then be adjusted and marked at the best height once for all. This will also indicate whether the air inlets and outlets are sufficiently free. More attention is generally given to the former than to the latter, although both are of equal importance, and it is no uncommon thing to find lanterns in which the air inlets are all that could be desired, but in which the outlet at the top of the chimney is so contracted or distorted as to neutralise the benefits derived from the care exercised at the other end.

Translucent Screens

are perhaps the most attractive method of displaying slides before small audiences. They are especially convenient when they can occupy a doorway between two rooms, the lantern and operator being in one, the audience in the other, and they should not be made too big if a brilliant

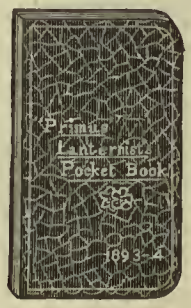
result be desired. Many house have two fair-sized rooms separated by folding doors; such places are admirably suited for a lantern display on a small scale. A light wooden frame should be constructed about four feet square, across which thin tissue or tracing paper must be stretched; it can be fastened by means of drawing pins. A vegetable parchment, which is admirably suited for the purpose, is supplied in rolls sixty inches wide. By reason of its toughness, it could probably be used many times before getting damaged. For very small screens of this kind finely ground glass answers perfectly. The spaces between such a screen and the door-posts and beam overhead can be draped with curtains, the frame itself being either hung or supported on legs, at such a height that its centre is about five feet from the ground. Employing an oil lantern with photographic slides of medium density in this way, a very satisfactory result can be obtained at less cost and with less trouble than with any form of limelight.

It must be borne in mind, however, that all kinds of tissue paper do not yield equally successful results, in some of the cheaper kinds the fibres are here and there gathered into almost opaque clusters, while others have a yellowish tinge by transmitted light. The best quality of white tissue should be employed, unless a thin light-blue coloured tracing paper (the "stag" brand is what I have used, but what mill or make that may be I cannot say) is accessible, which is by far the best material I have up to the present tried. JAMES LEWIS.

RECENT NOVELTIES IN LANTERN APPARATUS.

THE "PRIMUS" LANTERNISTS' POCKET-BOOK.

W. Butcher & Son, Blackheath.

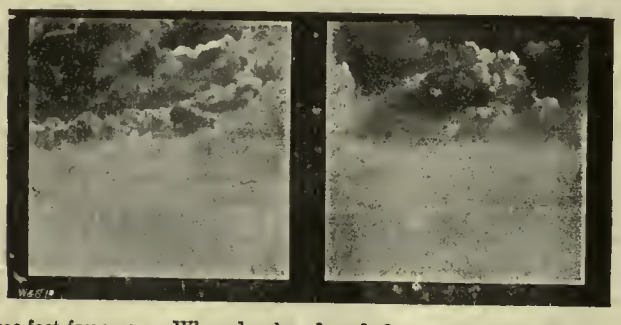


MESSRS. BUTCHER & SON are issuing the "Primus" Lanternists' Pocket-book, a neat and handy remembrancer for lanternists. It is prefaced by some useful tips on oil lamps, blow-through and mixed jets, cylinders, gases, reference tables as to size of discs in relation to lens focus, a diary for the winter months—November to March. Other spaces are also given for the entries of particulars of engagements, lists of slides, &c. Lanternists will find the "Primus" Pocket-book a decided convenience.

THE "PRIMUS" CLOUD NEGATIVES FOR LANTERN SLIDES.

MESSRS. BUTCHER are also issuing a series of cloud negatives on glass for lantern slides. A lantern slide of a land or seascape, however good, is imperfect without clouds judiciously chosen and introduced, and the excellent series of Messrs. Butcher should therefore be a boon to the slide-maker. They are cheap, and a variety is supplied. The following are the directions supplied for using them:—

"First make a trial exposure or two from cloud negatives only, at, say,



three feet from gas. When developed and dry, mark on these time of exposure, the developer used, and the time taken to develop. Put these aside, and keep for future reference.

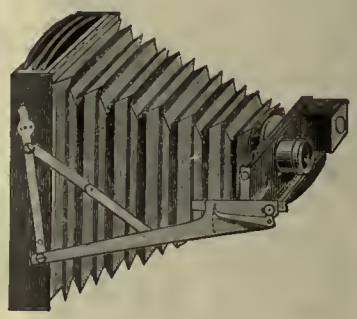
"Make the exposure for subject on to lantern plate first. Should the sky be thin and print through, it should be roughly shielded. Mark the outside of printing frame at each side with a pencil to show depth of sky portion, taking notice of any slight projection above the horizon. Replace the view negative by the cloud negative, taking care to keep the plate the right way up, and to place it so that the vignette of cloud negative comes across the horizon. (An ordinary quarter-plate printing frame is the best to use, which allows latitude for arranging the vignette.) Now expose for the clouds, the time, &c., being known from previous exposures. Any part of the lantern plate that is not covered up by the opaque part of cloud negative should be shielded by a piece of card or brown paper."

MR. ALFRED UNDERHILL, of 32, Clarendon-road, Croydon, has secured a valuable series of Botanical Negatives, by Mr. J. Packham, F.R.H.S., illustrating morphologically and histologically the minute structure of plant life. Slides from these negatives are in course of preparation, and a classified list will shortly be issued. In addition to the above series, Mr. Underhill intends to publish photo-micrographic, and other lantern slides, specially prepared for the advancement of technical education.

THE "NYDIA" CAMERA.

Newman & Guardia, Shaftesbury-avenue.

THIS is an extremely neat and portable camera of the pocket class, the chief points in which may be summarised as follows:—The lens is a Wray, 5½ inches focus, *f*-8, rapid rectilinear lens; two extra thin steel diaphragms, *f*-11 and *f*-16, are provided. The camera has full range of focus, from two yards to "infinity;" a lever, scale, and clamp enable the worker to alter or fix the focus in an instant. The shutter works between the lenses, immediately behind the diaphragm; it opens and closes from



the centre, by a vertical slit. It is provided with pneumatic regulation. "Time" exposures are easily given at will. The finder is fixed on a swivel joint, and can be used for both vertical and horizontal pictures. Solid double dark slides are used with the "Nydia" camera. They are of light but very strong construction, and the ebonite shutters draw right out. A light celluloid screen is always in the camera. It holds the dark slide in position, and when this is withdrawn the screen automatically springs into register. For its particular purpose, that of constituting a highly portable but efficient little camera, which can literally be carried in the pocket, the "Nydia" should be found extremely useful.

PROJECTED PORTRAITS.

I.—MR. GEORGE MASON.

MR. MASON is President of the Photographic Convention of the United Kingdom, President of the Photographers' Benevolent Association, and President of the Central Photographic Club, in spite of which he is not by any means proud, and one may actually speak to him without being charged an entrance fee, and be sure of a courteous response, which is not the case with some presidents. Mr. Mason combines the direction of the largest photographic-dealing business in Scotland with a taste for poetry, and he has achieved the rare feat of transmitting a love for the divine *afflatus* to one of his descendants. He is also an editor and author, and an enthusiastic devotee of optical lantern matters, his lantern lectures in the city of St. Mungo being highly popular. He is a shy orator, but a good story-teller, and a great smoker. Moreover, he is an artist in black and white, and has solved the problem of how to be genial without knowing it. Mr. Mason is making a collection of Dickens pictures for a lantern lecture on the great novelist. After his triple Presidency he will have no more (photographic) worlds to conquer. Happy man!

II.—MR. W. E. DEBENHAM.

Mr. Debenham is a concentrated encyclopædia of photographic information, but is, nevertheless, a good portrait photographer. Possibly he has fallen into a common misfortune and mistaken his vocation, his creative faculties being inferior to his critical acumen. He would have made a very capable reviewer. He has written (and spoken) on most, if not all, branches of applied photography, and is particularly happy in

discoursing of the properties of photographic objectives. His favourite themes are "flatness of field" and "photographic perspective the only true perspective," which cheerful topics he occasionally varies by denouncing the tricks and manners of the fuzzy school, and Mr. H. P. Robinson. He is the "hope of the stern and unbending Tories" of photographic definition, is a frequent Judge at photographic exhibitions, and is as fond of polemical writing as a bee is of honey. Mr. Debenham comes of a family prolific in photographers, but still, paradoxical as it may read, there is only *one* Debenham. There isn't room for two such in the photographic world. Mr. Debenham is a member of several societies, and his readiness to read papers to them and impart information on photography in general is highly creditable to his good nature.

III.— Mr. H. P. Robinson.

Mr. Robinson not long ago was unlucky enough to incur the title of "King of Photography," while his life and works formed the subject of a lantern lecture which was trotted round the country, presumably for the purpose of telling his Majesty's subjects what his claims to sovereignty were. The consequence was that, like the community of letters, the world of photography decided to remain a republic. Mr. Robinson has had a long, varied, successful and profitable career in photography and was evidently born under a lucky star. He was once a professional photographer, but now he can not only afford to despise the accumulation of filthy lucre out of the black art, but also to be finely scornful of medals at photographic Exhibitions. People are unkind enough to remind him that 'twas not always thus. Mr. Robinson has produced numerous good (and bad) photographs in his time. He has written several books on art principles applied to photography, but sometimes in his own work demonstrates the possession of an heroic courage in refusing to practise what he preaches. He is a keen and clever newspaper controversialist, but suffers under the disadvantage of always fighting on the wrong side, that is, his own. A year or two ago, he in a huff threw away a chance of becoming President of the Photographic Society of Great Britain; he may yet be President of the Camera Club. He likes his pictures well placed and hung, and they generally are. He is one of the founders of the Salon, and will be sorry for it. He boasts of his thick skin, and needs it. For all that, Mr. Robinson is personally a very pleasant gentleman, although few people would think so from his paper record. He resides at Tunbridge Wells and the Camera Club.

IV.—Mr. W. I. Chadwick.

Bleed Mr. Chadwick, and the resultant fluid would give off oxygen and *Bacilli lanterna et stereoscopisca*. He convulses the photographic world with comic advertisements, and is philanthropist enough to pay for the printing of them. In his salad days he wrote extensively about the optical lantern, and made it the subject of many inventions, which amused him in his leisure hours; and in revenge people have compelled him to convert his hobby into a profession. Hence it is not his fault if he is regarded as a high and practical authority on the optical lantern, and sells a very great quantity of what he calls the "tackle" in connexion therewith. It is a disagreeable fate—and he deserves it. He is fond of scientific projection and photo-micrography, and is laudably anxious to make those branches of photography popular by divesting them of unnecessary intricacies, difficulties, and superfluous brasswork. He will probably succeed. He took the egg of stereoscopic photography into his roost, and has hatched it into a vigorous chicken, which gives promise of developing into a hale and hearty fowl. He is of opinion that people who go in for monocular photography are "mostly f—ls." Mr. Chadwick was Hon. Secretary of the Manchester Society for fifteen years, and so little did the Society appreciate his services that it has condemned him to wear a handsome gold watch for the remainder of his life. His business and photographic energy are like gases in cylinders—kept under great pressure. He is extremely popular in the north. Him the poet probably had in his mind's eye when he wrote those immortal lines—

"He's all right when you know him;
But you've got to know him first."

But, then, who doesn't know Mr. Chadwick? Limelight.

(To be continued.)

LANTERN MEMS.

Compressed gas in cylinders has been the most important item for consideration during the past month, from the fact of the fatal explosion at Bradford necessitating a coroner's inquest, and experiments and statements by experts to show the strength of the cylinders and what risks are incurred in their use and conveyance.

* * * * *

Of their strength under ordinary conditions a great deal has been written at various times, and considerable pains taken by one, at least, of the Gas Compression Companies to find out really the strength of the various quality of solid-drawn and other steel tubes as against the old iron cylinders. Then, as to the tests employed before filling, everything seems to have been done that human forethought and ingenuity could suggest; but, when it comes to the distributing part, there the weakness of the whole system comes in.

* * * * *

Cautions there have been in plenty, showing it is not fair to the carriers or users to send cylinders unprotected by rail; and, after what has now happened, no one ought to send cylinders about except in the care of adults who understand the nature of their charge, or, if to go by carrier or railway, without being properly packed in an extra strong case. While the Gas Compressing Companies still continued to send cylinders unprotected, very little good came of isolated examples among opticians to bring about a more cautious treatment. Readers of The British Journal of Photography will remember I have alluded to this risk more than once, and felt the danger of cylinders being treated simply as "hardware" or bales of goods, and pitched and thrown down with the "usual care" of the proverbial railway porter.

* * * * *

Writing the above before the result of the coroner's inquest was known as my idea on the subject, I find the conclusions of the jury entirely endorse them, for, in their finding, "they strongly recommended that in future these cylinders, when sent out, should be protected, either by cases or otherwise." Users of compressed gas have only now to *insist* on their cylinders being sent them properly protected, and to make a point of putting a special mem. on their order for gas in new cylinders, that a strong box shall be supplied; and, if they already possess cylinders, have cases made three-quarters or one inch thick with extra strong ends, and fixing on for the nozzle of cylinders so as to prevent it knocking the end of case out.

* * * * *

The matter of the material (steel) suitable for gas cylinders will have to be settled by experts in metals and engineering, but the broad fact cannot be overlooked, that of the thousands of cylinders in use only one or two have failed, and these through rough treatment. Therefore, if lanternists and carriers are protected by cylinders being duly protected in transit, the use of compressed gas will be as popular as ever. A point of some importance, as a technical detail that has come to light since the accident, has been the necessity of reannealing each cylinder after testing.

* * * * *

I am indebted to Mr. Hatton, the Secretary of the Projectile Company for certain details connected with the manufacture of cylinders that are not only interesting but reassuring, for, from what I heard and saw at the works, everything seems to be done to make the best possible cylinder out of certified qualities of steel. The various processes of drawing, testing, pickling, tempering or annealing, and gauging for thickness and size being done with the utmost regularity and precision, and the various stages through which each cylinder passed ensuring a sequence of proper treatment that seemed to render any passing over of a needful item impossible.

* * * * *

Some question has been raised as to the proper strength of steel for these cylinders, and, while not venturing to give an opinion on such a special matter in any way opposite to that already published, it seems that a cylinder that will bear a strain of say thirty-five tons to the square inch with twenty to twenty-two per cent. of elasticity must be good material. This is practically the result of an expert's test of a cylinder of exactly similar make to the one that the accident occurred with—in fact, made in the same batch, under exactly the same conditions, from the same material of steel.

Owners of cylinders must be prepared for a little time to come to spare their cylinders, when sent to be filled, for a much longer time than usual, for each one will have to be reannealed periodically, and always after each time of testing, for it is now found to be necessary on account of the action on the steel when testing for strength (at, say, two tons' pressure) to somewhat soften the material again by slowly heating the cylinder and allowing to cool again, or annealing, as it is called.

* * * * *

At this season of the year many little points crop up in lantern working, especially with beginners or those taking up a new light, and the natural result is they write to the optician or supplier of the apparatus for explanation. In cases of this kind much valuable time would be saved if, instead of mixing up their queries with their letter, they would put them on a separate piece of paper, taking up half the sheet for the questions, and leaving the other half free for the answers, numbering each question in rotation. G. R. Baker.

GAS CYLINDERS AND EXPLOSIONS.

A good many lanternists know that a gas cylinder exploded a few days ago at Bradford, and that it killed the boy who was carrying it, and beyond the fact that it is said the metal of the cylinder was defective very little else is known. Of course, there is a slight scare at present, but the circumstances will soon blow over and be forgotten until another explosion occurs. In my opinion we may expect these explosions much more frequently from now.

I am not an alarmist, nor am I a timid man, but I do like to know something about the things I use, especially if those things are dangerous.

Some people say that gas cylinders are not dangerous, and it has been said, 'Fools rush in where angels fear to tread.' If we admit that a perfect cylinder, properly handled, is not dangerous, I would like to ask, How are the public to know that they are perfect, or that they have been properly handled even before coming into the user's possession?

The cylinder that exploded at Bradford was said to be defective. Then, why did the Oxygen Company fill a defective cylinder? The reply is easiest by saying that they did not know it was defective. Then, are there any other defective cylinders in use?

It is said that great improvements have of late been made in the manufacture and quality of material of gas cylinders. Then, what about those made before the improvements?

There are plenty of cylinders that have been in use for many years and are still in use to-day; but that is no guarantee for their safety to-day; on the contrary, perhaps.

Most lanternists know that cylinders expand (stretch) by pressure (when charged), and that they contract as the pressure is relieved (emptied); and so does a rubber band. Does this constant expansion under high pressure and contraction improve a cylinder? Does the metal always remain the same in quality? Certainly not.

I know of plenty of cases where cylinders that have been in use for years and not retested, and other cases where cylinders have been under the full pressure for three and four years; then, again, I know of plenty of cases where cylinders have been overcharged, one hundred and thirty to one hundred and thirty-five atmospheres is not uncommon. It will be remembered that some time ago I told the readers of the Journal that a friend of mine had had a cylinder charged in excess of these figures, and now I may tell the reader that "the friend" was my own self. I saw it done with my own eyes, when I wrote advocating a safety valve by which it would be impossible to overcharge a cylinder. The manager of one company replied that they already had such an appliance; of course I don't know what they have. I know that a branch of the same company had not, but what I have said is a mild experience compared with some things that could be told.

It will perhaps be remembered that up to a certain date both oxygen and coal-gas cylinders were provided with similar valves, and by which the various fittings or connexions could be used for either, and thus there was a possibility of charging a cylinder with the wrong gas or of mixing the gases; indeed, this has actually occurred more than once, with fatal results. Then an order was issued by certain firms that all cylinders for coal gas must be revalved, and uninterchangeable fittings provided, to prevent the possibility of filling a wrong cylinder, and this alteration was freely advertised, and considered a step in the right direction; but some few months after considerable expense had been incurred by revalving coal-gas cylinders and alterations to fittings my own carter brought me a nice little interchangeable adapter, by which we could connect an oxygen cylinder with a coal-gas cylinder, or use any fittings or connexion with either gas, and the adapter was sent to me as a present from the man who fills the cylinders, with the message that "I would find it very useful." Since that time these interchangeable adapters have become commercial articles.

Now, it would be interesting to know why we were obliged to have our coal-gas cylinders and fittings altered, for the security which was paid for is *gone*.

Surely what has actually occurred and has now been said ought to show that the public require protection. If a man goes to buy an eighteen-carat gold watchguard, he can have a guarantee by a Government test and stamped. If we want a sporting gun, we can have Government-tested and stamped barrels; but what is the bursting of a gun barrel to the bursting of a gas cylinder? If the gun barrel bursts, it might injure the user or it might kill him, but the explosion of a gas cylinder might just as easily kill 500 people as one. Take for instance, the last year's explosion at Ilkeston. That was a gas-bag explosion under very insignificant pressure compared with a gas cylinder, but the force of it was sufficient to bulge to many inches the narrow lead-tight windows of a very large newly built chapel, so that the pressure must have been enormous; and I remember, when inspecting the place, asking myself what would have been the result of a cylinder explosion? Why, the walls would have been blown out, and the roof would have come down amidst a room full of people.

It is all very well for some writers to try and smooth the matter over as best they can, to say the things are safe, or that by doing so-and-so there is no danger; that is all nonsense. As a rule, people who write such nonsense are either commercially interested or they don't know anything about it. A man may have used cylinders a dozen years, and yet know very little about the present subject.

In conclusion, I say again the public require protection, and the only way to get it that I can see is by a Government inspection and supervision. W. I. Chadwick.

CHARITABLE LANTERN ENTERTAINMENT SOCIETY.

The following are extracts from the first annual report of work and accounts, 1892–3:—"We beg to lay before you a brief report of the work done by the above Society during its first year—1892–3—which we are sure will be read with interest by the subscribers, and trust it may be the means of inducing others to also become subscribers.

"The Society was inaugurated in October, 1892, for the purpose of giving free lantern entertainments, accompanied with music, &c., to the inmates of our hospitals, infirmaries, workhouses, and similar institutions, during the winter months.

"The Society gave, last winter, twenty-five entertainments, among which were included the Temperance Hospital, two wards; St. Mary's, Paddington, two; Victoria Hospital for Children, two; North Eastern London Hospital for Children, two; the Children's Hospital, Great Ormond-street, W.C.; the Paddington Infirmary; St. Pancras Infirmary; Fox-court Ragged Schools, W.C.; St. Paul's, Herne Hill, Sunday Schools and Church of England Temperance Society; the British Home for Incurables, Clapham, S.W.; St. Stephen-the-Yeoman Mission, Jamaica-road, Bermondsey, two; St. Marylebone Workhouse; the Home for Incurable Children, Maida Vale; St. Jude's Mission, Brixton; Hanwell Asylum; the Y.M.C.A., Aldersgate-street; and others, which entertainments were highly appreciated, and gave great delight to the poor inmates.

"Our thanks are due to the Y.M.C.A., whose Secretaries—Mr. Burn and Mr. Puttrill—kindly placed a room, free of cost, at our disposal for meetings, &c., thus saving considerable expense.

"It will be seen by the balance-sheet that the receipts were 17*l.* 1*s.*, and the expenditure 22*l.* 13*s.* 9*d.*, which shows a deficit of 5*l.* 12*s.* 9*d.* The Society is indebted to one of its members for the use of the lantern and apparatus, sufficient funds not being forthcoming to enable one to be purchased for the Society.

"We therefore trust that kind friends will come forward to help us to fit the Society out with the necessary apparatus.

"In conclusion, we beg to thank our subscribers and members of the Society who have, by their kind help, enabled the work to be carried on with success, and trust that the ensuing season—1893–4—will bring new help, without which it will be impossible to carry on the Society, which, as before mentioned, needs funds by which a lantern and apparatus can be purchased.

"The Society is in urgent need of funds to enable it to carry on the work this winter, and subscriptions will be thankfully received and acknowledged by,

"Yours very faithfully,

"F. Simmons,

THE BURSTING OF AN OXYGEN CYLINDER AT BRADFORD.

On the 17th instant the Bradford Borough Coroner resumed his inquiry into the death of the lad, J. W. Fuller, who was killed by the bursting of an oxygen cylinder which he had dropped. After hearing expert and other evidence, the jury returned a verdict that the deceased met his death from the accidental bursting of a cylinder made of unsuitable metal, and they strongly recommended that in future these cylinders when sent out should be protected either by cases or otherwise.

The principal expert witness examined was Professor Goodman, of the Yorkshire College, who had inspected the fourteen pieces of metal in the possession of Superintendent Paul, and also the sound coal-gas cylinder. Every piece was carefully examined. The fractures in every part were crystalline—coarsely crystalline in the portions of the bottom and top of the cylinder, but of finer grain in the centre. There was a peculiar fracture near the top of the cylinder, which was different in shape from any other fracture. This might or might not have been due to a flaw in the material. The point was a doubtful one, and opinions might differ. The spot was carefully examined, but he could not come to any definite conclusion. The fractured pieces showed bulging, which might have been done in the accident. The thickness of the metal varied very much over the cylinder. It was impossible to avoid some little variation in making such cylinders, but he certainly thought the variation much greater than it ought to have been. In a well-made cylinder the variations would not be so great. He had only a limited knowledge of the manner of making such cylinders.

The Coroner: Would not the varying thickness of the metal be a source of weakness? Witness: Yes, and no. If the thinnest portion was sufficient to bear the pressure, the variation of the thickness would be no weakness, but, if the metal was so badly disposed that the thinnest portion was unable to bear the pressure, that would, of course, be a weakness. That risk of bulging, Mr. Goodman went on to say, would certainly be greatest where the metal was thinnest. He took away to Leeds two pieces of the broken cylinder which he first had photographed. The pieces were then cut up into test pieces, and subjected to a series of experiments. A sound cylinder supplied by Messrs. Riley as a duplicate was also handed to him, and this he caused to be cut into pieces, and found it as variable in thickness as the one which was broken. These pieces were also subjected to experiment, and the witness handed in a detailed report of the character of the tests inflicted and the results obtained. Steel ought not to be used of a greater tensile strength than 32 tons per square inch, and no boiler-maker would dare to use it of greater tensile strength for internal pressure. The steel of the cylinder in question was very high indeed in tensile strength. In some cases it was over fifty tons per square inch. This in itself was not harmful, but it was always considered that steel of very high tensile strength was very brittle, and therefore unsuitable for internal pressure, especially when, as in the case of an oxygen cylinder, it was likely to be subject to much knocking about. The remedy, of course, would be to use material of great ductility. The steel actually used was, in his opinion, unsuitable for the purpose. The maximum thickness of the body of the duplicate cylinder was found to be ·242 in., and the minimum was ·164 in. In the cylinder which burst he found that the pieces varied from ·172 in. to ·205 in. in thickness, though he might perhaps find a thicker piece on examination.

The Coroner: You have heard the evidence that this cylinder fell from the shoulder of the deceased on to the concrete floor. Does that explain its bursting?—Yes; after looking at the figures of my experiments, which show how very hard and brittle the material is. Although the tensile strength is very great, it has very little ductility. If the material used were good material, there ought not to be the slightest danger of an explosion from such a fall on to the floor. This morning, before coming here, I took one of the cylinders which we are constantly using at the Yorkshire College, and dropped it 22 ft. 6 in. on to a cast-iron block. There was no explosion, and the cylinder received only a small dent.

In reply to further questions, witness said that the cylinder of which he had just spoken was charged with oxygen at the time, and it was charged by the same firm—the Manchester Oxygen Company—which filled the cylinder that burst. But it was a cylinder of different make to that which burst. He then took a cylinder similar to the one he dropped that morning, and cut it up, and found that the thickness was—maximum ·232 in., and minimum ·178 in. A third cylinder was burst by hydraulic pressure, the bursting taking place at between 59 cwt. and 60 cwt. per square inch. These experiments confirmed his opinion that the material used in the cylinder which burst and killed the deceased was improper. The annealing of steel reduced the tensile strength somewhat, but increased its ductility and made it more capable of stretching without breaking. The annealing process was indispensable, and no cylinder ought to be sent out until it had been thoroughly annealed. With regard to tests, he believed that cylinders ought to be tested to a considerably greater extent than the working pressure, but he believed that it should not be as much as double the working pressure, as it was possible to permanently injure a cylinder in the testing.

The Coroner: Your opinion is that the cause of the bursting in this case was the defective material of which the cylinder was composed?—Witness: Yes; but I would hardly say "defective" material—it was unsuitable material, and if it had been annealed the chances of accident would have very much less. Witness went on to say that he did not think it could be said that there was any danger attending the use of a properly constructed and annealed cylinder. There were probably some hundreds of thousands of these cylinders in circulation in the country, and this was the very first accident which had ever occurred from the breaking of an oxygen cylinder or "bottle." Of course, if the cylinder or "bottle" were made of unsuitable material, there would be serious danger.

In reply to Mr. Morgan, witness said there would be no outward appearance to indicate that the cylinder in question was of unsuitable material and had not been annealed, for the cylinder had been painted. At the Yorkshire College the cylinders used were not subjected to any test whatever, the makers being trusted. He had himself never cut up and tested a cylinder before this accident. His predecessor, however, had on one occasion cut up a cylinder and made tests, of which witness had the result. There was a mark on the valve of the cylinder which burst and killed the deceased, indicating that it had been tested on a ton and a half per square inch. He declined to commit himself to any opinion as to whether this test was sufficient for a working pressure of 1800 lbs.

ENRICHMENT OF COAL GAS BY THE HYDRO-OXY PROCESS.

The lecture recently delivered by Professor Vivian B. Lewes, F.I.C., to the members of the Society of Engineers, entitled "Gas Substitutes," gives us, says *The Gas World*, the opportunity of referring in detail to the hydro-oxy process now in practical operation at Huddersfield, and by means of which results have been obtained of a more satisfactory character than were expected in the experimental stage.

Early in 1890 British gas managers became aware, by the publication of the English patent specifications, of the somewhat bold proposal of Mr. Edward Tatham, of New South Wales, to add considerable quantities of pure oxygen to warm, heavy oil gas, with the object of producing a stable gas of very high illuminating power. This oxy-oil gas was, later in the same year, brought more prominently before the gas world in a paper communicated to the Gas Institute by Dr. L. T. Thorne, giving the results of preliminary experiments with this gas, carried out on behalf of Brin's Oxygen Company. In this paper, whilst belief was expressed in the ultimate employment of rich oxy-oil gas as an illuminant *per se*, the more immediate prospect of its use for enriching gases of low or non-illuminating power was pointed out.

Owing to the illness of the representative in England of the Australian Syndicate, to the difficulties inherent in introducing a totally new and rather startling process, and to other causes, there has been considerable delay in the development of the oxy-oil gas process in England. At length, however, a fair start has been made. Whilst the Hydro-oxy Gas Patents Proprietary, Limited, have erected at 11, Salisbury-square, E.C., a complete experimental plant for showing the process, and for enabling gas managers to make their own tests, plant is being put up by the Corporation of Huddersfield for the purpose of enriching the coal gas supplied to that borough.

Though the Huddersfield installation is not yet completed, part of it is in practical work; and this new departure in enriching processes is of such great interest that we feel sure our readers will welcome the publication of results at the earliest possible moment, even though these results have been obtained under the necessarily adverse conditions of a new and hardly complete installation, and will therefore be subject to revision, and probable improvement, when the plant has been got into thorough working order.

The Huddersfield plant, when completed, will consist of an oxygen plant and four bays of oil-gas retorts, capable together of a daily make of 200,000 cubic feet of oxy-oil gas, with the necessary adjuncts of condensers, holders, &c.

The oxygen plant, which is completed and in full working order, has been erected by Brin's Oxygen Company, and is their newest type of producer. It is built in two sections, which may be worked either together or separately, according to the exigencies of the gas output. This producer will make 30,000 cubic feet of oxygen per day, and is the largest oxygen-producer ever yet erected.

Of the oil-gas plant one bay, capable of producing about 50,000 cubic feet per day, has been erected, and is now working. In this bay there are fifteen cast-iron retorts, 8 inches in diameter and 7 feet long, and having 5½ feet of heated length between the walls. These retorts are set with a very slight fall (about one inch) towards the back of the bay. The oil is fed into the retorts through 2-inch iron pipes passing through the front covers and terminating about half way along the retorts. These feed pipes are kept in duplicate and are fixed by clamp flanges. Thus, when one becomes stopped, it can be removed, and replaced by its duplicate in about two minutes. The oil is supplied to these feeds by means of specially constructed syphons carrying floats so arranged that any back pressure, caused by stoppage in the feed pips or pressure in the retort, at once raises the float, which in its turn shuts off the cock of the oil-supply pipe of that particular retort. Arrangements are also made for shutting off each row of retorts without interfering with the working of the other rows.

In the present setting the bottom (and hottest) retorts are arranged so as to be used for cracking the residuals from the upper retorts; but they may, at will, also be fed with clean oil. The oil is cracked at a low red heat, a canary-coloured oil gas giving the best results under this process. The oxygen is admitted to the oil gas soon after the latter leaves the retorts and whilst it is still warm, the two gases then passing together through the condenser. The admission of the oxygen is controlled by specially coupled meters, supplied by Messrs. W. Parkinson & Co. The meter registering the oxy-oil gas made is so coupled with a balanced oxygen meter that the oxygen is introduced into the oil gas in the proportion of 15 per cent. of the oxy-oil gas made. The admixture of oxygen is thus automatically adjusted to the quantity of oil gas being made; the working of the process is rendered very simple, the labour required being reduced to a minimum.

The intention is to run the oxy-oil gas into a special holder, from which it may be passed into the coal gas just before the station meter, the quantity being regulated, at the will of the manager, by a meter coupled with the station meter. At the time up to which our figures were taken the connexions with this storage holder had not been completed, and the oil gas made had been passed direct into the main carrying the coal-gas make from a portion of the works. Consequently no reliable tests of the illuminating power of the oil gas *per se* had been possible, but only of the enrichment produced on the coal gas.

In the twelve days during which the oxy-oil gas plant had been running, 244,600 cubic feet of oxy-oil gas had been made and run into the coal gas, the total quantity of enriched gas registered during this time being 4,103,000 cubic feet. Owing to the shortness of ordinary coal, on account of the strike, a large percentage of cannel coal had been used in the coal-gas make, with the result that the average candle power of the unenriched gas was 18 candles. This high candle power would, as far as present experience goes, be against the process, and the enrichment of a poor coal gas would probably give higher results. The oxy-oil gas added increased this to an average of 23·5 candles, or 5·5 candles increase for 5·96 per cent. addition of oxy-oil gas. This is equivalent to an enriching value of about 109 candles per 5 cubic feet of oxy-oil gas.

Taking the whole amount of oil used during this trial (a proceeding against the process, as in the early stages of the working some oil was undoubtedly wasted and more tar made than would be the case in regular work), the yield of oxy-oil gas per gallon of oil used works to about 90 cubic feet. On this basis the effective enriching power works out at more than 1900 candles per gallon of oil—a result which should secure for the gas the careful attention of gas managers.

With the experimental plant at Salisbury-square makes have been obtained of about 100 cubic feet of oxy-oil gas to the gallon of oil, showing 95 to 100 candles on the bar photometer against the Methven screen; and it is believed that the gas made at Huddersfield has not yet been brought up to this, its full standard.

The coke made averaged about 50 lbs. to the ton of oil cracked—a *very* low figure in gas-making. The residual tar was also very small; and the patentee believes that in continued practical working it will be reduced almost to nothing. In consequence of the small quantity of coke and tar produced, the retorts fed with clean oil required clearing only about every five days.

The question of the stability of oxy-oil gas, both *per se* and as an enricher, was some time ago carefully investigated by Dr. Thorne. It was also tested independently by Mr. W. R. Herring, the manager of the Huddersfield Corporation gasworks, when he was investigating oxy-oil gas before recommending to his Corporation its use as an enricher in place of cannel. Both of those gentlemen not only satisfied themselves on the practical permanence of the gas, but found that, when used for enriching purposes, it actually increases the stability of the enriched gas. The poor coal gas used in the experiments actually lost more illuminating power on keeping than the same gas enriched with oxy-oil gas did under identically similar conditions.

Turning to the question of cost, it is estimated that with oil ("solar distillate" of about 0·870 specific gravity) at 3*l.* 5*s.* per ton—the figure now being paid for the small quantities which can be stored on the works at Huddersfield—and with oxygen at 4*s.* per thousand cubic feet—including wear and tear, interest on plant, and special royalty payable under the hydro-oxy agreements, at which price it should certainly be made with a Brin plant of the size of that at Huddersfield—the cost of oxy-oil gas into the holder, including interest, wear and tear of plant, and royalty, should not exceed 3*s.* 9*d.* per 1000 cubic feet. As soon as arrangements for storage are completed the oil will certainly be obtainable at 2*l.* 15*s.*, if not lower; and this will reduce the cost of oxy-oil gas to about 3*s.* 3*d.* Calculating on the higher basis, the enrichment obtained at Huddersfield works out at less than 0·3*d.* per candle per 1000 cubic feet; and on the lower basis at ¼*d.*

This process is now also being introduced in foreign countries; and in America it has an especially favourable field. With the very low-priced oil obtainable in the United States, the Hydro-oxy Company is confident that it could manufacture a gas of, say, 80 candle power, free from smoke and sulphur, at a price even below the average cost of gas in that country, which would prove a very formidable rival to the electric light.

Lantern Queries.

Those correspondents who write regarding the cylinder accident at Bradford are referred to an extract from the evidence at the inquest, as well as to some remarks by Mr. G. R. Baker and Mr. W. I. Chadwick, which are given in this issue of The Lantern Record.

Cloud.—Your query arrives opportunely. You will see from "Recent Novelties in Lantern Apparatus" that cloud negatives for lantern slides are commercially obtainable.

C. Farrow.—Some years ago a series of articles on Colouring Lantern Slides, by the late Mr. A. W. Scott, appeared in The British Journal of Photography, to which we refer you.

Several articles are unavoidably held over.

Lime.—Possibly the limes were kept in an unsuitable receptacle. Keep them in a clean wide-mouthed bottle, and lute the stopper.

RECENT LANTERN PATENT.

PATENT COMPLETED.

Improvements in Carriers for Holding Magic-lantern Slides.

No. 16,177. Lewis Myer Isaacs, 40, Furnival-street, Holborn, Middlesex. *September* 9, 1893.

The object of this invention is to enable magic-lantern slides to be placed in front of the lens from either side and properly centered by any person, the displayed slide being pushed out into a position for easy withdrawal by the act of centering the new slide.

Now, according to this invention, I provide a frame carrying two lantern slides sliding within a skeleton frame, which fits the "lens aperture" in the lantern.

The upper rail of the sliding frame has attached thereto two or more rollers, over which runs a band of tape or other suitable material, the ends of which are attached to the inside of the upper rail of the skeleton frame.

To the centre of the band I attach a projection or carrier of metal, or other suitable material, for the purpose of pushing out the slides on either side consecutively to enable the same to be grasped and withdrawn by the operator. I attach also to the said band two suitable clips to carry the slides before the lens of the lantern.

I provide further a piece of wood or other suitable material sliding easily in the sliding frame, which serves to form a stop for the slide when in position, and also to close the opening left by the receding slide, thus shutting off the light from the lantern screen until the next slide is properly centered.

On Thursday, November 30, before the members of the Liverpool Amateur Photographic Association, a lantern lecture by Mr. W. P. Christian was delivered on *Quiet Corners in France and Italy*. The following is a synopsis of the lecture: Quiet nooks in the Riviera—St. Raphael; picturesque coast scenery; Nice; Monte Carlo. The Italian Riviera—Ventimiglia; the cattle market; Bordighera and its adjacent valleys; San Remo; Porto Maurizio; Oneglia; Alassio; fisher folk; studies of Italian character; quaint and sleepy towns; Genoa, its Campo Santo; Pisa, its wonders in marble; the Carrara marble quarries; Pavia; the Certosa; Padua; Milan. Venice—The Ducal Palace; St. Mark's; the Lagoons; Chiogga. The Italian lakes—Como; a beautiful retreat; Maggiore; Pallanza; Locarno; a pilgrimage shrine; valley of the Ticino; Faido; quaint châlets; a mountain valley; early market.

The Newtonian Lime Cylinder.—Messrs. Newton & Co., of Fleet-street, are placing on the market a new lime cylinder, which is made of an intensely luminous stone lime, and by the aid of special tools can be supplied accurately turned. The cylinders are treated chemically to enable them to resist damp, and are packed in tin tubes, without any loose lime dust. They should be very convenient to the lanternist, the central hole of the cylinder not being blocked up, and the limes therefore being much pleasanter to handle than the usual variety. They are of a hard kind. We shall take an early opportunity of trying the limes and reporting on their light-giving properties.
